Impacts on these species would be similar to the impacts on vegetation described in section 4.4. Project effects on the wetland and estuary species of traditional-cultural importance would be as described for wetlands and waters in section 4.3. Species that are protected by federal and/or state jurisdictions (e.g., various sedges) are also addressed elsewhere in this section and in appendix I.5.

The following list of mammals, bird, and fish is also not comprehensive, but does represent many of the CIT's species of concern:

- Terrestrial: deer, elk, coyote, cougar, bear, bobcat, raccoon, beaver, squirrel.
- Marine/ Estuary: lamprey, salmon (all available species), shellfish, crab, sea mammals, rockfish, lingcod, sculpin, halibut, flounder, perch, herring, greenling, candlefish (i.e., eulachon), snails, mussels, barnacles, chiton, sea urchin, abalone (*Haliotis spp*.), dentalium (*Dentalium spp*.) (other seasonally available estuary species).
- Streams: salmon (all available species), lamprey, sturgeon, trout, mussels.
- Birds: Eagles, hawks, owls, cormorant, kingfisher, herons, osprey, flicker (*Colaptes auratus*), woodpeckers (particularly pileated), grebe, crows and ravens, and colorful neo-tropicals.

Impacts on these species would be similar to the impacts on wildlife and aquatic resources described in section 4.5. Species that are protected by federal and/or state jurisdictions (e.g., owls) are also addressed elsewhere in this section and in appendix I.3.

4.6.3.5 Assessment of Other Special Status Species

Of the other special status species identified above as potentially occuring in counties coinciding with the Project, only a subset have the potential to be affected by the Project. Table 4.6.3.5-1 identifies the number of these other special status mammals, birds, fish, amphibians, reptiles, invertebrates, and vascular plants potentially affected by the Project. For species that are also BLM and Forest Service sensitive species or the Forest Service's Survey and Manage species, occurrence and potential effects on federal lands are also described below in section 4.6.4, Environmental Consequences on Federal Lands.

TABLE 4.6.3.5-1

Numbers of Other Special Status Species Potentially Affected by the Project a/

Taxonomic Group	Federal Status: FWS or NMFS Species of Concern	State Status: ODFW Sensitive or ODA Candidate	Total b/
Mammals	12	12	16
Birds	19	24	31
Non-anadromous Fish	4	4	5
Anadromous Fish	3	5	7
Amphibians and Reptiles	7	9	9
Aquatic Invertebrates	3	N/A	3
Terrestrial Invertebrates	1	N/A	1
Vascular Plants	2	2	2

Sources: FWS (2006d, 2006e, 2017c), NMFS (2006d), ORBIC (2006a, 2006b, 2017a), ODFW 2016b.

a/ Other Special Status Species include FWS and NMFS fish, wildlife, and plant species of concern and candidate species, ODFW Sensitive fish and wildlife species, and ODA candidate species for listing. Forest Service sensitive and Survey and Manage species and BLM sensitive species are only tallied here if they meet this criteria for Other Special Status Species. Species are not tallied here if they are also federal or state listed or proposed.

b/ Rows do not sum because a species is tallied in multiple columns where it is considered special status by multiple agencies.

Descriptions of expected habitat, documented or suspected occurrences, and potential Project effects on these other special status species within the Project area are presented in tables I-3, I-4, and I-5, respectively, in appendix I. Additionally, effects on these species and proposed measures to minimize effects would be similar to the those described for general fish and wildlife in section 4.5 of this EIS.

4.6.4 Environmental Consequences on Federal Lands

The BLM and Forest Service maintain lists of sensitive species to ensure that their actions do not contribute to or cause a trend toward listing under the ESA. Additionally, until 2016, the BLM and Forest Service maintained a list of Survey and Manage species, or species that are rare and uncommon or poorly understood that are closely associated with late successional or old-growth forests within the range of the NSO (Forest Service and BLM 2001a). In August 2016, the BLM issued two RODs for two new RMPs (BLM 2016a and 2016b). These two plans supersede the NWFP on BLM lands, and eliminated requirements to survey and manage for species included on the 2001 ROD Survey and Manage species list on BLM lands. Potential effects on Survey and Manage species on NFS lands are discussed here.

Species that are on both the sensitive list and the Survey and Manage list are discussed on NFS land under section 4.6.4.3, Survey and Manage Species. Additionally, although the Forest Service and BLM include federal and state threatened, endangered, proposed, and candidate species on their species lists, these species are not discussed in this section as they are presented above.

4.6.4.1 Description of BLM and Forest Service Sensitive Species

The BLM maintains a list of Special Status Species (including BLM sensitive species) as required by BLM 6840, Special Status Species Manual, to ensure that BLM actions do not contribute to a loss of viability or cause a trend toward listing under the ESA. Like the BLM, the Forest Service is required by Forest Service Manual (FSM) 2760 to maintain a list of sensitive species for each region, including species listed as federally threatened, endangered, or proposed under the ESA, as well as species that are threatened by human activities. Activities on NFS lands must be managed to ensure that current federally listed species do not become extirpated or that activities do not result in ESA listing for other sensitive species. As required in FSM 2760, the Forest Service is obligated to evaluate Project effects on sensitive species in a BE (see appendix F.7).

The Pacific Northwest Regional Office of the Forest Service and Oregon/Washington State Office of the BLM established an interagency program for the conservation and management of special status species. New criteria for BLM Special Status Species and Forest Service Sensitive Species were jointly approved in 2015 by the Region 6 Regional Forester and BLM Oregon/Washington State Director for determination of species included within the BLM and Forest Service Sensitive Species Program. The new criteria were designed to make the BLM and Forest Service more consistent in their approaches to the development of lists of species with conservation concerns. The BLM (2015) and Forest Service (Forest Service 2015) identify federally listed, federally proposed, and sensitive species required under their respective policies. Additionally, they have identified "strategic species" that are not considered sensitive under those policies. Strategic species include species with information gaps (e.g., distribution, habitat, threats, taxonomy) that are suspected to occur on NFS or BLM lands.

According to Instruction Memorandum No. OR-2015-028, sensitive species are those that are documented or suspected endangered or threatened at the federal or state level, federal de-listed species, are Oregon Heritage List 1 or List 2, and have been documented on at least one Oregon BLM district. These species should be managed to ensure that activities on BLM lands do not contribute to their listing.

Strategic species are not classified as Special Status for management purposes. The only requirement for this group of species is to record sites found during any survey efforts. Therefore, strategic species are not discussed in this section unless observed during surveys.

Table 4.6.4.1-1 lists the BLM and Forest Service sensitive species documented or suspected to occur within the districts and forests crossed by the Pacific Connector pipeline (BLM 2015; Forest Service 2015).

Not all species documented or suspected in BLM districts and national forests crossed by the Project occur within the area affected by the Project. Many were excluded from consideration after review of range and habitat information. Other species were excluded if they were not known to occur in the Project vicinity based on special status species locations within 3 miles of the Project obtained from the BLM Geographic Biotic Observations (GeoBOB) database and Forest Service Natural Resource Information System (NRIS) database (BLM 2006a, 2012, 2017a; Forest Service 2006, 2012, 2017c; NSR 2012), and through ORBIC data requests (ORBIC 2006a, 2012, 2017a).

Note: A species is tallied in multiple columns where it occurs and is sensitive on multiple BLM Districts or National Forests.
a/ Source: BLM 2015; Forest Service 2015

Pacific Connector conducted surveys from 2007 through 2018 for special status species, including BLM and Forest Service sensitive species. Special status mollusks, fungi, and vascular and non-vascular plants not detected during these complete, targeted surveys were determined to not be present, and thus not affected by the Project. Forest Service and BLM sensitive species that are documented or suspected to occur on BLM districts and/or national forests crossed by the Project, but were dropped from further consideration due to a lack of habitat or because they were not detected during targeted field surveys are listed in tables I-3, I-4, and I-5 in appendix I. Information provided for each of these species in appendix I includes expected habitat, county, national forest, and BLM district distribution, known occurrences in relation to the Project, and effects determination and rationale for this determination.

BLM and Forest Service sensitive species that may be affected by the Project are listed below in table 4.6.4.1-2, excluding the state and federally listed, proposed, and candidate species discussed above, and the Survey and Manage species on NFS land discussed below. Where suitable habitat was documented for a species, but species-specific surveys were not conducted, presence was assumed, and potential effects on these species are discussed here.

a/ Excluding state and federally listed, and select proposed and candidate species and Survey and Manage species, which are discussed in other sections of this EIS.

Excluding federal and state threatened, endangered, and select proposedand candidate species (discussed above), and Survey and Manage species on NFS lands (discussed below), a total of 60 BLM and Forest Service sensitive species have the potential to be affected by the Project: 5 mammal, 19 bird, 1 reptile, 1 amphibians, 20 invertebrate, 6 fish, 7 vascular plant, and 1 lichen species(table 4.6.4.1-2). Tables I-3, I-4, and I-5 in appendix I provide habitat descriptions for these species. Forest Service sensitive species that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7), and Survey and Manage species that would potentially be affected by the proposed action on NFS lands are addressed in more detail in the Survey and Manage Report (appendix F.5 of this EIS).

4.6.4.2 Assessment of BLM and Forest Service Sensitive Species

BLM and Forest Service sensitive species that may be present and potentially affected by construction of the pipeline on federal lands are described here. If species were documented during targeted surveys, those locations and potential effects are also described.

Mammals

There are five BLM and Forest Service sensitive mammals that may be present and potentially affected by construction of the pipeline on federal land: the pallid bat (*Antrozous pallidus pacificus*), Townsend's big-eared bat (*Corynorhinus townsendii*), fringed myotis (*Myotis thysanodes*), marten (*Martes caurina*), and fisher (*Pekania pennanti*). Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species within the Project area are presented in table I-3 in appendix I. As all five of these species are Forest Service sensitive, they are additionally addressed in the BE if effects are anticipated on NFS lands (appendix F.7). Marten and fisher are also discussed above as federal proposed threatened species.

Birds

There are 19 BLM and/or Forest Service sensitive birds that may be present and potentially affected by construction, maintenance, and operation of the pipeline on federal land. Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species as a result of the Project are presented in table I-3 in appendix

I. Forest Service sensitive birds that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7).

Fish

There are six BLM and/or Forest Service sensitive fish species that may be present along the LNG carrier transit route, in the waters of Coos Bay potentially affected by construction of the pipeline, or in waters crossed by the pipeline. Of these species, four are anadromous and two are non-anadromous. Descriptions of life histories, expected habitat, and potential occurrences of these special status fish species within the Project area are presented in table I-4 in appendix I. Forest Service sensitive fish that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7).

Amphibians and Reptiles

There are two BLM and Forest Service sensitive amphibians and reptiles that may be present and potentially affected by construction of the pipeline on federal land: western pond turtle (*Actinemys marmorata*) and foothill yellow-legged frog (*Rana boylii*). Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species within the Project area are presented in table I-3 in appendix I. As both species are Forest Service sensitive, they are additionally addressed in the BE (appendix F.7).

Invertebrates

Aquatic

There are nine BLM and Forest Service sensitive aquatic invertebrates that may be present and potentially affected by construction of the pipeline on federal land. All these species are associated with freshwater environments. Table I-4 in appendix I summarizes the life history, habitat associations, and occurrence of these invertebrates. Eight of these species are Forest Service sensitive aquatic invertebrates, and thus are additionally addressed in the BE if effects are anticipated on NFS lands (appendix F.7).

Terrestrial

There are 11 BLM and Forest Service sensitive terrestrial invertebrates that may be present and potentially affected by the construction of the pipeline on federal land. Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species within the Project area are presented in table I-3 in appendix I. As all 11 species are Forest Service sensitive terrestrial invertebrates they are additionally addressed in the BE (appendix F.7).

Approximately 20 acres of the ROW near known populations of two Forest Service sensitive terrestrial invertebrates (Mardon skipper and short-horned grasshopper) on the Dead Indian Plateau would be restored with grasses (including *Festuca* sp.) preferred by these species in addition to the rehabilitation required under BMP guidelines. This mitigation on the Rogue River National Forest has the potential to increase the habitat and local range for these two species.

Three BLM and Forest Service sensitive mollusk species were located during surveys for the Project: Siskiyou hesperian, traveling sideband, and Oregon shoulderband. These three species are discussed in the following paragraphs; Siskiyou hesperian and traveling sideband are additionally addressed in the BE as they were observed on NFS lands during surveys (appendix F.7).

Field Survey Locations and Potential Effects

Traveling sideband is a BLM and Forest Service sensitive species (BLM 2015; Forest Service 2015) and an Oregon endemic terrestrial snail. During surveys in 2007 and 2010, this species was observed at nine locations on the Rogue River and Winema National Forests (between MP 154.9 and 175.4), and at six locations on BLM land in the Lakeview and Medford BLM Districts (MPs 116.3 to 176.9). Shells and live individuals were located within and outside the ROW, as well as within proposed TEWAs and UCSAs (SBS 2008a, 2011b). During surveys in 2012 and 2015, this species was observed at five locations on the Rogue River and Umpqua National Forests (between MP 104.9 and 162.5) and four locations on BLM land in the Roseburg and Medford BLM Districts (MPs 91.7 to 116.9), adjacent to the ROW and TEWAs.[143]. Direct mortality could occur to this species if they are within the ROW during Project clearing or construction due to their low mobility. Clearing of the ROW could affect habitat by removing forest overstory, potentially making the area unsuitable for this species. Indirect effects could result from the alteration of composition and structure of vegetation resulting in changes in microclimate. Realignments following the 2007 and 2010 surveys resulted in avoidance of some but not all the sites observed during Project surveys. As currently proposed, Pacific Connector would directly affect 5 of the 14 sites observed during Project surveys on NFS lands, and 4 of the 10 sites observed during Project surveys on BLM-managed lands. Indirect effects are expected to the traveling sideband sites observed even if direct effects on these sites are avoided because 5 and 4 of the sites are within approximately 100 feet of Project disturbance on NFS lands and BLM-managed lands, respectively, and thus would be affected by changes in microclimate conditions.

Siskiyou hesperian is a BLM and Forest Service Sensitive species (BLM 2015; Forest Service 2015) and a riparian associated terrestrial snail. During Project surveys in 2007, 2008, and 2010, this species was observed at 14 locations on the Rogue River and Umpqua National Forests (between MPs 110.2 and 164.7), and 10 locations in the Medford and Roseburg BLM Districts (MPs 79.8 to 151.5). In 2011, 2012, and 2014, this species was observed at nine locations within the Rogue River and Winema National Forests (between MPs 154.5 and 168.9), and two locations in the Medford BLM District (MP 148.7 and 153.5). Shells and live individuals were observed within and outside the ROW, as well as proposed TEWAs and UCSAs (SBS 2008, 2011b; April 27, 2015 response to FERC data request). During surveys in 2015, this species was observed at eight locations on the Rogue River National Forest (between MP 155.7 and 160.6) and one location on BLM land in the Medford BLM District (MP 128.8), within and adjacent to the ROW and TEWAs.[144] During surveys in 2017, active individuals were observed at one location on the Rogue River National Forest (MP 154.6; Tona 2018). Direct mortality to individuals could occur if they are located within the ROW during Project clearing or construction. Another potential direct effect is destruction or alteration of hydrology of riparian, wetland, or aquatic habitats used by this species. Indirect effects could result from the alteration of composition and structure of vegetation resulting in changes in microclimate. The increase in sun exposure could reduce moisture levels

[143] See Table D.3-10 in Pacific Connector's Resource Report 3, included as part of their September 2017 filing with the FERC.

[144] See Table D.3-10 in Pacific Connector's Resource Report 3, included as part of their September 2017 filing with the FERC.

and potential decrease dispersal between populations or suitable habitat. As currently proposed, Pacific Connector would directly affect 11 of the 31 sites observed during Project surveys on NFS lands, and 6 of the 13 sites observed during Project surveys on BLM-managed lands. Indirect effects are expected to the Siskiyou hesperian sites observed even if direct effects on these sites are avoided as 16 and 5 of the sites on NFS lands and BLM-managed lands, respectively, are within approximately 100 feet of Project disturbance, and thus would be affected by changes in microclimate conditions.

Oregon shoulderband is a BLM and Forest Service sensitive species (BLM 2015; Forest Service 2015) and a terrestrial snail endemic to northern California and southwest Oregon. This species is also managed as a Survey and Manage species on NFS lands; however, it was not observed on NFS lands during surveys for the Project. During Project surveys in 2007, this species was observed at five locations in the Roseburg BLM District (MPs 64.6 to 76.0). Shells and live individuals were observed within and outside the ROW (SBS 2008a). Direct mortality to individuals could occur if they are located within the ROW during Project clearing or construction. Clearing of the ROW could affect habitat by removing forest overstory, potentially making the area unsuitable for this species. Indirect effects could result from the alteration of composition and structure of vegetation resulting in changes in microclimate. The increase in sun exposure could reduce moisture levels and potential decrease dispersal between populations or suitable habitat. As currently proposed, Pacific Connector would directly affect two of the five sites observed during Project surveys on BLM-managed lands. Indirect effects are expected to the Oregon shoulderband sites observed even if direct effects on these sites are avoided as two of the sites on BLM-managed lands are within approximately 100 feet of Project disturbance, and thus would be affected by changes in microclimate conditions.

Plants and Fungi

A total of 270 BLM and/or Forest Service sensitive bryophyte, lichen, fungus, and vascular plant species were identified as potentially occurring within the Project area (see table I-5 in appendix I). Between 2007 and 2018, SBS surveyed for special status fungi and vascular and non-vascular plant species in suitable habitat, where access was granted, within 50 feet (non-federal lands) or 100 feet (federal lands) of the ROW, TEWAs, UCSAs, and access roads (note that surveys continued through 2018). Plant and fungus species documented on federal lands during surveys are described below. Descriptions of expected habitat, documented or suspected occurrences, and potential Project effects on all species within the area affected by the Project are presented in table I-5 in appendix I. Forest Service sensitive plants and fungi that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7).

Of the 41 BLM and/or Forest Service sensitive bryophytes identified as potentially occurring within the area affected by the Project, none were documented during surveys of the currently proposed route. Two strategic bryophyte species (*Andreaea nivalis* and *Orthotrichum euryphyllum*) were documented during surveys. See table I-5 in appendix I for a list of sensitive and strategic bryophyte species identified as potentially occurring within the area affected by the Project, descriptions of their expected habitat, and documented or suspected occurrences, including documented occurrences of the two strategic species observed during Project surveys.

Lichens

There are 16 BLM and/or Forest Service sensitive lichens identified as potentially occurring within the area affected by the Project. Potential Project effects on lichens include trampling or killing of individual plants. One BLM and Forest Service sensitive species, *Bryoria subcana*, was documented during surveys of the currently proposed route. This species is also an Survey and Manage species under the 2001 ROD list (Forest Service and BLM 2001a).

Bryoria subcana is a BLM and Forest Service Sensitive coastal lichen species and was observed during Project surveys in the BLM Coos Bay District, approximately 100 feet of the ROW near MP 21.88BR. The species was observed just east of the area affected by the Project and may be avoided by activities within the corridor; however, construction would disturb vegetation and soils within 200 feet of the site and could modify microclimate conditions around the observation. The removal of trees and woody debris could negatively affect *Bryoria subcana* in adjacent areas by removing its habitat and affecting its association with the trees, affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions within 200 feet of the observation as a result of the Project construction and operation would likely make habitat within the site no longer suitable for the species. Restored portions of the corridor and TEWAs would be dominated by early seral vegetation for approximately 30 years, which would result in long-term changes to habitat conditions. A portion of the corridor would be maintained in low-growing vegetation for pipeline maintenance and would not provide habitat for the species during the life of the Project. *Bryoria subcana* is not likely to persist at the site following Project implementation; however, remaining sites of this species would continue to provide a reasonable assurance of species persistence.

Five BLM and/or Forest Service strategic lichen species (*Collema curtisporum, Collema quadrifidum, Leptogium platynum, Peltula euploca,* and *Sclerophora amabilis*) were also observed during Project surveys. See table I-5 in appendix I for a list of sensitive and strategic lichen species identified as potentially occurring within the Project area, descriptions of their expected habitat, and documented or suspected occurrences, including documented occurrences of the one sensitive and five strategic lichen species observed during Project surveys.

Fungi

Of the 25 BLM and/or Forest Service sensitive fungi identified as potentially occurring within the Project area, none were documented during surveys. Thirteen Forest Service and BLM strategic fungi were observed during surveys. See table I-5 in appendix I for the locations of these observations in relation to the Project.

Vascular Plants

There are 188 BLM and/or Forest Service sensitive vascular plants identified as potentially occurring within the Project area, 10 of which were documented during Project surveys: Rogue Canyon rockcress (*Arabis modesta*), Bensonia (*Bensoniella oregana*), Cox's mariposa lily, Umpqua mariposa lily, bristly sedge (*Carex comosa*), coastal lip fern (*Cheilanthes intertexta*), pine woods cryptantha (*Cryptantha simulans*), clustered lady's slipper (*Cypripedium fasciculatum*), California globe-mallow (*Iliamna latibracteata*), and Bellinger's meadowfoam. Two of these species—Cox's mariposa lily and Umpqua mariposa lily—are also state-listed species and are discussed above in section 4.6.2.3. One of these species, clustered lady's slipper, is a Forest Service Survey and Manage species and is discussed below under section 4.6.4.3. Potential effects on Umpqua mariposa lily, pine woods cryptantha, California globe-mallow, and Bellinger's meadowfoam on NFS lands are additionally discussed in the BE (appendix F.7 of this EIS).

Field Survey Locations and Potential Effects

Rogue Canyon rockcress is a regional endemic found within chaparral and lower montane coniferous forests in northern California and southern Oregon (CNPS 2018). In Oregon, it is only known from Jackson and Josephine Counties (NRCS 2018). This species has been found on dry, serpentine soils on exposed slopes and rocky cliffs in the Rogue River canyon at elevations between 490 and 1,480 feet (NatureServe 2018). Two sites of Rogue Canyon rockcress were observed during Project surveys in 2017 on state forest lands 24 feet and 90 feet north/northwest of TEWA 124.30-N. This species was not observed on BLM or Forest Service land during Project surveys.

Bensonia is found mainly within the Siskiyou Mountains of southwestern Oregon in Curry and Josephine Counties, with a few small disjunct populations in adjacent Humboldt County, California (NatureServe 2018). The rhizomatous species grows in wet meadows and edges near bogs and springs. Populations seem to be associated with cloud or fog banks that blanket the mountain tops at certain times of year. Most plants are in meadows on gentle slopes, and they thrive on partial shade. The species has been found at elevations between 2,000 to 4,750 feet (Hoover and Holmes 1998). One bensonia site was noted near the Project in 2011 in the Roseburg BLM District, approximately 100 feet east of the existing Signal Tree Road Quarry at MP 47. Pacific Connector surveyed this area in 2013 and no special status species were observed, including bensonia. Due to the distance between this site and the Project, no effects are anticipated.

Bristly sedge is found from Quebec to Minnesota and south, as well as in the Pacific Northwest and Montana (NatureServe 2018). This species habitat includes marshes, lakeshores, and wet meadows. In Oregon, this species is known from Columbia, Klamath, and Multnomah Counties; although it is believed to be extirpated or possibly extirpated in Columbia and Multnomah Counties (NatureServe 2018). One population of bristly sedge was documented in 2012 on private land 66 feet south of TEWA 184.30. This species was not observed on BLM or Forest Service land during Project surveys.

Coastal lip fern grows in crevices and bases of rocks and is found mainly in California, although it also occurs in Oregon and Nevada (The Jepson Herbarium 2018). In Oregon, this species is known from Douglas and Jackson counties (NRCS 2018). Two observations of coastal lip fern site were noted near the Project in the Medford BLM District. One observation is located approximately 65 feet west of the pipeline ROW near MP 148.9 and the other observation is greater than 100 feet from the pipeline ROW near MP 149.9. Due to the distance between these sites and the Project, direct effects are not anticipated; however, the Project could potentially indirectly affect individuals and/or habitat of this species.

Pine woods cryptantha is found in dry gravelly sites, disturbed areas, and open conifer forests from elevations between 820 and 8,530 feet (The Jepson Herbarium 2018). This species' range includes California north to Washington and east to Idaho (NRCS 2018). Five observations of pine woods cryptantha were documented during Project surveys in 2017. One site was located in the Rogue River-Siskiyou National Forest approximately 96 feet northwest of MP 155.8. One site was located on the Fremont-Winema National Forest pm the edge of Clover Creek Road and 10 feet from the pipeline ROW near MP 175.3, and two sites were located in the Lakeview BLM District:

1) within the ROW near MP 176.96 and 2) on the edge of Clover Creek Road near MP 176.98. Because this species was observed within the pipeline ROW, the Project may directly and indirectly affect individuals and habitat of this species.

California globe mallow is found in southwestern Oregon, extending into Humboldt County in northern California (Malaby 2005). This species inhabits moist forests, streamsides, lower montane coniferous forests, and montane chaparral; often in recently burned areas (Malaby 2005; CNPS 2018). In Oregon, California globe mallow is found in coastal ranges in Coos and Douglas counties and is also known from Curry, Jackson, Josephine, and Linn Counties. Three observations of California globe mallow were observed during Project surveys in 2017: one in the Roseburg BLM District and two in the Umpqua National Forest. The observation in the Roseburg BLM District was located within the pipeline ROW near MP 99.9, within the are burned during the Stouts Creek fire in 2015. The sites in the Umpqua National Forest are in the pipeline ROW near MP 106.2 and MP 106.7; both sites were in recently burned areas. Because this species was observed within the pipeline ROW, the Project may directly and indirectly affect individuals and habitat of this species.

Bellinger's meadowfoam (*Limnanthes floccosa* ssp. *bellingeriana*) is associated with vernally wet meadows or vernal pools and is generally found on basalt scablands at elevations between 1,000 and 4,000 feet in Jackson and Klamath Counties, Oregon, and Shasta County, California. Six Bellinger's meadowfoam populations were located in the Project area. Two populations were in the Rogue River-Siskiyou National Forest: within the pipeline ROW near MP 154.1 and within the pipeline ROW between MP 154.71 to 154.82. The other four populations were in the Medford BLM District: near MPs 120.3, MP 128.8, and MP 129.0, and TEWA 128.79-N. All these observations are located greater than 100 feet from the pipeline route, except for the observation in TEWA 128-79. Six hundred plants were observed in and near TEWA 128.79-N during Project surveys in 2017.

In 2010, 30,000 plants within less than one acre were documented between MPs 154.8 and 154.7, near Heppsie Mountain (SBS 2011a), also within the Rogue River National Forest. Potential effects on this site include removal of individuals, temporary disturbance, and permanent loss or alteration of habitat including changes in hydrology. The site is in a vernally moist scabland meadow within the ROW and a TEWA and therefore would be disturbed by the Project (SBS 2011a; Rolle 2014). Measures to avoid this site considered but excluded to avoid a rare fungus, *Gymnomyces abietis*, which was also found at the same location on the north end of the meadow at MP 154.8. *Gymnomyces abietis* is a Forest Service Survey and Manage species, discussed below in section 4.6.4.3. Although Project activities would affect the local population at MP 154.7, the species would not likely be eliminated from the site as it is able to grow on disturbed soil (Rolle 2014). Conservation measures at this site include recontouring, reseeding, and controlling for noxious weeds. Additionally, although the site that would be affected is one of only a few Bellinger's meadowfoam sites on NFS land, a large number of sites are known from BLM and private land in eastern Jackson County. More undocumented sites are likely to occur on unsurveyed private lands (Rolle 2014). Consequently, the expected loss of individuals and habitat at this site is not expected to affect the viability of Bellinger's meadowfoam over the broader geographic area of the low mountains and foothills of eastern Jackson County (Rolle 2014).

4.6.4.3 Survey and Manage Species

The BLM and Forest Service first identified Survey and Manage species in 1994 as rare amphibians, mammals, bryophytes, mollusks, vascular plants, fungi, lichens, and arthropods that occupy LSOG forests in the range of the NSO (see Forest Service and BLM 1994a, the NWFP ROD). The agencies established standards and guidelines for management of these rare species in the *Standards and Guidelines for Management for Late-Successional and Old-Growth Related Species in the Range of the Northern Spotted Owl* (Forest Service and BLM 1994b). The NWFP ROD established overall objectives for managing Survey and Manage species populations that were referred to as "persistence objectives." These objectives were based on the Forest Service viability provision in the 1982 National Forest System Land and Resource Management Planning Regulation for the National Forest Management Act of 1976.

In 2001, the Record of Decision and Standards and Guidelines for Amendments to the Survey and Manage, Protection Buffer, and other Mitigation Measures Standards and Guidelines (2001 ROD; Forest Service and BLM 2001a) modified the management direction provided in the NWFP ROD for Survey and Manage species and amended BLM and Forest Service land management plans in the range of the NSO accordingly. The management direction for Survey and Manage species varies based on its assigned category, which establishes varying levels of surveys and management of known sites (refer to the 2001 ROD and appendix F.5 to this EIS for additional details on the categories). For the Survey and Manage Standards and Guidelines, the major elements were retained with some restructuring for clarity, and the 1994 list of Survey and Manage species was modified to remove 72 species in all or part of their range because new information indicated they were secure or otherwise did not meet the basic criteria for Survey and Manage. Based on the history of the Survey and Manage rule, it should be noted that by definition, there is a general concern for persistence for any of the species listed in the 2001 ROD. That concern is the basic reason species are listed in the Survey and Manage Standards and Guidelines.

In 2004 and again in 2007, the BLM and Forest Service issued a ROD to eliminate the Survey and Manage requirements of the 2001 ROD and to provide protection for species on the Survey and Manage lists by managing them under the agencies' special-status species programs. In 2014, the Court issued a remedy order in the case of *Conservation Northwest et al. v. Bonnie et al.*, No 08-1067-JCC (W.D. Wash.)/No. 11-35729 (9th Circ.). As the latest step in the ongoing litigation challenging the 2007 ROD, this remedy order vacated the 2007 ROD to remove or modify the Survey and Manage mitigation measure standards and guidelines, which returned the agencies to the status quo in existence prior to the 2007 ROD. Thus, the 2001 ROD was reinstated, including any amendments or modifications to the 2001 ROD that were in effect as of March 21, 2004, returning the species to the category assigned in the 2001 ROD.

In accordance with the 2014 Court decision, this assessment was completed using the 2001 ROD Survey and Manage Standards and Guidelines, with the 2003 Annual Species Review (ASR) modifications for the species list and category assignments (excepting the 2003 ASR red tree vole removal).

In 2016, the BLM approved two new RMPs, including the Northwestern and Coastal Oregon RMP and the Southwestern Oregon RMP (BLM 2016a, 2016b). All lands managed by the BLM that occur in the Pacific Connector Project are within the revised RMPs' management areas. The past RMPs were developed consistent with the 1994 NWFP and thereby included Survey and Manage species measures. The 2016 RMPs revises the past RMPs in their entirety and removes all measures for Survey and Manage species, although Forest Service Survey and Manage species identified as BLM sensitive species would continue to receive protections consistent with BLM's sensitive species management program.

Although some species covered by the Survey and Manage Standards and Guidelines also occur on private land, land managed by the BLM, and areas outside the NSO range, the requirements of the 1994 NWFP and 2001 ROD apply only to lands managed by the Forest Service within the range of the NSO.

The NWFP ROD and the 2001 ROD do not prescribe a well-defined process for evaluating effects on species persistence or viability from a proposed activity. The 2001 ROD states "instead, common sense and agency expertise must be used in making determinations of compliance with the viability provision" (Standards and Guidelines). The Forest Service has embraced this approach for evaluating effects of the Project on the persistence of affected Survey and Manage species in the NSO range. The Standards and Guidelines and 2001 ROD are intended to "provide a reasonable assurance of species persistence" for all the Survey and Manage species. If the Project is constructed, it would affect numerous known sites of Survey and Manage species. This assessment seeks to determine, should the Project be constructed, whether there would be a reasonable assurance of species persistence for those Survey and Manage species affected by the Project in the NSO range. The evaluation of species persistence is presented in appendix F.5 to this EIS, and this section summarizes the results of the evaluation. Attachment A to appendix F.5 lists the Survey and Manage species considered in the persistence evaluation.

This section is organized by taxonomic group and includes a brief overview of the species considered in the persistence evaluation; a summary of the distribution of sites of the species in the NSO range; an analysis of the effects of the Project on the sites; and breakdowns of the number of sites of each species in the NSO range, the number of affected sites of each species across the analysis area, and the number of affected sites on the Umpqua, Rogue River-Siskiyou, and Fremont-Winema National Forests. Details on the methodology used for the persistence evaluation (e.g., establishment of sites for each species, mapping of general habitat and site distribution, analysis of effects on sites) and a glossary of key terms used in the evaluation available in appendix F.5. The factors used to evaluate the Project effects are outlined in appendix F.5 and were derived from the 2001 ROD criteria for species persistence and relative rarity. This persistence evaluation is not intended to serve as an annual species review or an evaluation of the relative rarity of the species. This analysis is focused only on the effects on the species that could result from implementation of the Project and is intended to provide sufficient information to support subsequent findings by the Forest Service.

This assessment provides a conservative site-specific analysis of effects on sites, which consist of the recorded observations of Survey and Manage species from agency geodatabases and a surrounding protection buffer, and generally assumes that site persistence would not be maintained following Project implementation if a site falls within the analysis area. This conservative approach was considered sufficient if Project-related effects on the sites would not substantially alter the distribution of the species across the NSO range (e.g., the species would still be well distributed or locally abundant near the Project area). However, if the initial analysis revealed that remaining sites (i.e., those not affected by the Project) may not provide a reasonable assurance of species persistence, a closer evaluation of the effects on each site was conducted to further assess effects of the Project and determine if site persistence would be maintained at any of the sites following Project implementation, or if measures would be needed to protect or avoid the site(s). Additional details on the methodology used to evaluate effects are presented in appendix F.5.

Incomplete or Unavailable Information

CEQ regulations 40 CFR 1502.22 require a discussion of incomplete or unavailable information. Information is incomplete or unavailable for:

- **Total populations of Survey and Manage species beyond those represented in the geodatabases of the agencies used in this report.** Although a statistically reliable region-wide survey has been completed for most of the Survey and Manage species (Forest Service and BLM 2007: 142), the results of those surveys have not been biologically interpreted, and the final results have not yet been published. In absence of a published interpretation of the results of those regional surveys, this assessment relies on the known sites of affected species that have been inventoried and recorded in the known site geodatabases of the BLM and Forest Service. These data constitute "best available information" for populations of Survey and Manage species and provide sufficient information to make a reasoned choice between the alternatives and to make an informed decision related to the persistence standards of the 2001 Survey and Manage ROD. A total population estimate is not necessary to make a reasoned choice between the alternatives.
- **Total acres of the specialized microsites and habitats used by certain Survey and Manage species.** This analysis was completed using geodatabase records of observations (i.e., "known sites"), regionally available vegetation inventory data, and evaluation criteria developed from the 2001 ROD. In many cases, Survey and Manage species rely on specialized habitats that may not be catalogued in agency geodatabase records or vegetation inventories. This is one of the reasons why pre-Project surveys are required for Survey and Manage species. Habitat requirements for each of the species considered are discussed in detail in appendix F.5. In this assessment, estimates are provided of the general areas where specialized habitats may be found, but these should not be interpreted as the actual acres of available specialized habitats; the actual acres of available specialized habitats are typically a fraction of the general habitat description. For example, some mollusks rely on moist microsites found in late-successional coniferous forests. A regional inventory of late-successional coniferous forests is available, but a regional inventory of moist microsites is not; there are many, many more acres of late-successional forests than there are acres of moist microsites within those forests. This assessment identifies known sites and broad habitat classifications such as "late-successional coniferous forests below 6,000 feet" where specialized habitats and the species in question may be found, but makes no estimates of, nor does the analysis rely on, estimates of specialized habitats that may exist within those broad vegetation categories. The cost of acquiring such an inventory of microsite environments over the entire area of the NWFP would be exorbitant and is not essential to making a reasoned choice between the alternatives. As noted in the Final Supplemental EIS for Survey and Manage Species, "the likelihood that an activity modifying late-successional forest will occur within the range of a truly rare or localized species population must be viewed in light of the relatively conservative degree of modification of late-successional forest projected to occur within the NWFP area. For example, management activities (timber harvest and prescribed fire) are projected to

modify approximately 3 percent of the late-successional forest within the area over the next decade" (Forest Service and BLM 2000: 180). Pre-Project survey data and existing known sites of Survey and Manage species within the area of the NWFP provide sufficient information to determine whether there is a "reasonable assurance of species persistence," which is the standard of the 2001 Survey and Manage ROD.

- **Recovery of occupied sites after disturbance.** Survey and Manage species are associated with LSOG forests on NFS lands. The construction corridor and TEWAs will be reforested and replanted with native vegetation similar to what occupied the Project area prior to disturbance. It will be at least 80 years before those areas provide late-successional habitat. A 30-foot-wide maintenance corridor centered along the pipeline route would be maintained in low growing brush and grass vegetation (no trees) for the life of the Project. When the Project is decommissioned, it would be at least an additional 80 years before this strip provides late-successional stand characteristics. Information is not generally available as to how effectively the affected Survey and Manage species will reoccupy these areas. This analysis presumes that if the "site" is within the construction clearing or TEWAs, the Project would result in a long-term loss of that site. This analysis does not speculate on when or if the affected species may reoccupy the site. Since sites are presumed lost if affected, and that provides the basis for the assessment, data related to recovery or reoccupation of sites are not essential to the decision to be made or the choice between alternatives.

Survey and Manage Species Surveys and Evaluations

Surveys conducted for the Project in and near the Project area through 2016 resulted in numerous observations of Survey and Manage species. These survey results in combination with results from prior surveys conducted near the Project area were used to identify the Survey and Manage species that could be affected by the Project. Observation data stored in agency geodatabases were converted to "sites" or "known sites" using a standardized mapping protocol based on buffer distances described in the 2001 ROD. Species evaluated include those that have sites on NFS lands in or near the Project area. The species considered include 31 fungi, 2 lichens, 1 vascular plant, 2 mollusks, 1 mammal, and 1 bird.

Fungi

The diverse fungi of the Pacific Northwest include several hundred saprobic (decomposers), parasitic, and symbiotic (mutualistic) macro- and micro-fungi species. The 2003 list includes 194 species of fungi under the Survey and Manage Standards and Guidelines. Of these species, 31 are considered in this evaluation of the Project because they have been documented on NFS lands in or near the Project area. Appendix F.5 of this EIS presents additional details on each species, while the key information used to evaluate Project-related effects is summarized in this section.

The fungi considered in this analysis consist primarily of mycorrhizal or symbiotic species, which include truffles, false truffles, chanterelles, boletes, coral fungi, and gilled mushrooms. Some of the species are saprobic gilled mushrooms or parasitic fungi. The mycorrhizal fungi form symbiotic relationships with vascular plants to exchange nutrients and water for photosynthate. The saprobic species are found on dead or decaying wood, including snags. The fungi fruit at different times of year, and many do not fruit annually, although they may still be present in the soil. Although surveys have been conducted across the Project area and in other parts of the NSO range, the difficulty in detecting fungi when fruiting bodies are not present has limited the ability to fully describe the range and distribution of many species within the NSO range. The fungi species considered in this analysis are listed in table 4.6.4.3-1 with the currently known number of sites in the NSO range. Many of these species are likely more abundant than currently documented, and more survey effort would be expected to locate additional sites of the species.

TABLE 4.6.4.3-1

Regional Site Count of Fungi Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/

Spathularia flavida	194	81	52 (64%)
Tremiscus helvelloides	318	62	34 (55%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent “Riparian Reserves” across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in NFS reserves to total sites on NFS lands.

Habitat for these species varies and has generally been classified as coniferous, mixed hardwood-coniferous, and/or hardwood forests, including the LSOG component of these forests. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The data are the best available data on forest types across the NSO range but likely overestimate the amount of potential habitat available in the region for many of the species considered in this analysis, particularly those with microsite conditions that have not been mapped at a regional scale. The extent of potential habitat for each species varies based on its distribution across the NSO range and its habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of 31 Survey and Manage fungi at one or more sites in or near the Project area. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soil within sites and could result in the removal of populations or individuals of fungi. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase, although not all species are affected by open corridors or change in forest age (e.g., *P. fallax*, *P. piceae*, *P. sipei*, and *P. spadicea*). The removal of coniferous, mixed hardwood-coniferous, and hardwood forests, including the LSOG component of these forests, and disturbance to soil, understory substrate (e.g., rocks, downed logs), and roots of trees could negatively affect the fungi in adjacent areas by removing their habitat, disturbing soil or duff around trees or roots of trees, and affecting mycorrhizal associations with the trees or other relationships between the fungi and their hosts, potentially affecting site persistence even if the entire site is not disturbed. For some species that are found in more open habitats (e.g., *C. olympianus*, *H. caeruleus*, *S. flavida*), these microclimate changes may not affect site persistence. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor and TEWAs could make habitat within the sites no longer suitable for the species. Material storage within UCSAs would disturb understory habitat in some sites, which could also modify microhabitats near extant populations or individuals, potentially making the habitat no longer suitable for the species. Road improvements and establishment could remove habitat and extant populations or individuals of the fungi. The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-2 presents a summary of the number of sites of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-2

Fungi Sites Potentially Affected by the Project

Species	**Total Affected NFS Sites a/**	**Affected Sites in NFS Reserves**	**Remaining Sites on NFS Lands in NSO Range**	**Remaining Sites on all Lands in NSO Range**

a/ Affected sites are those on NFS land that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5.

b/ Although one or more sites would be affected by the Project, individuals within some of the sites would not be affected, and site persistence would be maintained for those sites following project implementation. The remaining site count includes sites that may be affected, but for which site persistence is expected to be maintained. Only sites for which site persistence would be affected were removed from the remaining site count.

The species listed below appear to be more common than previously documented or are relatively common across the NSO range based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. For these species, the Project would affect individuals or habitat at one or more sites and could affect site persistence, but the remaining sites in the NSO range would continue to provide a reasonable assurance of species persistence:

Clavariadelphus occidentalis
Clavariadelphus sachalinensis
Clavariadelphus truncatus
Collybia bakerensis
Cortinarius olympianus
Cudonia monticola
Galerina atkinsoniana
Gastroboletus subalpinus
Gomphus clavatus
Gomphus kauffmanii
lbatrellus ellisii
Mycena overholtsii
Polyozellus multiplex
Ramaria araiospora
Ramaria coulterae
Ramaria coulterae
Ramaria rubrievanescens
Ramaria rubripermanens
Ramaria rubripermanens
Ramaria stuntzii
Rhizopogon truncatus
Rhizopogon truncatus
Sparassis crispa
Spathularia flavida
Tremiscus helvelloides

The species listed below are not necessarily more common than previously documented despite new information available from pre-disturbance surveys for the Project and/or other sources since these species were listed in the 2001 ROD. For these species, the Project would affect individuals or habitat at one or more sites and could affect site persistence, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence:

Arcangeliella crassa
Boletus pulcherrimus

Choiromyces alveolatus
Collybia racemose
Cortinarius magnivelatus
Cortinarius verrucisporus
Gymnomyces abietis
Hygrophorus caeruleus
Sedecula pulvinata

The species listed below is not necessarily more common than previously documented despite new information available from pre-disturbance surveys for the Project and/or other sources since these species were listed in the 2001 ROD. For this species, the Project would affect site persistence at one or more sites, and the remaining sites in the NSO range may not provide a reasonable assurance of species persistence. These species are known from a low number of sites within a part of the NSO range, has limited habitat requirements, and has a distribution pattern in which every site may be important for dispersal opportunities to ensure the persistence of the species in the NSO range:

Sarcodon fuscoindicus

The Project would affect a portion of one site where two observations of this species have been documented on NFS lands. This site is located in the Trail Creek watershed on the ridge just east of the South Fork Cow Creek watershed between MPs 111.5 and 111.6. Approximately 1.2 acres (30 percent of the site) is associated with the construction corridor (0.8 acres) and associated UCSA (0.4 acres). The location of this site is illustrated in appendix F-5 (Section 2.27, Figure SAFU-5).

The Project would result in ground disturbance and vegetation removal in the eastern half of the site near MP 111.5. The two recorded observations within the site may be avoided by construction activities within the corridor, but fruiting bodies, if present, could be disturbed in one of the observations during material storage within a UCSA (see Figure SAFU-5). The species would also be subject to indirect effects associated with the Project based on the proximity of project activities to the observations.

Establishment of the 95-foot wide construction corridor would disturb vegetation and soils within the site. The area within the site is mostly forested, and the establishment of the corridor could modify microclimate conditions around the recorded observations. The removal of forests and host trees and disturbance to soil could negatively affect *S. fuscoindicus* in adjacent areas by removing its habitat, disturbing soil or duff around trees or roots of trees, and affecting its mycorrhizal association with the trees, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions within 100 feet of an observation as a result of the corridor could make habitat within the site no longer suitable for the species. Restored portions of the corridor would be dominated by early seral vegetation for approximately 30 years, which would result in long-term changes to habitat conditions. A 30-foot wide portion of the corridor would be maintained in low-growing vegetation for pipeline maintenance and would not provide habitat for the species during the life of the Project. Material storage within UCSAs could damage individuals and would disturb understory habitat within the site, which could modify microhabitats near individuals that are not removed or damaged, potential making the habitat no longer suitable for the species.

Based on this analysis of the site on NFS lands, *S. fuscoindicus* is not likely to persist following Project implementation. The site is the only site on NFS lands in the local area and the nearest sites on NFS lands are approximately 45 miles to the northeast and 75 miles to the southwest.

Lichens

Lichens are distinct symbiotic organisms that consist of a fungus and an algae or cyanobacterium, which make them members of two or three biological kingdoms. They play a major ecological role, particularly in old-growth forests, by cycling nutrients and producing biomass. Lichens tend to be dispersal limited and grow slower than vascular plants. The 2001 Survey and Manage ROD including the 2003 ASR modifications to the species list includes 45 lichen species. Of these, two are considered in this evaluation because they have been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on each species, while the key information used to evaluate Project-related effects is summarized in this section.

Both lichens considered in this analysis are epiphytic lichens, which grow directly on trees or shrubs. *Chaenotheca subroscida* commonly occurs on pine trees in upland habitats and *Leptogium teretiusculum* tends to be associated with riparian habitat.

Although surveys have been conducted across the Project area and in other parts of the NSO range, the difficulty in detecting some lichens because of their size has limited the ability to fully describe the range and distribution of some species within the NSO range. The lichen species considered in this analysis are listed in table 4.6.4.3-3 with the currently known number of sites in the NSO range, and the distributions of the species are briefly discussed after the table.

TABLE 4.6.4.3-3

Regional Site Count of Lichen Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/
Chaenotheca subroscida	396	110	73 (66%)
Leptogium teretiusculum	267	16	9 (56%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent “Riparian Reserves” across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands.

Habitat for these species has been classified as coniferous, mixed hardwood-coniferous, and/or hardwood forests, including the LSOG component of these forests. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for each species varies based on its distribution across the NSO range and habitat preferences. Additional details on habitat for these species are presented in appendix F.5.

The Project could affect site persistence of two Survey and Manage lichens at one or more sites on NFS lands in or near the Project area. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soil within sites and could result in the removal of populations or individuals of lichens. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of coniferous, mixed hardwood-coniferous, and hardwood forests, including the LSOG component of these forests, and disturbance to soil, understory substrate (e.g., rocks, downed logs), and roots of trees could negatively affect the lichens in adjacent areas by removing their habitat, disturbing soil or substrate around trees or roots of trees, and affecting associations with the trees or other substrate, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor and TEWAs could make habitat within the sites no longer suitable for the species. Material storage within UCSAs would disturb understory habitat in some sites, which could also modify microhabitats near extant populations or individuals, potentially making the habitat no longer suitable for some of the species. Road improvements and establishment could remove habitat and extant populations or individuals of the lichens. The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-4 presents a summary of the number of sites of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-4

Lichen Sites Potentially Affected by the Project

Species	Total Affected NFS Sites a/	Affected Sites in NFS Reserves	Remaining Sites on NFS Lands in NSO Range	Remaining Sites on all Lands in NSO Range
Chaenotheca subroscida	6	4	104	382
Leptogium teretiusculum	1	1	15	261

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Using the spatial analysis process described in appendix F.5, these sites may be clipped by the Project area or fall outside the Project area, but within the analysis area.

The two lichen species analyzed appear to be more common than previously documented or are relatively common across the NSO range based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. The Project would affect site persistence at one or more sites, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

Measures incorporated into the Project as design features would be implemented to minimize soil and vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on all Survey and Manage lichens in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendment of the land management plans for the National Forests that encompass the Project area. Table 4.6.4.3-5 lists the lichen species and the number of affected sites on each National Forest.

TABLE 4.6.4.3-5

a/ All sites are directly affected (i.e., are located in the Project area).

Vascular Plants

Vascular plants are the most dominant organism in LSOG forests and serve an essential role by providing a food source and cover or shelter for animals and influencing microclimate conditions for other species, such as fungi and lichens. Vascular plants include seed-bearing plants, such as flowering plants and conifer trees, and spore-bearing forms, such as ferns, horsetails, and clubmosses. The Survey and Manage 2001 ROD including 2003 ASR modifications includes 12 plant species. Of the 12 species, clustered lady's slipper (*Cyripedium fasciculatum*) is evaluated for this Project because it has been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on the species, while the key information used to evaluate Project-related effects is summarized in this section.

Surveys for vascular plants have been conducted in much of the NSO range, and the results of these surveys have contributed information to characterize the known extent of the plants in the NSO range. Additional surveys for Survey and Manage species were conducted for the Project as recently as the fall of 2018.[144] Table 4.6.4.3-6 includes the currently known number of *C. fasciculatum* sites in the NSO range. The range of *C. fasciculatum* in the NSO range is relatively well known, and more survey effort would be expected to locate additional sites of the species within its currently known range.

TABLE 4.6.4.3-6

Regional Site Count of Plant Species Potentially Affected by the Project

Species	**Total Sites in NSO Range a/**	**Sites on NFS Lands in NSO Range b/**	**Sites in NFS Reserves in NSO Range c/**
Cypripedium fasciculatum	1,392	1540	198 (37%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent "Riparian Reserves" across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands.

C. fasciculatum is well distributed across most of its known range in the NSO range. Sites are distributed in two general groups in the Klamath Mountains and Cascade Range in Oregon and California and the eastern Cascade Range in Washington. The species appears to be well distributed in the Klamath Mountains in California and Oregon.

General habitat for this species consists of coniferous and mixed hardwood-coniferous forests, including the LSOG component of these forests, across each species' currently known range. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for each species varies based on its distribution across the NSO range and habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of *C. fasciculatum* at one site on NFS land in the Project area. The site occurs on the Umpqua National Forest. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soil within sites and could

[144] Results from these will be incorporated into the final EIS.

result in the removal of populations or individuals of plants. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of coniferous and mixed hardwood-coniferous forests, including the LSOG component of these forests, and disturbance to soil could negatively affect the plants in adjacent areas by removing their habitat, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor and TEWAs could make habitat within the sites no longer suitable for the species. Material storage within UCSAs would disturb understory habitat in some sites, which could also modify microhabitats near extant populations or individuals, potentially making the habitat no longer suitable for some of the species. Road improvements and establishment could remove habitat and extant populations or individuals of the plants. The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-7 presents a summary of the sties that would remain after the single site is affected by Project activities; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-7

Vascular Plant Sites Potentially Affected by Project

Species	Total Affected NFS Sites a/	Affected Sites in Reserves	Remaining Sites on NFS Lands in NSO Range	Remaining Sites on all Lands in NSO Range
Cypripedium fasciculatum	1	1	1,539	1,390

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Using the spatial analysis process described in appendix F.5, these sites may be clipped by the Project area or fall outside the Project area, but within the analysis area.

Cypripedium fasciculatum appears to be more common than previously documented based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. Many sites have been documented in southwest Oregon since the 2001 ROD was published. Should the Project be constructed, it is unlikely that the loss of one site from Project effects would affect the status of *C. fasciculatum* in the NSO range. The Project would affect site persistence at one site on NFS lands, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

Measures incorporated into the Project as design features would be implemented to minimize soil and vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on Survey and Manage plants in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendments to the land management plans for National Forests that encompass the Project area.

Mollusks

Approximately 350 species of mollusks, including land snails, aquatic snails, slugs, and clams, are found in the Pacific Northwest (Forest Service and BLM 2000). Slugs and snails are found in colonies, which may consist of hundreds to many thousands of individuals. Most mollusks are found in moist forests and riparian areas near streams, springs, and seeps. The 2001 ROD including 2003 ASR modifications includes 38 species of mollusks. Of these species, two are considered in this evaluation of the Project because they have been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on each species, while the key information used to evaluate Project-related effects is summarized in this section.

The mollusk species considered in this analysis include evening fieldslug (*Deroceras hesperium*) and Chace sideband (*Monadenia chaceana*). *Deroceras hesperium* is a land slug that requires high moisture environments and is found along the forest floor. A recent study on the molecular characteristics of *D. hesperium* revealed that the mollusk is likely a variant of the more common *D. laeve* (Roth et al. 2013), and *D. hesperium* may no longer belong on the Survey and Manage list, pending an annual species review. Since the species is on the 2003 list, it is evaluated like other Survey and Manage species on the list in this assessment. *Monadenia chaceana* is a land snail that is found in talus or under rocks in moist forests. Both mollusks may be associated with Riparian Reserves.

Surveys for mollusks have been conducted in parts of the NSO range, and the results of these surveys have contributed information to characterize the known extent of the mollusks in the NSO range. Surveys for the Project resulted in several observations of both species. The mollusk species considered in this analysis are listed in table 4.6.4.3-8 with the currently known number of sites in the NSO range. The ranges of these species in the NSO range are relatively well known, and more survey effort would be expected to locate additional sites of the species within their currently known ranges.

The distribution of the species and their ranges within the NSO range vary. *Deroceras hesperium* has a distribution pattern with limited potential for connectivity between isolated sites or site clusters. Sites are found in four general areas in Oregon, including a relatively large cluster of sites located in the southern Cascade Range, and other clustered sites located in the northern Cascade Range and southern Coast Range. Scattered sites are in the northern Cascade Range, and several isolated sites are in other areas. *Monadenia chaceana* has multiple sites or clusters of sites that are nested within a web of potential interconnections. Sites are primarily found in a large group of several clusters in the eastern Klamath Mountains and southern Cascade Range in Oregon and extreme northern California.

TABLE 4.6.4.3-8

Regional Site Count of Mollusk Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/
Deroceras hesperium	54	27	13 (48%)
Monadenia chaceana	258	246	34 (14%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent "Riparian Reserves" across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands.

General habitat for these species consists of a subcomponent (e.g., moist riparian areas, shaded rocky areas) of coniferous, mixed hardwood-coniferous, and hardwood forests, including the LSOG component of these forests, across each species' currently known range. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for the species varies based on its distribution across the NSO range and habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of two Survey and Manage mollusk species at one or more sites in or near the Project area. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soils within sites and could result in injury or mortality to individuals of mollusks. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of forests and understory components could negatively affect the mollusks in adjacent areas by removing their habitat, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor could make habitat within sites no longer suitable for the species. Material storage within UCSAs could disturb understory habitat in sites, which could remove rocks, logs, or woody debris, potentially making the habitat unsuitable for the species or injuring individuals.

The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-9 presents a summary of the number of sites of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-9

Mollusk Sites Potentially Affected by the Project

Species	**Total Affected NFS Sites a/**	**Affected Sites in NFS Reserves**	**Remaining Sites on NFS Lands in NSO Range**	**Remaining Sites on all Lands in NSO Range**
Deroceras hesperium	1	1	26	53
Monadenia chaceana	9	9	249	396

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Direct effects are those that would take place within the Project area, such as from ground disturbance, vegetation removal, or removal of individuals. Indirect effects are those that would take place outside of the Project area, such as from edge effects or increased open canopy. Using the spatial analysis process described in appendix F.5, these sites may be clipped by or fall outside the Project area, but within the analysis area.

Deroceras hesperium is not necessarily more common than previously documented despite new information available from pre-disturbance surveys for the Project and/or other sources since this species was listed in the 2001 ROD. The Project would affect site persistence at one site, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence. Although this species has a somewhat limited distribution in the NSO range, the affected site is part of a large cluster of sites in the southern Cascade Range in Oregon. The distribution and connectivity of the species would likely remain the same despite the loss of one site.

Monadenia chaceana appears to be more common than previously documented based on new information available from surveys for the Project and/or other sources since this species was listed in the 2001 ROD. The Project would affect site persistence at nine sites, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

Measures incorporated into the Project as design features would be implemented to minimize soil and vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on Survey and Manage mollusks in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendments to the land management plans for the National Forests that encompass the Project area. Table 4.6.4.3-10 lists the mollusk species and the number of affected sites in each National Forest.

TABLE 4.6.4.3-10

a/ First number presents sites directly affected (i.e., in Project area), number in parentheses presents sites indirectly affected (i.e., sites wholly in analysis area). a

Vertebrates

A diverse array of vertebrate species, including mammals, birds, amphibians, and reptiles, inhabit the forests of the Pacific Northwest and provide essential functions in the ecosystem, such as dispersing fungal spores and lichens and serving as a food source for predators. The 2001 ROD including the 2003 ASR modifications to the species list includes seven vertebrate species. Two vertebrate species are considered in this evaluation of the Project because they have been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on each species, and the key information used to evaluate Project-related effects is summarized in this section.

The vertebrate species considered in this analysis include red tree vole (*Arborimus longicaudus*) and great gray owl (*Strix nebulosa*). *Arborimus longicaudus* is a small arboreal rodent that lives in tree canopies of coniferous and mixed hardwood-coniferous forests and seldom goes to the forest floor (Forest Service and BLM 2001b). It is a primary prey item of the northern spotted owl, as well as other predators found in coniferous forests. *Strix nebulosa* is a forest owl that uses existing stick nests constructed by other raptors and large corvids, and nests between March 1 and July 31 (Williams 2012). It forages in natural forest openings, typically larger than 10 acres, and nests in coniferous and mixed hardwood-coniferous forests.

Surveys for the vole and owl have been conducted across much of the NSO range, and the results of these surveys have contributed information to characterize the known extent of the species in the NSO range. Surveys for the Project resulted in multiple observations of both species in the surveyed areas. The vertebrate species considered in this analysis are listed in table 4.6.4.3-11 with the currently known number of sites in the NSO range, and the distributions of the species are briefly discussed after the table. The ranges of these species in the NSO range are relatively well known, and more survey effort would be expected to locate additional sites of the species within their currently known ranges.

TABLE 4.6.4.3-11

Regional Site Count of Vertebrate Species Potentially Affected by the Project

Species	**Total Sites in NSO Range a/**	**Sites on NFS Lands in NSO Range b/**	**Sites in NFS Reserves in NSO Range c/**
Arborimus longicaudus	34,946	1,524	624 (34%)
Strix nebulosa	177	55	16 (12%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent "Riparian Reserves" across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands

The distribution of the species and their ranges within the NSO range vary. Both species have multiple sites or clusters of sites that are nested within a web of potential interconnections. Most *A. longicaudus* sites are found in the Klamath Mountains in Oregon, where sites are abundant and close together in large clusters or groups. Sites are more scattered in the western Cascade Range in Oregon, although they are still relatively abundant. *Arborimus longicaudus* appears to be well distributed within its range in Oregon. Most *S. nebulosa* sites are found in a large group in the southern Cascade Range and eastern Klamath Mountains, where the species appears to be well distributed.

General habitat for *A. longicaudus* consists of LSOG coniferous and mixed hardwood-coniferous forests across the species' currently known range in Oregon. General habitat for *S. nebulosa* consists of coniferous and mixed hardwood-coniferous forests, including the LSOG component of these forests, with a subcomponent of natural forest openings (e.g., meadows) that are used for foraging. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for the species varies based on its distribution across the NSO range and habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of two Survey and Manage vertebrates at more than one site or habitat area in or near the Project area. Vegetation removal in the construction corridor and TEWAs and along roads could result in the removal of trees that support *A. longicaudus* nests or cause injury or mortality to individuals. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of forests and potential nest trees could negatively affect *A. longicaudus* in adjacent areas by removing its habitat and opening the tree canopy, potentially affecting site persistence at the habitat areas even if the entire habitat area is not disturbed. In particular, modification of shading and habitat conditions as a result of the corridor, TEWAs, and roads could make entire habitat areas no longer suitable for the species because of the preference for closed canopy habitats. Activities within the corridor and TEWAs would result in extensive noise disturbance during vegetation clearing, grading, and pipeline installation and could result in *S. nebulosa* nest abandonment and loss of young during the nesting season. No active *S. nebulosa* nest sites were documented in the Project area; therefore, direct effects on the owl (e.g., removal of active nests, injury to owls) are not anticipated. Vegetation removal across the Project area would also result in a long-term loss of habitat that may be suitable for the species. Conversely, if constructed, the construction corridor would also create an early seral plant community suitable for foraging by great grey owls.

The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-12 presents a summary of the number of sites (habitat areas for *A. longicaudus*) of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

Both species appear to be more common than previously documented based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. The Project would affect site persistence at multiple sites or habitat areas of each species, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

TABLE 4.6.4.3-12

Vertebrate Sites Potentially Affected by the Project

Species	Total Affected NFS Sites a/	Affected Sites in NFS Reserves	Remaining Sites on NFS Lands in NSO Range	Remaining Sites on All Lands in NSO Range
Arborimus longicaudus	525 (55) b/	10 (24)	1,469 c/	4,843
Strix nebulosa	1	1	54	171

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Direct effects are those that would take place within the Project area, such as from ground disturbance, vegetation removal, or removal of individuals. Indirect effects are those that would take place outside of the Project area, such as from edge effects or increased open canopy. Using the spatial analysis process described in appendix F.5, these sites may be clipped by or fall outside the Project area, but within the analysis area.
b/ *A. longicaudus* sites are habitat areas (55 sites were converted to 25 habitat areas in the analysis area), as mapped in accordance with the management recommendations for the species (Forest Service and BLM 2001b).
c/ The total of remaining sites is based on site data, not habitat areas. Habitat areas were not produced for the entire regional area, just the analysis area.

Measures incorporated into the Project as design features would be implemented to minimize vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on Survey and Manage vertebrates in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendments to the land management plans for the National Forests that encompass the Project area. Table 4.6.4.3-13 lists the vertebrate species and the number of affected sites or habitat areas in each National Forest.

TABLE 4.6.4.3-13

Affected Vertebrate Sites by National Forest

	Number of Sites Affected a/		
Species	**Umpqua**	**Rogue River-Siskiyou**	**Fremont-Winema**
Arborimus longicaudus b/	125	—	—
Strix nebulosa	—	0 (1)	—

a/ First number presents sites directly affected (i.e., in Project area), number in parentheses presents sites indirectly affected (i.e., sites wholly in analysis area).
b/ *A. longicaudus* sites are habitat areas, as mapped in accordance with the management recommendations for the species (Forest Service and BLM 2001b).

In conclusion, the Project could affect site persistence of 38 Survey and Manage species at one or more sites or habitat areas in or near the Project area. The remaining sites of 37 of these 38 species, however, would provide a reasonable assurance of these species persistence. The Project as proposed would affect site persistence of the fungi *Sarcodon fuscoindicus* at one or more sites, and the remaining sites may not provide a reasonable assurance of this species persistence. However, above we have recommended that Pacific Connector avoid affecting the *Sarcodon fuscoindicus* site by incorporating a pipeline route variation that avoids this site into the proposed action (see chapter 3). Therefore, the analysis summarized in this section, supported by the information presented in appendix F.5, indicate that construction and operation of the Project would provide a reasonable assurance of persistence of Forest Service Survey and Manage species that would be affected.

4.7.1.1 Land Ownership and Existing Land Use

Land Ownership

The 197-acre LNG terminal site (figure 4.7-1a) is owned by Fort Chicago Holdings II US LLC (Fort Chicago Holdings), an affiliate of Jordan Cove. As depicted in figure 4.7-1a, the terminal site consists of two parcels that are connected by an access corridor. The two parcels are commonly referred to as the Ingram Yard and South Dunes properties. The associated terminal sites depicted in figures 4.7-1b and 4.7-1c are privately owned lands that Jordan Cove has secured or would secure agreements to use. Ownership of lands required for the Project is summarized in table 4.7.1.1-1. With the exception of BLM land crossed by the industrial wastewater pipeline (within an existing utility corridor), no federal lands would be used for the Jordan Cove Project.

In addition, the COE possesses a 40-acre perpetual easement that coincides with the boundaries of the Ingram Yard loading terminal site. Located between Roseburg Forest Products and Jordan Cove lands, this easement reserves: "*[t]he perpetual right, power, privilege and easement in, upon, over, and across the lands described herein for sand stabilization*." As part of the COE Section 408 process, the COE would need to issue a "consent to easement structures," which would address the COE's rights and how Jordan Cove would provide alternatives should the rights need to be exercised.

TABLE 4.7.1.1-1

Land Ownership of the Jordan Cove Project Area Facilities

Project Facility/Activity	Ownership
Construction and Operation	
LNG Terminal	Fort Chicago Holdings II US LLC
Ingram Yard	
South Dunes Site (including Workforce Housing Facility)	
Access and Utility Corridor	
Slip	
Access Channel	State of Oregon (easement)
Material Offloading Facility (MOF)	State of Oregon (easement)
Industrial Wastewater Pipeline	Designated Trans-Pacific Parkway roadway, railway, & utility corridor (permission from Coos County and an easement from BLM)
Meteorological Station Site	Oregon International Port of Coos Bay
Temporary Construction	
LNG Terminal	Fort Chicago Holdings II US LLC
Ingram Yard Laydown Area	
South Dunes Laydown, Housing, and Parking Area	
Hydraulic Dredge Pipeline	
Trans-Pacific Parkway/U.S. 101 Widening	ODOT and Coos County Rights-of-Way
Roseburg Laydown Site	Roseburg Forest Products Company
Port Laydown Site	Oregon International Port of Coos Bay
APCO Laydown Site	APCO Coos Properties, LLC
Boxcar Hill Staging Area	Oregon Dunes Sand Park, LLC
Myrtlewood Offsite Park & Ride	Private
Temporary Dredge Lines	State of Oregon (easement)
Kentuck Line	State of Oregon (easement)
Environmental Mitigation Areas	
Kentuck Project Site	Fort Chicago Holdings II US LLC and private
Eelgrass Mitigation Site	State of Oregon
Lagoon Site	Oregon International Port of Coos Bay
North Bank Site	Fort Chicago Holdings II US LLC
Panhandle Site	Oregon International Port of Coos Bay

Figure 4.7-1c

Land Ownership

Existing Land Use

The LNG terminal site consists of a combination of brownfield decommissioned industrial facilities, an existing landfill requiring closure, and open land covered by grasslands, sand, and shrubs, as well as an area of forested dunes (see figures 4.7-2a, 4.7-2b, and 4.7-2c). Portions of the proposed site and the Port Laydown site were previously used for disposal of dredged material.

Land uses affected by construction and operation of the LNG terminal and associated facilities are identified in table 4.7.1.1-2. Lands affected during construction include areas that would be permanently and temporarily altered. Operation-related estimates include only those lands that would be permanently affected. Lands affected by operation would be permanently converted from their former uses to the project facilities identified in table 4.7.1.1-2.

Forest/Woodland

A total of 122 acres of forest/woodland would be affected during construction, with 71 acres permanently affected (table 4.7.1.1-2). More than three-quarters of the forest/woodland affected during construction is located on the terminal site, with an additional 12 percent on the adjacent Roseburg laydown site. Almost all of the permanently affected forest/woodland is located on the terminal site. Permanently affected areas would remain cleared of vegetation for the life of the Project. Areas temporarily disturbed during construction would be restored and, to the extent possible, native plant species would be used for stabilization and to prevent erosion of the disturbed areas. Impacts on vegetation are discussed in more detail in section 4.4.

Industrial/Commercial

Industrial/commercial lands that would be used during construction include parts of the terminal site and also the Roseburg Laydown Site, Port Laydown Site, and off-site park and ride sites. With the exception of the industrial/commercial lands that would become part of the terminal site, almost all impacts on existing industrial/commercial lands would be temporary.

Open Land

Open land disturbed during construction would primarily be located on the terminal site (68 percent) and the APCO Sites 1 and 2 (14 percent) (table 4.7.1.1-2). Open land on the terminal site includes land covered by grasslands, sand, and shrubs. Approximately 73 of the 129 acres of open land that would be disturbed on the terminal site during construction would be permanently affected and converted to site uses. The remaining acres would be restored following construction. Although no permanent facilities are proposed for the APCO Sites 1 and 2, the sites would be used for dredge disposal, with disposal expected to raise site elevations above existing grade by between 37 and 49 feet over a 30 year planning horizon.

In addition to the acres of open land identified in table 4.7.1.1-2, approximately 104 acres of the Kentuck project site would be converted to a wide-ranging habitat of mudflats, salt marsh, willowed scrub/shrubs, and fish structures to provide mitigation for both the Jordan Cove and Pacific Connector projects. Formerly a golf course, the Kentuck project site is currently used for pasture.

Open Water

An estimated 77 acres of open water would be affected during construction, with 28 acres permanently affected (table 4.7.1.1-2). Open water would primarily be disturbed during construction as part of activities related to the access channel (40 percent) and the four dredge areas (40 percent). Impacts related to construction of the access channel that would connect the terminal to the Federal Navigation Channel would be permanent.

Other

The industrial wastewater pipeline would be located entirely within an existing roadway, railway, and utility corridor. Installation would disturb approximately 0.2 acre of the existing corridor, with no permanent effects anticipated.

Residential

No residential lands would be affected by construction and operation of the Project (table 4.7.1.1-2). However, mitigation activities associated with the Kentuck Project site would affect an estimated 7.4 acres currently designated for residential use. Impacts on existing residences are discussed in section 4.7.1.3.

4.7.1.2 Coastal Zone Management

The Jordan Cove LNG terminal would be located within the Oregon coastal zone. The coastal zone is formally defined as extending from the Washington border on the north to the California border on the south; seaward to the extent of state jurisdiction as recognized by federal law (i.e., the territorial sea, extending 3 nautical miles offshore); and inland to the crest of the Oregon Coast Range. The Oregon Coastal Management Program of the ODLCD coordinates management of the State's coastal zone and reviews project-specific compliance and consistency with the CZMA. Procedures for ODLCD coastal zone reviews are specified in federal (15 CFR 930) and state regulations (OAR 660-035). Jordan Cove and Pacific Connector are currently in the process of filing their Coastal Zone Management Act (CZMA) application with the State. The Commission cannot authorize the start of construction until a consistency determination has been provided by the Oregon Coastal Management Program. Therefore, **we recommend that**:

- **Jordan Cove and Pacific Connector <u>should not begin construction</u> of the Project <u>until</u> they file with the Secretary a copy of the determination of consistency with the Coastal Zone Management Plan issued by the State of Oregon.**

4.7.1.3 Existing Residences, Commercial Buildings, and Planned Developments

The nearest residential structure to the LNG terminal site is about 1.1 miles to the southeast. There are no residences within 50 feet of any of the Jordan Cove LNG Project area facilities or the navigation route, with the exception of one residence located approximately 20 feet from the Kentuck project site and another located approximately 30 feet from the North Bank site. Neither of these residences are expected to be affected by Project-related construction or operations. All structures within 0.25 mile of the Project facilities are shown in figure 4.7-3a, figure 4.7-3b, and figure 4.7-3c. The following structures are located within 50 feet of the Jordan Cove facilities:

- one Coos Bay-North Bend Water Board (CBNBWB) facility approximately 50 feet from the Trans-Pacific Parkway work area;
- two structures within the construction work area for the Roseburg Laydown site;
- three structures within the construction work area for the Boxcar Hill site: one business and one shed that would not be affected, and one shed that would be removed; and
- one structure, the Myrtlewood Factory and Gift Shop, within the parking area that would be used as the Myrtlewood Off-site Park & Ride.

With the exception of the shed that would be removed from the construction work area for the Boxcar Hill site, none of these structures would be affected and no mitigation is proposed.

There are currently no planned residential or commercial developments identified within 0.25 mile of the Jordan Cove Project site. However, the Coos County Airport District is planning to extend one of the runways at the Southwest Oregon Regional Airport, which is approximately 0.55 mile south of the LNG terminal site. According to the October 2013 Southwest Oregon Regional Airport Master Plan Update (Coos County Airport District 2013), the Airport Layout Plan and the implementation plan included a proposed 400-foot-long extension of Runway 4-22; however, current plans do not identify this large of an extension. Current proposals are limited to cordoning off the northeast corner of the existing runway to gain land acreage for safety purposes to meet FAA regulations (Krug 2018).

Figure 4.7-3c

Structures within 0.25 Mile of the Jordan Cove Site

The City of North Bend has indicated that it expects to consider adoption of a proposed North Point Area Master Plan for the North Point District in the near future. The North Point District consists of approximately 80 acres made up of the northernmost parcels of North Point. The District is located southeast across Coos Bay from the LNG terminal site, and east across Pont Slough from the airport. The City of North Bend is also proposing to redevelop Simpson Park along Highway 101 to include a new Visitor Information Center and Parks Department facilities. The closest Project components to these areas would be the APCO sites. Advanced Health has demolished the McAuley Hospital in downtown Coos Bay, approximately 3 miles south of the proposed LNG terminal site, and is redeveloping the site to provide housing for Oregon Health and Science University medical students (Johnson 2018). Construction and operation of the LNG terminal is not expected to affect these plans or future uses.

4.7.1.4 Timber

The dune areas at the LNG terminal site currently contain non-merchantable timber. Before mobilizing earth-moving equipment, the trees would be felled and selectively processed for commercial timber. Scrub and stumps from across the site would be processed into mulch for use during construction operations.

4.7.2 Pacific Connector Pipeline and Associated Facilities

4.7.2.1 Land Ownership

The pipeline would cross public and private lands. Approximately 64 percent of the land crossed is privately owned, 34 percent is federal land and 2 percent is state lands (table 4.7.2.1-1). No tribal-owned lands or county lands would be crossed. Federally managed lands are discussed below.

TABLE 4.7.2.1-1

Land Crossed by the Pacific Connector Pipeline by Ownership

	Federal Land		State Land		Private Land		
County	**Miles**	**Percent of Overall Total**	**Miles**	**Percent of Overall Total**	**Miles**	**Percent of Overall Total**	**Total**

Note: Rows and columns may not sum correctly due to rounding. Miles are rounded to the nearest tenth of a mile (values below 0.1 are shown as "<0.1").

A summary of acres affected by the construction and operation of the Pacific Connector pipeline is presented in table 4.7.2.2-2.

Developed Land

Pipeline construction would affect an estimated 721 acres of developed lands, mainly consisting of existing industrial land (49 percent; 350 acres) and transportation/communication corridors (44 percent; 316 acres) (table 4.7.2.2-2). The majority of the construction-related disturbance on existing industrial land (331 acres) would be related to temporary pipe storage. An estimated 111 developed acres would be permanently disturbed, with more than 91 percent of this disturbance related to the permanent ROW. The majority (86 percent) of the ROW disturbance would be located in existing transportation/communication corridors. Other developed areas disturbed during construction would be allowed to return to their existing uses.

TABLE 4.7.2.2-2

Note: Rows and columns may not sum correctly due to rounding. Acres rounded to nearest whole acre (values below 1 are shown a "<1").
a/ Construction disturbance associated with the aboveground facilities is included in the pipeline construction ROW effects.
b/ Portions of some of the PARs are located within the construction ROW and, therefore, there is some duplication in the acreage calculations.
c/ The permanent easement is located within the disturbed acreage of the construction ROW. It is not an addition to the construction effects.
d/ Operation-related disturbance from aboveground facilities is summarized by facility in table 4.7.2.2-3.

CS = communication station; PAR = permanent access road; TAR = temporary access road

Agricultural Land

About 552 acres of cropland and pastureland would be temporarily affected by pipeline construction, with approximately 2 acres of orchards, groves, vineyards, and nurseries also expected to be affected (table 4.7.2.2-2). The majority of this disturbance would be associated with the construction ROW (65 percent) and TEWAs (31 percent). Grazing and other agricultural uses would not be allowed in the affected areas during construction. With the exception of the permanent ROW in orchards, agricultural lands disturbed during construction would be restored and returned to their original condition. Shallow-rooted crops and pasture grasses may be grown across the entire 50-foot-wide permanent easement. The planting of deep-rooted crops, such as orchards and vineyards, would not be permitted directly over the pipeline. Pacific Connector would negotiate with landowners and provide compensation for crop losses or orchards taken out of use as a result of pipeline construction. Landowners could select seed mixes or crops to be planted over the ROW in agricultural crop land or pastures.

To lessen effects on agricultural lands, Pacific Connector would segregate topsoil and repair any damaged irrigation systems or drain tiles. The segregation of topsoil is discussed in section 4.2. In addition, in agricultural areas the pipeline would have a minimum depth cover of 5 feet over the top of the pipe, where possible, to avoid operational effects. The largest proportion of agricultural lands that would be crossed by the pipeline are irrigated cropland in Klamath County.

Rangeland

Pipeline construction would affect an estimated 851 acres of rangeland (table 4.7.2.2-2). Temporary disturbance would result from the construction ROW (45 percent), TEWAs (20 percent), and pipe yards (31 percent). During construction, fences would be temporarily removed and affected lands would be unavailable for grazing. To reduce effects on rangelands (and pasture), Pacific Connector would erect temporary fences and gates to landowner specifications. Fences that are cut during construction would be braced and secured to prevent slack wires. If construction activities break or destroy a natural barrier used for livestock control, gaps would be temporarily fenced to prevent passage of livestock. After construction, fences, gates, and cattle guards (including any natural barriers broken) would be restored to their original state as soon as practical. Pacific Connector would contact the owners of fences prior to disturbing them and provide landowners with an opportunity to remove livestock from the construction ROW. Hayfields and pastures would not be cleared except in areas directly over the trench or where grading would be required to create a level working surface. Potential effects on grazing allotments on federal lands are discussed below in section 4.7.3.

Forest Land

Excluding areas along the pipeline route that have been clear cut recently and storage areas where trees would not be cleared, about 1,957 acres of upland forest would need to be cleared during pipeline construction activities. Less than one acre of forest would be permanently removed for access roads. During operation of the pipeline, a 30-foot-wide corridor centered on the pipeline would be kept in an herbaceous state, resulting in a permanent loss of about 804 acres of forest land. Outside of that 30-foot-wide corridor, forest would be restored within the remainder of the construction ROW. Pacific Connector would also follow the procedures for cutting forest along all lands crossed by its pipeline as outlined in the *Right-of-Way Clearing Plan for Federal Lands*[145] (note that although the title of the plan specifies "federal lands," the plan contains measures that would be applied on all lands). However, even with restoration, this would be a long-term to permanent effect, as it takes many years for trees to mature.

Approximately 65 miles of commercial private forestlands would be affected by the pipeline. Forest operations are not expected to be significantly altered, nor would the costs of forestry operations be expected to increase due to the presence of the pipeline; however, the Coquille Tribe raised concerned regarding the ability of operators to cross the pipeline. Surrounding forestry operators would be able to cross the pipeline ROW with heavy hauling and logging equipment, provided they coordinate those crossings with Pacific Connector and safety precautions are implemented to protect the integrity of the pipeline. While the requirement to coordinate with the pipeline operator would be an inconvenience for some forest operators, it does not constitute a significant change in forestry operations because the operator would be able to continue to cross the pipeline area in order to access or haul timber. Additionally, timber operators generally develop and carefully consider future harvesting and access plans. The need to consult with the pipeline operator if those plans include future crossings of the pipeline ROW would not represent a significant imposition or significant change in normal planning activities. The coordination requirement would also not significantly increase the cost of conducting forestry operations. In some situations, however, the presence of a pipeline along a ridge would require a change in log landing locations, which would affect timber operations. See additional discussion of potential effect on timber operations, including impacts on State Forest lands, in section 4.7.2.4.

Other

Other land uses that would be affected during construction include an estimated 8 acres of beaches and 49 acres of strip mines, quarries, and gravel pits (table 4.7.2.2-2). The affected beaches would primarily be used for TEWAs. The affected strip mines, quarries, and gravel pits would be used for TEWAs (46 percent) and rock source/disposal (54 percent). Approximately 0.1 acre of beach and 0.1 acre of strip mines, quarries, and gravel pits would be permanently affected.

Aboveground Facilities

Table 4.7.2.2-3 identifies the land uses that would be permanently affected by operation of the aboveground facilities.

TABLE 4.7.2.2-3

Acres Affected by Operation of Pacific Connector Proposed Aboveground Facilities

Facility a/	MP	Acres Disturbed During Construction b/	Land Use	Jurisdiction

Robinson Butte Communication Site – Jackson County f/	~159	0.2		Forest Service
Stukel Mountain Communication Site – Klamath County f/	~209	0.2		BLM
	Total	**1.6**		
	Grand Total	**22.8**		

Note: Rows and columns may not sum correctly due to rounding. Miles are rounded to the nearest tenth of a mile.
a/ MLVs denoted as AMLV are automated valves and would include a 40-foot-tall communication tower.
b/ Temporary construction disturbance associated with the aboveground facilities is included within the Pipeline construction ROW, and is not double counted in total Pipeline disturbance estimates.
c/ The 17 mainline block valves (MLVs) would be located within areas disturbed by the construction right-of way or within associated aboveground facility footprints (*i.e.*, meter stations and the compressor station); however, the permanent operation acres provided would remain as permanent disturbance associated with these graded, graveled and fenced facilities.
d/ The Jordan Cove meter station would be located entirely within the proposed LNG terminal.
e/ Communication facilities are included in the disturbed areas associated with the meter station, block valves and compressor station.
f/ Communication facilities would utilize existing towers and equipment buildings, where space is available for lease, with no associated disturbance. If construction of new facilities is required, Pacific Connector would obtain an approximate 100 x 100 foot (0.23 acre) area in the immediate area of the existing communication tower facilities.
g/ The Harness Mountain Communication Tower is an existing communication facility, with no new disturbance is required.

4.7.2.3 Coastal Zone Management

Coos County and a portion of Douglas County, up to the crest of the Coastal Range, are within Oregon's coastal zone. Therefore, Pacific Connector would need to obtain a finding from the ODLCD that the portion of its pipeline within the coastal zone (MPs 1.5 R to 53) is consistent with the CZMA. This consistency determination would be made for both the pipeline portion as well as the LNG portion of the Project. Coastal zone management is discussed further in section 4.7.1.2.

4.7.2.4 Existing Residences, Commercial Buildings, and Planned Developments

Existing Residences

No commercial buildings or residences are located within 50 feet of the proposed pipeline or aboveground facility workspaces. The edge of the construction work area for the pipeline would be located within 50 feet of seven residences (see table 4.7.2.4-1). Two of these residences are abandoned and would be removed as part of the Project. For the residences within 50 feet of construction work areas, Pacific Connector developed site-specific drawings depicting the temporary and permanent ROWs and has noted special construction techniques and mitigation measures (see appendix J). We are seeking any additional comments from the affected landowners on these site-specific drawings.

TABLE 4.7.2.4-1

Residences within 50 Feet of the Construction ROW or Temporary Extra Work Areas

MP	Distance from Pipeline (feet)	Distance from Edge of Construction Work Area (feet)	Number of Residences
49.7	106	41	1
56.9 a/	0	0	1
57.5	57	17	1
65.6	112	47	1
65.9	92	15	1
199.7	161	33	1
228.8 a/	1,680	0	1

a/ Abandoned residences at MP 56.9 and 228.8 would be removed prior to construction.

Within 50 feet of residences, the edge of the construction work area would be fenced for a distance of 100 feet on either side to ensure that construction equipment and materials, including the spoil pile, remain within the construction work area. Fencing would be maintained, at a minimum, throughout the open trench phases of pipeline installation. Where possible, the width of the construction ROW would be reduced near residences, and TEWAs would be located as far away from residences as practical. Pacific Connector would also limit the period of time the trench remains open prior to backfilling in residential areas.

Pacific Connector would implement numerous measures to reduce effects on residential properties including:

- Landowners would be notified at least 45 days prior to construction, and Pacific Connector would implement a Landowner Complaint Resolution Procedure. If a landowner is not satisfied with Pacific Connector's response to a complaint, they would be directed to call or email FERC's Dispute Resolution Division for further assistance.
- Pacific Connector would install orange safety fence between the construction ROW and the residence.
- Pacific Connector would attempt to schedule activities during normal working hours. Pacific Connector does not currently plan to work on Sundays; however, certain activities, such as waterbody crossing construction and hydrotesting, may require a 24-hour work schedule.
- Pacific Connector would comply with all local noise ordinances.

- Access and traffic flows would be maintained during construction activities through residential areas, particularly for emergency vehicles. Access to residences would be maintained at all times.
- Dust minimization techniques such as watering would be used on-site and all litter and debris would be removed daily from the construction site.
- Mature trees, vegetation screens, and landscaping would be preserved to the extent possible. Landowners would be compensated for the removal of any trees.
- Immediately after backfilling the trench, all lawn areas and landscaping within the construction work area would be restored.
- Pacific Connector would provide alternative sewer facilities if septic system is disturbed during construction. Pacific Connector would repair and restore septic systems affected by construction.
- Pacific Connector would compensate landowners for damage to homes should the home be damaged by pipeline construction.

During the scoping process, many landowners expressed concern about the pipeline and requested that the pipeline be moved off their property. Section 3.4 evaluates route alternatives to lessen effects on specific tracts where landowners raised routing concerns. Other comments expressed concern about effects on water wells, utility lines, septic systems, slope erosion, farming operations, loss of future development opportunities, and effects on environmental resources. As appropriate, these comments have been addressed throughout this analysis.

Concerns were raised about the location of the pipeline relative to the Woods Valley Airport, a licensed airport located near Trail, Oregon. As currently proposed, the pipeline would cross the runway. Pacific Connector outlined the measures that it proposes to implement to reduce impacts on the airport in a filing with FERC dated January 3, 2018. These measures include crossing the grassed airstrip as a tie-in crossing, scheduling construction at a time negotiated with the landowner, and either salvaging and replacing the existing sod or installing new sod following construction. In a letter to the FERC dated August 17, 2018, legal counsel for the property owner indicated that they believed Pacific Connector's January 3, 2018 response to be inadequate and requested that FERC require Pacific Connector to relocate the pipeline to avoid crossing the airstrip. Concerns expressed in the letter include safety concerns related to burying a natural gas pipeline several feet below a runway that is the location of aircraft take-offs and landings.

Planned Developments

Pacific Connector's communications with Coos County, the City of North Bend, Douglas County, Jackson County, and Klamath County did not identify any large-scale residential, commercial, or business projects/planned developments within 0.25 mile of the pipeline.

Comments received from affected landowners and other interested parties during scoping expressed concern that the pipeline would affect the ability of landowners to undertake small-scale developments, such as adding a home site, barn, or other structure, or subdividing a lot into two parcels for development. In some cases, Pacific Connector modified the route of the pipeline to avoid improvements on private parcels, as discussed in section 3.4 (Pipeline Route Alternatives) of this EIS.

4.7.2.5 Timber

Pipeline construction would require clearing all forested vegetation and timber from a 95-foot-wide temporary ROW and associated TEWAs. Timber removal and construction activities would take place over two years. While Pacific Connector anticipates that timber clearing would typically be done from May through November (the usual dry period in Oregon), timing restrictions would be imposed within habitat for federally listed NSO and MAMU (see section 4.6). Timber clearing within MAMU stands or within 300 feet of MAMU stands would not occur during the MAMU breeding season, which occurs between April 1 to September 15, in order to prevent impacts on nesting MAMU. Habitat removal within 0.25 mile of an NSO activity center would occur outside of the NSO's breeding season (see section 4.6).

Impacts on forest and timber resources would depend on the clearing (logging) methods used, quantity of lumber removed, and the age of affected stands. The Pacific Connector pipeline would cross approximately 39.3 miles of LSOG forests, 43.7 miles of mid-seral forests, and 59.5 miles of recently harvested forested lands. Table 4.7.2.5-1 lists the log types that occur along the pipeline's route.

TABLE 4.7.2.5-1

Merchantable Timber to be Cleared for the Proposed Pacific Connector Pipeline, by Class and Age

Type of Timber	Diameter to Breast Height (inches dbh)	Inside Top Bark Height Diameter (inches)	Age
Small conifer sawlog	10-20	6-10	26–60 years
Medium conifer sawlog	20-30	8-12	61–100-125 years
Large conifer sawlog	30 and larger	8-16	125–250 years; with an unquantified population of ancient relic trees 300 to 500 years

While timber cruises have not yet been conducted, information available indicates that approximately 1,573 acres of large mature trees over 40 years in age and approximately 1,177 acres of small to medium trees under 40 years in age would be harvested to construct the pipeline. A portion of these 1,177 acres of small to medium trees would not be merchantable (e.g., those less than 25 years in age). Future timber production would be lost on these younger (small and medium) stands. The exact number and board feet of these non-merchantable trees would be determined during timber cruises. Operating the pipeline would permanently affect approximately 514 acres of forest, which would be removed from the future timber base.

Timber cruises would be conducted prior to vegetation clearing to determine timber volumes, values, and species composition within forested lands. These timber cruises would be completed on private lands in compliance with professional forestry standards and on federal lands to required federal agency standard. Information gathered from timber cruises would be used to determine damage payments during easement acquisition. Pacific Connector would be required to retain qualified foresters and logging engineers to develop site-specific logging plans for each area to be logged. These plans would identify the size, height, volume, and value of trees in each portion of the construction ROW, how the timber would be felled and yarded, where landings and log decks would be placed, the haul routes that would be used to remove the logs, and how logging debris would be disposed of. Logging methods would vary by location, and would not be known until timber contractors evaluate site-specific conditions. The exact timber harvest and decking requirement locations would be determined by the contractor within the access roads and staging areas already approved for the pipeline.

Merchantable timber would be cut and removed from the construction ROW and TEWAs. In limited areas, TEWAs have been identified for log storage and decking. Clearing of forest is a two-step process: tree felling followed by yarding. Pacific Connector's ***Right-of-WayROW** Clearing Plan for Federal Lands* outlines different scenarios that may be used to cut and remove timber from the ROW along the pipeline route, based on slope, stand density, and tree types. Ground-based skidding and cable (where feasible) logging methods would likely be the standard method.

In some isolated rugged topographic areas with poor access, helicopter logging may be used. Cable and helicopter logging methods would minimize the potential for soil compaction. Any timber cleared from the ROW that would be used for instream or upland wildlife habitat diversity structures would be stored on the edge of the ROW or in TEWAs for later use during restoration efforts. Prior to clearing operations, the EI or Pacific Connector's authorized representative would flag existing snags on the edges of the construction ROW or TEWAs where feasible to save from clearing. These snags would be saved as and used in placement projects to benefit primary and secondary cavity nesting birds, mammals, reptiles, and amphibians. During this process, other large diameter trees on the edges of the construction ROW and TEWAs would also be flagged to save/protect as green recruitment or habitat/shade trees, where feasible. Some of these trees would be girdled to create snags to augment the number of snags along the ROW to benefit cavity nesting birds, mammals, reptiles, and amphibians; however, snags that are determined to be a threat to worker safety would be removed.

Danger trees are those trees at risk of falling on workers or vehicles and thus would need to be removed for safety reasons. A tree may be at risk of falling for a number of reasons including the tree's location and the presence of defects, insects, disease, work activities, and weather conditions. Such trees would be felled in advance of logging, pipeline construction, road construction/reconstruction, and road maintenance. Additionally, danger trees could be created from trees felled for the pipeline. This would occur if trees outside of approved construction areas are damaged during felling of harvested timber. While this could result in growth loss, for which Pacific Connector would compensate the land-management agency (or landowner on private lands) for any trees removed and any loss in timber productivity, the FERC requires that all operations be contained within the certificated work areas. Danger trees would be designated by qualified Pacific Connector representatives, in accordance with OSHA standards and the Forest Service/BLM–published *Field Guide for Danger Tree Identification and Response* (Forest Service and BLM 2008). Danger trees exterior to the ROW would be directionally felled, when consistent with OSHA guidelines, away from the construction ROW if trees are to be left, and towards the construction ROW if trees are to be removed. To ensure safety during construction, Pacific Connector has requested a variance to Section IV.A.1 of the FERC's *Plan* for removing danger trees outside the approved construction limits. Pacific Connector would compensate the respective land manager/owner for any merchantable danger trees that are felled.

Logs would not be stored next to conifer trees bordering the sides of the ROW to avoid damage to live trees. Logs planned for removal from the site would be hauled off the site as soon as practical following yarding in order to prevent disease problems, as well as potential theft problems. Slash pieces larger than 8 inches in diameter may be decked for short periods in agency or landowner designated and approved storage areas or in places where roads cross the ROW and made available to the public. However, Pacific Connector has stated that they may place LWD in UCSAs adjacent to standing conifers.

Where feasible, logs yarded out of wetlands or riparian zones would be skidded with at least one end suspended from the ground so as to minimize soil disturbance. Pacific Connector proposes that any debris entering a waterbody as a result of felling and yarding of timber would be removed as soon as practical after entry into the waterbody and shall be placed outside the 100-year floodplain where practical, unless specified otherwise by the applicable landowner or land-managing agency. Logs and slash would not be yarded across perennial streams unless fully suspended. During logging/clearing operations, the direction of log or slash movement would be conducted to minimize sediment delivery to waterbodies, including intermittent streams. Logs firmly embedded in the bed or bank of waterbodies that are in place prior to felling and yarding of timber would not be disturbed, unless they prevent trenching and fluming operations. Any existing logs that are removed from waterbodies to construct the pipeline crossing would be returned to the waterbody after the pipeline has been installed, backfilling is complete, and during the time the streambanks are being restored.

In addition to the above mentioned impact minimization measures, Pacific Connector would implement the following measures to further reduce impacts on timber:

- All tree felling and vegetation clearing would occur within the certificated construction work areas, except for danger trees adjacent to the ROW, additional work areas, and travel corridors. Trees within the certificated construction work areas would be directionally sheared or felled so as to prevent damage to adjacent trees, facilities, or structures.
- Where ground skidding is used, the following measures would be employed to minimize significant detrimental soil disturbance (compaction and displacement):
  - low ground weight (pressure) vehicles would be used;
  - logging machinery would be restricted to the 30-foot permanent ROW wherever possible to prevent soil compaction;
  - the removal of soil duff layers would be avoided in order to maintain a cushion between the soil and the logs and the logging equipment;
  - designed skid trails would be used to restrict detrimental soil disturbance (compaction and displacement) to a smaller area of the ROW over the pipeline trenching area; and
  - landings, yarding, and load-out areas used for timber harvesting would be scarified or after use and prior to the rainy season where the potential for sediment delivery to waterbodies is possible.
- Material designated to remain on site to meet resource concerns would be placed in designated UCSAs along the edge of the ROW and then scattered/redistributed across the ROW during final cleanup and reclamation (following seeding). In upland areas, stump removal would be limited to the trenchline and areas where grading is necessary to construct a safe, level working plane.
- Off-site slash disposal and/or burning may occur in areas where slash is concentrated, such as landings. Slash would be machine or hand piled with the outer edge of piles no closer than 20 feet from the outer drip line of live trees, and burned according to state burning

requirements and landowner, BLM, and Forest Service stipulations. Burns would occur during the wet season.

- Outside of the 30-foot-wide permanent pipeline easement, which would be kept clear of trees with roots that could compromise the integrity of the pipeline coating, the temporary construction area would be restored and revegetated using native seeds, to the extent possible, and saplings according to the ECRP.

State Lands

The proposed route would cross the Southwest Oregon and the Eastern Oregon Forest Practices Regions, which contain mature forest. Trees within this portion of the ROW would be cut and merchantable trees would be sold as directed by Oregon Department of Forestry (ODF). As stipulated within ORS 527.670(3), a written plan must be submitted to the ODF State Forester before extracting timber within:

- 100 feet of a stream classified as Type F (stream with fish or fish and domestic water use) or Type D (stream with domestic water use but no fish use);
- 300 feet of a specific site involving threatened or endangered wildlife species, or sensitive nesting, roosting, or water sites;
- 300 feet of any resource site identified in OAR 629-665-0100 (Sensitive Bird Nesting, Roosting, and Watering Resource Sites on Forestlands), OAR 629-665-0200 (threatened and endangered species that use Resource Sites on Forestlands), or OAR 629-645-0000 (Significant Wetlands); and
- 300 feet of any nesting or roosting site, or critical habitat of threatened or endangered species listed by the FWS or by the ODFW Commission.

If necessary, Pacific Connector would prepare and submit to the ODF State Forester for approval a written plan describing how the pipeline would be in compliance with the Forest Practices Act (OAR 629-605-0170), prior to harvesting activities. In addition to the written plan, Pacific Connector would be required to submit a Notification to the ODF. The Notification serves three purposes: notification of a forest operation (ORS 527.670), a request for a Permit to Use Fire or Power Driven Machinery (PDM, ORS Chapter 477), and notice to the Department of Revenue of timber harvest (ORS 321.550).

4.7.3 Environmental Consequences on Federal Lands

4.7.3.1 Land Requirements on Federal Lands

The Pacific Connector pipeline would cross approximately 31 miles of NFS lands and 47 miles of BLM lands (table 4.7.3.1-1). Between MPs 200.5 and 227.2, the pipeline would cross 31 irrigation facilities that fall under the jurisdiction of Reclamation.

Temporary impacts of the pipeline on federal lands would include timber and brush clearing, grading, trenching, impacts to visual quality at some locations, and soil compaction as a result of equipment driving and storage of logs, slash, pipe lengths, and other supplies. Long-term impacts include the time it would take trees to grow back within the temporary construction ROW. Permanent impacts would include the conversion of forest to herbaceous vegetation within a 30-foot-wide corridor kept clear of trees, and prohibitions of use of the operating pipeline easement. The pipeline and associated facilities would not cross, and therefore no acreage would be removed from, any federally designated wilderness, wildlife refuge areas, or inventoried roadless areas.

TABLE 4.7.3.1-1

Federal Lands Affected by the Pacific Connector Pipeline Project

Pipeline Facility/Component	Jurisdiction BLM	Forest Service	Reclamation
Miles Crossed by Pipeline	46.8	30.6	0.3
Temporary Construction Acreage Requirements (acres)			
Construction ROW	535	350	4
Temporary Extra Work Areas	166	103	<1
Uncleared Storage Areas	184	124	0
Off-site Source/Disposal	7	9	0
Existing Roads Needing Improvements in Limited Locations	2	1	0

Total Temporary Impacts (acres)	**894**	**587**	**4**
Permanent Construction Acreage Requirements (acres)			
Permanent Easement	245	185	2
Permanent Access Roads (PAR)	<1	0	0
Existing Roads Needing Improvements in Limited Locations a/	2	1	0
Aboveground Facilities	<1	0	0
Total Permanent Impacts (acres)	**248**	**186**	**2**
ROW (acres)			
30-Foot Maintained ROW (acres)	147	111	1

Note: Columns may not sum correctly due to rounding. Miles rounded to the nearest tenth of a mile (values below 0.1 are shown as "<0.1"). Acres rounded to the nearest whole acre (values less than 1 shown as "<1").

a/ Road improvements necessary for construction would not be restored; however, no additional maintenance would occur on access roads improved for construction of the Project. Acres are not included in the Permanent Construction acres total.

Pacific Connector would protect its pipeline from corrosion over time through a CP system. The CP system would consist of a number of sites where below ground rectifier/anode beds would be installed that input a low voltage electrical charge into the pipeline. These rectifier/anode beds would typically be spaced about 15 to 20 miles apart, usually installed within the previously disturbed pipeline construction ROW. The CP system would be installed about one year after the pipeline would be constructed, to allow the trench to stabilize and for collection of post-construction data on electro-conductivity soil potentials, which is required before the system can be designed and installed. Pacific Connector would consult with appropriate federal, state, and local regulatory agencies after pipeline construction to acquire the permits necessary for the CP system. A *Corrosion Control Plan* was included as Appendix F to Pacific Connector's POD. Based on a preliminary analysis of CP sites that could create a potential for new electrical service, there is no need for new electrical service on federal lands.

Table 4.7.3.1-2 provides acres affected by the pipeline broken out by land use type and ownership for each federal jurisdiction.

TABLE 4.7.3.1-2

Federal Lands Required for Construction and Operation of the Pacific Connector Pipeline by Land Use Type (acres)

Note: Rows may not sum correctly due to rounding. Acres rounded to nearest whole acre (values below 1 are shown as "<1".

a/ Construction disturbance associated with pipeline facilities including construction ROW, TEWAs, UCSAs, TARs, existing roads needing improvements, pipe yards, off-site source and disposal areas, and hydrostatic discharge locations outside the ROW.

b/ The operational ROW is located within the disturbed acreage of the construction ROW. It is not an addition to the construction impacts.

c/ Portions of some of the PARs are located within the construction ROW and, therefore, there is some duplication in the acreage calculations.

BLM Lands

The Pacific Connector pipeline would cross approximately 47 miles of BLM lands within the Coos Bay, Roseburg, Medford, and Lakeview Districts. Of the aboveground facilities, three MLVs would be located on BLM lands. Pacific Connector also proposes to construct one new TAR to support construction and three new PARs on BLM lands to support construction and operation.

Acres of BLM lands, by land use classification, that would be affected by pipeline construction and operation are listed above in table 4.7.3.1-2. For all of the BLM land crossed combined, construction of the Pacific Connector pipeline would affect about 669 acres of forest, 60 acres of rangeland, 54 acres of transportation-utility lands, less than 0.1 acre of agricultural land, 0.8 acre of wetlands, 1 acre of water, and about 2 acres of barren lands/quarries. The BLM expressed concerns regarding impact of the pipeline on current and future forest management activities on federally administered lands that might result from prohibited or restricted land management and use activities within or near the pipeline ROW. In response, Pacific Connector provided a list of activities that would be prohibited or restricted on the pipeline ROW (table 4.7.3.1-3).

TABLE 4.7.3.1-3

Land Management and Land Use Activities That Would be Prohibited or Restricted on the Proposed Pacific Connector Pipeline Construction and Operational Rights-of-Way

Location	Prohibited/ Restricted Activities	Duration
Directly over the pipeline	Obstructions that may endanger, hinder or conflict with the construction, operation, inspection, protection, maintenance and use of the pipeline (i.e. trees, engineered structures, buildings, roads-parallel, other utilities-parallel, logging, blasting, mining)	During the construction, operations, and maintenance of the pipeline facilities.
Within the pipeline ROW clearing limits	Obstructions that may endanger, hinder or conflict with the construction, operation, inspection, protection, maintenance and use of the pipeline (i.e. engineered structures, buildings, roads-parallel, limited logging, blasting, mining)	During the construction of the pipeline facilities.
Within the pipeline ROW	Obstructions that may endanger, hinder or conflict with the construction, operation, inspection, protection, maintenance and use of the pipeline (i.e. engineered structures, buildings, roads-parallel, limited logging, blasting, mining)	During the construction, operations, and maintenance of the pipeline facilities.
Within one-quarter mile of the pipeline	Some blasting and mining	During operation and maintenance of the pipeline facilities.
On existing federally managed roads and trails	Only when within the ROW, obstructions that may, endanger, hinder or conflict with the construction, operation, inspection, protection, maintenance, and use of the pipeline as described above; otherwise none	During the construction, operations, and maintenance of the pipeline facilities.

The BLM also expressed concerns about how prohibited or restricted activities within the pipeline ROW may affect parties who hold valid existing rights of federal lands in the Project area. In response, Pacific Connector stated that such situations would be handled on a case-by-case basis. In general, Pacific Connector would identify all landowners and interested parties in each of these situations and would work with them, following the guidelines in the Williams Gas Pipeline Developers' Handbook. The BLM also asked Pacific Connector to identify the requirements and timelines for notification to Pacific Connector when activities are planned on the federal lands, either by the agency or a third party. Pacific Connector responded that for any aboveground alterations Pacific Connector would rely on its Operations & Maintenance Manual Public Awareness and Damage Prevention (Policy 10.17.00.09). This policy requires the company to notify in writing at least once per year any landowner or interested party within 660 feet from either side of the pipeline. The notification would include written information of where the pipeline is and who and how to reach Pacific Connector for any concerns they may have with the pipeline. These notifications would provide the landowner or interested party with the information they need to contact the company to discuss any work around the pipeline or ROW.

National Forest System Lands

The pipeline would cross through approximately 30.6 miles of NFS lands within the Umpqua, Rogue River, and Winema National Forests. Acreages of NFS lands, by land use classification, that would be affected by pipeline construction or operation of the Pacific Connector pipeline and associated aboveground facilities are included above in table 4.1.3.1-2. On NFS land, the pipeline would affect about 512 acres of forest, 32 acres of transportation-utility lands, 28 acres of barren lands/quarries, 8 acres of rangelands, 0.5 acre of water, and 0.6 acre of wetlands.

Reclamation Lands

Between MPs 200.5 and 227.2, Pacific Connector's pipeline route would cross two parcels of withdrawn land totaling 0.7 mile, and 31 irrigation facilities that are managed by Reclamation's Klamath Basin Area Office of the Mid-Pacific Region. Acres of Reclamation land, by land use classification, that would be affected by the Project are included above in table 4.1.3.1-2. Construction of the Pacific Connector pipeline across Reclamation lands and facilities would affect less than half an acre of agricultural land, about 4 acres of rangeland, and less than a tenth of an acre of irrigation ditches.

Construction in the Klamath Basin would occur between October 15 and March 15 to minimize impacts to agricultural activities in the area and to cross the Reclamation irrigation facilities when they are not likely to be used or contain water. Pacific Connector included a *Klamath Facilities Crossing Plan* as Appendix O of its POD, and a *Winter Construction Plan for the* Klamath Basin as Appendix 1E in Resource Report 1 of its 2017 application to the FERC.

During construction across Reclamation lands and features, their use would be temporarily interrupted. However, after pipeline installation, Pacific Connector would restore those lands and features to their original condition and use.

4.7.3.2 Grazing Allotments on BLM and NFS Lands

The proposed Pacific Connector pipeline route would cross 11[146] livestock grazing allotments, 5 of which occur on NFS lands managed by the Umpqua, Rogue River, and Winema National Forests, and 6 of which occur on BLM lands managed by the Medford and Lakeview Districts (see table's 4.7.3.2-1 and 4.7.3.2-2). Pacific Connector believes grazing deferments would not be necessary for the Project because grazing is not a dominant land use crossed by the pipeline route. Pacific Connector has consulted with the BLM and the Forest Service regarding grazing resources.

[146] One additional allotment (Fish Lake) on the Rogue River National Forest would also be included. The pipeline corridor does not cross this allotment; the only portion affected by Pacific Connector is an old quarry which has been identified as a rock source and disposal area near MP 160.4.

TABLE 4.7.3.2-1

Grazing Allotments on National Forest System Lands Crossed by the Pacific Connector Pipeline Project

Allotment Number	Allotment Name/Pasture	MP	Allotment Acres	Management Category a/	Total AUMs b/	3-Year Average AUMs	Season Used	Livestock Kind	Grazing System	Notes
Umpqua National Forest – Tiller Ranger District										
00R12	Diamond Rock	105.4 - 113.2	23,565	PB: I, A, F	680	187	5/1-10/31	Cow/Calf	Continuous Season	Managed in conjunction with an adjoining allotment.
Rogue River National Forest – Ashland Ranger District										
00R08	South Butte	153.8 - 167.5	25,592	PB: A, F	230	230	6/1-10-15	Cow/Calf	Continuous	1035 AUs
00R07	Deadwood	167.5 - 167.9	21,337	PB: A, F	382/150 Total of 532	382/150	6/1-10/15 See notes	Cow/Calf	Deferred	Managed with BLM Odd yrs. = 6/1–8/15 on FS Even yrs. = 8/16–10/15 on FS
Winema National Forest – Klamath Ranger District										
OR250	Indian	167.9 - 171.3	10,619	PB: I,A, F	906	665	7/1-10/15	Cow/Calf	Continuous Season	Managed with Buck Allotment as 1 Allotment.
OR220	Buck	171.3 - 172.4	15,932	PB: I,A, F						Same as Indian, managed as 1 Allotment.

a/ 'PB' classification indicates that allotments that have potential to be managed under a quality management strategy. Basic resource damage is not occurring.
P = lack of permittee interest participation;
I = lack of total AMP implementation;
A = lack of reliable range analysis data, and
F = lack of funding to implement quality management.
b/ AUM = animal unit month

TABLE 4.7.3.2-2

Grazing Allotments on BLM Lands Crossed by the Pacific Connector Pipeline Project

Allotment Number	Allotment Name/Pasture	MP	Allotment Acres	Management Category a/	Total AUMs	3-Year Average AUMs	Season Used	Livestock Kind	Grazing System b/	Notes
Medford District										
10038	Crowfoot	123.5 - 128.4	7,400	I			4\15-6\30	Cattle	SS	
10031	Summit Prairie/McNeil	131.4 - 131.8	30,578	I	1,158	827	6\1-10\30	Cattle	DF	
10024	Big Butte	133.6 - 141.9	21,802	I	1,663	301	4\16-5\31	Cattle	SL	Rice Place pasture now closed to grazing
00126	Heppsie Mountain	148.8 - 153.8	4,105	I	294	277	5/1-10/15	Cattle	SL	
Lakeview District										
0147	Grubb Spring	178.3 - 189.1	3,564 e/	C	130 c/	130 c/	5/1 – 9/15	Cattle	d/	
0848	Pope	216.5 - 216.8	446 f/	C	48 c/	63 c/	5/1 – 7/31	Cattle	d/	

a/ I = intensive management
C = custodial
M = maintain

b/ SS = Spring/Summer: Use throughout the critical growing season annually.
DF = Deferred: Delay of livestock grazing on an area for an adequate period of time to provide for plant reproduction, establishment of new plants, or restoration of vigor of existing plants.
SL = Season Long: Season long use annually, including during the growing season (spring, summer, and fall).

c/ BLM licensed AUMs only.

d/ Grazing is every year for the listed season; no other specific grazing system.

e/ BLM Klamath Falls Resource Area acres only listed

f/ A portion of the allotment was recently sold reducing the acreage.

Potential impacts to grazing allotments may occur from the temporary loss of forage from Project vegetation clearing and grading activities. In addition, construction activities could disturb improvements such as developed springs and fences or other barriers that restrict livestock to the allotment. From current survey activities, Pacific Connector is not aware of any range improvements such as springs that would be impacted. Pacific Connector does not believe it is necessary to remove livestock from the allotments during construction activities because of the significant size of most of the allotments crossed. Prior to construction, Pacific Connector would coordinate with the BLM and Forest Service regarding lease holder notifications.

Pacific Connector would mitigate impacts on grazing allotments during construction by installing temporary fences as needed to control livestock movement. After construction, permanent repairs to fences and natural barriers or other improvements that were disrupted by construction activities would occur to equivalent or better standards to ensure that livestock do not trail outside the allotment. Additional permanent fences may also be required during operation. After the pipeline is installed, the ROW would be restored and revegetated, as discussed in section 4.4. Revegetation is expected to return allotment forage quantity and values to preconstruction conditions within one to two growing seasons.

4.7.3.3 BLM and Forest Service Land Use Plans and Land Allocations

Federal lands are managed under a framework of laws passed by Congress, regulations promulgated through the federal rule-making process by the Secretaries of the Interior and Agriculture to implement these laws passed, Executive Orders issued by the President, and policies developed by the agencies to govern day-to-day actions. Each administrative unit of the BLM and Forest Service has a land management plan that provides a framework for on-the-ground implementation of these various laws, regulations and agency policies.

Overview of Statutes Applicable to Federal Land Use Planning

Although a number of federal statutes apply to the Pacific Connector pipeline where it crosses federal lands, there are six primary federal land-use laws that provide the framework for federal land use plans:

- The Multiple Use, Sustained Yield Act of 1960 (MUSY)
- The National Environmental Policy Act of 1969 (NEPA),
- The Endangered Species Act of 1973 (ESA),
- The Federal Land Policy and Management Act of 1976 (FLPMA),
- The National Forest Management Act of 1976 (NFMA), and
- The Oregon and California Revested Lands Sustained Yield Management Act of 1937 (O&C Act).

Three of these statutes—NEPA, ESA, and FLPMA—apply to both the BLM and the Forest Service. The relevance of NEPA and ESA to federal land management along the route of the Pacific Connector pipeline is discussed in chapter 1 of this EIS. For the Pacific Connector pipeline, the O&C Act applies primarily to BLM lands and to a lesser degree to NFS lands. BLM's RMPs are based on the requirements of FLPMA. The Forest Service's LRMPs are based on the requirements of the NFMA. FLPMA and NFMA were enacted in a manner to complement each other. Reclamation does not have any land use plans or land allocations administered by the

Klamath Basin Area Office that would be amended or modified or which need to be addressed in this EIS.

The O&C Act of 1937 applies to lands granted by the federal government to the Oregon and California Railroad Company. These lands were reconveyed to the federal government when the Oregon and California Railroad (O&C) went bankrupt. A similar, but smaller land grant in 1869 to the Southern Oregon Company was associated with the Coos Bay Wagon Road. These lands were also subsequently reconveyed to the federal government. The O&C Act of 1937 requires the Secretary of the Interior to manage Coos Bay Wagon Road lands and O&C lands for permanent forest production in conformity with the principle of sustained yield. These lands must also be managed in accordance with BLM RMPs in addition to applicable environmental laws such as the ESA. The O&C and Coos Bay Wagon Road land grants resulted in a patchwork of alternating federal and non-federal parcels across western Oregon and northern California. Table 4.7.3.3-1 lists the O&C and Coos Bay Wagon Road lands crossed by the Pacific Connector pipeline.

TABLE 4.7.3.3-1

O&C Lands, Coos Bay Wagon Road Lands, and Reserved Public Domain Lands Crossed by the Pacific Connector Pipeline (miles) a/

Jurisdiction	O&C Lands	Coos Bay Wagon Road Lands	Reserved Public Domain Lands b/	Total
BLM – Coos Bay District	1.14	15.8	0.13	17.07
BLM – Roseburg District	10.84	1.79	0.72	13.35
BLM – Medford District	12.29	0.0	2.86	15.15
BLM – Lakeview District	1.03	0.0	0.26	1.29
Total BLM	**25.3**	**17.59**	**3.97**	**46.86**

Forest Service– Rogue River NF	0.0	0.0	13.72	13.72
Forest Service – Winema NF	0.0	0.0	6.05	6..05
Total NFS	**3.44**	**0.0**	**27.14**	**30.58**
Total	**28.5**	**17.59**	**30.98**	**77.44**

Note: Rows and columns may not sum correctly due to rounding. Miles are rounded to the nearest tenth of a mile (values below 0.1 are shown as "<0.1").
a/ Source: Table 8.5-5, Resource Report 3, p. 36.
b/ Reserved Public Domain Lands are the remaining lands not classified as O&C or Coos Bay Wagon Road lands

Enacted in 1976, the FLPMA established a unified, comprehensive, and systematic approach to managing and conserving public lands to provide for multiple uses and sustained yield of goods and services from public lands. The act includes provisions for withdrawing or otherwise designating or dedicating federal lands for specified purposes. It also establishes procedures for disposing of public lands, acquiring non-federal lands for public purposes, exchanging lands consistent with the prescribed mission of the department or agency involved and for issuing ROW Grants across lands administered by multiple federal agencies. The BLM is the authorizing agency for the Pacific Connector pipeline ROW grant application.

The BLM under Title II of the FLPMA, and the Forest Service under the provisions of the MUSY, are required to manage lands sustainably for multiple uses. Although there are distinct differences between the BLM and Forest Service planning regulations, the following elements are common to the two agencies:

- use of a systematic, interdisciplinary approach that utilizes information from the physical, biological, economic, and other sciences;
- considering present and potential uses of public lands;
- giving priority to areas of critical environmental concern;
- considering the relative scarcity of the various values of public lands;
- weighing long-term and short-term public benefits;
- complying with applicable pollution control laws; and
- coordinating land-use planning with other relevant federal and state agencies.

The Forest Service is also subject to the requirements of the NFMA, which was enacted as an amendment to the 1974 Forest and Rangeland Renewable Resources Planning Act. In NFMA, Congress established a comprehensive notice and comment process for adopting, amending, and revising LRMPs for units of the NFS (e.g., National Forests). Planning regulations later promulgated by the Secretary of Agriculture explain that National Forest planning and decision making occurs at four levels: nationwide, region wide, LRMPs, and projects. One of the statutory requirements of the NFMA is to "specify…guidelines for LRMPs developed to achieve the goal of providing for diversity of plant and animal communities based on the suitability and capability of the specific lands area in order to meet multiple use objectives." This biodiversity requirement led to the development of the NWFP, which currently guides the management of NFS lands in southwest Oregon and meets the NFMA's biodiversity goal.

Northwest Forest Plan

In 1994, the Secretaries of Agriculture and Interior jointly signed a *Record of Decision for Amendments to Forest Service and BLM Planning Documents within the Range of the Northern Spotted Owl* (otherwise known as the Northwest Forest Plan (NWFP); Forest Service and BLM 1994a). This decision amended national forest LRMPs and established the following land allocations to be used on NFS lands in the area covered by the NWFP.[147]

- **Congressionally Reserved Areas -** Lands reserved by act of Congress including National Parks and Monuments, Wilderness Areas, Wild and Scenic Rivers, National Wildlife Refuges and Department of Defense lands.

- **Late-Successional Reserves** (LSRs) - in combination with other land allocations and standards and guidelines are intended to maintain functional, interactive LSOG forest ecosystems for species that are dependent on this type of habitat.[148]

- **Adaptive Management Areas -** Areas designed to develop and test new management approaches to integrate and achieve ecological, economic and other social and community objectives.

[147] When the NWFP was signed in 1994, it applied to both national forest and BLM lands in the range of the northern spotted owl. Subsequently in August 2016 the BLM revised its management plans in southwest Oregon and replaced the management direction from the NWFP. As a result, the NWFP no longer applies to BLM lands.
[148] Appendix F.3 of this EIS provides a comprehensive discussion of LSRs as they relate to the Project.

- **Administratively Withdrawn Areas—**Areas identified in Forest Service LRMPs not scheduled for timber harvest (e.g., recreation sites, administrative facilities).
- **Key Watersheds—**Large watersheds that are a system of refugia that either provide, or are expected to provide, high-quality habitat that is crucial for maintaining and recovering habitat for at-risk stocks of anadromous salmonids and resident fish species. Key Watersheds are not a designated area or matrix but overlay all land allocations. Tier 1 Key Watersheds contribute directly to conservation of at-risk stocks of anadromous salmonids, bull trout and resident fish. While Tier 2 Key Watersheds may not contain at-risk fish species, they are important sources of high-quality water.
- **Riparian Reserves—**Areas along all streams, wetlands, ponds, lakes and unstable and potentially unstable areas where the conservation of aquatic and riparian-dependent terrestrial resources receives primary emphasis. Riparian Reserves are also intended to serve as connectivity corridors between other reserves and the Matrix lands.[149] Riparian Reserves exist within all land allocations of the NWFP.
- **Matrix—**The lands outside the other designated areas listed above. Matrix lands are the area in which most timber harvest and other silvicultural activities would be conducted.

Attachment A to the NWFP ROD, "Standards and Guidelines for Management of Habitat for Late-Successional and Old-Growth Species within the Range of the Northern Spotted Owl," provides detailed requirements and instructions for how land managers should treat forest lands subject to the NWFP (Forest Service and BLM 1994b).[150] Some standards and guidelines apply to all NFS lands, while others are only applicable to certain land allocations or activities. More than one set of standards and guidelines may apply in some areas. Where standards and guidelines overlap, both are applied. Where there are conflicts, the standard and guideline that provides the most protection for LSOG-associated species governs. The acres of NWFP allocations affected by the Pacific Connector pipeline are displayed in table 4.7.3.3-2.

Forest Service Land and Resource Management Plans

Current Forest Service LRMPs for the Rogue River, Umpqua, and Winema National Forests were adopted in the early 1990s (Forest Service 1990a, 1990b, and 1990c). In 1994, the NWFP ROD amended the LRMPs for those portions of National Forests within the range of the NSO to include the NWFP land allocations and standards and guidelines in addition to the existing direction in those plans. Wherever there were conflicts between the NWFP and the underlying land management plan, the direction that provided the most protection for late-successional and old-growth–dependent species was adopted.

[149] Appendix F.4 of this EIS provides a comprehensive discussion of Riparian Reserves as they relate to the Project.

[150] Standards and Guidelines: "the rules and limits governing actions, and the principles specifying environmental conditions or level to be achieved or maintained" (Forest Service and BLM 1994b: C-1).

a/ Due to differences between the landownership and land use allocation shapefiles, the acres will vary slightly when compared to the vegetation and land use tables organized by jurisdiction.
b/ Riparian Reserves overlay other land use allocations.

BLM Resource Management Plans

The BLM revised its management plans in August 2016. Land allocations in BLM plans provide a sustained yield of timber, contribute to the conservation and recovery of an threatened and endangered species, provide clean water in watersheds, provide recreation opportunities, and coordinate management of land surrounding the Coquille Forest with the Coquille Tribe.

The **Northwestern and Coastal Region Record of Decision** applies to the Coos Bay and the Swiftwater Field Office of Roseburg District. Land allocations are as follows:

- **Congressionally Reserved Lands and National Conservation Areas –** Lands reserved by act of Congress including National Parks and Monuments, Wilderness Areas, Wild and Scenic Rivers, National Wildlife Refuges, and Department of Defense lands.

- **District Designated Reserves –** Lands reserved from sustained-yield timber production for other purposes

  - **Areas of Critical Environmental Concern –** Lands managed to maintain or restore relevant and important values in Areas of Critical Environmental Concern, including Research Natural Areas and Outstanding Natural Areas.

  - **Timber Production Capability Classification –** Manage areas identified as unsuitable for sustained-yield timber production through the Timber Production Capability Classification system, for other uses if those uses are compatible with the reason for which the BLM has reserved these lands (as identified by the Timber Production Capability Classification codes).

  - **Lands Managed for their Wilderness Characteristics –** Protect wilderness characteristics (i.e., roadlessness, naturalness, opportunities for solitude and primitive unconfined recreation, and identified supplemental values), while allowing competing resource demands that do not conflict with preserving long-term wilderness characteristics.

- **Harvest Land Base—** Manage forest stands to achieve continual timber production that can be sustained through a balance of growth and harvest.

  - **Low Intensity Timber Area –** Use low intensity management to provide complex early-successional ecosystems, develop diverse late-successional ecosystems for a portion of the rotation and provide a variety of forest structural stages distributed both temporally and spatially.

  - **Moderate Intensity Timber Area –** Use moderate intensity management to provide complex early-successional ecosystems, develop diverse late-successional ecosystems for a portion of the rotation and provide a variety of forest structural stages distributed both temporally and spatially.

- **Late Successional Reserve –** Lands are managed to maintain nesting-roosting habitat for the northern spotted owl and nesting habitat for the marbled murrelet, promote the development of nesting-roosting habitat for the northern spotted owl in stands that do not currently support northern spotted owl nesting and roosting, promote the development of nesting habitat for the marbled murrelet in stands that do not currently meet nesting habitat criteria, promote the development and maintenance of foraging habitat for the northern spotted owl, including creating and maintaining habitat to increase diversity and abundance of prey for the northern spotted owl.

- **Riparian Reserves –**Areas along streams and wetlands where the conservation of aquatic and riparian-dependent terrestrial resources receives primary emphasis. Riparian Reserves exist in all land allocations. Conservation and recovery of ESA-listed fish species and their habitats and provide for conservation of Bureau Special Status fish and other Bureau Special Status riparian-associated species.

The **Southwestern Oregon Record of Decision and Approved Resource Management Plan** applies to the Klamath Falls Field Office of Lakeview District, Medford District, and South River Field Office of Roseburg District. Land allocations are as follows:

- **Congressionally Reserved Lands and National Conservation Areas –** Lands reserved by act of Congress including National Parks and Monuments, Wilderness Areas, Wild and Scenic Rivers, National Wildlife Refuges, and Department of Defense lands.

- **District Designated Reserves –** Lands reserved from sustained-yield timber production or for other purposes.

  - **Areas of Critical Environmental Concern –** Lands managed to maintain or restore relevant and important values in Areas of Critical Environmental Concern, including Research Natural Areas and Outstanding Natural Areas.

  - **Timber Production Capability Classification –** Manage areas identified as unsuitable for sustained-yield timber production through the Timber Production Capability Classification system, for other uses if those uses are compatible with the reason for which the BLM has reserved these lands (as identified by the Timber Production Capability Classification codes).

  - **Lands Managed for their Wilderness Characteristics –** Protect wilderness characteristics (i.e., roadlessness, naturalness, opportunities for solitude and primitive unconfined recreation, and identified supplemental values), while allowing competing resource demands that do not conflict with preserving long-term wilderness characteristics.

- **Harvest Land Base—** Manage forest stands to achieve continual timber production that can be sustained through a balance of growth and harvest.

  - **Low Intensity Timber Area –** Use low intensity management to provide complex early-successional ecosystems, develop diverse late-successional ecosystems for a portion of the rotation and provide a variety of forest structural stages distributed both temporally and spatially.

  - **Moderate Intensity Timber Area –** Use moderate intensity management to provide complex early-successional ecosystems, develop diverse late-successional ecosystems for a portion of the rotation and provide a variety of forest structural stages distributed both temporally and spatially.

  - **Harvest Land Base –** Uneven Aged Timber Area – Use uneven – aged timber management to increase diversity of stocking levels and size classes within and among the stands.

- **Late Successional Reserve –** Lands are managed to maintain nesting-roosting habitat for the northern spotted owl and nesting habitat for the marbled murrelet, promote the development of nesting-roosting habitat for the northern spotted owl in stands that do not currently support northern spotted owl nesting and roosting, promote the development of nesting habitat for the marbled murrelet in stands that do not currently meet nesting habitat criteria, promote the development and maintenance of foraging habitat for the northern spotted owl, including creating and maintaining habitat to increase diversity and abundance of prey for the northern spotted owl.

- **Late-Successional Reserve Dry –** Applied variously on drier sites, lands are managed to Enable forests to: (1) recover from past management measures, (2) respond positively to climate-driven stresses, wildfire and other disturbance with resilience, (3) ensure positive or neutral ecological impacts from wildfire, and (4) contribute to northern spotted owl recovery.

- **Riparian Reserves** –Areas along streams and wetlands where the conservation of aquatic and riparian-dependent terrestrial resources receives primary emphasis. Riparian Reserves exist in all land allocations. Conservation and recovery of ESA-listed fish species and their habitats and provide for conservation of Bureau Special Status fish and other Bureau Special Status riparian-associated species. Riparian Reserves are further disaggregated into moist and dry zones that recognize the broad diversity of BLM landscapes by applying different implementing standards and guidelines.

Although Late Successional Reserves and Riparian Reserves are land allocations on both BLM and NFS lands and have similar objectives, implementing standards and guidelines in BLM management plans vary significantly from those on NFS lands because of the greater geologic and geographic diversity of BLM lands. BLM east-side management area land allocations do not apply to the Pacific Connector project area. The acres of BLM RMP allocations affected by the Pacific Connector pipeline is displayed in table 4.7.3.3-3.

4.7.3.4 Proposed Amendments to BLM and Forest Service Land Management Plans

Amendment of BLM Resource Management Plans

BLM lands are managed according to the direction in Resource Management Plans (RMP). Approximately 46.9 miles of the proposed Pacific Connector pipeline route would cross federal land administered by the BLM in southwest Oregon. The Coos Bay District and the Roseburg District-Swiftwater Field Office are managed according to the provisions of the Northwestern and Coastal Oregon RMP (BLM 2016a). The Lakeview District-Klamath Field Office, Medford District and the Roseburg District-South River Field Office are managed according to the provisions of the Southwestern Oregon RMP (BLM 2016b).

FLPMA as amended, and its implementing regulations in Title 43, CFR part 1600 requires all projects on BLM lands, including third-party projects authorized by permits or right of way grants, to be consistent with the RMP of the administrative unit where the project occurs. Where projects would not be consistent with the underlying RMP, the project cannot be implemented unless the RMP is amended to make provision for the project, or the project is modified to be consistent with RMP direction. An RMP does not authorize projects or activities or commit the BLM to act. A plan may constrain the agency from authorizing or carrying out projects and activities, or the manner in which they may occur.

For the Pacific Connector pipeline project, the BLM worked cooperatively with the FERC staff, other cooperating agencies, and the applicant to incorporate BMPs, design features and project requirements which would avoid, minimize, rectify, reduce or eliminate environmental consequences (40 CFR 1502.14(f) and 1508.20(a-d)). The BMPs, design features, or requirements specific to BLM lands are included as attachments to the project proponent's POD. There are 28 appendices in the POD; they include draft monitoring elements to ensure that the actions are implemented. Collectively, the POD is incorporated into the project's description, and is summarized in section 2.6.3 of the DEIS.

Given the linear nature of the pipeline corridor, resources on BLM lands and the topography of BLM lands in southwest Oregon it is not possible for the Pacific Connector project to conform to every requirement of the respective BLM RMPs. Pacific Connector has cooperated with the BLM to make its proposal consistent with the BLM RMPs as much as is feasible, but even with route adjustments, modified project design features, and BMPs, the proposed ROW for the Project on BLM-managed lands would not conform to the Southwestern Oregon RMP and the Northwestern and Coastal RMP (RMPs for Western Oregon). Amendment of these RMPs would be necessary to make provision for the project to allow it to proceed.

The RMPs for Western Oregon allow for the construction of linear rights-of-way within the LSR "as long as northern Spotted Owl (NSO) nesting-roosting habitat continues to support nesting and roosting at the stand level, and NSO dispersal habitat continues to support movement and survival at the landscape level", and construction of linear rights-of-way "as long as the occupied stand continues to support marbled murrelet nesting" (Southwestern Oregon ROD page 71, Northwestern and Coastal ROD, page 65). BLM staff initially evaluated that the proposed ROW would cross approximately 268 acres of LSR and approximately 116 acres of known or presumed occupied MAMU habitat and/or NSO nesting-roosting habitat within the LSR land allocation. Additional analysis concluded that the clearing and removal of vegetation required within the LSR for the proposed Project would result in the loss of stand-level NSO nesting and roosting habitat and MAMU nesting habitat in the project corridor.

BLM management direction in the RMPs for Western Oregon specific to wildlife prohibits activities that "disrupt marbled murrelet nesting at occupied sites ... within all land use allocations within 35 miles of the Pacific Coast and... within reserved land use allocation between 35-50 miles of the Pacific Coast" (Southwestern Oregon ROD, page 118, Northwestern and Coastal ROD, page 98). BLM staff concluded that construction of the Project would likely result in disruption of MAMU nesting at some occupied sites within these two discrete geographic ranges.

In order to consider the ROW Grant, the BLM must address these inconsistencies by amending the affected RMPs to make provisions for the Pacific Connector project. BLM therefore proposes to amend the RMPs to re-allocate all lands within the proposed temporary use area and ROW to a District-Designated Reserve, with management direction to manage said lands for the purposes of the Pacific Connector Gas Pipeline ROW. Approximately 885 acres would be re-allocated from existing land allocations in the affected RMPs to the District Designated Reserves (see Resource Report 8).

District-Designated Reserve is an existing land use allocation in both the Northwestern and Coastal Oregon RMP and the Southwestern Oregon RMP. Under these RMPs, District-Designated Reserves encompass a wide variety of lands, including constructed facilities, infrastructure, roads, communication sites, seed orchards, quarries, lands biologically or physically unsuitable for timber production, Areas of Critical Environmental Concern, and lands managed for their wilderness characteristics. District-Designated Reserves are reserved from sustained-yield timber production in order to manage them for another set of specific values and resources. Within the District-Designated Reserve, the BLM would maintain the values and resources necessary for construction, operation, maintenance, and decommissioning of the proposed Pacific Connector project.

Specifically, BLM proposes to add the following text to the RMPs for Western Oregon (Northwestern and Coastal ROD, page 59, Southwestern Oregon ROD, page 57):

District-Designated Reserve – Pacific Connector Gas Pipeline

Management Objectives

- *See District-Designated Reserves management objectives.*
- Maintain the values and resources for which the BLM has granted the ROW for the Pacific Connector Gas Pipeline Project.

Management Direction

Allow the construction, operation, maintenance, and decommissioning of the Pacific Gas Connector Pipeline, notwithstanding the restrictions and requirements of management direction described for resource programs.

District-Designated Reserve allocations establish specific management for a specific use or to protect specific values and resources. The project-specific amendment would not change RMP requirements for other projects or authorize any other actions within the *District-Designated Reserve – Pacific Connector Gas Pipeline* .Other uses that are compatible with the purpose of the District-Designated Reserve maybe authorized on a case-by-case basis following completion of environmental analysis. The environmental consequences of this proposed amendment are the same as the environmental consequences of construction and operation of the Pacific Connector project and are discussed at length elsewhere in this EIS.

Therefore, the resource impacts of the proposed plan amendments are those associated with construction, operation, maintenance and decommissioning of the proposed pipeline. With this amendment, the granting of a ROW on BLM-managed lands for the Pacific Connector Project would conform to the Southwestern Oregon Record of Decision and Resource Management Plan (BLM 2016b) and the Northwestern and Coastal Oregon ROD and RMP (BLM 2016a).

Amendments to Forest Service Land and Resource Management Plans

This section summarizes DEIS appendix F2 (Forest Service Forest Plan Amendments and Compensatory Mitigation), which contains the full text of the independent Forest Service analysis. Reviewers who seek additional information should review the applicable sections in appendix F.2. Section numbers that refer to sections in the appendix are so noted.

The Forest Service amendment process is described in section 1.3.3 of this DEIS and in section 1.1 of appendix F.2. The proposed amendments to Forest Service LRMPs are described in section 2.1.3.2 of this DEIS and in section 2 of appendix F.2. The Forest Service compensatory mitigation plans are discussed in sections 1.3.3 and 2.1.5 of this DEIS and throughout appendix F.2. The proposed Forest Plan amendments and related compensatory mitigation evaluated in this section are unique for each national forest and are addressed separately in the following sections.

Evaluation of Umpqua National Forest Proposed Forest Plan Amendments

The proposed Pacific Connector pipeline incorporates the most up-to-date engineering and technological practices for pipeline construction and operation. However, even with following these practices, it has been determined that one Forest Plan standard associated with rare and/or isolated species (Survey and Manage), and three Forest Plan standards associated with the soil, water, and riparian resources, would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Umpqua National Forest LRMP as amended by the NWFP and the January 2001 Record of Decision for Amendments to the Survey and Manage Protection Buffer, and Other Mitigation Measures Standards and Guidelines (Survey and Manage ROD). One additional amendment proposes to reallocate acres from the Matrix land allocation to the LSR land allocation.

Forest Plan Amendments Related to Rare Aquatic and Terrestrial Plant and Animal Communities (FS-1, UNF-4):

*Amendment FS-1**:** Project-Specific Amendment to Exempt Management Recommendations for Survey and Manage Species on the Umpqua National Forest.*

One Forest Plan standard associated with rare and/or isolated species (Survey and Manage) would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Umpqua National Forest LRMP as amended. This standard is:

- Management Direction: Manage All Known Sites (Survey and Manage ROD, Standards and Guidelines Page 8). Current and future known sites will be managed according to the

Management Recommendation for the species. Professional judgment, Appendix J2 in the Northwest Forest Plan Final SEIS, and appropriate literature will be used to guide individual site management for those species that do not have Management Recommendations.

The proposed amendment to this standard is:

- Management Direction: Manage All Known Sites (Survey and Manage ROD, Standards and Guidelines Page 8). Current and future known sites will be managed according to the Management Recommendation for the species, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Professional judgment, Appendix J2 in the Northwest Forest Plan Final SEIS, and appropriate literature will be used to guide individual site management for those species that do not have Management Recommendations. (Proposed amendment FS-1 on the Umpqua National Forest)

While the amendment would provide an exception to meeting this standard, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore, any effects of the pipeline's construction and operation on Survey and Manage species within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

The purpose of this project-level amendment is to make the proposed Pacific Connector pipeline project consistent with the Umpqua National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to this amendment are:

- 36 CFR 219.9(a)(2)(ii) – [the plan must include plan components to maintain or restore] "Rare aquatic and terrestrial plant and animal communities."
- 36 CFR 219.9(b)(1) – "The responsible official shall determine whether or not the plan components required by paragraph (a) provide ecological conditions necessary to: …maintain viable populations of each species of conservation concern within the plan area."

Because the proposed amendment is "directly related" to these two substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendment (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the amendment, it is important to recognize that the applicable sections of 36 CFR 219.9(a) and (b) that are described above, requires plan components to maintain or restore rare aquatic and terrestrial plant and animal communities, across the entire planning area (i.e., the Umpqua National Forest). This plan amendment does not alter these LRMP plan requirements for managing rare plant and animal communities across 99.98 percent of the Umpqua National Forest. The proposed pipeline construction corridor including the temporary extra work areas (TEWAs) and the uncleared storage areas (UCSAs) is approximately 205 acres of the 983,129 acre Umpqua National Forest. Within this 205 acre construction corridor surveys have identified 107 Survey and Manage sites that could be potentially impacted by construction activities. The proposed amendment does not waive the persistence objective for Survey and Manage species. The analysis that was conducted (see section 4.6.4.3 of the DEIS and appendix F.5) determined the Survey and Manage persistence objectives would be met. This means that for Umpqua National Forest lands within the project area, individual sites of Survey and Manage species may be impacted or lost to construction activities, but affected species are expected to persist within the range of the NSO despite the loss of these individual sites.

The amendment modifies this standard so that in the 205 acres of the project construction area the project need not be in compliance with this standard' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 205 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the management requirement described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.9(a) and (b) rule requirements within the "scope and scale" of the proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.9(a) and (b) requirements are being addressed.

How the Required Mitigation Measures would Maintain or Restore Effects to Rare Aquatic and Terrestrial Plant and Animal Communities and Meet the Applicable 36 CFR 219.9(a) and 36 CFR 219.9 (b) Requirements

The Forest Service has worked to inventory, analyze, and evaluate rare aquatic, terrestrial plant and animal communities that could be affected by this project. In addition, a third-party consultant for technical support was also utilized in reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures incorporated into amendments for Survey and Manage species are designed to minimize, maintain or restore the potential for habitat fragmentation, edge effects, and loss of long-term habitats associated with effected species. To ensure adequate restoration and revegetation of the ROW, design features are identified in the *Erosion Control and Revegetation Plan* (POD I), *Right-of-Way Clearing Plan* (POD U), *Leave Tree Protection Plan* (POD P). In addition, routing considerations were identified during project development to ensure avoidance of known populations of rare plant and animal communities (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands). As well as, appendix F.5, *Survey and Manage Persistence Evaluations*, and proposed amendment UNF-4 Reallocation of Matrix Lands to LSR.

As a basis for Survey and Manage determinations, appendix F.5 provides background research on Survey and Manage species that could be affected by the Pacific Connector Project; a review of survey reports prepared by others for the Pacific Connector Project; and processing and analysis of spatial data obtained from the BLM, Forest Service, and other sources over the past 12 years. Background information was used in combination with new information available as a result of surveys for the Pacific Connector Project and recent surveys in other portions of old growth forests to discuss the currently known distribution of the species in old growth forests within the NSO range. Impacts to sites as a result of the Pacific Connector Project were analyzed to determine if the species would continue to have a reasonable assurance of persistence in the NSO range following implementation of the Pacific Connector Project, taking into consideration the status and distribution of the species and general habitat in the NSO range.

Some of the required mitigation measures in the POD sections to protect rare plant and animal communities include: flagging existing snags on the edges of the construction ROW or TEWAs where feasible to save from clearing; snags would be saved as and used in LWD placement post-construction to benefit primary and secondary cavity nesting birds, mammals, reptiles, and amphibians; other large diameter trees on the edges of the construction ROW and TEWAs would also be flagged to save/protect as green recruitment or habitat/shade trees, where feasible; trees would be girdled to create snags to augment the number of snags along the ROW to benefit cavity nesting birds, mammals, reptiles, and amphibians. See POD's P & U and 4.7—*Land Use* of the DEIS for a complete list of applicable mitigation measures for pipeline construction. Additional measures include low ground weight (pressure) vehicles would be used; logging machinery would be restricted to the 30-foot permanent ROW wherever possible to prevent soil compaction; the removal of soil duff layers would be avoided in order to maintain a cushion between the soil and the logs and the logging equipment; designed skid trails would be used to restrict detrimental soil disturbance (compaction and displacement) to a smaller area of the ROW over the pipeline trenching area; and the temporary construction area would be restored and revegetated using native seeds, to the extent possible, and saplings (POD I).

In an effort to minimize, maintain or restore the impacts to Survey and Manage species, Pacific Connector adopted route variations to avoid certain species identified in the Survey and Manage Persistence Evaluations by co-locating the proposed construction corridor adjacent to existing roads, through managed timber stands or otherwise avoid unique LSOG habitats to the maximum extent practicable (See chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands).

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (Environmental Briefings and Compliance Plan, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer's designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to soil, water and riparian resources, are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

Amendment UNF-4: Reallocation of Matrix Lands to LSR

The other proposed Forest Plan amendment related to rare aquatic and terrestrial plant and animal communities on the Umpqua National Forest is UNF-4. This proposed amendment would change the designation of approximately 585 acres from the Matrix land allocation to the LSR land allocation in Sections 7, 18, and 19, T.32S., R.2W.; and Sections 13 and 24, T.32S., R.3W., W.M., OR. (see figure 2.1-4). This change in land allocation is proposed as mitigation for the potential adverse impact of the Pacific Connector Pipeline project on LSR 223 on the Umpqua National Forest. This is a plan level amendment that would change future management direction for the lands reallocated from Matrix to LSR (for additional information on consistency with LSR Standards and Guidelines see section 4.7.3.6. and appendix F.3 of the DEIS).

The purpose of this amendment is to make the proposed Pacific Connector pipeline project consistent with the Umpqua National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to this amendment are:

- 36 CFR 219.8(a)(1)(i) – [the plan must include plan components to maintain or restore] "Interdependence of terrestrial and aquatic ecosystems in the plan area."
- 36 CFR 219.8(b)(1) – [the plan must include plan components to guide the plan area's contribution to social and economic sustainability] "Social, cultural and economic conditions relevant to the area influenced by the plan."
- 36 CFR219.9(b)(1) "The responsible official shall determine whether or not the plan components required by paragraph (a) of this section provide the ecological conditions necessary to: contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and maintain a viable population of each species of conservation concern within the plan area,"
- 36 CFR 219.9(a)(2)(ii) – [the plan must include plan components to maintain or restore] "Rare aquatic and terrestrial plant and animal communities."

Because the proposed amendment is "directly related" to these four substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendment (36 CFR 219.13 (b)(5)). However, because this proposed amendment would simply modify the area to which existing direction applies, the existing formatting for the planning requirements listed above would be retained (36 CFR 219.13(b)(4)).

In considering the "scope and scale" of the amendment, it is important to recognize that the applicable sections of 36 CFR 219.8 and 219.9 that are described above, requires plan components to maintain or restore rare aquatic and terrestrial plant and animal communities, and provide for social and economic sustainability across the entire planning area (i.e., the Umpqua National Forest). This plan amendment does not alter these LRMP plan requirements across 99.94 percent of the Umpqua National Forest. The proposed land reallocation is approximately 585 acres of the 983,129 acre Umpqua National Forest. The proposed amendment would benefit rare aquatic and terrestrial plant and animal communities by placing these acres in a late successional reserve where providing habitat for these species is the primary goal.

The timber probable sale quantity (directly related to economic conditions) would not be affected before the Umpqua National Forest LRMP is revised because the Forest has the capacity to maintain probable sale quantity without the acres of matrix lands that would be reallocated to LSR. If a linear relationship between acres and outputs is assumed, the potential effect would be less than two-tenths of one percent of the Forest's probable sale quantity since this proposed amendment would affect less than two-tenths of one percent of the Forest's matrix land base. This proposed amendment would not prevent future vegetation management activities such as thinning that would benefit LSR habitat and could also contribute to the local forest products industry.

How the Compensatory Mitigation Actions would help to Maintain or Restore Rare Aquatic and Terrestrial Plant and Animal Communities in the Plan Area (36 CFR 219.9(a), 36 CFR 219.9 (b)).

In addition to reallocation of 585 acres of Matrix to LSR, the CMP on the Umpqua National Forest includes proposals for stand density fuel breaks on 3,105 acres, stand density management on 816 acres, terrestrial habitat improvements on 478 acres and decommissioning approximately 5 miles of roads that would benefit rare plant and animal communities. The CMP on the Umpqua National Forest also includes proposals to improve aquatic and riparian habitat that would benefit rare aquatic plant and animal communities (see the discussion of *How the Compensatory Mitigation Actions would help to Maintain or Restore the Ecological Integrity of Riparian Areas, Soils, and Soil productivity in the Plan Area (36 CFR 219.8(a)(3)(i), (36 CFR 219.8(a)(2)(ii))* below for a discussion of benefits to aquatic habitats).

Stand density fuel breaks would reduce the threat of losing late-successional habitat to fire. High intensity fire has been identified as the single factor most impacting late successional and old growth forest habitats on federal lands in the area of the NWFP. Construction of the pipeline and associated activities removes both mature and developing stands and would increase fire suppression complexity; however the corridor also provides a fuel break. Fuels reduction adjacent to the corridor would increase the effectiveness of the corridor as a fuel break. Density management would increase longevity of existing mature stands by reducing losses from disease, insects and fire. Stand density management and fuels reduction would lower the risk of loss of developing and existing mature stands and other valuable habitats to high-intensity fire.

Stand density management would enhance LSOG habitat by increasing the growth, health, and vigor of the trees remaining in the stands, and restoring species and structural diversity to those considered characteristic under a natural disturbance regime. Thinning of young stands is a recognized treatment within LSR if designed to accelerate development of late-successional habitat characteristics. The proposed treatments include 228 acres of pre-commercial thinning, 288 acres of commercial thinning and 300 acres of off-site pine removal. The Pacific Connector pipeline would result in additional fragmentation and preclude the recovery of fragmented habitat for those stands adjacent to the pipeline corridor. Both mature stands and developing stands would be removed during pipeline construction. Density management of forested stands would assist in the recovery of late-seral habitat, impact from fragmentation, reduction in edge effects and enhance resilience of mature stands over time. Accelerating development of mature forest characteristics would shorten the impacts of those biological services loss due to pipeline construction.

Terrestrial habitat improvements include proposals for large woody debris placement on 164 acres, snag creation on 324 acres, noxious weed treatments on 6.7 miles of road and 124 acres of Lupine meadow restoration. Large wood replacement would partially mitigate for the barrier effect of the corridor by creating structure across the corridor for use by small wildlife species. Placement in wood deficient areas adjacent to the corridor allows for scattering of stockpiled wood, reducing localized fuel loads while improving habitat in deficient stands. Larger logs maintain moisture longer and are less likely to be fully consumed by fire. Managing for the proposed levels provide for a greater assurance of species abundance. The objective of snag creation is to mitigate for the immediate and future impacts to snag habitat from the clearing of the pipeline ROW. The construction and operation of the pipeline project has the potential to create vectors for noxious weeds. The proposed noxious weed treatments are intended to reduce populations of noxious weeds that are in close proximity to the pipeline project ROW. The long-term benefits of meadow restoration would include the restoring of native plant populations and species diversity. Restoring native plant communities and increasing vegetation diversity generally contributes to restoring habitat for a broad group of plant and animal species.

Although the Pacific Connector project has been routed to avoid LSOG habitat as much as possible, the project would cause habitat fragmentation within LSR 223. Road decommissioning reduces the edge effects over time by revegetating road surfaces and eliminating road corridors. Revegetating selected roads in conjunction with the density management proposed for adjacent plantations would create larger blocks of late successional habitat in the future.

These projects have been designed by an interdisciplinary team of resource professionals on the Umpqua National Forest with input and coordination with the U.S. Fish and Wildlife Service, NOAA Fisheries, and State agencies. They were planned within the watersheds that would be affected by the Pacific Connector pipeline project. They are a component of the Pacific Connector application and would be a requirement of the ROW grant. Overall, these projects would help maintain and restore rare aquatic and terrestrial plant and animal communities on the Umpqua National Forest (see table 2.1.1-3 and 2.1.1-4 and figure 2.1-1 through 2.1-5 in appendix F.2 for additional information).

Forest Plan Amendments Related to Soil, Water and Riparian Areas (UNF-1, UNF-2, and UNF-3):

Three Forest Plan standards associated with the soil, water, and riparian resources would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Umpqua National Forest LRMP. These standards are:

- Standard & Guideline 1 (UNF LRMP IV-33). Maintain all effective shading vegetation on perennial streams. Utilize silvicultural practices to establish shade on perennial streams where currently lacking.

- Prescriptions C2-II (LRMP IV-173 par.1, 1st sentence) and C2-IV (LRMP IV-177 last par. last sentence) Utility/transportation corridors, roads or transmission lines may cross but must not parallel streams and lake shores within the riparian unit.
- Standard & Guideline 1 (UNF LRMP IV-67). The combined total amount of unacceptable soil condition (detrimental compaction, displacement, puddling or severely burned) within an activity area (e g., cutting unit, range allotment, site preparation area) should not exceed 20 percent. All roads and landings, unless rehabilitated to natural conditions, are considered to be in detrimental condition, and are included as part of this 20 percent.

The proposed amendments to these standards are:

- Standard & Guideline 1 (UNF LRMP IV-33). Maintain all effective shading vegetation on perennial streams, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Utilize silvicultural practices to establish shade on perennial streams where currently lacking. (proposed amendment UNF-1)
- Prescriptions C2-II (LRMP IV-173 par.1, 1st sentence) and C2-IV (LRMP IV-177 last par. last sentence) Utility/transportation corridors, roads or transmission lines may cross but must not parallel streams and lake shores within the riparian unit, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. (proposed amendment UNF-2)
- Standard and Guideline 1 (UNF LRMP IV-67). The combined total amount of unacceptable soil condition (detrimental compaction, displacement, puddling or severely burned) within an activity area (e g., cutting unit, range allotment, site preparation area) should not exceed 20 percent. All roads and landings, unless rehabilitated to natural conditions, are considered to be in detrimental condition, and are included as part of this 20 percent, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. (proposed amendment UNF-3)

While the amendments would provide an exception to meeting these standards, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore any effects of the pipeline's construction and operation on the soil, water and riparian resources within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

The purpose of these three project-level amendments is to make the proposed Pacific Connector pipeline project consistent with the Umpqua National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to these three amendments are:

- 36 CFR 219.8(a)(3)(i) – The plan must include plan components "to maintain or restore the ecological integrity of riparian areas in the plan area, including plan components to maintain or restore structure, function, composition, and connectivity.

- 36 CFR 219.8(a)(2)(ii) – [The plan must include plan components to maintain or restore] "soils and soil productivity, including guidance to reduce soil erosion and sedimentation."

Because the three proposed amendments are "directly related" to these two substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendments (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the three amendments, it is important to recognize that the applicable sections of 36 CFR 219.8(a) that are described above, requires plan components to "maintain or restore" the soil, water and riparian resources across the entire planning area (i.e., the Umpqua National Forest). These plan amendments do not alter these LRMP plan requirements for managing the soil, water, and riparian resources across 99.98 percent of the Umpqua National Forest. The proposed pipeline construction corridor including the TEWAs and the UCSAs is approximately 205 acres of the 983,129 acre Umpqua National Forest. Of the 205 acres of pipeline corridor construction it is estimated that approximately 4 of these acres would not meet the standards for riparian area management described above and approximately 54 to 127 acres would not meet standards for soils described above.

The amendments modify three standards so that in the 205 acres of the project construction area the project need not be in compliance with these standards' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 205 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the three management requirements described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.8(a) rule requirements within the "scope and scale" of these proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.8(a) requirements are being addressed.

How the Required Mitigation Measures would Maintain or Restore Effects to Soil, Water, and Riparian Resources and Meet the Applicable 36 CFR 219.8(a) Requirements

The Forest Service has worked with Pacific Connector Gas Pipeline to inventory, analyze, and evaluate the geologic, soil, and hydrologic resources that could be affected by this project. In addition, a third-party consultant for technical support was also utilized in reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration are enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures, incorporated into amendments for soil, water, and riparian resources are designed to minimize, maintain or restore the potential for soil movement, slope stability, water quality, and to ensure adequate restoration and revegetation. These measures are identified in: the

Erosion Control and Revegetation Plan (POD I); *Right-of-Way Clearing Plan* (POD U); *Wetland and Waterbody Crossing Plan* (POD BB); the *Forest Service Site Specific Stream Crossing Prescriptions* (NSR 2014); the *Stream Crossing Risk Analysis*; and *Stream Crossing Risk Analysis Addendum* (GeoEngineers 2017d, 2018a). Pacific Connector would also follow the FERC's applicant prepared Wetland Procedures and the Best Management Practices for the State of Oregon. To further reduce potential for landslides on steep slopes, the Forest Service, BLM, and FERC are also recommending additional industry best management practices and measures identified from the *Technical Report on Soil Risk and Sensitivity Assessment* (NSR 2014) be incorporated into Pacific Connector's terms and conditions of the ROW Grant as described in the POD's identified above. See 4.2.3.3 of the DEIS for a description of soil risk and sensitivity assessment.

Areas with soils rated moderate to very high for risk or sensitivity (39 acres total) would be recommended for more site-specific validation of the risk criteria used in the *Technical Report on Soil Risk and Sensitivity Assessment* (NSR 2014) to confirm that specific locations merit consideration of the more aggressive soil remediation measures, such as: a 2- to 3-inch organic mulch surface application (80 percent coverage) of woodchips, logging slash, and/or straw; adaptive seed mixes and vegetation to better fit site conditions; deep subsoil decompaction with hydraulic excavators that leave constructed corridor mounded and rough with maximum water infiltration so that water cannot flow downhill for any appreciable distance; more aggressive use of constructed surface water runoff dispersion structures such as closely placed and more pronounced slope dips and water bars, etc.; more aggressive use of constructed surface runoff entrapments such as silt fencing, sediment settling basins, or straw bale structures, etc.; more aggressive placement (100 percent coverage) and depth (3 to 4 inches) of ground cover using woodchips, logging slash, straw bales, wattles (see POD's U and I). In efforts to protect soil productivity, topsoil segregation would be required for pipeline construction at wetland and waterbody crossings on NFS lands (POD U).

Some of the required mitigation measures in the POD BB and *Forest Service Site Specific Stream Crossing Prescriptions* (NSR 2014) to protect wetlands and minimize, maintain or restore compaction include: limiting the construction ROW width to 75 feet through wetlands; placing equipment on mats; using low-pressure ground equipment; limiting equipment operation and construction traffic along the ROW; locating temporary workspace (TEWAS) more than 50 feet away from wetland boundaries; cutting vegetation at ground level; limiting stump removal to the construction trench; segregating the top 12 inches of soil, or to the depth of the topsoil horizon; using "push-pull" techniques in saturated wetlands; limiting the amount of time that the trench is open by not trenching until the pipe is assembled and ready for installation; not using imported rock and soils for backfill; and not using fertilizer, lime, or mulch during restoration in wetlands. Pacific Connector must also follow the FERC Waterbody and Wetland Construction and Mitigation Procedures. See 4.3.3.2 of the DEIS for a complete list of applicable mitigation measures for pipeline construction at specific waterbody and stream crossings.

In an effort to minimize, maintain or restore the impacts to streams and riparian areas, Pacific Connector adopted route variations to co-locate the proposed construction corridor adjacent to existing roads and along dry ridge tops (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands). In addition, Pacific Connector has committed to limit construction at waterbody crossings to times of dry weather or low water flow. Pacific Connector would implement the required erosion control measures at the proposed stream crossings to minimize, maintain or restore potential erosion and sedimentation impacts. The applicable mitigation measures and monitoring requirements in the POD relating to water waterbody crossings are included in the *Site Specific Forest Service Stream Crossing Prescriptions, and Wetland and Waterbody Crossing Plan* (POD BB). In addition, applicable mitigation measures from the FERC approved applicant prepared Procedures for Wetland and Waterbody Crossings would be required.

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to: facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (Environmental Briefings and Compliance Plan, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer's designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to soil, water and riparian resources, are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

How the Compensatory Mitigation Actions would help to Maintain or Restore the Ecological Integrity of Riparian Areas, Soils, and Soil productivity in the Plan Area (36 CFR 219.8(a)(3)(i), (36 CFR 219.8(a)(2)(ii)).

Part of the CMP on the Umpqua National Forest includes proposals to remove eleven old culverts that may block fish passage either by poor design or by failure over time, decommission approximately 7.2 miles and storm proof approximately 11.4 miles of road.

Removing culverts that block fish passage and replacing them with fish-friendly designs can allow fish and other aquatic organisms to access previously unavailable habitat. Stream crossing replacement would directly improve stream connectivity and habitat for aquatic species by immediately restoring access to formerly inaccessible habitats. Indirectly, these projects would reduce potential sediment levels in the long term by decreasing the potential for road failure. Stream crossing projects also reduce stream velocities by increasing stream crossing sizes, eliminating flow restrictions and allowing passage to additional reaches of habitat by removing barriers to aquatic species which improves access to spawning and rearing habitat and allows unrestricted movement throughout stream reaches during seasonal changes in water levels (Hoffman 2007).

Decommissioning and storm proofing roads can substantially reduce sediment delivery to streams (Madej 2000; Keppeler et al. 2007). Proposed road decommissioning and storm proofing would increase infiltration of precipitation, reduce surface runoff, and reduce sediment production from road-related surface erosion in the watershed where the impacts from the Project would occur. Decommissioning roads would restore natural drainage patterns and thereby avoid large volumes of added sediment to the stream network that would be likely to eventually occur. In addition limited road maintenance dollars could be focused on the remaining road systems resulting in more maintenance of culverts and ditchlines resulting in less potential for catastrophic failure. Madej (2000) concluded that by eliminating the risk of stream diversions and culvert failures, road removal treatments significantly reduce long-term sediment production from retired logging roads.

These projects have been designed by an interdisciplinary team of resource professionals on the Umpqua National Forest with input and coordination with the U.S. Fish and Wildlife Service, NOAA Fisheries, and State agencies. They were planned within the watersheds that would be affected by the Pacific Connector pipeline project. They are a component of the Pacific Connector application and would be a requirement of the ROW grant. Overall, these projects would help maintain and restore riparian and soil resources on the Umpqua National Forest (see table 2.1.1-3 and 2.1.1-4 and figure 2.1-1 through 2.1-5 in appendix F.2 for additional information).

Evaluation of Rogue River National Forest Proposed Forest Plan Amendments

The proposed Pacific Connector pipeline incorporates the most up-to-date engineering and technological practices for pipeline construction and operation. However, even with following these practices, it has been determined that one Forest Plan standard associated with rare and/or isolated species (Survey and Manage), two Forest Plan standards associated with the soil, water, and riparian resources, and four Forest Plan standards associated with visual resources would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Rogue River National Forest LRMP as amended by the NWFP and the January 2001 Survey and Manage ROD.

Forest Plan Amendments Related to Rare Aquatic and Terrestrial Plant and Animal Communities (FS-1, RRNF-7):

*Amendment FS-1**:** Project-Specific Amendment to Exempt Management Recommendations for Survey and Manage Species on the Rogue River National Forest.*

One Forest Plan standard associated with rare and/or isolated species (Survey and Manage) would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Rogue River National Forest LRMP as amended by the NWFP and the January 2001 Survey and Manage ROD. This standard is:

- Management Direction: Manage All Known Sites (Survey and Manage ROD, Standards and Guidelines Page 8). Current and future known sites will be managed according to the Management Recommendation for the species. Professional judgment, Appendix J2 in the Northwest Forest Plan Final SEIS, and appropriate literature will be used to guide individual site management for those species that do not have Management Recommendations.

The proposed amendment to this standard is:

- Management Direction: Manage All Known Sites (Survey and Manage ROD, Standards and Guidelines Page 8). Current and future known sites will be managed according to the Management Recommendation for the species, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Professional judgment, Appendix J2 in the Northwest Forest Plan Final SEIS, and appropriate literature will be used to guide individual site management for those species that do not have Management Recommendations. (Proposed amendment FS-1 on the Rogue River National Forest)

While the amendment would provide an exception to meeting this standard, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore any effects of the pipeline's construction and operation on Survey and Manage species within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

The purpose of this project-level amendment is to make the proposed Pacific Connector pipeline project consistent with the Rogue River National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to this amendment are:

- 36 CFR 219.9(a)(2)(ii) – [the plan must include plan components to maintain or restore] "Rare aquatic and terrestrial plant and animal communities."
- 36 CFR 219.9(b)(1) – "The responsible official shall determine whether or not the plan components required by paragraph (a) provide ecological conditions necessary to: …maintain viable populations of each species of conservation concern within the plan area."

Because the proposed amendment is "directly related" to these two substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendment (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the amendment, it is important to recognize that the applicable sections of 36 CFR 219.9(a) and (b) that are described above, requires plan components to maintain or restore rare aquatic and terrestrial plant and animal communities, across the entire planning area (i.e., the Rogue River National Forest). This plan amendment does not alter these LRMP plan requirements for managing rare plant and animal communities across 99.97 percent of the Rogue River National Forest. The proposed pipeline construction corridor including the TEWAs and the UCSAs is approximately 206 acres of the 628,443 acre Rogue River National Forest. Within this 206 acre construction corridor surveys have identified 36 Survey and Manage sites that could be potentially impacted by construction activities. The proposed amendment does not waive the persistence objective for Survey and Manage species. The analysis that was conducted (see section 4.6.4.3 of the DEIS and appendix F.5) determined the Survey and Manage persistence objectives would be met. This means that for Rogue River National Forest lands within the project area, individual sites of Survey and Manage species may be impacted or lost to construction activities, but affected species are expected to persist within the range of the NSO despite the loss of these individual sites.

The amendment modifies this standard so that in the 206 acres of the project construction area the project need not be in compliance with this standard' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 206 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the management requirement described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.9(a) and (b) rule requirements within the "scope and scale" of the proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.9(a) and (b) requirements are being addressed.

How the Required Mitigation Measures would Maintain or Restore Effects to Rare Aquatic and Terrestrial Plant and Animal Communities and Meet the Applicable 36 CFR 219.9(a) and 36 CFR 219.9 (b) Requirements

The Forest Service has worked to inventory, analyze, and evaluate rare aquatic, terrestrial plant and animal communities that could be affected by this project. In addition, a third-party consultant for technical support was also utilized in reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures incorporated into amendments for Survey and Manage species are designed to minimize, maintain or restore the potential for habitat fragmentation, edge effects, and loss of long-term habitats associated with effected species. To ensure adequate restoration and revegetation of the ROW, design features are identified in the *Erosion Control and Revegetation Plan* (POD I), *Right-of-Way Clearing Plan* (POD U), *Leave Tree Protection Plan* (POD P). In addition, routing considerations were identified during project development to ensure avoidance of known populations of rare plant and animal communities (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands). As well as, appendix F.5, *Survey and Manage Persistence Evaluations*, and proposed amendment RRNF-7 Reallocation of Matrix Lands to LSR.

As a basis for Survey and Manage determinations, appendix F.5 provides background research on Survey and Manage species that could be affected by the Pacific Connector Project; a review of survey reports prepared by others for the Pacific Connector Project; and processing and analysis of spatial data obtained from the Bureau of Land Management (BLM), Forest Service, and other sources over the past 12 years. Background information was used in combination with new information available as a result of surveys for the Pacific Connector Project and recent surveys in other portions of old growth forests to discuss the currently known distribution of the species in old growth forests within the NSO range. Impacts to sites as a result of the Pacific Connector Project were analyzed to determine if the species would continue to have a reasonable assurance of persistence in the NSO range following implementation of the Pacific Connector Project, taking into consideration the status and distribution of the species and general habitat in the NSO range.

Some of the required mitigation measures in the POD sections to protect rare plant and animal communities include: flagging existing snags on the edges of the construction ROW or TEWAs where feasible to save from clearing; snags would be saved as and used in LWD placement post-construction to benefit primary and secondary cavity nesting birds, mammals, reptiles, and amphibians; other large diameter trees on the edges of the construction ROW and TEWAs would also be flagged to save/protect as green recruitment or habitat/shade trees, where feasible; trees would be girdled to create snags to augment the number of snags along the ROW to benefit cavity nesting birds, mammals, reptiles, and amphibians. See POD's P & U and 4.7—*Land Use* of the DEIS for a complete list of applicable mitigation measures for pipeline construction. Additional measures include low ground weight (pressure) vehicles would be used; logging machinery would be restricted to the 30-foot permanent ROW wherever possible to prevent soil compaction; the removal of soil duff layers would be avoided in order to maintain a cushion between the soil and the logs and the logging equipment; designed skid trails would be used to restrict detrimental soil disturbance (compaction and displacement) to a smaller area of the ROW over the pipeline trenching area; and the temporary construction area would be restored and revegetated using native seeds, to the extent possible, and saplings (POD I).

In an effort to minimize, maintain or restore the impacts to Survey and Manage species, Pacific Connector adopted route variations to avoid certain species identified in the Survey and Manage Persistence Evaluations by co-locating the proposed construction corridor adjacent to existing roads, through managed timber stands or otherwise avoid unique LSOG habitats to the maximum extent practicable (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands).

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (Environmental Briefings and Compliance Plan, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer's designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to soil, water and riparian resources, are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

Amendment RRNF-7: Reallocation of Matrix Lands to LSR

The other proposed Forest Plan amendment related to rare aquatic and terrestrial plant and animal communities on the Rogue River National Forest is RRNF-7. This proposed amendment would change the designation of approximately 522 acres from the Matrix land allocation to the LSR land allocation in Section 32, T.36S., R.4E. W.M., OR. (see figure 2.2-1). This change in land allocation is proposed as mitigation for the potential adverse impact of the Pacific Connector Pipeline project on LSR 227 on the Rogue River National Forest. This is a plan level amendment that would change future management direction for the lands reallocated from Matrix to LSR (for additional information on consistency with LSR Standards and Guidelines see section 4.7.3.6. and appendix F.3 of the DEIS).

The purpose of this amendment is to make the proposed Pacific Connector pipeline project consistent with the Rogue River National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to this amendment are:

- 36 CFR 219.8(a)(1)(i) – [the plan must include plan components to maintain or restore] "Interdependence of terrestrial and aquatic ecosystems in the plan area."
- 36 CFR 219.8(b)(1) – [the plan must include plan components to guide the plan area's contribution to social and economic sustainability] "Social, cultural and economic conditions relevant to the area influenced by the plan."
- 36 CFR219.9(b)(1) "The responsible official shall determine whether or not the plan components required by paragraph (a) of this section provide the ecological conditions necessary to: contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and maintain a viable population of each species of conservation concern within the plan area,"
- 36 CFR 219.9(a)(2)(ii) – [the plan must include plan components to maintain or restore] "Rare aquatic and terrestrial plant and animal communities."

Because the proposed amendment is "directly related" to these four substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendment (36 CFR 219.13 (b)(5)). However, because this proposed amendment would simply modify the area to which existing direction applies, the existing formatting for the planning requirements listed above would be retained (36 CFR 219.13(b)(4)).

In considering the "scope and scale" of the amendment, it is important to recognize that the applicable sections of 36 CFR 219.8 and 219.9 that are described above, requires plan components to maintain or restore rare aquatic and terrestrial plant and animal communities, and provide for social and economic sustainability across the entire planning area (i.e., the Rogue River National Forest). This plan amendment does not alter these LRMP plan requirements across 99.92 percent of the Rogue River National Forest. The proposed land reallocation is approximately 522 acres of the 628,443 acre Rogue River National Forest. The proposed amendment would benefit rare aquatic and terrestrial plant and animal communities by placing these acres in a late successional reserve where providing habitat for these species is the primary goal.

The timber probable sale quantity (directly related to economic conditions) would not be affected before the Rogue River National Forest LRMP is revised because the Forest has the capacity to maintain probable sale quantity without the acres of matrix lands that would be reallocated to LSR. If a linear relationship between acres and outputs is assumed, the potential effect would be less than one-half of one percent of the Forest's probable sale quantity since this proposed amendment would affect less than one-half of one percent of the Forest's matrix land base. This proposed amendment would not prevent future vegetation management activities such as thinning that would benefit LSR habitat and could also contribute to the local forest products industry.

How the Compensatory Mitigation Actions would help to Maintain or Restore Rare Aquatic and Terrestrial Plant and Animal Communities in the Plan Area (36 CFR 219.9(a), 36 CFR 219.9 (b)).

In addition to the reallocation of 522 acres of Matrix to LSR, the CMP on the Rogue River National Forest includes proposals for stand density management on 618 acres, terrestrial habitat improvements on 1153 acres and decommissioning approximately 57.5 miles of roads that would benefit rare plant and animal communities. The CMP on the Rogue River National Forest also includes proposals to improve aquatic and riparian habitat that would benefit rare aquatic plant and animal communities (see the discussion of **How the Compensatory Mitigation Actions would help to Maintain or Restore the Ecological Integrity of Riparian Areas, Soils, and Soil productivity in the Plan Area (36 CFR 219.8(a)(3)(i), (36 CFR 219.8(a)(2)(ii))** below for a discussion of benefits to aquatic habitats).

Stand density management would enhance LSOG habitat by increasing the growth, health, and vigor of the trees remaining in the stands, and restoring species and structural diversity to those considered characteristic under a natural disturbance regime. Thinning of young stands is a recognized treatment within LSR if designed to accelerate development of late-successional habitat characteristics. The proposed treatments include 618 acres of pre-commercial thinning. The Pacific Connector pipeline would result in additional fragmentation and preclude the recovery of fragmented habitat for those stands adjacent to the pipeline corridor. Both mature stands and developing stands would be removed during pipeline construction. Density management of forested stands would assist in the recovery of late-seral habitat, impact from fragmentation, reduction in edge effects and enhance resilience of mature stands over time. Accelerating development of mature forest characteristics would shorten the impacts of those biological services loss due to pipeline construction.

Terrestrial habitat improvements include proposals for large woody debris placement on 511 acres, snag creation on 622 acres, and 20 acres of habitat planting for the Mardon Skipper butterfly. Large wood replacement would partially mitigate for the barrier effect of the corridor by creating structure across the corridor for use by small wildlife species. Placement in wood deficient areas adjacent to the corridor allows for scattering of stockpiled wood, reducing localized fuel loads while improving habitat in deficient stands. Larger logs maintain moisture longer and are less likely to be fully consumed by fire. Managing for the proposed levels provide for a greater assurance of species abundance. The objective of snag creation is to mitigate for the immediate and future impacts to snag habitat from the clearing of the pipeline ROW. The Dead Indian Plateau region is one of four known sites for Mardon Skipper butterflies in the world. It is also adjacent to a known site for Short-horned grasshoppers. Both of these species are on the Regional Forester's Sensitive Species list. As a long-term opening, the pipeline corridor would provide a unique opportunity to develop habitat for these two species. Planting the corridor with plants preferred by these species has the potential to increase the habitat and local range for both species. This action would provide both short-term and long-term habitat for the local population of Mardon Skipper butterflies and Short-horned grasshoppers.

Although the Pacific Connector project has been routed to avoid LSOG habitat as much as possible, the project would cause habitat fragmentation within LSR 227. Road decommissioning reduces the edge effects over time by revegetating road surfaces and eliminating road corridors. Revegetating selected roads in conjunction with the density management proposed for adjacent plantations would create larger blocks of late successional habitat in the future.

These projects have been designed by an interdisciplinary team of resource professionals on the Rogue River National Forest with input and coordination with the U.S. Fish and Wildlife Service, NOAA Fisheries, and State agencies. They were planned within the watersheds that would be affected by the Pacific Connector pipeline project. They are a component of the Pacific Connector application and would be a requirement of the ROW grant. Overall, these projects would help maintain and restore rare aquatic and terrestrial plant and animal communities on the Rogue River National Forest (see table 2.2.1-3 and 2.2.1-4 and figure 2.2-1 and 2.2-2 in appendix F.2 for additional information).

Forest Plan Amendments Related to Soil, Water and Riparian Areas (RRNF -5, RRNF-6):

Two Forest Plan standards associated with the soil, water, and riparian resources would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Rogue River National Forest LRMP. These standards are:

- Management Prescription 26 Restricted Riparian Standard & Guidelines for Facilities (10), (RRNF LRMP 4-308). Helispots and transmission corridors should be located outside this management area.
- Standard & Guideline for Soils (3) (RRNF LRMP 4-41, 4-83, 4-97, 4-123, 4-177, 4-307). No more than 10 percent of an activity area should be compacted, puddled or displaced upon completion of project (not including permanent roads or landings). No more than 20 percent of the area should be displaced or compacted under circumstances resulting from previous management practices, including roads and landings. Permanent recreation facilities or other permanent facilities are exempt.

The proposed amendments to these standards are:

- Management Prescription 26 Restricted Riparian Standard & Guidelines for Facilities (10), (RRNF LRMP 4-308). Helispots and transmission corridors should be located outside this management area, **with the exception of the operational right-of-way and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented**. (Proposed amendment RRNF-5)

- Standard & Guideline for Soils (3) (RRNF LRMP 4-41, 4-83, 4-97, 4-123, 4-177, 4-307). No more than 10 percent of an activity area should be compacted, puddled or displaced upon completion of project (not including permanent roads or landings). No more than 20 percent of the area should be displaced or compacted under circumstances resulting from previous management practices, including roads and landings, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Permanent recreation facilities or other permanent facilities are exempt. (Proposed amendment RRNF-6)

While the amendments would provide an exception to meeting these standards, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore any effects of the pipeline's construction and operation on the soil, water and riparian resources within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

The purpose of these two project-level amendments is to make the proposed Pacific Connector pipeline project consistent with the Rogue River National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to these three amendments are:

- 36 CFR 219.8(a)(3)(i) – The plan must include plan components "to maintain or restore the ecological integrity of riparian areas in the plan area, including plan components to maintain or restore structure, function, composition, and connectivity
- 36 CFR 219.8(a)(2)(ii) – [The plan must include plan components to maintain or restore] "soils and soil productivity, including guidance to reduce soil erosion and sedimentation."

Because the two proposed amendments are "directly related" to these two substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendments (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the two amendments, it is important to recognize that the applicable sections of 36 CFR 219.8(a) that are described above, requires plan components to "maintain or restore" the soil, water and riparian resources across the entire planning area (i.e., the Rogue River National Forest). These plan amendments do not alter these LRMP plan requirements for managing the soil, water, and riparian resources across 99.97 percent of the Rogue River National Forest. The proposed pipeline construction corridor including the TEWAs and the UCSAs is approximately 206 acres of the 628,443 acre Rogue River National Forest. Of the 206 acres of pipeline corridor construction it is estimated that approximately 2.5 of these acres would not meet the standards for riparian area management described above and approximately 62 to 144 acres would not meet standards for soils described above.

The amendments modify two standards so that in the 206 acres of the project construction area the project need not be in compliance with these standards' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 206 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the two management requirements described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.8(a) rule requirements within the "scope and scale" of these proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.8(a) requirements are being addressed.

How the Required Mitigation Measures would Maintain or Restore Effects to Soil, Water, and Riparian Resources and Meet the Applicable 36 CFR 219.8(a) Requirements.

The Forest Service has worked with Pacific Connector Gas Pipeline to inventory, analyze, and evaluate the geologic, soil, and hydrologic resources that could be affected by this project. In addition, a third-party consultant for technical support was also utilized in reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration are enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures, incorporated into amendments for soil, water, and riparian resources are designed to minimize, maintain or restore the potential for soil movement, slope stability, water quality, and to ensure adequate restoration and revegetation. These measures are identified in: the *Erosion Control and Revegetation Plan* (POD I); *Right-of-Way Clearing Plan* (POD U); *Wetland and Waterbody Crossing Plan* (POD BB); the *Forest Service Site Specific Stream Crossing Prescriptions* (NSR 2014); the *Stream Crossing Risk Analysis*; and *Stream Crossing Risk Analysis Addendum* (GeoEngineers2017d, 2018a). Pacific Connector would also follow the FERC's applicant prepared Wetland Procedures and the Best Management Practices for the State of Oregon. To further reduce potential for landslides on steep slopes, the Forest Service, BLM, and FERC are also recommending additional industry best management practices and measures identified from the *Technical Report on Soil Risk and Sensitivity Assessment* (NSR 2014) be incorporated into Pacific Connector's terms and conditions of the ROW Grant as described in the POD's identified above. See 4.2.3.3 of the DEIS for a description of soil risk and sensitivity assessment.

Areas with soils rated moderate to very high for risk or sensitivity (17 acres total) would be recommended for more site-specific validation of the risk criteria used in the *Technical Report on Soil Risk and Sensitivity Assessment* (NSR 2014) to confirm that specific locations merit consideration of the more aggressive soil remediation measures, such as: a 2- to 3-inch organic mulch surface application (80 percent coverage) of woodchips, logging slash, and/or straw; adaptive seed mixes and vegetation to better fit site conditions; deep subsoil decompaction with hydraulic excavators that leave constructed corridor mounded and rough with maximum water infiltration so that water cannot flow downhill for any appreciable distance; more aggressive use of constructed surface water runoff dispersion structures such as closely placed and more pronounced slope dips and water bars, etc.; more aggressive use of constructed surface runoff entrapments such as silt fencing, sediment settling basins, or straw bale structures, etc.; more aggressive placement (100 percent coverage) and depth (3 to 4 inches) of ground cover using woodchips, logging slash, straw bales, wattles (see POD's U and I). In efforts to protect soil productivity, topsoil segregation would be required for pipeline construction at wetland and waterbody crossings on NFS lands (POD U).

Some of the required mitigation measures in the POD BB and *Forest Service Site Specific Stream Crossing Prescriptions* (NSR 2014) to protect wetlands and minimize, maintain or restore compaction include: limiting the construction ROW width to 75 feet through wetlands; placing equipment on mats; using low-pressure ground equipment; limiting equipment operation and construction traffic along the ROW; locating temporary workspace (TEWAS) more than 50 feet away from wetland boundaries; cutting vegetation at ground level; limiting stump removal to the construction trench; segregating the top 12 inches of soil, or to the depth of the topsoil horizon; using "push-pull" techniques in saturated wetlands; limiting the amount of time that the trench is open by not trenching until the pipe is assembled and ready for installation; not using imported rock and soils for backfill; and not using fertilizer, lime, or mulch during restoration in wetlands. Pacific Connector must also follow the FERC Waterbody and Wetland Construction and Mitigation Procedures. See 4.3.3.2 of the DEIS for a complete list of applicable mitigation measures for pipeline construction at specific waterbody and stream crossings.

In an effort to minimize, maintain or restore the impacts to streams and riparian areas, Pacific Connector adopted route variations to co-locate the proposed construction corridor adjacent to existing roads and along dry ridge tops (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands). In addition, Pacific Connector has committed to limit construction at waterbody crossings to times of dry weather or low water flow. Pacific Connector would implement the required erosion control measures at the proposed stream crossings to minimize, maintain or restore potential erosion and sedimentation impacts. The applicable mitigation measures and monitoring requirements in the POD relating to water waterbody crossings are included in the *Site Specific Forest Service Stream Crossing Prescriptions, and Wetland and Waterbody Crossing Plan* (POD BB). In addition, applicable mitigation measures from the FERC approved applicant prepared Procedures for Wetland and Waterbody Crossings would be required.

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to: facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (Environmental Briefings and Compliance Plan, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer's designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to soil, water and riparian resources, are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

How the Compensatory Mitigation Actions would help to Maintain or Restore the Ecological Integrity of Riparian Areas, Soils, and Soil Productivity in the Plan Area (36 CFR 219.8(a)(3)(i), 36 CFR 219.8(a)(2)(ii)).

Part of the CMP on the Rogue River National Forest includes proposals to place large woody debris in-stream for 1.5 miles, repair stream crossings at 32 sites, and decommission approximately 57.5 miles of road.

Placement of LWD in streams adds structural complexity to aquatic systems by creating pools and riffles, trapping fine sediments and can contribute to reductions in stream temperatures over time (Tippery et al. 2010). Placing LWD in streams affects channel morphology, the routing and storage of water and sediment, and provides structure and complexity to stream systems. Complex pools and side channels created by instream wood provide overwintering habitat to stream salmonids and other aquatic organisms (Solazzi et. al. 2000). They also provide cover from predators during summer low flow periods when predation is at its highest. Providing more stream channel structure results in better over wintering habitat, improved summer pool habitat, and more abundant spawning gravels.

Restoring stream crossings reconnects aquatic habitats by allowing the passage of aquatic biota and restoring riparian vegetation. Stream crossing replacement would directly improve stream connectivity and habitat for aquatic species by immediately restoring access to formerly inaccessible habitats. Indirectly, these projects would reduce potential sediment levels in the long term by decreasing the potential for road failure. Stream crossing projects also reduce stream velocities by increasing stream crossing sizes, eliminating flow restrictions and allowing passage to additional reaches of habitat by removing barriers to aquatic species which improves access to spawning and rearing habitat and allows unrestricted movement throughout stream reaches during seasonal changes in water levels (Hoffman 2007).

Decommissioning roads can substantially reduce sediment delivery to streams (Madej 2000; Keppeler et al. 2007). Proposed road decommissioning and stormproofing would increase infiltration of precipitation, reduce surface runoff, and reduce sediment production from road-related surface erosion in the watershed where the impacts from the Project would occur. Decommissioning roads would restore natural drainage patterns and thereby avoid large volumes of added sediment to the stream network that would be likely to eventually occur. In addition limited road maintenance dollars could be focused on the remaining road systems resulting in more maintenance of culverts and ditchlines resulting in less potential for catastrophic failure. Madej (2000) concluded that by eliminating the risk of stream diversions and culvert failures, road removal treatments significantly reduce long-term sediment production from retired logging roads.

These projects have been designed by an interdisciplinary team of resource professionals on the Rogue River National Forest with input and coordination with the U.S. Fish and Wildlife Service, NOAA Fisheries, and State agencies. They were planned within the watersheds that would be affected by the Pacific Connector pipeline project. They are a component of the Pacific Connector application and would be a requirement of the ROW grant. Overall, these projects would help maintain and restore riparian and soil resources on the Rogue River National Forest (see table 2.2.1-3 and 2.2.1-4 and figure 2.2-1 and 2.2-2 in appendix F.2 for additional information).

Forest Plan Amendments Related Visual Resources (RRNF -2, RRNF-3, RRNF-4):

- Four Forest Plan standards associated with visual resources would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Rogue River National Forest LRMP. These standards are:
- Management Strategy 6, Foreground Retention, Standard and Guideline (1), (RRNF LRMP 4-72). Manage the area for Retention Visual Quality Objective. Catastrophic occurrences may dictate a need for short term departure from Retention. Assess the impacts to visual resources in all project environmental analysis. Specifically address how the visual quality objective will be met.
- Management Strategy 7, Foreground Partial Retention, Standard and Guideline (4), (RRNF LRMP 4-86). Correct unacceptable form, line, color or texture as a result of management activities either during the operation or within two years after completion of the activity.
- Management Strategy 7, Foreground Partial Retention, Standard and Guideline (1), (RRNF LRMP, 4-86). Manage the area for Partial Retention Visual Quality Objective. Catastrophic occurrences may dictate a need for short-term departure from Partial Retention Visual Quality Objective. Blend and shape regeneration openings with the natural terrain to the extent possible. Assess the impacts to visual resources in all project environmental analysis. Specifically address how the visual quality objective will be met.
- Management Strategy 9, Middle Ground Partial Retention, Standard and Guideline (1), (RRNF LRMP, 4-112). Manage the area for Partial Retention Visual Quality Objective. Catastrophic occurrences may dictate a need for short-term departure from Partial Retention Visual Quality Objective. Blend and shape regeneration openings with the natural terrain to the extent possible. Assess the impacts to visual resources in all project environmental analysis. Specifically address how the visual quality objective will be met.

The proposed amendments to these standards are:

- Management Strategy 6, Foreground Retention, Standard and Guideline (1), (RRNF LRMP 4-72). Manage the area for Retention Visual Quality Objective (VQO), with the exception of the Pacific Connector Pipeline ROW, where the VQO would be amended to Foreground Partial Retention where the pipeline would cross the Big Elk Road. The applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Catastrophic occurrences may dictate a need for short term departure from Retention. Assess the impacts to visual resources in all project environmental analysis. Specifically address how the visual quality objective will be met. (Proposed amendment RRNF-2)
- Management Strategy 7, Foreground Partial Retention, Standard and Guideline (4), (RRNF LRMP 4-86). Correct unacceptable form, line, color or texture as a result of management activities either during the operation or within two years after completion of the activity,

with the exception of the Pacific Connector Pipeline ROW which shall attain the amended VQO within 10 - 15 years after completion of the construction phase of the project where the pipeline crosses the Big Elk Road. The applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. (Proposed amendment RRNF-2)

- Management Strategy 7, Foreground Partial Retention, Standard and Guideline (1), (RRNF LRMP, 4-86). Manage the area for Partial Retention Visual Quality Objective. Catastrophic occurrences may dictate a need for short-term departure from Partial Retention Visual Quality Objective (VQO), with the exception of the Pacific Connector Pipeline ROW, where the VQO would be amended to Modification where the pipeline would cross the Pacific Crest Trail. The applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented**.** Blend and shape regeneration openings with the natural terrain to the extent possible. Assess the impacts to visual resources in all project environmental analysis. Specifically address how the visual quality objective will be met. (proposed amendment RRNF-3)
- Management Strategy 7, Foreground Partial Retention, Standard and Guideline (4), (RRNF LRMP 4-86). Correct unacceptable form, line, color or texture as a result of management activities either during the operation or within two years after completion of the activity, with the exception of the Pacific Connector Pipeline ROW which shall attain the amended VQO within 15 - 20 years after completion of the construction phase of the project where the pipeline crosses the Pacific Crest Trail. The applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. (Proposed amendment RRNF-3)
- Management Strategy 9, Middle Ground Partial Retention, Standard and Guideline (1), (RRNF LRMP, 4-112). Manage the area for Partial Retention Visual Quality Objective, with the exception of the Pacific Connector Pipeline ROW which shall attain the VQO within 10 - 15 years after completion of the construction phase of the project where the pipeline is adjacent to Highway 140.[151] The applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Catastrophic occurrences may dictate a need for short-term departure from Partial Retention Visual Quality Objective. Blend and shape regeneration openings with the natural terrain to the extent possible. Assess the impacts to visual resources in all project environmental analysis. Specifically address how the visual quality objective will be met. (Proposed amendment RRNF-4)

While the amendments would provide an exception to meeting these standards, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore any effects of the pipeline's construction and operation on the visual resources within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

[151] Duration of impact specifications are found in the National Forest Landscape Management Handbook 462 (USDA Forest Service 1974). The recommended duration to meet standards for Middleground Partial Retention is 3 years (see RRNF LRMP FEIS p. III-119).

The purpose of these five project-level amendments is to make the proposed Pacific Connector pipeline project consistent with the Rogue River National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to these five amendments are:

- 36 CFR 219.10(a)(1) – […the responsible official shall consider: …] "(1) Aesthetic values,… scenery,... viewsheds...".
- 36 CFR 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities,…and scenic character…"

Because the proposed amendments are "directly related" to these two substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendments (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the five amendments, it is important to recognize that the applicable sections of 36 CFR 219.10 that are described above, requires plan components to provide for aesthetic values and scenic character across the entire planning area (i.e., the Rogue River National Forest). These plan amendments do not alter these LRMP plan requirements for managing visual resources across 99.99 percent of the Rogue River National Forest. The proposed pipeline construction corridor including the TEWAs and the UCSAs is approximately 206 acres of the 628,443 acre Rogue River National Forest. Of the 206 acres of pipeline corridor construction it is estimated that approximately 19 of these acres would not meet the standards for visual resources described above.

The amendments modify four standards so that in the 206 acres of the project construction area the project need not be in compliance with these standards' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 206 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the four management requirements described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.10 rule requirements within the "scope and scale" of these proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.10 requirements are being addressed.

How the Required Mitigation Measures would Consider, Minimize, Maintain or Restore Effects to Aesthetic Values and Scenic Character and Meet the Applicable 36 CFR 219.10(a) and 36 CFR 219.10(b) Requirements.

The Forest Service has worked to inventory, analyze, and evaluate visual resources, view sheds, and aesthetics that could be affected by this project. Forest Service landscape architect provided technical support to FERC and Forest Service third-party contractors by reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures incorporated into amendments for Visual Quality Objectives, are designed to minimize, maintain or restore the potential for long-term impacts to visually sensitive areas. To ensure adequate restoration and revegetation of the ROW, design features are identified in the *Erosion Control and Revegetation Plan* (POD I), *Right-of-Way Clearing Plan* (POD U), *Leave Tree Protection Plan* (POD P), *Aesthetics Management Plan* (POD A), and *Recreation Management Plan* (POD S). In addition, routing considerations were identified during project development to ensure reduced visual impacts at the Pacific Crest Trail crossing by modifying the route to include a 45 degree angle and avoiding straight line impacts to trail users. (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands)

A visual assessment was conducted to determine the potential effects on visual resources associated with the pipeline. Representative viewpoint points (also referred to as KOPs) were identified within the view shed for the pipeline, defined as the area from which the pipeline would be potentially visible. Photographs of existing visual conditions were used in preparing computerized visual simulations for each KOP. Because the appearance of the pipeline ROW would change with time, a series of simulations were prepared to illustrate how the pipeline ROW would look at different timeframes following construction. These KOPs would also serve as monitoring points for mitigation.

Pacific Connector produced POD A that outlined measures to reduce visual impacts along its pipeline route. To the extent feasible, Pacific Connector would use revegetation efforts to shape and blend the pipeline easement, enhance the setting, and mimic the natural features of the landscape. These measures would consist of revegetating all disturbed areas and replanting trees in TEWAs and any other areas of the temporary construction ROW that were forested prior to construction (see POD I).

On Forest Service lands, Pacific Connector would maintain a cleared 30-foot width centered over the pipe allowing the remainder of the permanent easement to be reforested. This allows trees to naturally reestablish along the edges of the permanent easement at a staggered, more natural-looking interval. Replacing slash in forested areas of the ROW during restoration activities would immediately affect the visual contrast in color and texture of the disturbed ROW areas. Over time, as the ROW revegetates and narrows in width and changes in form, texture and color, potential visual impacts would diminish.

Additionally, a row, or if necessary, clusters of trees and/or shrubs would be planted across the ROW to provide visual screens at key road and trail crossings in sensitive view sheds. For all revegetation practices, Pacific Connector and/or its contractors would only use agency-approved tree and plant species, in compliance with management plan objectives and in consultation with agency specialists.

Site Specific Crossing Prescriptions:
<u>Big Elk Road (MP 161.41).</u> Within the Rogue River National Forest, the Pipeline crosses an area managed for Foreground Retention with high scenic integrity. Pacific Connector would neck down to a width of 50 feet immediately adjacent to either side of the Big Elk Road crossing. The construction ROW would then expand from 50 feet to the full 95-foot construction ROW width at

100 feet from either side of the road. To ensure that the appropriate large trees are conserved on either side of Big Elk Road, Pacific Connector's Environmental Inspectors would verify the limits of the staked construction limits in conjunction with a Forest Service representative (see POD P). Pacific Connector would implement the mitigation recommendations detailed in Section 3.2 and 3.3 and further described in the POD I to minimize, maintain or restore potential visual effects at this road crossing, and a buffer of vegetation would mask the ROW on both sides of the road. Pacific Connector would additionally revegetate the ROW using large native trees and shrubs to begin the mitigation process.

<u>Pacific Crest National Scenic Trail Corridor.</u> The area where the Pipeline intersects the PCT on the Rogue River National Forest supports a stand of old-growth forest and is managed for Foreground Partial Retention to maintain the aesthetic forest appeal for trail users. The typical construction ROW width is 95 feet, which could devalue this trail crossing segment during construction. To minimize, maintain or restore impacts to the scenic quality of the area, Pacific Connector would "neck down" the construction ROW from 95 feet to 75 feet in width for a distance of more than 300 feet on either side of the trail. UCSAs (no tree clearing) have also been located behind these neck downs, outside of the immediate foreground visual area, to minimize, maintain or restore disturbance. These UCSAs would be used to store slash and stumps during construction that would be redistributed across the ROW during restoration. To further minimize, maintain or restore potential visual impacts at the PCT crossing, the route was realigned at the request of the Forest Service to shorten the potential visual corridor down the ROW. Additional impact minimization measures include:

- Identifying trees along the edge of the construction ROW that can be saved from clearing, based on hazard tree and construction safety.
- Scalloping adjacent edges of timber as directed by the Forest Service landscape architect.
- Salvaging topsoil (duff and A horizon) to a depth of 12-inches along the trench line, segregate from spoil material, and replace during restoration.
- Minimizing grading within the 75-foot construction ROW based on safety requirements. Stumps would be removed, or gridded as necessary to provide a safe equipment working plane.
- Replanting a 75-foot wide visual screen on either side of the trail with nursery trees and shrubs within 6 days of final grading, dependent on seasonal planting constraints (and not within the 30 foot-operational easement). Replanting would be with mixed conifer species of differing age class per the Forest Service landscape plan and would include hydro-mulch seeding.
- Revegetating the remaining ROW with nursery trees and shrubs planted along the edges of the ROW in scalloped arrangement.
- Hydro-mulch seeding all disturbed soils.
- Placing logs and LWD in the construction ROW as directed by the Forest Service landscape plan.
- Using a gravity drip irrigation system with a water source from the well at Brown Mountain Shelter, to improve replanting establishment.
- Replanting would occur if mortality exceeds 30 percent.

Construction of the trail crossing would also be completed as a "tie-in" so that trenching, pipe stringing, and installation activities do not interrupt trail users for extended periods. It is expected that construction of the trail tie-in would be completed within 48 hours or less to minimize, maintain or restore potential impacts to trail users and reduce the need for trail detours.

Upon completion of construction in the area, Pacific Connector would revegetate the construction ROW using native trees (not within the 30 foot-operational easement), shrubs, and plants. Section 3.0 of the POD A describes additional measures to be used on federal lands for protecting and mitigating for visual resources. Pacific Connector would coordinate with the Forest Service and the Pacific Crest Trail Association regarding the need for and location of trail detours.

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to: facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (*Environmental Briefings and Compliance Plan*, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer's designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to visual resources and recreational resources are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

Evaluation of Winema National Forest Proposed Forest Plan Amendments

The proposed Pacific Connector pipeline incorporates the most up-to-date engineering and technological practices for pipeline construction and operation. However, even with following these practices, it has been determined that one Forest Plan standard associated with rare and/or isolated species (Survey and Manage), two Forest Plan standards associated with the soil, water, and riparian resources, and three Forest Plan standards associated with visual resources would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Winema National Forest LRMP as amended by the NWFP and the January 2001 Survey and Manage ROD.

Forest Plan Amendments Related to Rare Aquatic and Terrestrial Plant and Animal Communities (FS-1):

One Forest Plan standard associated with rare and/or isolated species (Survey and Manage) would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Winema National Forest LRMP as amended by the NWFP and the January 2001 Survey and Manage ROD. This standard is:

- Management Direction: Manage All Known Sites (Survey and Manage ROD, Standards and Guidelines Page 8). Current and future known sites will be managed according to the Management Recommendation for the species. Professional judgment, Appendix J2 in the Northwest Forest Plan Final SEIS, and appropriate literature will be used to guide individual site management for those species that do not have Management Recommendations.

The proposed amendment to this standard is:

- Management Direction: Manage All Known Sites (Survey and Manage ROD, Standards and Guidelines Page 8). Current and future known sites will be managed according to the Management Recommendation for the species, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Professional judgment, Appendix J2 in the Northwest Forest Plan Final SEIS, and appropriate literature will be used to guide individual site management for those species that do not have Management Recommendations. (Proposed amendment FS-1 on the Winema National Forest)

While the amendment would provide an exception to meeting this standard, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore any effects of the pipeline's construction and operation on Survey and Manage species within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

The purpose of this project-level amendment is to make the proposed Pacific Connector pipeline project consistent with the Winema National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to this amendment are:

- 36 CFR 219.9(a)(2)(ii) – [the plan must include plan components to maintain or restore] "Rare aquatic and terrestrial plant and animal communities."
- 36 CFR 219.9(b)(1) – "The responsible official shall determine whether or not the plan components required by paragraph (a) provide ecological conditions necessary to: …maintain viable populations of each species of conservation concern within the plan area."

Because the proposed amendment is "directly related" to these two substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendment (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the amendment, it is important to recognize that the applicable sections of 36 CFR 219.9(a) and (b) that are described above, requires plan components to maintain or restore rare aquatic and terrestrial plant and animal communities, across the entire planning area (i.e., the Winema National Forest). This plan amendment does not alter these LRMP plan requirements for managing rare plant and animal communities across 99.99 percent of the Winema National Forest. The proposed pipeline construction corridor including the TEWAs and the UCSAs is approximately 92 acres of the 1,043,547 acre Winema National Forest. Within this 92 acre construction corridor surveys have identified 45 Survey and Manage sites that could be potentially impacted by construction activities. The proposed amendment does not waive the persistence objective for Survey and Manage species. The analysis that was conducted (see section 4.6.4.3 of the DEIS and appendix F.5) determined the Survey and Manage persistence objectives would be met. This means that for Winema National Forest lands within the project area, individual sites of Survey and Manage species may be impacted or lost to construction activities, but affected species are expected to persist within the range of the NSO despite the loss of these individual sites.

The amendment modifies this standard so that in the 92 acres of the project construction area the project need not be in compliance with this standard' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 92 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the management requirement described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.9(a) and (b) rule requirements within the "scope and scale" of the proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.9(a) and (b) requirements are being addressed.

How the Required Mitigation Measures would Maintain or Restore Effects to Rare Aquatic and Terrestrial Plant and Animal Communities and Meet the Applicable 36 CFR 219.9(a) and 36 CFR 219.9 (b) Requirements

The Forest Service has worked to inventory, analyze, and evaluate rare aquatic, terrestrial plant and animal communities that could be affected by this project. In addition, a third-party consultant for technical support was also utilized in reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures incorporated into amendments for Survey and Manage species are designed to minimize, maintain or restore the potential for habitat fragmentation, edge effects, and loss of long-term habitats associated with effected species. To ensure adequate restoration and revegetation of the ROW, design features are identified in the *Erosion Control and Revegetation*

Plan (POD I), *Right-of-Way Clearing Plan* (POD U), *Leave Tree Protection Plan* (POD P). In addition, routing considerations were identified during project development to ensure avoidance of known populations of rare plant and animal communities (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands, as well as, appendix F.5, *Survey and Manage Persistence Evaluations*).

As a basis for Survey and Manage determinations, appendix F.5 provides background research on Survey and Manage species that could be affected by the Pacific Connector Project; a review of survey reports prepared by others for the Pacific Connector Project; and processing and analysis of spatial data obtained from the Bureau of Land Management (BLM), Forest Service, and other sources over the past 12 years. Background information was used in combination with new information available as a result of surveys for the Pacific Connector Project and recent surveys in other portions of old growth forests to discuss the currently known distribution of the species in old growth forests within the NSO range. Impacts to sites as a result of the Pacific Connector Project were analyzed to determine if the species would continue to have a reasonable assurance of persistence in the NSO range following implementation of the Pacific Connector Project, taking into consideration the status and distribution of the species and general habitat in the NSO range.

Some of the required mitigation measures in the POD sections to protect rare plant and animal communities include: flagging existing snags on the edges of the construction ROW or TEWAs where feasible to save from clearing; snags would be saved as and used in LWD placement post-construction to benefit primary and secondary cavity nesting birds, mammals, reptiles, and amphibians; other large diameter trees on the edges of the construction ROW and TEWAs would also be flagged to save/protect as green recruitment or habitat/shade trees, where feasible; trees would be girdled to create snags to augment the number of snags along the ROW to benefit cavity nesting birds, mammals, reptiles, and amphibians. See POD's P & U and 4.7—*Land Use* of the DEIS for a complete list of applicable mitigation measures for pipeline construction. Additional measures include low ground weight (pressure) vehicles would be used; logging machinery would be restricted to the 30-foot permanent ROW wherever possible to prevent soil compaction; the removal of soil duff layers would be avoided in order to maintain a cushion between the soil and the logs and the logging equipment; designed skid trails would be used to restrict detrimental soil disturbance (compaction and displacement) to a smaller area of the ROW over the pipeline trenching area; and the temporary construction area would be restored and revegetated using native seeds, to the extent possible, and saplings (POD I).

In an effort to minimize, maintain or restore the impacts to Survey and Manage species, Pacific Connector adopted route variations to avoid certain species identified in the Survey and Manage Persistence Evaluations by co-locating the proposed construction corridor adjacent to existing roads, through managed timber stands or otherwise avoid unique LSOG habitats to the maximum extent practicable (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands).

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (Environmental Briefings and Compliance Plan, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer's designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to soil, water and riparian resources, are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

How the Compensatory Mitigation Actions would help to Maintain or Restore Rare Aquatic and Terrestrial Plant and Animal Communities in the Plan Area (36 CFR 219.9(a), 36 CFR 219.9 (b)).

The CMP on the Winema National Forest includes proposals to improve aquatic and riparian habitat that would benefit rare aquatic plant and animal communities (see the discussion of *How the Compensatory Mitigation Actions would help to Maintain or Restore the Ecological Integrity of The Soils and Soil Productivity, including guidance to reduce soil erosion and sedimentation in the Plan Area (36 CFR 219.8(a)(2)(ii))* below for a discussion of benefits to aquatic habitats). The CMP also includes proposals to decommission approximately 29.2 miles of road.

Although the Pacific Connector project has been routed to avoid LSOG habitat as much as possible and is aligned along existing roads, the project would still cause some habitat fragmentation. Road decommissioning reduces the edge effects over time by revegetating road surfaces and eliminating road corridors. Revegetating selected roads could create larger blocks of late successional habitat in the future.

These projects have been designed by an interdisciplinary team of resource professionals on the Winema National Forest with input and coordination with the U.S. Fish and Wildlife Service, NOAA Fisheries, and State agencies. They were planned within the watersheds that would be affected by the Pacific Connector pipeline project. They are a component of the Pacific Connector application and would be a requirement of the ROW grant. Overall, these projects would help maintain and restore rare aquatic and terrestrial plant and animal communities on the Winema National Forest (see table 2.3.1-3 and 2.3.1-4 and figure 2.3-1 and 2.3-2 in appendix F.2 for additional information).

Forest Plan Amendments Related to Soil, Water and Riparian Areas (WNF -4, WNF-5):

Two Forest Plan standards associated with the soil, water, and riparian resources would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Winema National Forest LRMP. These standards are:

- Detrimental Soils Conditions, Standard and guideline 12-5, (WNF LRMP, 4-73). The cumulative effects of detrimental soil conditions should not exceed 20 percent of the total acreage within the activity area: any reason for exceeding the limitation shall be documented in an environmental assessment. Detrimental soil conditions include compaction, displacement, puddling, and moderately or severely burned soil from all activities (including roads, skid trails, and landings). Sites where the standards for displacement, puddling, and compaction are not currently met will require rehabilitation such as ripping, backblading, or fertilization. The potential for creating detrimental soil conditions will be specifically addressed through project environmental analyses. If needed, alternative management practices will be developed, and mitigating measures will be planned and implemented.
- Soil and Water, Standard & Guideline 3 (WNF LRMP 4-137). The cumulative total area of detrimental soil conditions in riparian areas shall not exceed 10 percent of the total riparian acreage within an activity area. Detrimental soil conditions include compaction, displacement, puddling, and moderately or severely burned soil.

The proposed amendments to these standards are:

- Detrimental Soils Conditions, Standard and guideline 12-5, (WNF LRMP, 4-73). The cumulative effects of detrimental soil conditions should not exceed 20 percent of the total acreage within the activity area: any reason for exceeding the limitation shall be documented in an environmental assessment, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Detrimental soil conditions include compaction, displacement, puddling, and moderately or severely burned soil from all activities (including roads, skid trails, and landings). Sites where the standards for displacement, puddling, and compaction are not currently met will require rehabilitation such as ripping, backblading, or fertilization. The potential for creating detrimental soil conditions will be specifically addressed through project environmental analyses. If needed, alternative management practices will be developed, and mitigating measures will be planned and implemented. (Proposed amendment WNF-4)
- Soil and Water, Standard & Guideline 3 (WNF LRMP 4-137). The cumulative total area of detrimental soil conditions in riparian areas shall not exceed 10 percent of the total riparian acreage within an activity area, with the exception of the operational ROW and the construction zone for the Pacific Connector Pipeline, for which the applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. Permanent recreation facilities or other permanent facilities are exempt. (Proposed amendment WNF-5)

While the amendments would provide an exception to meeting these standards, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore any effects of the pipeline's construction and operation on the soil, water and riparian resources within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

The purpose of these two project-level amendments is to make the proposed Pacific Connector pipeline project consistent with the Winema National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to these two amendments are:

- 36 CFR 219.8(a)(2)(ii) – [The plan must include plan components to maintain or restore] "soils and soil productivity, including guidance to reduce soil erosion and sedimentation."

Because the two proposed amendments are "directly related" to this substantive requirement, the Responsible Official must apply the requirements within the scope and scale of the proposed amendments (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the two amendments, it is important to recognize that the applicable sections of 36 CFR 219.8(a) that are described above, requires plan components to "maintain or restore" the soil resources across the entire planning area (i.e., the Winema National Forest). These plan amendments do not alter these LRMP plan requirements for managing the soil resources across 99.99 percent of the Winema National Forest. The proposed pipeline construction corridor including the TEWAs and the UCSAs is approximately 92 acres of the 1,043,547 acre Winema National Forest. Of the 92 acres of pipeline corridor construction it is estimated that approximately 27 to 62 acres would not meet standards for soils described above.

The amendment modifies 2 standards so that in the 92 acres of the project construction area the project need not be in compliance with these standards' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 92 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the two management requirements described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.8(a) rule requirements within the "scope and scale" of these proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.8(a) requirements are being addressed.

How the Required Mitigation Measures would Maintain or Restore Effects to Soil, Water, and Riparian Resources and Meet the Applicable 36 CFR 219.8(a) Requirements.

The Forest Service has worked with Pacific Connector Gas Pipeline to inventory, analyze, and evaluate the geologic, soil, and hydrologic resources that could be affected by this project. In addition, a third-party consultant for technical support was also utilized in reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration are enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures, incorporated into amendments for soil, water, and riparian resources are designed to minimize, maintain or restore the potential for soil movement, slope stability, water quality, and to ensure adequate restoration and revegetation. These measures are identified in: the *Erosion Control and Revegetation Plan* (POD I); *Right-of-Way Clearing Plan* (POD U); *Wetland and Waterbody Crossing Plan* (POD BB); the *Forest Service Site Specific Stream Crossing Prescriptions* (NSR 2014); the *Stream Crossing Risk Analysis*; and *Stream Crossing Risk Analysis Addendum* (GeoEngineers2017d, 2018a). Pacific Connector would also follow the FERC's applicant prepared Wetland Procedures and the Best Management Practices for the State of Oregon. To further reduce potential for landslides on steep slopes, the Forest Service, BLM, and FERC are also recommending additional industry best management practices and measures identified from the *Technical Report on Soil Risk and Sensitivity Assessment* (NSR 2014) be incorporated into Pacific Connector's terms and conditions of the ROW Grant as described in the POD's identified above. See 4.2.3.3 of the DEIS for a description of soil risk and sensitivity assessment.

Areas with soils rated moderate to very high for risk or sensitivity (28 acres total) would be recommended for more site-specific validation of the risk criteria used in the *Technical Report on Soil Risk and Sensitivity Assessment* (NSR 2014) to confirm that specific locations merit consideration of the more aggressive soil remediation measures, such as: a 2- to 3-inch organic mulch surface application (80 percent coverage) of woodchips, logging slash, and/or straw; adaptive seed mixes and vegetation to better fit site conditions; deep subsoil decompaction with hydraulic excavators that leave constructed corridor mounded and rough with maximum water infiltration so that water cannot flow downhill for any appreciable distance; more aggressive use of constructed surface water runoff dispersion structures such as closely placed and more pronounced slope dips and water bars, etc.; more aggressive use of constructed surface runoff entrapments such as silt fencing, sediment settling basins, or straw bale structures, etc.; more aggressive placement (100 percent coverage) and depth (3 to 4 inches) of ground cover using woodchips, logging slash, straw bales, wattles (see POD's U and I). In efforts to protect soil productivity, topsoil segregation would be required for pipeline construction at wetland and waterbody crossings on NFS lands (POD U).

Some of the required mitigation measures in the POD BB and *Forest Service Site Specific Stream Crossing Prescriptions* (NSR 2014) to protect wetlands and minimize, maintain or restore compaction include: limiting the construction ROW width to 75 feet through wetlands; placing equipment on mats; using low-pressure ground equipment; limiting equipment operation and construction traffic along the ROW; locating temporary workspace (TEWAS) more than 50 feet away from wetland boundaries; cutting vegetation at ground level; limiting stump removal to the construction trench; segregating the top 12 inches of soil, or to the depth of the topsoil horizon; using "push-pull" techniques in saturated wetlands; limiting the amount of time that the trench is open by not trenching until the pipe is assembled and ready for installation; not using imported rock and soils for backfill; and not using fertilizer, lime, or mulch during restoration in wetlands. Pacific Connector must also follow the FERC Waterbody and Wetland Construction and

Mitigation Procedures. See 4.3.3.2 of the DEIS for a complete list of applicable mitigation measures for pipeline construction at specific waterbody and stream crossings.

In an effort to minimize, maintain or restore the impacts to streams and riparian areas, Pacific Connector adopted route variations to co-locate the proposed construction corridor adjacent to existing roads and along dry ridge tops (See Chapter 3, DEIS Route Design and Modifications on Forest Service Managed Lands). In addition, Pacific Connector has committed to limit construction at waterbody crossings to times of dry weather or low water flow. Pacific Connector would implement the required erosion control measures at the proposed stream crossings to minimize, maintain or restore potential erosion and sedimentation impacts. The applicable mitigation measures and monitoring requirements in the POD relating to water waterbody crossings are included in the *Site Specific Forest Service Stream Crossing Prescriptions, and Wetland and Waterbody Crossing Plan* (POD BB). In addition, applicable mitigation measures from the FERC approved applicant prepared Procedures for Wetland and Waterbody Crossings would be required.

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to: facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (Environmental Briefings and Compliance Plan, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer’s designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to soil, water and riparian resources, are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

How the Compensatory Mitigation Actions would help to Maintain or Restore the Ecological Integrity of The Soils and Soil Productivity, including guidance to reduce soil erosion and sedimentation in the Plan Area (36 CFR 219.8(a)(2)(ii)).

Part of the CMP on the Winema National Forest includes proposals to place large woody debris in-stream for 1.0 miles, repair stream crossings at 25 sites, provide Riparian Planting for 0.5 miles, provide Riparian Fencing for 6.5 miles, and decommission approximately 29.2 miles of road.

Placement of LWD in streams adds structural complexity to aquatic systems by creating pools and riffles, trapping fine sediments and can contribute to reductions in stream temperatures over time (Tippery et al. 2010). Placing LWD in streams affects channel morphology, the routing and storage of water and sediment, and provides structure and complexity to stream systems. Complex pools and side channels created by instream wood provide overwintering habitat to stream salmonids and other aquatic organisms (Solazzi et. al. 2000). They also provide cover from predators during summer low flow periods when predation is at its highest. Providing more stream channel structure results in better over wintering habitat, improved summer pool habitat, and more abundant spawning gravels.

Riparian planting is proposed along Spencer Creek just upstream of Buck Lake. This is a meadow site that has lost streamside vegetation and has compacted soils. There is an overall need to restore health and vigor to riparian stands by maintaining and improving riparian reserve habitat. Shade provided by the plantings would contribute to moderating water temperatures in Spencer Creek. Root strength provided by new vegetation would increase bank stability, decrease erosion and sediment depositions to Spencer Creek and provide habitat for species that use riparian habitats. Riparian fencing would serve to divide the Buck Indian Allotment into pastures north and south at Clover Creek Road. This fence would keep cattle from grazing newly revegetated areas in the construction corridor, including areas where the corridor crosses Spencer Creek, thus helping to ensure that erosion control and revegetation objectives are met. It would also serve to separate anticipated increased cattle grazing of the construction corridor from the highway; greatly reducing a safety hazard for vehicles traveling the Clover Creek road.

Restoring stream crossings reconnects aquatic habitats by allowing the passage of aquatic biota and restoring riparian vegetation. Over time, these actions reduce sediment and restore shade. Restoration of these crossings includes riparian planting as a mitigation which would help offset the impact of shade removal at pipeline crossings. The proposed pipeline would cross Spencer Creek upstream of Buck Lake. It is occupied by redband trout. Spencer Creek has been identified by NMFS as habitat for federally listed Southern Oregon/Northern California Coast Coho salmon. Additionally, once fish passage is provided through the Klamath River hydro facilities, steelhead would re-colonize Spencer Creek. Improving habitat quality at Spencer Creek provides the opportunity to be pro-active in providing quality habitat for SONC Coho, mitigating for any detrimental effects to other SONC Coho habitats, while improving habitat for redband trout and other aquatic species. Spencer Creek appears on the Oregon DEQ 303(d) list as water quality impaired from increased sedimentation. Improvements at this location would immediately benefit all downstream aquatic habitats and the species associated with those habitats.

Decommissioning roads can substantially reduce sediment delivery to streams (Madej 2000; Keppeler et al. 2007). Proposed road decommissioning and stormproofing would increase infiltration of precipitation, reduce surface runoff, and reduce sediment production from road-related surface erosion in the watershed where the impacts from the Project would occur. Decommissioning roads would restore natural drainage patterns and thereby avoid large volumes of added sediment to the stream network that would be likely to eventually occur. In addition limited road maintenance dollars could be focused on the remaining road systems resulting in more maintenance of culverts and ditchlines resulting in less potential for catastrophic failure. Madej (2000) concluded that by eliminating the risk of stream diversions and culvert failures, road removal treatments significantly reduce long-term sediment production from retired logging roads.

These projects have been designed by an interdisciplinary team of resource professionals on the Winema National Forest with input and coordination with the U.S. Fish and Wildlife Service, NOAA Fisheries, and State agencies. These projects have been planned within the watersheds that would be affected by the Pacific Connector pipeline project. These projects have been proposed by the Applicant as part of their application and would be a requirement of the ROW grant. These projects would help maintain and restore soil resources including reducing soil erosion and sedimentation on the Winema National Forest (see table 2.3.1-3 and 2.3.1-4 and figure 2.3-1 and 2.3-2 in appendix F.2 for additional information).

Forest Plan Amendments Related Visual Resources (WNF -1, WNF-2, WNF-3):

Three Forest Plan standards associated with visual resources would need to be modified so that the proposed construction and operation of the Pacific Connector pipeline can be in compliance with the Winema National Forest LRMP. These standards are:

- Management Area 3, Lands, Standard and Guideline (4), (WNF LRMP 4-103). This management area is an avoidance area for new transportation and utility corridors.
- Management Area 3A, Foreground Retention, Standard and Guideline Scenic (1), (WNF LRMP 4-103 and 104). Evidence of management activities from projects that produce slash (tree harvest) or charred bark (underburning) will not be noticeable one year after the work has been completed.
- Management 3B, Foreground Partial Retention, Standard and Guideline Scenic (1), (WNF LRMP, 4-107). Evidence of management activities from projects that produce slash (tree harvest) or charred bark (underburning) should not be noticeable from two to three years after the work has been completed.

The proposed amendments to these standards are:

- Management Area 3, Lands, Standard and Guideline (4), (WNF LRMP 4-103). This management area is an avoidance area for new transportation and utility corridors, with the exception of the Pacific Connector Pipeline ROW. The applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. (Proposed amendment WNF-1)
- Management Area 3A, Foreground Retention, Standard and Guideline Scenic (1), (WNF LRMP 4-103 and 104). Evidence of management activities from projects that produce slash (tree harvest) or charred bark (underburning) will not be noticeable one year after the work has been completed, with the exception of the Pacific Connector Pipeline ROW which shall attain the VQO within 10 - 15 years after completion of the construction phase of the project where the pipeline crosses Management area 3A. The applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. (Proposed amendment WNF-2)
- Management 3B, Foreground Partial Retention, Standard and Guideline Scenic (1), (WNF LRMP, 4-107). Evidence of management activities from projects that produce slash (tree harvest) or charred bark (underburning) should not be noticeable from two to three years after the work has been completed, with the exception of the Pacific Connector Pipeline ROW, which shall attain the VQO within 10 - 15 years after completion of the construction phase of the project where the pipeline crosses Management area 3B. The applicable

mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented. (proposed amendment WNF-3)

While the amendments would provide an exception to meeting these standards, there would also be requirements to do what is appropriate, applicable and feasible to minimize, maintain or restore any effects of the pipeline's construction and operation on the visual resources within the area affected by the pipeline. Consequently, each amended standard includes the requirement that the "applicable mitigation measures identified in the POD and Pacific Connector project design requirements must be implemented".

The purpose of these three project-level amendments is to make the proposed Pacific Connector pipeline project consistent with the Winema National Forest LRMP. Thus, the substantive planning rule requirements that are directly related to these three amendments are:

- 36 CFR 219.10(a)(1) – […the responsible official shall consider: …] "(1) Aesthetic values,… scenery,... viewsheds...".
- 36 CFR 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities,…and scenic character…"

Because the proposed amendments are "directly related" to these two substantive requirements, the Responsible Official must apply the requirements within the scope and scale of the proposed amendments (36 CFR 219.13 (b)(5)).

In considering the "scope and scale" of the three amendments, it is important to recognize that the applicable sections of 36 CFR 219.10 that are described above, requires plan components to provide for aesthetic values and scenic character across the entire planning area (i.e., Winema National Forest). These plan amendments do not alter these LRMP plan requirements for managing visual resources across 99.99 percent of the Winema National Forest. The proposed pipeline construction corridor including the TEWAs and the UCSAs is approximately 92 acres of the 1,043,547 acre Winema National Forest. Of the 92 acres of pipeline corridor construction it is estimated that approximately 70 of these acres would not meet the standards for visual resources described above.

The amendments modify three standards so that in the 92 acres of the project construction area the project need not be in compliance with these standards' specific requirements but instead, it is the "applicable mitigation measures identified in the POD and the Pacific Connector Project design requirements" that must be implemented. Or stated in another way, for the 92 acres of National Forest lands that would be within the operational ROW and construction zone for the Pacific Connector Pipeline, the three management requirements described above would be replaced with the full set of management requirements that comprise the "applicable mitigation measures identified in the POD and Pacific Connector Project Design requirements". The inclusion of these management requirements as a part of the plan component language for the LRMP in this plan amendment, addresses the applicable 36 CFR 219.10 rule requirements within the "scope and scale" of these proposed plan amendments. The sections below describe in more detail how the applicable 36 CFR 219.10 requirements are being addressed.

How the Required Mitigation Measures would Consider, Minimize, Maintain or Restore Effects to Aesthetic Values and Scenic Character and Meet the Applicable 36 CFR 219.10(a) and 36 CFR 219.10(b) Requirements.

The Forest Service has worked to inventory, analyze, and evaluate visual resources, view sheds, and aesthetics that could be affected by this project. Forest Service landscape architect provided technical support to FERC and Forest Service third-party contractors by reviewing the information gathered for the project. The POD is a document developed between the Forest Service, BLM, FERC, and Pacific Connector that contains the design features, mitigation measures, roles and responsibilities, monitoring, and procedures for the construction and operation of the pipeline on NFS lands. In addition, FERC's applicant prepared Plan and Procedures for construction and restoration enforceable, where applicable, for additional design features and mitigation. The design requirements and mitigation measures of the POD would be required by the modified standards and incorporated into BLM's ROW grant.

The mitigation measures incorporated into amendments for Visual Quality Objectives are designed to minimize, maintain or restore the potential for long-term impacts to visually sensitive areas. To ensure adequate restoration and revegetation of the ROW, design features are identified in the *Erosion Control and Revegetation Plan* (POD I), *Right-of-Way Clearing Plan* (POD U), *Leave Tree Protection Plan* (POD P), *Aesthetics Management Plan* (POD A), and *Recreation Management Plan* (POD S).

A visual assessment was conducted to determine the potential effects on visual resources associated with the pipeline. Representative viewpoint points (also referred to as KOPs) were identified within the view shed for the pipeline, defined as the area from which the pipeline would be potentially visible. Photographs of existing visual conditions were used in preparing computerized visual simulations for each KOP. Because the appearance of the pipeline ROW would change with time, a series of simulations were prepared to illustrate how the pipeline ROW would look at different timeframes following construction. These KOPs would also serve as monitoring points for mitigation.

Pacific Connector produced POD A that outlined measures to reduce visual impacts along its pipeline route. To the extent feasible, Pacific Connector would use revegetation efforts to shape and blend the pipeline easement, enhance the setting, and mimic the natural features of the landscape. These measures would consist of revegetating all disturbed areas and replanting trees in TEWAs and any other areas of the temporary construction ROW that were forested prior to construction (see POD I).

On Forest Service lands, Pacific Connector would maintain a cleared 30-foot width centered over the pipe allowing the remainder of the permanent easement to be reforested. This allows trees to naturally reestablish along the edges of the permanent easement at a staggered, more natural-looking interval. Replacing slash in forested areas of the ROW during restoration activities would immediately affect the visual contrast in color and texture of the disturbed ROW areas. Over time, as the ROW revegetates and narrows in width and changes in form, texture and color, potential visual impacts would diminish.

Additionally, a row, or if necessary, clusters of trees and/or shrubs would be planted across the ROW to provide visual screens at key road and trail crossings in sensitive view sheds. For all revegetation practices, Pacific Connector and/or its contractors would only use agency-approved tree and plant species, in compliance with management plan objectives and in consultation with agency specialists.

Site Specific Crossing Prescriptions:

Clover Creek Road (intersection of Dead Indian Memorial Highway and Clover Creek Road). Viewsheds in this area are managed for Foreground and Middleground Retention and Partial Retention, but also contain areas of private lands with recently harvested timber and several clusters of rural residential homes. The proposed alignment would cross the Dead Indian Memorial Highway perpendicularly in a thick forest foreground setting (at MP 168.83). Pacific Connector would implement the mitigation recommendations detailed in Section 3.2 and 3.3 and further described in the POD I. These pipeline restoration efforts would include regrading to the approximate original contours, reseeding, scattering slash across the ROW, and replanting, which would minimize, maintain or restore visual contrast of the ROW. During restoration, Pacific Connector would plant trees within forested areas to within 15 feet of the Pipeline, which would allow a strip of trees to establish along the easement and between the Pipeline and the road in this area. Because the Pipeline was recommended to abut the road and to eliminate the strip of trees between the road and the Pipeline easement, the Forest Service and BLM would specify if tree planting would occur on federal lands between the centerline and Clover Creek Road (but not within 15 feet of the pipeline). Pacific Connector would also implement the mitigation recommendations in the Federal Lands Scenery Management Analysis at this location which include:

During construction of the Project, Compliance Monitors representing FERC are present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to FERC and the Forest Service. Objectives of the Compliance Monitoring program are to: facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval from the applicable land management agencies. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Pacific Connector.

Additionally, environmental compliance oversight responsibilities for Pacific Connector, FERC, Forest Service and BLM are described in the POD (*Environmental Briefings and Compliance Plan*, POD G) that would apply to the construction, operation, and maintenance of the project specifically on NFS lands. The Forest Service Authorized Officer would coordinate with the BLM in administering and enforcing ROW grant provisions and would have stop-work authority. The Forest Service Authorized Officer's designated representatives would ensure that the stipulations and mitigation measures included in the POD that are designed to minimize, maintain or restore the effects to visual resources and recreational resources are adhered to during project construction, operation, and maintenance. The BLM Authorized Officer would coordinate with the Forest Service to ensure the work is being conducted in accordance with the ROW grant and agreed upon conditions. BLM and the Forest Service would have stop-work authority. Field variance requests would be coordinated with the Authorized Officers.

How the Compensatory Mitigation Actions would help to Provide for Aesthetic Values and Scenic Character in the Plan Area (36 CFR 219.10(a)(1), 36 CFR 219.10(b)(i)).

Part of the CMP on the Winema National Forest includes a proposal to reduce stand densities on 114 acres in a way that would help soften the visual impact of the Pacific Connector Project. The Pacific Connector pipeline would create a hard line along the timbered edge of the corridor that does not fit with the visual objectives for the Clover Creek Road or the Dead Indian Memorial Highway. Thinning and fuels treatments can be used to soften the edge to a more natural appearing texture by restoring stand density to more natural levels and creating small openings that are consistent with the landscape. This proposal would restore stand density, species diversity, and structural diversity more characteristic under a natural disturbance regime.

This project has been designed by an interdisciplinary team of resource professionals on the Winema National Forest with input and coordination with the FWS, NOAA Fisheries, and State agencies. It was planned within the watersheds that would be affected by the Pacific Connector pipeline project. It is a component of the Pacific Connector application and would be a requirement of the ROW grant. This project would help to restore visual resources on the Winema National Forest (see table 2.3.1-3 and 2.3.1-4 and figure 2.3-1 and 2.3-2 in appendix F.2 for additional information).

4.7.3.5 Resource Values and Conditions on Federal Lands: The Aquatic Conservation Strategy on National Forest System Lands

Introduction

This section summarizes appendix F.4, Aquatic Conservation Strategy (ACS) Technical Report, which contains the full text of the independent Forest Service analysis. Those who seek additional information should review the applicable section in appendix F.4. Section, figure, and table numbers that refer to sections in appendix F.4 are so noted.

Background of the Aquatic Conservation Strategy

The ACS was developed as an element of the NWFP to "restore and maintain the ecological health of watersheds and aquatic ecosystems on public lands contained within them" within the range of the northern spotted owl (Forest Service and BLM 1994a, 1994b). The ACS applies on the Umpqua, Rogue River – Siskiyou national forests and portions of the Winema national forest within the range of the northern spotted owl. The ACS does not apply to lands managed by the BLM.[152]

The ACS established Riparian Reserves and Key Watersheds as land allocations on NFS lands. The ACS also established watershed assessment requirements, management objectives and special standards and guidelines for management and protection of aquatic resources. Forest Service line officers must determine whether activities that occur on NFS lands retard or prevent attainment of the ACS objectives on their respective national forests (Forest Service and BLM 1994a, 1994b;). Projects that retard or prevent attainment of the ACS objectives would not be consistent with the ACS. In making the ACS consistency finding (Goodman et al. 2007), the decision maker must:

[152] The ACS also applied to BLM lands managed under the BLM's 1995 Resource Management Plans (RMP) as amended. The ACS was replaced by Riparian Management Areas in BLM RMPs in 2016 when those RMPs were revised. As a result, the ACS is no longer applicable on BLM lands.

- Review projects against the ACS objectives at the project or site scale, rather than only at the watershed scale.
- Evaluate the immediate (short-term) impacts, as well as long-term impacts of an action.
- Provide a description of the existing watershed condition, including the important physical and biological components of the 5th field watershed.
- Provide written evidence that the decision maker considered relevant findings of watershed analysis.

Appendix F.4 and this summary provide the basis for Forest Supervisors of the Rogue River, Umpqua and Winema National Forests to independently determine whether the Pacific Connector Pipeline Project would retard or prevent attainment of ACS objectives or otherwise be inconsistent with the ACS objectives.

Overview of the Project

The Pacific Connector Pipeline Project would traverse approximately 31 miles of NFS lands and 47 miles of BLM lands on its 232 -mile route from Malin to Coos Bay, Oregon. This assessment and appendix F.4 apply only to the portion of the Pacific Connector Project on NFS lands.

Table 4.7.3.5-1 provides a breakdown of provinces, river basins and fifth field watersheds on NFS lands where the ACS applies.

TABLE 4.7.3.5-1

Provinces, River Basins and Watersheds on NFS Lands Subject to the ACS

Province	River basin	Fifth field Watershed	Hydrologic Unit Code	Key Water-shed	Total Miles All Owners	Umpqua NF Miles	Rogue River NF Miles	Winema NF Miles	Total Forest Service Miles
Klamath Siskiyou	Umpqua	Days Cr.-S. Umpqua	1710030205	Yes	19.15	1.56	0.00	0.00	1.56
Klamath Siskiyou — Western Cascades	Umpqua	Elk Cr.-S. Umpqua	1710030204	Yes	3.26	2.67	0.00	0.00	2.67

Ecological Provinces Crossed by the Pacific Connector Pipeline Project

<u>Klamath-Siskiyou Province MP 47–105, 118–153</u>

The Klamath-Siskiyou Province encompasses the Klamath and Siskiyou Mountains and lies between the Coast Range and the Cascades, south of the Willamette Valley. The Project would traverse the northeast corner of the Klamath-Siskiyou Province for approximately 93 miles (appendix F.4, figure 1-1). It includes parts of the Umpqua and Rogue River National Forests. This landscape is typified by deeply dissected valleys and jutting ridges and foothills. Much of this province lies within a rain shadow sheltered from the Pacific maritime influences by the mountains of the Coast Range. The region has a rugged landscape, with high peaks and deep canyons. Elevations range from about 1,000 to 7,000 feet above MSL.

The Klamath-Siskiyou Province is known for its highly complex geology. Most of the area is composed of highly deformed volcanic and marine sedimentary rocks with some metamorphic terranes. Also included are deformed pieces of oceanic crust and granitic intrusive bodies. Bedrock is often intensely metamorphosed and fractured. Well-developed floodplains and terraces near major rivers give way to highly dissected mountains with high-gradient streams. Many streams in this province flow only intermittently because of high gradients and low summer precipitation.

Erosional processes in the Klamath-Siskiyou Province are dominated by mass wasting associated high-intensity rainfall events. Erosional processes are accelerated where these rainfall events overlap with large, high severity stand-replacing fires. Precipitation gradients decrease from west to east, so landslide frequency decreases with decreased precipitation. Hydraulic mining during the 19th century dramatically altered landscapes and downstream channels where this activity occurred.

Western Cascades Province MP 105-113

Approximately eight miles of the pipeline corridor cross the north-south trending Western Cascades Province (appendix F.4, figure 1-1). This province, which drains westward to the Pacific Ocean, reaches elevations of 4,400 feet above MSL in watersheds crossed by the Pacific Connector Pipeline Project. Portions of the Upper Cow Creek and Trail Creek fifth-field watersheds are in the Western Cascades Province.

The landforms in the Western Cascades Province are distinguished from the High Cascades by older volcanic activity and longer glacial history. Ridge crests at generally similar elevations are separated by steep, deeply dissected valleys. Complex volcanoclastic formations juxtapose relatively stable volcanic deposits that weather to thick soils and are subject to earthflows. Unconsolidated alluvial and glacial deposits are subject to streambank erosion and landslides. Tributary channels flow at large angles into wide, glaciated valleys. Stream gradients are typically moderate to high (2 to 30 percent).

High Cascades Province MP 153-180

Approximately 23 miles of the Project corridor would be in the High Cascades Province (appendix F.4, figure 1-1). This Province consists of one north-south trending mountain chain that drains both westward to the Pacific Ocean and eastward into Klamath and Columbia Basins (see appendix F.4, figure 1-1). The High Cascades Province reaches a peak elevation of 9,493 feet MSL at the summit of Mt. McLoughlin. Portions of the Little Butte Creek and Spencer Creek fifth-field watersheds are in this province.

The province consists of volcanic landforms with varying degrees of historic glaciation. Lava flows form relatively stable plateaus, capped with pumice and ash deposits by the recent Cascade volcanoes. Drainages are generally not yet well developed or otherwise disperse into highly permeable volcanic deposits. Geologically recent volcanic pumice and ash deposits are subject to large debris flows when saturated by snowmelt. This province is composed primarily of approximately 3 million year old volcanic material, primarily andesite and basalt that were subsequently glaciated. Mountains in this province are moderately dissected. Headwater streams have medium to high gradients and are often associated with large meadow-spring complexes. Expansive pumice plateaus associated with the eruption of Mt. Mazama about 5,000 years ago (Dead Indian Plateau, Clover Creek) with droughty soils characterized by high snowmelt infiltration and low summer water retention fill valley floors adjacent to volcanic peaks.

Watersheds Crossed by the Pacific Connector Pipeline Project

The Project would cross portions of 19 fifth-field watersheds, six of which include NFS lands where the ACS applies. Figure 4.7-4 (reproduced from figure 1-1 in appendix F.4) shows watersheds and aquatic provinces crossed by the Pacific Connector Pipeline Project.

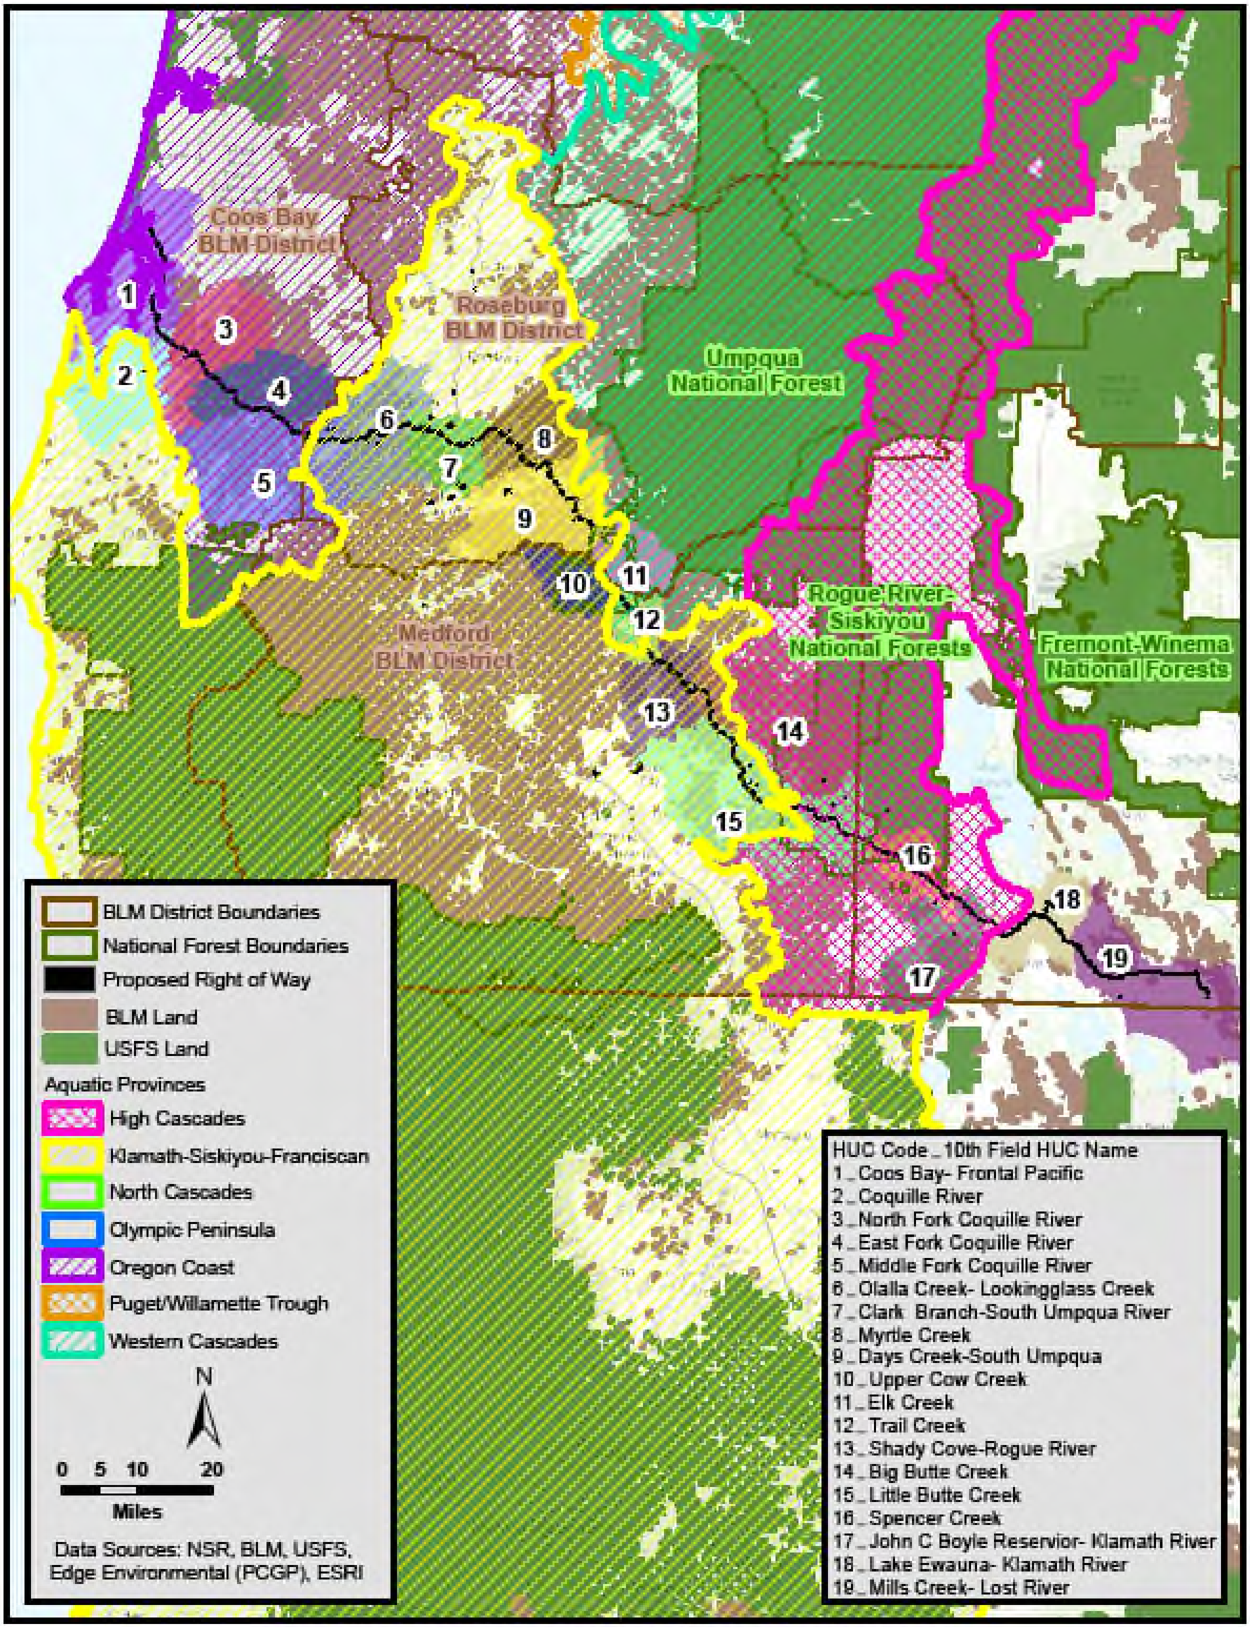

Figure 4.7-4. Provinces, and Watersheds Crossed by the Pacific Connector Pipeline Project

Table 4.7.3.5-2 summarizes (1) the number and acreage of Riparian Reserves of perennial and intermittent streams and forested wetlands that would be “crossed” by the pipeline NFS lands, and (2) the number and acreage of Riparian Reserves that would be “clipped” where a portion of the Riparian Reserve is impacted without the pipeline trench crossing a waterbody or wetland.

Table 4.7.3.5-3 shows the age-class structure of vegetation that would be cleared within the proposed Pacific Connector ROW. Most of the Pacific Connector Pipeline Project is routed on ridge tops to avoid stream and riparian-area crossings. To the degree possible, Project routing has avoided late-successional and old-growth forest in Riparian Reserves. Of the vegetation cleared in the construction corridor and TEWAs, approximately 67 percent or about 15.3 acres of the 22.7 acres are in in mid or early seral vegetation while approximately 33 percent or 7.4 acres are in late-successional or old-growth forest.

Table 4.7.3.5-4 (table 2-3 from appendix F.4) summarizes forest plan land allocations for the watersheds crossed by the Pacific Connector.

TABLE 4.7.3.5-2

Summary of Riparian Reserves, Stream Channels and Wetlands Crossed by the Pacific Connector Pipeline on NFS Lands by Administrative Unit

	Perennial Streams Crossed a/		Intermittent Streams Crossed		Wetlands Crossed b/		Total Stream Channels or Wetlands Crossed		Riparian Reserves Clipped without Stream or Wetland Crossings c/		Total d/	
Agency a/	**Stream Channels Crossed e/ (number)**	**Riparian Reserves Cleared (Acres)**	**Stream Channels Crossed (number)**	**Riparian Reserves Cleared (Acres)**	**Wetlands Crossed (number)**	**Riparian Reserves Cleared (Acres)**	**Total Crossed (number)**	**Total Riparian Reserves Cleared (Acres)**	**Riparian Reserves Clipped (number)**	**Total Riparian Reserves (Acres)**	**Affected Riparian Reserves (number)**	**Cleared (Acres)**

Data Source: Resource Report 3, table 2A-3A and FS Riparian Reserve Assessment, database.

a/ "Crossed" means that the pipeline trench (cleared or modified land) crosses the stream channel or delineated wetland area.

b/ "Wetlands" refers to delineated wetland areas that are not already counted as streams. Where the Riparian Reserve of a wetland is fully encompassed in the adjacent Riparian Reserve of a stream channel, the acres are counted as part of the stream channel to avoid double counting and are shown as 0 in this table.

c/ "Clipped" means that the Riparian Reserve associated with a stream channel or wetland was cleared as part of the construction corridor, Temporary Extra Work Area (TEWA) or Hydrostatic Test, but the pipeline trench did not cross the stream channel or delineated wetland area.

d/ This table includes only areas where vegetation is cleared in the construction corridor, hydrostatic test sites, and TEWAs. An additional 11.45 acres of Riparian Reserves are used as Uncleared Storage Areas (UCSA) where habitat may be modified but vegetation is not removed.

e/ Irrigation ditches or other man-made water conveyances are crossed by the Project, but they do not create Riparian Reserves and are not subject to the requirements of the ACS

TABLE 4.7.3.5-3

Vegetation Age Class Structure of Riparian Reserves Cleared in Construction Corridor and TEWAs by Administrative Unit, Forest Service

Source: Appendix F.4, table 2-3

The proposed Pacific Connector pipeline route would follow ridgelines and existing rights-of-way, such as powerlines and roads, wherever possible. To the extent possible, route location avoided crossing or modifying Riparian Reserves. In 30.6 miles of Right of Way on NFS lands, approximately 32.74 acres or 0.11 percent of Riparian Reserves on NFS lands in the affected watersheds would be cleared or modified by the Pacific Connector (appendix F.4, table 2-3).

Project impacts on aquatic habitats at stream crossings are generally comparable to construction of a road crossing with a culvert installation. Possible short-term impacts could include sediment transport to waterbodies where construction at stream crossings causes surface erosion, disturbance of banks and stream bottoms, and minor increases in water temperature from removal of effective shade.

Removal of mid and late seral forest vegetation at stream crossings would result in a long-term change in vegetative condition at the site scale. Early seral vegetation removed would recover as early seral vegetation and is less of a change in condition. Use of roads, including standards for reconstruction, would be subject to applicable ACS standards and guidelines. In order to minimize potential adverse impacts on fish, timing of instream work in streams with flowing water would be tied to work windows established by the ODFW. These time periods were established to avoid the vulnerable life stages of potentially affected fish species, including migration, spawning, and rearing.

The ACS is intended to prevent long-term adverse on riparian dependent resources (Forest Service and BLM 1994c, p. 3.4-69). This summary and appendix F.4 show that other than change in vegetative condition, impacts on NFS Riparian Reserves and aquatic habitats would be temporary or minor in scale in any given fifth-field watershed or sixth-field subwatershed. Changes in vegetation at stream crossings are a long-term effect because the 50-foot-wide maintenance corridor for the Pacific Connector pipeline must be kept in low-growing vegetation. This would not prevent attainment of the ACS objectives because the widely dispersed nature of crossings and the small amount of vegetation removed at each site. See appendix F.4 for a complete discussion and analysis of environmental consequences.

Project Effects Related to the ACS in Affected Watersheds on NFS Lands

Umpqua River Basin, Days Creek–South Umpqua River Watershed, HUC 1710030205, Umpqua National Forest

Discussions of watershed analysis recommendations, natural disturbances, range of variability and other elements of the ACS are found in appendix F.4. Table 4.7.3.5-5 (table 2-11 from appendix F.4) compares the Project effects against the objectives of the ACS. The Project does not cross any stream channels in this watershed. It affects approximately 1.71 acres of the Riparian Reserves of which 0.15 acres would be cleared and 1.56 acres would be modified. All affected Riparian Reserves are associated with isolated forested wetland swales on or near the watershed divide between Stouts Creek and Corn Creek that have no apparent surface connection to drainages.

TABLE 4.7.3.5-5

Compliance of the Project with ACS Objectives, Days Creek–South Umpqua River Watershed

ACS Objective	Project Impacts
Maintain and restore the distribution, diversity, and complexity of watershed and landscape-scale features to ensure protection of the aquatic systems to which species, populations, and communities are uniquely adapted.	Riparian Reserves are landscape-scale features that would be affected by the Project. The Project ROW would impact 2.2% of the NFS land in the Days Creek–South Umpqua River watershed. Approximately 0.15 acre of Riparian Reserves would be cleared. All of the vegetation cleared would be mid seral. While the cutting of trees where the Project ROW intersects two localized Riparian Reserves would result in a long-term change in vegetation condition, it would be minor in scale and well within the range of natural variability for vegetative change, given the fire history of the Days Creek–South Umpqua River watershed. The application of BMPs and erosion control measures, use of native vegetation, and the anticipated rapid revegetation of disturbed areas would likely further reduce Project impacts. The level of impacts is well within the range of natural variability for disturbance processes described by Everest and Reeves (2007) and Agee (1993) and as documented in the South Umpqua Watershed Assessment (BLM 2001). The NFS lands in the Days Creek–South Umpqua River watershed are approximately 32% LSOG.
Maintain and restore spatial and temporal connectivity within and between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact refugia. These network connections must provide chemically and physically unobstructed routes to areas critical for fulfilling life-history requirements of aquatic and riparian-dependent species.	The Project is not expected to affect spatial or temporal connectivity on NFS lands in the Days Creek–South Umpqua River watershed. No streams would be crossed and impacts in Riparian Reserves would be minimal. Any residual levels of disturbance are anticipated to be well within the range of natural variability.
Maintain and restore the physical integrity of the aquatic system, including shorelines, banks, and bottom configurations.	The Project would have no discernible impact on streambanks or bottoms in the Days Creek–South Umpqua River watershed because no stream channels would be crossed. The few impacts in Riparian Reserves are associated with near ridge-top intermittent streams or ridge top (wetland) swales that have no apparent surface connectivity to the drainage system. Therefore, there would be little influence on the physical integrity of the aquatic system.

TABLE 4.7.3.5-5 (continued)

Compliance of the Project with ACS Objectives, Days Creek–South Umpqua River Watershed

ACS Objective	Project Impacts
Maintain and restore water quality necessary to support healthy riparian, aquatic, and wetland ecosystems. Water quality must remain within the range that maintains the biological, physical, and chemical integrity of the system and benefits survival, growth, reproduction, and migration of individuals composing aquatic and riparian communities.	Sediment impacts are expected to be as described in Appendix F.4, Section 1.4.1. Minor amounts of sediment would be mobilized during construction, but these impacts are expected to be short term and limited to the immediate Project area. Connectivity to aquatic systems is limited since no stream channels would be crossed. With application of the ECRP and BMPs, no long-term impacts associated with sediment transport are anticipated. No impacts on water temperature are expected because the two waterbodies that would be crossed are isolated and not connected to an intermittent or perennial stream and no effective shade would be removed.
Maintain and restore the sediment regime under which aquatic ecosystems evolved. Elements of the sediment regime include the timing, volume, rate, and character of sediment input, storage, and transport.	Areas of unstable soils have been avoided in Project routing. There would be no stream channels crossed in the watershed because the route lies on a ridge top and connections to aquatic systems that would transport sediment do not exist. Sediment fluxes are expected to be minor, short-term, and well within the range of natural variability for the Klamath-Siskiyou Province with implementation of the erosion control measures in ECRP and BMPs as well as the anticipated rapid revegetation that is characteristic of the province. Erosional impacts are, therefore, expected to be consistent with those described in appendix F.4, Section 1.4.1.
Maintain and restore instream flows sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows must be protected.	It is highly unlikely that the Project would affect flows because there is no connectivity between the two isolated wetlands to any drainage system. The Project routing is on a ridge top in the watershed and would not cross any stream channels. The watershed is hydrologically recovered (BLM 2001:143) and the Project would affect less than 0.5% of the watershed (appendix F.4, table 2-6) so changes in peak flows as a result of construction are highly unlikely.
Maintain and restore the timing, variability, and duration of floodplain inundation and water table elevation in meadows and wetlands.	Two small forested wetlands would be crossed in or near a ridge top swale in the Stouts Creek subwatershed at MP 102.1 and 102.2. Trench plugs would be installed on each side of these wetlands to block subsurface flows and maintain water table elevations, as required by FERC's Wetland and Waterbody Construction and Mitigation Procedures. By restricting crossings to the dry season (July 1 to Sept. 15), possible impacts on water tables of these wetland areas are expected to be minor and short-term. These features appear to have no surface connectivity with the Stouts Creek drainage network.
Maintain and restore the species composition and structural diversity of plant communities in riparian areas and wetlands to provide adequate summer and winter thermal regulation; nutrient filtering; and appropriate rates of surface erosion, bank erosion, and channel migration and to supply amounts and distributions of coarse, woody debris sufficient to sustain physical complexity and stability.	Approximately 0.15 acre or less than 0.01% of Riparian Reserves in the watershed would be cleared by the Project. All affected Riparian Reserves are located at or near ridge tops and contribute little to the thermal regulation, nutrient filtering, bank erosion, and channel stability of the drainage networks in the watershed. Existing herbaceous and brush cover would be maintained in Riparian Reserves to the extent practicable. Replanting with native species would facilitate recovery of vegetation communities. These restoration and off-site mitigation efforts would contribute to the maintenance and restoration and physical functions of the Riparian Reserves in the watershed.
Maintain and restore habitat to support well-distributed populations of native plant, invertebrate and vertebrate riparian-dependent species.	Impacts to Riparian Reserves would be minimal. All of the Riparian Reserves are located at or near ridge tops. To maintain riparian habitat, construction BMPs would be implemented. Revegetation would be encouraged by planting of native riparian species. The persistence of riparian-dependent Survey and Manage species would not be threatened by Project construction and operation in the watershed (see appendix F.5).

Source: Appendix F.4, table 2-11

It is highly unlikely that construction and operation of the Project would prevent attainment of ACS objectives due to the relatively small portion of NFS lands affected, the relative lack of intersections with waterbodies, and the small acreage of Riparian Reserve affected in the Days

Creek-South Umpqua River watershed. No Project impacts relevant to the ACS have been identified that are outside of the range of natural variability for disturbance processes in the watershed (appendix F.4, table 2-17). The proposed amendment to the Umatilla National Forest LRMP to waive protection measures for Survey and Manage species would not prevent attainment of ACS objectives because the Project does not threaten the persistence of any riparian-dependent Survey and Manage species. Mitigations associated with the Project are responsive to watershed assessment recommendations and would improve watershed conditions where they are applied (appendix F.4, table 2-10).

Umpqua River Basin, Elk Creek–South Umpqua River Watershed, HUC 1710030204, Umpqua National Forest

Discussions of watershed analysis recommendations, natural disturbances, range of variability and other elements of the ACS are found in appendix F.4. Table 4.7.3.5-6 (table 2-21 in appendix F.4) and this section shows Project effects compared to each of the nine ACS objectives. The Project does not cross any stream channel or clip any riparian reserve on NFS lands.

TABLE 4.7.3.5-6

Compliance of the Project with ACS Objectives, Elk Creek–South Umpqua River Watershed

ACS Objective	Project Impacts
Maintain and restore the distribution, diversity, and complexity of watershed and landscape-scale features to ensure protection of the aquatic systems to which species, populations, and communities are uniquely adapted.	Riparian Reserves are landscape-scale features that are affected by the Project. The Project affects (cleared and modified) 0.09% of the NFS land in the Elk Creek-South Umpqua River watershed (Appendix F.4, table 2-12). No Riparian Reserves are crossed or clipped in the Elk Creek watershed since the Project is routed on a ridgetop. The application of BMPs and erosion control measures, use of native vegetation, and the anticipated rapid revegetation of disturbed areas would likely further reduce Project effects. The level of impact is well within the natural range of variability for disturbance processes described by Everest and Reeves (2007) and Agee (1993) and as documented in the South Umpqua Watershed Assessment (Forest Service 1996b).
Maintain and restore spatial and temporal connectivity within and between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact refugia. These network connections must provide chemically and physically unobstructed routes to areas critical for fulfilling life-history requirements of aquatic and riparian-dependent species.	The Project is not expected to impact spatial or temporal connectivity on NFS lands in the Elk Creek–South Umpqua River watershed. No streams are crossed, and no riparian reserves are clipped. Aquatic system connectivity would be enhanced by replacement of five culverts within the watershed. Any residual levels of disturbance are anticipated to be well within the range of natural variability (see appendix F.4, table 2-17).
Maintain and restore the physical integrity of the aquatic system, including shorelines, banks, and bottom configurations.	The Project would have no discernible impact on streambanks or bottoms in the Elk Creek–South Umpqua River watershed because no stream channels are crossed. Off-site mitigations involving LWD within Riparian Reserves would help restore physical integrity and complexity (appendix F.4, p. 2-47).
Maintain and restore water quality necessary to support healthy riparian, aquatic, and wetland ecosystems. Water quality must remain within the range that maintains the biological, physical, and chemical integrity of the system and benefits survival, growth, reproduction, and migration of individuals composing aquatic and riparian communities.	Minor amounts of sediment would be mobilized during construction, but these effects are expected to be short-term and limited to the immediate Project area. Connectivity to aquatic systems is limited since no stream channels are crossed. With application of the ECRP and BMPs, there should be no long-term effects associated with sediment transport and delivery. No impacts to water temperature are expected because no channels are crossed, and no effective shade is removed. Any sediment transport to aquatic systems that may occur would be offset by off-site road drainage enhancement, surface upgrade, and storm-proofing mitigation Projects.

TABLE 4.7.3.5-6 (continued)

Compliance of the Project with ACS Objectives, Elk Creek–South Umpqua River Watershed

ACS Objective	Project Impacts
Maintain and restore the sedimentary erosion, transportation and deposition regime under which aquatic ecosystems evolved. Elements of the sediment regime include the timing, volume, rate, and character of sediment input, storage, and transport.	Areas of unstable soils have been avoided in Project routing. There are no stream channels crossed in the watershed and the route lies on a ridge top; therefore, connections to aquatic systems that would transport sediment do not exist. As a result, sediment fluxes are expected to be minor and short-term and well within the range of variability for the Klamath–Siskiyou Province due to implementation of the erosion control measures in ECRP, BMPs, and the anticipated rapid revegetation that is characteristic of the province. As a result, erosional effects are expected to consistent with those described in Section 1.4.1. Road decommissioning and storm proofing would help reduce sediment effects in the watershed and move the sediment regime closer to the desired condition (appendix F.4 p. 2-47-51).
Maintain and restore in-stream flows sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows must be protected.	It is highly unlikely that the Project would impact flows because of the lack of connectivity to aquatic systems. The Project routing is on a ridge top in the watershed and does not cross any stream channels. The watershed is hydrologically recovered, and the Project affects 0.07% of the watershed (appendix F.4, table 2-13). In addition, analysis by FERC showed that the Project was highly unlikely to contribute to increases in peak flows because of the small area affected by the Project as a proportion of the watershed (FERC 2009).
Maintain and restore the timing, variability, and duration of floodplain inundation and water table elevation in meadows and wetlands.	The Project would not affect floodplains and water table elevations in meadows because these features are not crossed by the Project in the Elk Creek–South Umpqua River watershed.
Maintain and restore the species composition and structural diversity of plant communities in riparian areas and wetlands to provide adequate summer and winter thermal regulation; nutrient filtering; and appropriate rates of surface erosion, bank erosion, and channel migration and to supply amounts and distributions of coarse, woody debris sufficient to sustain physical complexity and stability.	No vegetation in Riparian Reserves is removed. Existing herbaceous and brush cover would be maintained in Riparian Reserves to the extent practicable. Replanting with native species would facilitate recovery of vegetation communities. LWD placement within 26 acres of Riparian Reserves would help to enhance physical complexity of the aquatic habitats (appendix F.4, p. 2-47-51). These restoration efforts, along with the limited effects to which they are directed, would maintain and restore biological and physical functions of the Riparian Reserves in the watershed.
Maintain and restore habitat to support well-distributed populations of native plant, invertebrate and vertebrate riparian-dependent species.	Existing herbaceous and brush cover would be maintained to the extent practicable. To maintain riparian habitat, construction BMPs would be implemented. LWD placement within 26 acres of Riparian Reserves would help to enhance physical complexity of the aquatic habitats (appendix F.4, p. 2-47-51). Revegetation would be encouraged by planting of native riparian species. The Project would waive application of Management Recommendations for Survey and Manage species in the watershed but would not threaten the persistence of riparian-dependent Survey and Manage species or prevent attainment of the ACS objectives (see appendix F.5).

Source: Appendix F.4, table 2-21

It is highly unlikely that the Project construction and operation would prevent attainment of ACS objectives on NFS land in the Elk Creek–South Umpqua River watershed based on the Project's ridgetop location and the lack of intersection with waterbodies or riparian reserves. Amendments of the Umatilla National Forest LRMP to waive protection measures for Survey and Manage species would not prevent attainment of ACS objectives because the Project does not threaten the persistence of any riparian-dependent species (appendix F.5). No Project effects relevant to the ACS have been identified that are outside of the range of variability for disturbance processes in the watershed (see appendix F.4, table 2-17).

Umpqua River Basin, Upper Cow Creek Fifth Field Watershed, HUC 1710030206, Umpqua National Forest

Discussions of watershed analysis recommendations, natural disturbances, range of variability and other elements of the ACS are found in appendix F.4. Table 4.7.3.5-7 (table 2-35 in appendix F.4) and this section evaluates Project effects against each of the ACS objectives. National Forest System lands where the ACS applies comprise about 51 percent of the Upper Cow Creek watershed (appendix F.4, table 2-22). Timber harvest and removal of LWD from creek channels has reduced structural complexity of the aquatic habitat and its ability to retain sediments. Chronic, fine-grained sediment deposition, primarily related to roads, has negatively affected aquatic habitats. The presence of roads has segregated some stream reaches from upslope habitats that are needed for replenishment of LWD (appendix F.4, p. 2-66-69). A total of 10.83 acres or 0.13 percent of the Riparian Reserves in the (appendix F.4, table 2-25) watershed would be cleared on:

- Four perennial stream channel crossings,
- Two intermittent stream channel crossings,
- One forested wetland crossing,
- One intermittent stream and six forested wetlands where Riparian Reserves are clipped, but the associated waterbodies are not crossed by the Project.

TABLE 4.7.3.5-7

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Upper Cow Creek Watershed

ACS Objective	Project Impacts
Maintain and restore the distribution, diversity, and complexity of watershed and landscape-scale features to ensure protection of the aquatic systems to which species, populations, and communities are uniquely adapted.	Riparian Reserves are watershed-scale features that would be affected by the Project. There would be four perennial and two intermittent stream crossings in the South Fork Cow Creek subwatershed. [Note that Hydrofeature N at MP 111.01 is a perennial stream but, because of an upstream diversion, it is dry in the summer. It is counted here as an intermittent stream since that it is its current condition]. One small shrub-dominated wetland is also crossed. Riparian Reserves associated with1 perennial stream and 6 forested wetlands are clipped. The Project ROW is located primarily in early or mid seral forests and largely on or near ridge tops to minimize impacts on aquatic habitats. The Project ROW would affect 73.76 acres or about 0.31% of NFS lands in the Upper Cow Creek watershed and about 10.06 acres or 0.13% of the Riparian Reserves within the watershed. Impacts to aquatic systems are expected to be short-term and minor and limited to the Project scale because of application of BMPs and erosion control measures. LWD cleared in construction of the corridor would be used to stabilize and restore stream crossings. Off-site mitigation measures including road decommissioning and installation of fish-friendly culverts are expected to improve watershed conditions in the Upper Cow Creek watershed (appendix F.4, p. 2-89-90; table 2-33). While there are long-term changes in vegetation in Riparian Reserves from construction clearing of the corridor, these would be minor in scale and well within the range of natural variation given the disturbance history of the Upper Cow Creek watershed (see appendix F.4, p. 2-70-83).

TABLE 4.7.3.5-7 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Upper Cow Creek Watershed

ACS Objective	Project Impacts
Maintain and restore spatial and temporal connectivity within and between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact refugia. These network connections must provide chemically and physically unobstructed routes to areas critical for fulfilling life-history requirements of aquatic and riparian-dependent species.	The Project is not expected to affect spatial or temporal connectivity in the Upper Cow Creek watershed except during the construction period because the pipeline would be buried in all aquatic habitats crossed, consistent with the requirements of the Wetland and Waterbody Crossing Plan. In the short-term, connectivity would be disrupted during construction. At each crossing, the corridor would be narrowed down to 75 feet wide. Bed and bank disturbances associated with equipment and trenching are small (<15 feet wide). After construction, all disturbed areas would be returned to their approximate original contours to restore preconstruction contours and drainage patterns. The temporary construction ROW would be restored and revegetated with native grasses, forbs, conifers, and shrubs, as outlined in the ECRP. After construction, key habitat components such as LWD and boulders would be restored onsite and the bed and banks would be returned to preconstruction conditions. By implementing these measures, lateral and longitudinal connectivity at the site scale would be maintained, although in the short-term during construction, connectivity may be disrupted. Except for a few days during the construction of the crossing, access to areas necessary for life-histories of aquatic- and riparian-dependent species would not be obstructed. By restricting stream crossing operations to the ODFW in-stream work window, possible impacts to sensitive life stages of aquatic biota would be minimized. Connectivity would be improved by installation of fish-friendly culverts at six sites that currently preclude passage of aquatic organisms (see appendix F.4 table 1-14, p. 2-89-91). The residual levels of disturbance are anticipated to be well within the range of natural variability in the Klamath–Siskiyou Province.
Maintain and restore the physical integrity of the aquatic system, including shorelines, banks, and bottom configurations.	Impacts to the beds and banks of aquatic features would be minor and limited to the site of construction because the pipeline would be buried, and the actual area of bank and stream bottom disturbance associated with equipment crossing and trenching is small at each crossing (<15 feet wide). After construction, key habitat components such as LWD and boulders would be restored onsite and the beds and banks would be returned to preconstruction conditions, consistent with the POD requirements. By implementing these measures, the physical integrity of the aquatic system at the site scale would be maintained, although in the short-term (during construction), elements of the aquatic system could be disturbed. This level of disturbance is well within the range of natural variability for the watersheds of the Klamath-Siskiyou Province.
Maintain and restore water quality necessary to support healthy riparian, aquatic, and wetland ecosystems. Water quality must remain within the range that maintains the biological, physical, and chemical integrity of the system and benefits survival, growth, reproduction, and migration of individuals composing aquatic and riparian communities.	Mercury from abandoned mercury mines in the South Fork Cow Creek subwatershed is a known issue. Broeker (2010b) and GeoEngineers (2013d) assessed the potential risk of release of mercury from disturbance of affected sediments. Mercury concentration of 0.29 parts per million (ppm)), which is in exceedance of the ODEQ threshold of 0.1 ppm, was detected in soil and stream sediment samples at one site. Special measures including maintenance of 100% effective ground cover have been adopted as recommended by ODEQ. As a result, the presence of inorganic mercury is not anticipated to cause any health risk. Minor amounts of sediment would be mobilized during construction, particularly during the dry open-cut and dam and pump crossing of the East Fork Cow Creek and its perennial tributaries (GeoEngineers 2013b). Water quality impacts from sediment are expected to be short-term and limited to the general area of construction (section appendix F.4 Section 1.4.1.2). No long-term impacts on water quality are expected because of application of the ECRP, including maintenance of effective ground cover (Section 1.3.1 and previous discussion) and BMPs during construction. Approximately 3.1 total acres of effective shading vegetation would be removed at four perennial stream crossings. A site-specific shade analysis conducted by Pacific Connector (NSR 2009, 2014) showed minor temperature increases were possible at the Project scale but no impacts would occur beyond the immediate area of construction; there were no temperature impacts at the stream-network scale. Water quality is expected to remain within the range that supports aquatic biota.

TABLE 4.7.3.5-7 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Upper Cow Creek Watershed

ACS Objective	Project Impacts
Maintain and restore the sediment regime under which aquatic ecosystems evolved. Elements of the sediment regime include the timing, volume, rate, and character of sediment input, storage, and transport.	The Upper Cow Creek watershed sediment regime was historically characterized by pulse-type disturbances (Forest Service 1995a, Everest and Reeves 2007). The East Fork Cow Creek, a drainage in the South Fork Cow Creek subwatershed, is characterized in the Cow Creek watershed analysis as being "in balance" for sediment transport and deposition. The Project is not likely to alter these conditions. Eighty percent (3.73 of 5.27 miles) of the Project in the Upper Cow Creek watershed is on ridge tops with little or no aquatic connectivity. Site-specific field reviews by geologists show the Project is unlikely to cause landslides or activate currently stable earth-flow terrains because unstable areas have been avoided (GeoEngineers 2009b; Hanek 2011; Koler 2012). Surface erosion and sediment transport to streams would be minimized because the Project would maintain 100% effective ground cover, effective sediment barriers, and other erosion control measures as needed (see the sediment discussion at the beginning of this section). Sediment generated during construction is expected to be minor and to be limited to the general area of construction using dry dam-and-pump measures that isolate the crossing from flowing water during construction (section 1.3.1). The Project is not expected to alter the balance of sediment transport and storage in the East Fork Cow Creek. The Project is not expected to alter either the pulse-type disturbance or surface erosion sediment regimes of the Upper Cow Creek watershed (appendix F.4, Section 1.4.1.2). A pulse of sediment could be observed following the first seasonal rain, but this is likely to dissipate within a few hundred feet and would be indistinguishable from background levels.
Maintain and restore instream flows sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows must be protected.	Instream flows would be interrupted for a short time during installation of dams during dam and pump crossings. The area of construction that is between upstream and downstream dams would be dewatered during the actual crossing construction. During construction, water would be pumped around the construction site to maintain downstream flows. It is possible that there would be local increases in runoff from canopy removal but, at the watershed scale, flow regimes would not be altered by the Project because of the small scale of the Project relative to the watershed, the relatively high proportion (85%) of the watershed that is hydrologically recovered, and the lack of connectivity of most of the route to any stream network. See the discussion of peak flow processes in appendix F.4, p. 2-70-83 for additional information.
Maintain and restore the timing, variability, and duration of floodplain inundation and water table elevation in meadows and wetlands.	The Project ROW clips the Riparian Reserve of six forested wetlands and crosses one delineated wetland. Trench plugs would be installed on each side of these wetlands as needed to block subsurface flows and maintain water table elevations, as required by FERC's Wetland and Waterbody Construction and Mitigation Procedures. Regardless, Project construction may have short-term impacts on water tables in these isolated forest wetlands. These site-specific impacts would be minor (i.e., limited to the general area of construction) and are not connected to larger wetland areas; they may also be regulated under Section 404 of the Clean Water Act. By restricting crossings to the dry season (July 1 to Sept. 15), possible impacts on water tables of these wetland areas are expected to be minor and short-term.
Maintain and restore the species composition and structural diversity of plant communities in riparian areas and wetlands to provide adequate summer and winter thermal regulation; nutrient filtering; and appropriate rates of surface erosion, bank erosion, and channel migration and to supply amounts and distributions of coarse, woody debris sufficient to sustain physical complexity and stability.	Project impacts on riparian vegetation in the Upper Cow Creek watershed would be minor. In the short term, all vegetation would be removed from the Project ROW. About 4.45 acres of the Riparian Reserves to be cleared in the Project ROW are LSOG (table 2-25). Existing herbaceous and brush cover would be maintained in Riparian Reserves to the extent practicable. Overall, Project construction would affect ~0.13% of the Riparian Reserves in the watershed (table 2-25). Following construction, replanting with native species would facilitate reestablishment of vegetation communities. LWD and boulders from the corridor would be returned to disturbed riparian areas. These restoration efforts, along with the limited impacts to which they are directed, would maintain and restore biological and physical functions of the Riparian Reserves in the watershed.

TABLE 4.7.3.5-7 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Upper Cow Creek Watershed

ACS Objective	Project Impacts
Maintain and restore habitat to support well-distributed populations of native plant, invertebrate and vertebrate riparian-dependent species.	Project impacts on riparian vegetation in the Upper Cow Creek watershed would be minor (10.06 acres, or 0.13%, of the Riparian Reserves in the watershed) (table 2-25). Existing herbaceous and brush cover within the Project clearing limits would be maintained to the extent practicable. Consistent with the requirements of the POD, LWD and boulders removed from the corridor during construction would be replaced to restore and stabilize channel crossings. Revegetation would be accomplished using native riparian species. The persistence of riparian-dependent Survey and Manage species would not be threatened by Project construction and operation in the watershed. See appendix F.5.

Source: Appendix F.4, table 2-35

Through application of the ECRP BMPs and the FERC Wetland and Waterbody plans, sediment transport would be minimized, and instream flow regimes would be maintained (appendix F.4, section 1.4.1). No known riparian-related Survey and Manage species would be affected by Project construction and operation (see appendix F.5).

The South Fork Cow Creek subwatershed has four perennial stream crossings within one mile. This is the highest number of perennial stream crossings in one subwatershed on NFS lands. Construction of the Project in the Upper Cow Creek watershed has high potential for impacts that could prevent attainment of ACS objectives particularly as related to sediment, water temperature and mobilization of naturally occurring mercury (see appendix F.4, p. 2-70-84). The Project has addressed these issues as follows:

- **Project Routing—**Approximately 80 percent of the route in the Upper Cow Creek watershed is on a ridgetop with little or no connectivity to aquatic habitats or Riparian Reserves. Between MPs 109 and 110 in the South Fork Cow Creek subwatershed, the route has been selected and modified to avoid potentially unstable areas. The Forest Service has participated extensively in routing of the Project and concurs that the location is unlikely to trigger mass wasting or excessive surface erosion.
- **Implementation of Water Quality Best Management Practices—**A site-specific BMP implementation plan based on construction impact and site-response risk has been prepared that is expected to maintain water quality (GeoEngineers 2013b). Within Riparian Reserves for all hydrologic features crossed by the pipeline between MPs 109 and 110, the Project would provide 100 percent post-construction ground cover on all disturbed areas. Wood fiber is the preferred material. In addition, the Project would construct water bars at 50-foot intervals. Other erosion control measures would be used as needed to prevent surface erosion associated with stream crossings or to prevent sediment transport and deposition that may affect riparian systems.
- **Mitigation of Potential Impacts on Stream Temperature—**A temperature analysis on perennial stream crossings showed the Project may have minor temperature impacts (~

0.1°C) at the project scale (NSR 2009, NSR 2014).[153] Although the analysis showed there would be no impact at the next downstream reach below the crossings because of ground water discharge, flow volumes and existing shade, the Project would transplant larger conifers to riparian areas and use logs and slash to provide shade at perennial crossings in the East Fork Cow Creek to mitigate for temperature impacts at the project scale. Temperatures are expected to remain below those specified by the State of Oregon for streams in the Umpqua basin.

- **Mercury--** The Forest Service contracted with a professional consulting geologist with extensive local experience to collect soil and stream sediment samples for analytical testing and reporting of mercury and other naturally-occurring minerals along a 2,000-foot section of the proposed pipeline route between MP 109 and the East Fork Cow Creek (Broeker 2010b; GeoEngineers 2013a). Geochemical analysis of the soil and stream sediment samples have been determined to have very low to nominal concentrations of naturally occurring mercury mineralization. The mercury level at one of the stream sediment sites was 0.29 part per million, which was above the Level II screening level value of 0.1 part per million for invertebrates (ODEQ 1998, cited in GeoEngineers 2013c). In order to prevent this naturally-occurring mercury from mobilizing during and after construction, additional erosion control measures and monitoring would be conducted at these sites. The proposed pipeline construction activities by Pacific Connector within the East Fork Cow Creek subwatershed are not anticipated to disturb and expose soils and bedrock strata that contains more than low amounts of natural occurring mercury mineralization; and any sediment that is generated is not likely to reach the aquatic environment due to implementation of short-term and permanent mitigation measures outlined in Pacific Connector's ECRP and as listed in GeoEngineers (2013a).

There are approximately 7,849.12 acres of Riparian Reserves (NFS lands only) in the Upper Cow Creek watershed (appendix F.4, table 2-22) of which approximately 3,313.66 acres are LSOG. Approximately 10.83 acres of Riparian Reserves or 0.13 percent of the Riparian Reserves on NFS lands in the watershed would be cleared (appendix F.4, table 2-3, 2-24). Of this, approximately 2.81 acres are LSOG (appendix F.4, table 2-25). This is about 0.13 percent of the LSOG in Riparian Reserves on NFS lands in the Upper Cow Creek watershed. Early and mid-seral forest vegetation constitutes the remaining 8.02 acres of the affected Riparian Reserve vegetation. LSOG (2.81 acres) and mid-seral vegetation (4.37 acres) cleared (7.18 acres total) in the corridor would be a change in vegetation condition that is long-term but well within the range of natural variability for the Upper Cow Creek watershed considering its history of disturbance from stand replacement fire and subsequent landslides (appendix F.4, 2-70-83). Federal lands are currently 35.20 percent LSOG and exceed minimum watershed thresholds for LSOG forest after consideration of Pacific Connector Pipeline Project impacts (appendix F.4, p. 2-56).

Several site-specific proposed amendments of the Umatilla National Forest LRMP are required to make provision for the Pacific Connector Project. These proposed amendments are not expected

[153] A temperature increase of this scale is so small that may be outside the confidence limits of the model for precise predictions. In other words, this is possibly "noise" in the metrics, and may not actually occur in the field. Even if the predicted temperature increase does occur, it would quickly dissipate because of downstream shade, hyporheic flows and input from other streams (NSR 2009).

to prevent attainment of the ACS in the Upper Cow Creek watershed (appendix F.4, p. 2-83; table 2-32):

- Proposed amendment UNF-1 would allow removal of effective shade on perennial streams. This amendment would not prevent attainment of ACS objectives because a site-specific temperature assessment (NSR 2009, 2014) showed that any temperature increase resulting from removal of effective shade would be minor and limited to the point of maximum impact at the site of construction.
- Proposed amendment UNF-2 would allow the Pacific Connector corridor to run parallel to an existing stream within the riparian zone. The amendment would not prevent attainment of ACS objectives because an uncut buffer 30 to 60 feet wide remains between the corridor and the East Fork Cow Creek. An estimated 94 percent of the effective shade is maintained adjacent to the East Fork Cow Creek, erosion control measures specified in the ECRP are expected to be effective at controlling surface erosion and LWD would not be removed from the stream. Sources of LWD would remain on both sides of the channel.
- Proposed amendment UNF-3 would allow the Project to exceed detrimental soil conditions within the construction corridor. This would not prevent attainment of ACS objectives because soil decompaction and remediation required in Riparian Reserves is expected to effectively moderate detrimental soil conditions. Implementation of measures in the ECRP is expected to effectively control surface erosion and restore native vegetation (see section 4.3.4 of this EIS).
- Proposed amendment UNF-4 would reallocate approximately 588 acres from the matrix land allocation to the LSR allocation. This would benefit aquatic habitats because this area would be managed for late-successional stand conditions that provide additional aquatic protections.
- Proposed amendment of the Umatilla National Forest LRMP to waive protection measures for Survey and Manage species would not prevent attainment of ACS objectives because the Project does not threaten the persistence of any riparian-dependent species (see appendix F.5).

The routing of the Project through NFS lands, coupled with the relatively small area of NFS land affected by Project construction (73.76 acres or 0.31 percent of the NFS lands in the fifth-field watershed – appendix F.4, table 2-23), makes it highly improbable that Project impacts could affect watershed conditions. Although there are project-level impacts (e.g., short-term sediment and a long-term change in vegetative condition at stream crossings), these would be minor in scale and largely limited to the boundaries of the Project area (appendix F.4, Section 1.4.1.2).

No Project-related impacts that would prevent attainment of ACS objectives have been identified (table 4.7.3.5-7 or appendix F.4, table 2-35). All relevant Project impacts are within the range of natural variability for watersheds in the Western Cascades and Klamath Provinces, although some of these processes have been altered from their natural condition (appendix F.4, p. 2-70-83).

Rogue River Basin, Trail Creek Fifth-Field Watershed HUC 1710030706, Umpqua National Forest

Discussions of watershed analysis recommendations, natural disturbances, range of variability and other elements of the ACS are found in appendix F.4. Table 4.7.3.5-8 (table 2-44 in appendix F.4) compares the Project impacts to the objectives of the ACS for the Trail Creek watershed. The

Project would not affect any Riparian Reserves in the watershed (appendix F.4, table 2-3, 2-38). National Forest System lands where the ACS applies comprise about 12 percent of the Trail Creek watershed (appendix F.4, p. 2-99). Watershed conditions and recommendations are found in the Trail Creek watershed assessment (BLM 1999) and described in detail in appendix F.4. In the Trail Creek watershed, timber harvest and removal of LWD from creek channels has reduced structural complexity of the aquatic habitat and its ability to retain sediments. Chronic, fine-grained sediment, most recently related to roads and timber harvest, has negatively affected aquatic habitats by adding large volumes of sediment. The presence of roads has segregated some stream reaches from upslope habitats that are needed for replenishment of LWD.

TABLE 4.7.3.5-8

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Trail Creek Watershed

ACS Objective	Project Impacts
Maintain and restore the distribution, diversity, and complexity of watershed and landscape-scale features to ensure protection of the aquatic systems to which species, populations, and communities are uniquely adapted.	Riparian Reserves are watershed landscape-scale features that would be affected by the Project. No Riparian Reserves are affected in the Trail Creek watershed (table 2-41). On NFS lands subject to the ACS, the Project ROW is located primarily in early or mid seral forests (table 2-41). There are no river or stream crossings on NFS lands, and the Project ROW is located largely on or near ridge tops to minimize impacts on aquatic habitats. No wetlands or streams are crossed or clipped in the watershed. Use of native vegetation and the anticipated rapid revegetation of disturbed areas would likely further reduce Project impacts. Off-site mitigation measures including road stormproofing and decommissioning are expected to improve watershed conditions in the Trail Creek watershed (see appendix F.4, p.2-113-115).
Maintain and restore spatial and temporal connectivity within and between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact refugia. These network connections must provide chemically and physically unobstructed routes to areas critical for fulfilling life-history requirements of aquatic and riparian-dependent species.	The Project is not expected to affect spatial or temporal connectivity in the Trail Creek watershed because no wetlands or waterbodies are crossed. No rivers or streams would be crossed on NFS lands.
Maintain and restore the physical integrity of the aquatic system, including shorelines, banks, and bottom configurations.	No stream channels are crossed on NFS lands where the ACS applies so the physical integrity of banks and stream bottoms would not be affected.
Maintain and restore water quality necessary to support healthy riparian, aquatic, and wetland ecosystems. Water quality must remain within the range that maintains the biological, physical, and chemical integrity of the system and benefits survival, growth, reproduction, and migration of individuals composing aquatic and riparian communities.	No wetlands or streams are crossed on NFS lands in the Trail Creek watershed. No long-term impacts on water quality are expected because of application of the ECRP, including maintenance of effective ground cover and BMPs during construction (see Section 1.4.1 and previous discussion).

TABLE 4.7.3.5-8 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Trail Creek Watershed

ACS Objective	Project Impacts
Maintain and restore the sediment regime under which aquatic ecosystems evolved. Elements of the sediment regime include the timing, volume, rate, and character of sediment input, storage, and transport.	The Trail Creek watershed was historically characterized by pulse-type depositions of coarser sediments from landslides and surface erosion following major disturbances such as fires and high-intensity winter storms (BLM 1999, Everest and Reeves 2007). Chronic erosion and deposition of fine sediments, primarily from roads and to a lesser degree from land use, have replaced these pulse-type disturbances in the watershed. Project construction and operation are not likely to alter sediment erosion and deposition in the watershed nor are they likely to exacerbate these conditions. Proposed mitigation projects would contribute to a reduction of adverse sediment scouring and depositing and restoration of aquatic functions (see appendix F.4, p. 2-113-115).
Maintain and restore instream flows sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows must be protected.	The Project is not likely to affect peak flows in the Trail Creek watershed because of its predominately ridge top location, the relatively small area of the watershed affected (less than 1%), the absence of stream crossings, and the relative lack of connectivity to aquatic systems. The Trail Creek watershed assessment noted that increases in peak flows are a low risk in all the subwatersheds and in the watershed as a whole.
Maintain and restore the timing, variability, and duration of floodplain inundation and water table elevation in meadows and wetlands.	The Project would not cross any meadows or wetlands in the Trail Creek watershed on NFS lands, so there would be no impact from the Project on water tables or seasonal inundation of these areas
Maintain and restore the species composition and structural diversity of plant communities in riparian areas and wetlands to provide adequate summer and winter thermal regulation; nutrient filtering; and appropriate rates of surface erosion, bank erosion, and channel migration and to supply amounts and distributions of coarse, woody debris sufficient to sustain physical complexity and stability.	The Project would not affect Riparian Reserves in the Trail Creek watershed (table 2-39). Following construction, replanting with native species would facilitate reestablishment of vegetation communities.
Maintain and restore habitat to support well-distributed populations of native plant, invertebrate and vertebrate riparian-dependent species.	The Project would not affect any Riparian Reserves in the Trail Creek watershed (table 2-39). Consistent with the requirements of the POD, LWD and boulders removed from the corridor during construction would be replaced to restore and stabilize channel crossings. Revegetation would be accomplished using native riparian species. The Project would waive application of Management Recommendations for Survey and Manage species in the watershed but would not threaten the persistence of riparian-dependent Survey and Manage species or prevent attainment of the ACS objectives (see appendix F.5).

Source: Appendix F.4, table 2-44

Given the ridgetop location of the pipeline corridor on NFS lands, the lack of intersects with waterbodies, and lack of impacts to Riparian Reserves it is highly unlikely that Project construction and operation would prevent attainment of ACS objectives on NFS land in the Trail Creek watershed.

The high clay-content soils in the watershed (BLM 1999:1-4) presents a potential issue with respect to possible compaction and sediment that could be mobilized by overland flow. Subsoil ripping (including the use of hydraulic excavators) is a proven method to reduce soil compaction. Measures in the ECRP including soil remediation with organic materials, rapid revegetation and maintenance of effective ground cover are likely to successfully control surface erosion. The Forest Service may require additional erosion control measures if needed.

Off-site mitigation measures, identified by the Forest Service, would supplement onsite minimization, mitigation, and restoration actions. These proposed offsite mitigation measures are responsive to recommendations in the Trail Creek watershed assessment and would contribute to improving terrestrial and aquatic conditions within the watershed (see appendix F.4, p. 2-113-115).

A site-specific amendment of the Umatilla National Forest LRMP to waive limitation on detrimental soil compaction is proposed to make a provision for the Project. This proposed amendment is minor in scope and is not expected to prevent attainment of ACS objectives because of implementation of the ECRP and the fact that there are no stream intersects on NFS lands in the Trail Creek watershed. The proposed amendment of the Umatilla National Forest LRMP to waive protection measures for Survey and Manage species would not prevent attainment of ACS objectives because species viability would be maintained (see appendix F5).

The relatively small area of NFS land affected by Project construction (50.27 acres or 1.15 percent of NFS lands in the watershed), makes it highly improbable that Project impacts could affect watershed conditions beyond the site scale. Although there are project-level impacts such as short-term surface erosion these would be minor and limited to the boundaries of the Project area (see appendix F.4, section 1.4.1).

No Project-related impacts that would retard or prevent attainment of ACS objectives have been identified (appendix F.4, table 2-44). Impacts, as they relate to relevant ecological processes, are within the range of natural variability for watersheds in the Western Cascade and Klamath-Siskiyou Provinces, although some of these processes have been altered from their natural condition (appendix F.4, p. 2-105-109, table 2-40).

Rogue River Basin, Little Butte Creek Fifth Field Watershed, HUC 1710030708, Rogue-Siskiyou National Forest

Discussions of watershed analysis recommendations, natural disturbances, range of variability are found in appendix F.4. Table 4.7.3.5-9 (table 2-62 in appendix F.4) compares the Project impacts to the objectives of the ACS for the Little Butte Creek watershed. National Forest System lands where the ACS applies comprise approximately 59,900.38 acres or 25.10 percent of the Little Butte Creek watershed (appendix F.4, table 2-45). Riparian Reserves comprise approximately 8,096.50 acres (about 3.39 percent of the entire watershed [appendix F.4, table 2-45]) on NFS lands. Watershed conditions and recommendations are found in the Little Butte Creek watershed assessment (BLM and Forest Service 1997). A total of 10.22 acres or 0.13 percent of the Riparian Reserves in the watershed would be affected of which 7.66 acres are cleared and 2.56 acres (appendix F.4, table 2-47) are modified on:

- One perennial stream channel crossing
- One intermittent stream channel crossing
- One intermittent stream and one wetland where Riparian Reserves are clipped, but the associated waterbodies are not crossed by the Project.

TABLE 4.7.3.5-9

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Little Butte Creek

ACS Objective	Project Impacts
Maintain and restore the distribution, diversity, and complexity of watershed and landscape-scale features to ensure protection of the aquatic systems to which species, populations, and communities are uniquely adapted.	Riparian Reserves are watershed-scale features. The Project would affect about 10.22- acres or about 0.13% of Riparian Reserves on NFS lands in the Little Butte Creek watershed (table 2-47). There is one intermittent and one perennial stream channel crossed in the Little Butte Creek watershed on NFS lands. Impacts to aquatic systems are expected to be short-term and minor and limited to the project scale because of application of BMPs and erosion control measures (see appendix F.4, Section and 1.4.1). Large woody debris cleared in construction of the Project would be used to stabilize and restore stream crossings. Off-site mitigation measures including 57.5 miles of road decommissioning, approximately 1.5 -miles of instream projects, snag creation and coarse woody debris placement are expected to improve watershed conditions in the Little Butte Creek watershed (see appendix F.4, p. 2-149 158, tables 2-57, 2-58, 2-59, 2-60). While there are long-term changes in vegetation in Riparian Reserves from construction clearing of the Project ROW, these would be minor in scale and well within the range of natural variability given the disturbance history of the watershed (see appendix F.4, p. 2-105-109, table 2-40).
Maintain and restore spatial and temporal connectivity within and between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact refugia. These network connections must provide chemically and physically unobstructed routes to areas critical for fulfilling life-history requirements of aquatic and riparian-dependent species.	The Project is not expected to affect spatial or temporal connectivity in the Little Butte Creek watershed because the pipeline would be buried in all aquatic habitats crossed, consistent with the requirements of the exhibits specified in the Wetland and Waterbody Crossing Plan. At each crossing, bed and bank disturbances from equipment crossing and trenching are small (<15 -feet -wide). After construction, all disturbed areas would be returned to their approximate preconstruction contours and drainage patterns. The temporary construction ROW would be restored and revegetated with native grasses, forbs, conifers, and shrubs, as outlined in the ECRP. After construction, key habitat components such as LWD and boulders would be restored onsite and the bed and banks would be returned to preconstruction conditions. By implementing these measures, lateral and longitudinal connectivity at the site scale would be maintained, although in the short-term during construction, connectivity may be disrupted. Except for a few days during the construction of the crossings, access to areas necessary for life-histories of aquatic and riparian dependent species would not be obstructed. By restricting stream crossing operations to the ODFW in-stream work window, possible impacts to sensitive life stages of aquatic biota would be minimized. Road decommissioning that occurs within Riparian Reserves (approximately 18-acres) would contribute to restoration of aquatic connectivity. The residual levels of disturbance are anticipated to be well within the range of natural variability in the Klamath-Siskiyou Province and the High Cascades Province. (appendix F.4, p. 2-136-141, table 2-54)
Maintain and restore the physical integrity of the aquatic system, including shorelines, banks, and bottom configurations.	Impacts to the bed and banks of aquatic features would be minor and limited to the site of construction because the pipeline would be buried, and the actual area of bank and stream bottom disturbance is small at each crossing (<15-feet -wide). This level of disturbance is comparable to a bank slough (see Section 1.4.1.) or a culvert installation and well within the range of natural variability that for watersheds of the Klamath-Siskiyou Province and the High Cascades Province (see (appendix F.4, p. 2-136-141, table 2-54)). After construction, key habitat components such as LWD and boulders would be restored onsite and the bed and banks would be returned to preconstruction conditions, consistent with the exhibits to the POD. By implementing these measures, the physical integrity of the aquatic system at the site scale would be maintained.

TABLE 4.7.3.5-9 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Little Butte Creek

ACS Objective	Project Impacts
Maintain and restore water quality necessary to support healthy riparian, aquatic, and wetland ecosystems. Water quality must remain within the range that maintains the biological, physical, and chemical integrity of the system and benefits survival, growth, reproduction, and migration of individuals composing aquatic and riparian communities.	Minor amounts of sediment would be mobilized during construction. These impacts are expected to be short-term and limited to the general area of construction (see appendix F.4, Section 1.4.1). No long-term impacts on water quality are expected because of application of the ECRP that includes maintenance of effective ground cover and BMPs during construction (see appendix F.4, Section 1.4.1.1). Effective shade would be removed at the crossing of the South Fork Little Butte Creek at MP 162.45. A site-specific shade analysis (NSR 2009) found no temperature impacts at the site or at the stream network scale at this crossing.
Maintain and restore the sediment regime under which aquatic ecosystems evolved. Elements of the sediment regime include the timing, volume, rate, and character of sediment input, storage, and transport.	The Little Butte Creek watershed sediment regime was historically characterized by pulse-type depositions of coarser sediments from landslides and surface erosion following major disturbances such as fires and high-intensity winter storms (BLM and Forest Service 1997). The current sediment regime in the watershed has replaced these pulse-type disturbances with more chronic erosion and deposition of fine sediments primarily from urban and agricultural land use, timber harvest and roads. Project construction and operation is not likely to alter this sediment pattern nor is it likely to exacerbate these conditions because of implementation of measures in the ECRP (see Section 1.4.1) including maintenance of effective ground cover, water bars to dissipate overland flows and maintenance of sediment barriers until revegetation is successful. Sediment impacts from construction are expected to be like those described in section 1.4.1.2. A pulse of sediment could be observed following the first seasonal rain, but that this is likely to dissipate within a few hundred feet and would be indistinguishable from background levels. Any sediment impacts are expected to be well within the range of natural variability for the Klamath-Siskiyou Province and the High Cascades Province (see appendix F.4, p. 2-134 140, table 2-54). Proposed mitigation projects including road decommissioning would contribute to reduction of sediments and restoration of aquatic functions at the watershed scale (see appendix F.4, p. 2-148-158, table 2-57).
Maintain and restore instream flows sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows must be protected.	The Project is unlikely to affect peak flows in the Little Butte Creek watershed because of the dispersed nature of impacts, the current hydrologically recovered conditions in the watershed, the relatively small proportion of the watershed affected (0.25%), and the relative lack of connectivity to aquatic systems (see appendix F.4, table 2-54, p. 2-139). Decommissioning roads (57.5 miles) as part of the offsite mitigation plan would contribute substantively the restoration of flow patterns by restoring hydrologic connectivity at stream crossings that are decommissioned (see appendix F.4, p. 2-148-158, table 2-57).
Maintain and restore the timing, variability, and duration of floodplain inundation and water table elevation in meadows and wetlands.	The Project clips one small wetland on NFS land but does not cross it. Application of the ECRP including maintenance of effective ground cover and BMPs during construction will be applied (see section 1.4.1.1). In addition, decommissioning 57.5 miles of roads, 18- acres of which are in Riparian Reserves (see appendix F.4, p. 2-148-158, table 2-57)) would contribute substantially to restoring floodplain functions where these projects occur.
Maintain and restore the species composition and structural diversity of plant communities in riparian areas and wetlands to provide adequate summer and winter thermal regulation; nutrient filtering; and appropriate rates of surface erosion, bank erosion, and channel migration and to supply amounts and distributions of coarse, woody debris sufficient to sustain physical complexity and stability.	The Project impacts on riparian vegetation in the Little Butte Creek watershed would be minor. Approximately 10.22 acres or 0.13% of the Riparian Reserves in the watershed are potentially affected by the Project (table 2-48). Existing herbaceous and brush cover would be maintained in Riparian Reserves to the extent practicable. Following construction, replanting with native species would facilitate reestablishment of vegetation communities. Large woody debris and boulders from the Project ROW would be returned to disturbed riparian areas. Coarse woody debris placement and snag creation on 126- acres in Riparian Reserves, along with revegetation on 18 acres of Riparian Reserves in roads that would be decommissioned would help to reestablish species composition and structural diversity of plant communities in Riparian Reserves (see appendix F.4, p. 2-148-158, table 2-57).

TABLE 4.7.3.5-9 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Little Butte Creek

ACS Objective	Project Impacts
Maintain and restore habitat to support well-distributed populations of native plant, invertebrate and vertebrate riparian-dependent species.	The Project impacts on riparian vegetation in the Little Butte Creek watershed would be minor. Approximately 10.22 acres or 0.13% of the Riparian Reserves in the watershed are potentially affected by the Project. Following construction, replanting with native species would facilitate reestablishment of vegetation communities. Large woody debris and boulders from the Project ROW would be returned to disturbed riparian areas. Coarse wood placement and snag creation on 126- acres in Riparian Reserves, along with revegetation on 18 acres of Riparian Reserves in roads that would be decommissioned would help to reestablish species composition and structural diversity of plant communities in Riparian Reserves. The Project would waive application of Management Recommendations for Survey and Manage species in the watershed but would not prevent attainment of the ACS objectives because the viability of riparian-dependent Survey and Manage species would not be threatened. (see appendix F.5).

Source: Appendix F.4, table 2-62

The Little Butte Creek watershed is the largest, and in some ways, the most complex watershed crossed by the Project. With 13.75 miles of corridor, and 207.17 acres of clearing on NFS lands, this watershed has the most NFS land area affected of all watersheds crossed by the Project. The watershed is geologically complex with both Klamath-Siskiyou Province and the High Cascades Province landscapes. It is ecologically diverse and important, providing some of the most productive coho salmon streams in the Upper Rogue Basin. Little Butte Creek watershed is a Tier 1 Key Watershed above the confluence of the North and South Forks of Little Butte Creek (appendix F.4, table 1-2), and roughly 88 percent of the NFS lands in the watershed are managed as LSR (appendix F.4, table 1-1). Against this backdrop, compliance with the ACS is an important measure of Project impacts.

Pacific Connector has modified the Project to respond to the ACS objectives and has incorporated measures consistent with the Riparian Reserve Standards and Guidelines into the ECRP and other elements of their plan of development (e.g., Wetlands and Water Body Crossing Plan). The assessment in appendix F.4 demonstrates that short-term impacts associated with the Project would occur to streambanks, and substrates at the site scale. Change in vegetative condition from clearing of forest within the Project ROW is a long-term impact. These impacts, however, are well within the range of natural variability given the disturbance processes that function in the watershed (see appendix F.4, p. 2-134 – 2-141, table 2-54). This is especially apparent when considering the total amount of Riparian Reserves that are located within the Little Butte Creek watershed (8,096.50 acres) and the amount of clearing (10.22 acres) in Riparian Reserves (0.13 percent of the Riparian Reserves in the watershed) (appendix F.4, table 2-47). Also, because of the linear characteristic of the pipeline, the Riparian Reserve crossings would be spread out across the landscape.

Off-site mitigation measures including over 66 miles of road decommissioning (57.5 miles are within Key Watershed), 1.5 miles of LWD instream projects, identified by the Forest Service, would supplement onsite minimization, mitigation, and restoration actions. These proposed offsite mitigation measures are responsive to recommendations in the Little Butte Creek watershed assessment (1997) and the South Cascades Late-Successional Reserve Assessment (1998).

Mitigations measures encompassed with the Project description described in chapter 2 of this EIS are responsive to watershed assessment recommendations and would improve watershed conditions where they are applied (see appendix F.4, p. 2-148-158, table 2-57, 2-58).

To make provisions for the Project, three site-specific amendments of the Rogue River National Forest LRMP related to the ACS are proposed (see appendix F.4, p. 143-148).

- Proposed amendment RRNF-5 would allow the Project to cross the MA-26 Restricted Riparian land allocation at one location on the South Fork of Little Butte Creek a perennial stream. This amendment would not prevent attainment of ACS objectives because a site-specific temperature assessment (NSR 2009) showed there would be no temperature increase from shade removal at this location, effective ground cover and sediment barriers would be maintained and implementation of the ECRP is expected to control surface erosion and reestablish native vegetation.
- Proposed amendment RRNF-6 would allow the Project to exceed detrimental soil conditions within the construction corridor. This would not prevent attainment of ACS objectives because the Project would require soil remediation as needed with biosolids or other organic materials in areas with potential revegetation difficulty, soil decompaction, maintenance of effective ground cover, application of BMPs, and application of offsite mitigations. Therefore, any sediment impacts from detrimental soil conditions are expected to be minor and short term and the methods described above would be expected to effectively moderate detrimental soil conditions. Implementation of measures in the ECRP is expected to effectively control surface erosion and restore native vegetation (see section 4.3.4 in this EIS).
- Proposed amendment of the Rogue River National Forest LRMP to waive protection measures for Survey and Manage species would not prevent attainment of ACS objectives because the persistence of riparian dependent survey and manage species would not be threatened (see appendix F.5).

The Project is otherwise consistent with Standards and Guidelines for activities in Riparian Reserves for the Rogue River National Forest.

The routing of the pipeline through NFS lands, coupled with the relatively small area of NFS land affected by Project construction (0.46 percent of NFS lands in the fifth-field watershed), makes it highly improbable that Project impacts could affect watershed conditions. The relative lack of intersections with aquatic systems serves to further minimize possible impacts. Although there are project-level impacts from short-term sediment and long-term change in vegetative condition at stream crossings, these would be minor in scale (appendix F.4, table 2-62).

No Project-related impacts that would prevent attainment of ACS objectives have been identified (appendix F.4, section 1.4.1, table 2-62). All relevant Project impacts are within the range of natural variability for watersheds in the Klamath-Siskiyou and High Cascades Provinces, although some of these processes have been altered from their natural condition (appendix F.4, p. 2-236).

Klamath River Basin, Spencer Creek Fifth Field Watershed, HUC 180102206, Winema National Forest

Discussions of watershed analysis recommendations, natural disturbances, range of variability etc. are found in appendix F.4. Table 4.7.3.5-10 (table 2-77 in appendix F.4) and this section compares the Project impacts to the objectives of the ACS for the Spencer Creek watershed. National Forest System lands where the ACS applies comprise approximately 41 percent of the Spencer Creek watershed (appendix F.4, table 1-1). Watershed conditions and recommendations are found in the Spencer Creek watershed analysis (BLM et al. 1995). The Project would include approximately 6.05 miles on NFS lands. A total of 9.98 acres of Riparian Reserves or 0.60 percent of the Riparian Reserves in the watershed (appendix F.4, table 2-65) would be affected of which 8.63 acres are cleared and 1.35 acres (appendix F.4, table 2-3 are modified on:

- Four intermittent stream channels and two wetlands crossed by the Project.
- Four intermittent streams and two wetlands where Riparian Reserves are clipped but the associated stream channel or wetland is not crossed.

TABLE 4.7.3.5-10

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Spencer Creek Watershed

ACS Objective	Project Impacts
Maintain and restore the distribution, diversity, and complexity of watershed and landscape-scale features to ensure protection of the aquatic systems to which species, populations, and communities are uniquely adapted.	Riparian Reserves are watershed-scale features. The Project would clear about 8.63-acres or about 0.52% of Riparian Reserves on NFS lands in the Spencer Creek watershed (table 2-67). There are four intermittent stream channels crossed in the Spencer Creek Watershed. No perennial streams are crossed. Riparian Reserves associated with two forested wetlands and four intermittent streams are clipped. Impacts to aquatic systems are expected to be short-term or minor and limited to the project scale because of application of BMPs and erosion control measures (see appendix F.4, section 1.4.1.). Clearing of 4.58 -acres of LSOG vegetation in Riparian Reserves is a long-term change in condition, but is minor in scale, and within the range of natural variability given the disturbance processes in Spencer Creek (appendix F.4, p. 2-176-2-181). Spencer Creek watershed remains above the 15% threshold on federal lands for LSOG vegetation established in the NWFP (appendix F.4, p. 1-174). Large woody debris cleared in construction of the Project ROW would be used to stabilize and restore stream crossings. Off-site mitigation measures including 29.2-miles of road decommissioning, one mile of instream projects, fencing and riparian planting projects are expected to improve watershed conditions in the Spencer Creek watershed. While there are long-term changes in vegetation in Riparian Reserves from construction clearing of the Project ROW, these would be minor in scale and well within the range of natural variability given the disturbance history of the watershed (see appendix F.4, p. 2-176-2-181).

TABLE 4.7.3.5-10 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Spencer Creek Watershed

ACS Objective	Project Impacts
Maintain and restore spatial and temporal connectivity within and between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact refugia. These network connections must provide chemically and physically unobstructed routes to areas critical for fulfilling life-history requirements of aquatic and riparian-dependent species.	The Project is not expected to affect spatial or temporal connectivity in the Spencer Creek watershed because the pipeline would be buried in all aquatic habitats crossed, consistent with the requirements of the exhibits specified in the POD (i.e., Wetland and Waterbody Crossing Plan). Additionally, all the channels crossed in Spencer Creek are intermittent and are likely to be dry at the time of crossing. In the short-term, during construction, connectivity could be disrupted for 1-5 days. At each crossing, bed and bank disturbances are small (<15 feet wide). After construction all disturbed areas would be returned to their approximate preconstruction contours and drainage patterns. The temporary Project ROW would be restored and revegetated with native grasses, forbs, conifers, and shrubs, as outlined in the ECRP. After construction, key habitat components such as LWD and boulders would be restored onsite and the bed and banks would be returned to preconstruction conditions. By implementing these measures, lateral and longitudinal connectivity at the site scale would be maintained, although in the short-term, during construction, connectivity may be disrupted. Except for a few days during the construction of the crossing, access to areas necessary for life-histories of aquatic and riparian dependent species would not be obstructed. By restricting stream crossing operations to the ODFW in-stream work window, possible impacts to sensitive life stages of aquatic biota would be minimized. Road decommissioning that occurs within Riparian Reserves (approximately 9.63- acres) would contribute to restoration of aquatic connectivity (see appendix F.4, p. 2-186-191). The residual levels of disturbance are anticipated to be well within the range of natural variability in the High Cascades Province (see appendix F.4, p. 176-181).
Maintain and restore the physical integrity of the aquatic system, including shorelines, banks, and bottom configurations.	Impacts to the stream bed and banks would be minor and limited to the site of construction because the pipeline would be buried, and the actual area of bank and stream bottom disturbance is small at each crossing (<15- feet -wide). This level of disturbance is comparable to a bank failure (see Section 1.4.1) and well within the range of natural variability for watersheds in the High Cascades Province (see Section appendix F.4, p. 176-181). After construction, key habitat components such as LWD and boulders would be restored onsite and the bed and banks would be returned to preconstruction conditions, consistent with the exhibits to the POD (i.e., Wetland and Waterbody Crossing Plan). By implementing these measures, the fluvial integrity of the aquatic system at the site- scale would be maintained. Offsite mitigation measures (see section 2.6.3.6) would substantively improve watershed conditions by decommissioning 29.22 miles of roads (50- acres total of which 12.6- acres are in Riparian Reserves), replanting willows along 0.5 -miles of perennial streams and restoring LWD in 1 mile of Spencer Creek (appendix F.4, p. 2-186-191, 2-73, table 2-74).
Maintain and restore water quality necessary to support healthy riparian, aquatic, and wetland ecosystems. Water quality must remain within the range that maintains the biological, physical, and chemical integrity of the system and benefits survival, growth, reproduction, and migration of individuals composing aquatic and riparian communities.	Project stream crossings in the Spencer Creek watershed are expected to occur when intermittent stream channels are dry. Minor amounts of sediment would be generated during construction that may be mobilized during the onset of seasonal precipitation in the fall. These impacts are expected to be short -term and limited to the general area of construction (see section 1.4.1). No long-term impacts on water quality are expected because of application of the ECRP including maintenance of effective ground cover (see section 1.4.1) and BMPs during construction (see section 1.4.1.1) Offsite mitigation measures (see appendix F.4, p. 2-186 – 191, table 2-73) address key issues identified in the watershed assessment and are expected to substantially improve watershed conditions.
Maintain and restore the sediment regime under which aquatic ecosystems evolved. Elements of this sediment regime include the timing, volume, rate, and character of sediment input, storage, and transport.	The Spencer Creek watershed sediment regime was historically characterized by pulse-type depositions of coarser sediments from streambank erosion following major disturbances such as fires and high-intensity winter storms. More chronic erosion and deposition of fine-grained sediments primarily from roads, and to a lesser degree from land use has replaced these pulse-type disturbances in the current sediment regime in the watershed. The Project construction and operation are not likely to alter this sediment pattern nor is it likely to exacerbate these conditions. Sediment impacts from construction are expected to be like those described in section 1.4.1.2. Proposed mitigation projects including 29.5 miles of road -decommissioning would contribute to reduction of sediments and restoration of aquatic functions at the watershed scale. Any sediment impacts are expected to be well within the range of natural variability given the disturbance history of the Spencer Creek watershed (see appendix F.4, p. 2-176-181).

TABLE 4.7.3.5-10 (continued)

Compliance of the Pacific Connector Pipeline Project with ACS Objectives, Spencer Creek Watershed

ACS Objective	Project Impacts
Maintain and restore instream flows sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows must be protected.	The Project is unlikely to affect flow patterns in the Spencer Creek watershed because of the dispersed nature of impacts, high infiltration rates and the relatively small proportion of the watershed affected (0.41%) (appendix F.4, p 2-191, table 2-64). Decommissioning roads (29.5 miles) as part of the offsite mitigation plan would contribute substantively the restoration of flow patterns by restoring hydrologic connectivity at stream crossings that are decommissioned (see appendix F.4, p. 2-186 – 191, table 2-73)).
Maintain and restore the timing, variability, and duration of floodplain inundation and water table elevation in meadows and wetlands.	The Project crosses two small wetland areas and clips the Riparian Reserve of another two forested wetlands. Trench plugs would be installed on each side of these wetlands as needed to block subsurface flows and maintain shallow, unconfined aquifer water table elevations, as required by FERC's *Procedures*. By restricting crossings to the dry season (July 1 to Sept. 15), possible impacts on shallow ground water tables of these wetland areas are expected to be minor and short-term.
Maintain and restore the species composition and structural diversity of plant communities in riparian areas and wetlands to provide adequate summer and winter thermal regulation; nutrient filtering; and appropriate rates of surface erosion, bank erosion, and channel migration and to supply amounts and distributions of coarse, woody debris sufficient to sustain physical complexity and stability.	The Project impacts on riparian vegetation in the Spencer Creek watershed would be minor. Approximately 9.98 or 0.60% of the Riparian Reserves in the watershed are potentially affected by the Project (table 2-65). Existing herbaceous and brush cover would be maintained in Riparian Reserves to the extent practicable. Following construction, replanting with native species would facilitate reestablishment of vegetation communities. Large woody debris and boulders from the Project ROW would be returned to disturbed riparian areas. Revegetation of 12.6 acres of Riparian Reserves in roads that would be decommissioned would help to reestablish species composition and structural diversity of plant communities in Riparian Reserves (appendix F.4, p. 2-186 – 191, table 2-74)).
Maintain and restore habitat to support well-distributed populations of native plant, invertebrate and vertebrate riparian-dependent species.	The Project impacts on riparian vegetation in the Spencer Creek watershed would be minor. Approximately 9.98 acres or 0.60% of the Riparian Reserves in the watershed are potentially affected by the Project (appendix F.4, table 2-65). Following construction, replanting with native species would facilitate reestablishment of vegetation communities. Large woody debris and boulders from the Project ROW would be returned to disturbed riparian areas. Revegetation on 12.6 acres of Riparian Reserves in roads that would be decommissioned would help to reestablish species composition and structural diversity of plant communities in Riparian Reserves. The Project would waive application of Management Recommendations for Survey and Manage species in the watershed but would not prevent attainment of the ACS objectives because the viability of riparian-dependent survey and manage species would not be not threatened. (see appendix F.5).

Source: Appendix F.4, table 2-77

The Spencer Creek watershed is the easternmost and driest watershed where the ACS applies that is crossed by the Project in the High Cascades Province. It is also a Tier 1 Key Watershed in the NWFP. Stream densities are much lower than watersheds west of the Cascade crest. Precipitation patterns show a strong declining gradient from 40 inches a year on the crest of the Cascades to less than 12 inches where Spencer Creek flows into the Klamath River. The pumice soils in the watershed have high infiltration rates and rarely exhibit overland flows and mass wasting events that influence riparian and aquatic resources in other watersheds crossed by the Project. By locating the Project adjacent to the Clover Creek Road for much of its length, impacts on wetlands and stream channels have been minimized when compared to the impacts of creating a new corridor.

Pacific Connector has modified the Project to respond to the ACS objectives and has incorporated measures consistent with the Riparian Reserve Standards and Guidelines. The assessment demonstrates that short-term impacts would occur to streambanks, and substrates at the site scale. Change in vegetative condition from clearing the Project ROW is a long-term impact that would occur on 8.63 acres of Riparian Reserves. These impacts, however, are well within the range of natural variability given the disturbance processes that function in the watershed (see appendix F.4, p. 2-176-181, table 2-70). Also, because of the linear characteristic of the Project, the Riparian Reserve crossings would be spread out across the landscape.

Off-site mitigation measures, identified by the Forest Service, would supplement on-site minimization, mitigation, and restoration actions. These proposed off-site mitigation measures are responsive to recommendations in the Spencer Creek Watershed Assessment (BLM et al. 1995) and would improve watershed conditions where they are applied (appendix F.4, p. 2-186-191, table 2-73).

Three site-specific amendments of the Winema National Forest LRMP that have a nexus with the ACS are proposed to make provision for the Project (see appendix F.4, p. 2-183-186).

- Proposed amendments WNF-4 and WNF-5 would allow the Project to exceed detrimental soil conditions within the Project ROW. This would not prevent attainment of ACS objectives because soil decompaction and remediation required in Riparian Reserves is expected to effectively moderate detrimental soil conditions. Implementation of measures in the ECRP is expected to effectively control surface erosion and restore native vegetation (see section 4.3.4 of this EIS).
- Proposed amendment of the Winema National Forest LRMP to waive protection measures for Survey and Manage species would not prevent attainment of ACS objectives because the Project does not threaten the persistence of any riparian-dependent species (see appendix F.5).

The Project is otherwise consistent with Standards and Guidelines for activities in Riparian Reserves for the Winema National Forest.

The routing of the Project through NFS lands, coupled with the relatively small area of NFS land affected (0.41 percent of NFS in the fifth-field watershed), makes it highly improbable that the Project impacts could affect watershed conditions. Although there are project-level impacts (e.g., short-term sediment and long-term a change in vegetative condition at stream crossings), these would be minor in scale (see appendix F.4, table 2-77).

No Project-related impacts that would prevent attainment of ACS objectives have been identified. All relevant impacts are within the range of natural variability given the disturbance patterns and fire history of watersheds in the High Cascades Province (see appendix F.4, p. 2-176-181, table 2-70).

4.7.3.6 Resource Values and Conditions on Federal Lands: The Late Successional Reserve (LSR) System on National Forest System Lands

This section summarizes appendix F.3 (LSR Technical Report), which contains the full text of the independent Forest Service analysis. Reviewers who seek additional information should review the applicable section in appendix F.3. Section numbers that refer to sections in the appendix are so noted.

The LSR Network

The NWFP allocated a network of LSRs to conserve species of concern within the existing configuration of land ownership and the location of remaining LSOG forests within the range of the NSO (see appendix F.3 section 1.2).[154] The reserve network is embedded in a matrix of "working" forests and was designed to maintain LSOG forests in a well-distributed pattern across these federal lands (Moeur et al. 2011).

The LSR network is composed primarily of areas of large (mapped) reserves, but also includes smaller areas of "unmapped" reserves that are composed of sites occupied by marbled murrelets or are known northern spotted owl activity centers (KOAC). As presently configured the Pacific Connector pipeline would not cross any "unmapped reserves." The LSR standards and guidelines are designed to guide management activities occurring within these LSRs to protect and enhance the conditions of the LSOG forest ecosystems contained therein (Forest Service and BLM 1994b). The proposed Pacific Connector pipeline route would cross two mapped LSRs (LSR 223 on the Umpqua National Forest, and LSR 227 on the Rogue River National Forest).

LSR Standards and Guidelines

The standards and guidelines for LSRs are contained in Attachment A (pages C-9 through C-21) of the NWFP ROD. They are designed to protect and enhance conditions of LSOG forest ecosystems that serve as habitat for LSOG species. They are written to apply to specific management actions such as silviculture, range management, mining, new developments, etc., and should be interpreted in that context. The standards and guidelines that apply to new developments such as pipelines are addressed on page C-17 of the NWFP standards and guidelines. The standard on page C-17states:

> *Developments of new facilities that may adversely affect Late-Successional Reserves should not be permitted. New development proposals that address public needs or provide significant public benefits, such as powerlines, pipelines, reservoirs, recreation sites, or other public works projects would be reviewed on a case-by-case basis and may be approved when adverse impacts can be minimized and mitigated. These would be planned to have the least possible adverse impacts on Late-Successional Reserves. Developments would be located to avoid degradation of habitat and adverse impacts on identified late-successional species.*

The LSR standards and guidelines provide the framework upon which the proposed LSR mitigation actions and related plan amendments for the Pacific Connector pipeline are evaluated (see section 1.3.3 of appendix F.3). To meet this direction, the Forest Service has provided input to the applicant regarding project design. First, in routing the proposed project, LSRs have been avoided where possible. Second, where impacts to LSRs are unavoidable, on-site "Design Features" or "Project Requirements" have been developed to minimize the impacts. Third, in order to ensure that the objectives would continue to be achievable in these LSRs, land reallocations are being proposed as part of a compensatory mitigation plan. These proposed land reallocations would take non-LSR (i.e., matrix) lands and designate them as LSRs. The reallocations will require amendments of the LRMPs for the Umpqua National Forest and Rogue River National

[154] Originally the NWFP covered federal lands managed by the LM) and Forest Service within the range of the NSO. However, in August 2016, the BLM issued new Resource Management Plans that replaced the management direction for BLM lands. Therefore, the management direction in the NWFP no longer applies to BLM lands.

Forest. Fourth, off-site compensatory mitigation actions have been proposed to aid in off-setting unavoidable adverse impacts.

Project Impacts on LSRs on NFS Lands

The proposed pipeline would cross three national forests (Rogue River, Umpqua, and Winema) for a total of approximately 31 miles. The proposed project would affect mapped LSRs on the Rogue River and Umpqua National Forests. As presently configured, the proposed Pacific Connector project would not cross any LSRs on the Winema National Forest. Table 4.7.3.6-1 and figure 4.7-5 provide an overview of the number of acres that would be directly affected by the Project within LSRs on each affected unit of the Forest Service. The mapped LSR that would be crossed on the Umpqua National Forest is depicted in figure 4.7-5, and the mapped LSR that would be crossed on the Rogue River National Forest is depicted in figure 4.7-5.

TABLE 4.7.3.6-1

Direct Effects (a/) of the Proposed Project on Mapped LSRs (acres)

Forest	Cleared	Modified	Total Direct Effects
Umpqua National Forest	68	17	84
Rogue River National Forest	206	70	276
Total	**274**	**87**	**359**

a/ Direct effects include Pipeline corridor clearing, TEWAs, and UCSAs
Data source: Forest Service, GIS layers

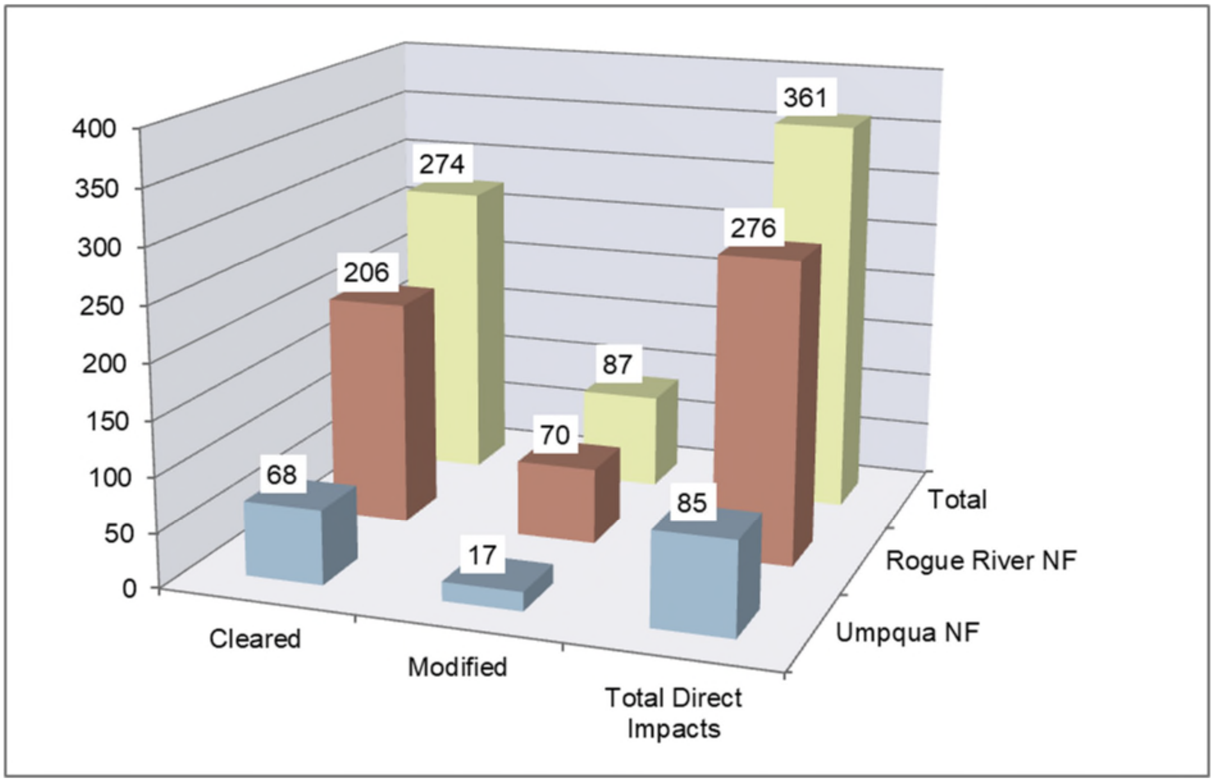

Figure 4.7-5. Direct Effects of the Proposed Project on Mapped LSRs (acres)

Direct effects would occur in the areas that would be cleared (i.e., forest vegetation would be removed) for the pipeline ROW and the TEWAs. Direct effects would also occur on acres that would be "modified" by the pipeline project. These acres include UCSAs that would not be cleared of trees during construction. These areas would be used to store forest slash, stumps, and dead and downed log materials that would be scattered across the ROW after construction, which would be considered temporary habitat modifications.

Indirect effects from construction of the pipeline are also expected within LSRs that have interior forest that the NSO rely on for nesting habitat. The conversion of large tracts of LSOG forest to small, isolated forest patches with large edge areas can create changes in microclimate, vegetation species, and predator-prey dynamics. Such edge effects–the magnitude of changes over distance from the edge to forest interior–would depend on the general orientation to the sun. Two main physical factors affecting and creating an edge microclimate are sun and wind (Forman 1995, Chen et al. 1995, Harper et al. 2005). Together, sun and wind: 1) desiccate leaves by increasing evapotranspiration; 2) influence which plant species survive and thrive along the edge, usually favoring shade-intolerant species; and 3) impact the soil, insects, and other animals along the edge. Compared to the forest interior, areas near edges receive more direct solar radiation during the day, lose more long-wave radiation at night, have lower humidity, and receive less short-wave radiation. However, such effects are dependent on such local conditions as orientation of an edge: the magnitudes of change in humidity with distance from an edge are most extreme with south-facing edges compared to east- and west-facing edges (Chen et al. 1995). These effects would vary along the pipeline route as a function of route orientation and the facing direction of each edge. Because the Pacific Connector pipeline generally trends from northwest to southeast, edge effects would be most pronounced on the southwest-facing edges and weakest along the northeast-facing edges. Fundamental changes in the microclimate (moisture, temperature, solar radiation) of a stand have been recorded greater than 700 feet from the forest edge (Chen et al. 1995).

Using recommendations from the ESA Sub-Task Group and Habitat Quality Subtask Group, indirect effects are considered to extend for 100 meters from the created edge in LSOG forest. In making their recommendation, the sub-task groups considered the study done by Karen A. Harper et al., which looked at edge influence on forest structure in fragmented landscapes (Harper et al. 2005). The study reviewed the effects caused by forest edges on multiple response variables, including: 1) forest processes of tree mortality/damage, recruitment, growth rate, canopy foliage, understory foliage, and seedling mortality, 2) forest structure by canopy trees, canopy cover, snags and logs, understory tree density, herbaceous cover, and shrub cover, and 3) stand composition by species, exotics, individual species, and species diversity. The study found that the mean distance of edge influence on any single response variable did not exceed 300 feet (100 meters). Therefore, indirect effects for the project are estimated to extend for 100 meters beyond the cleared area on each side of the corridor in LSOG forest habitat. There is no corresponding research for edge effects in younger forest stands (less than 80 years old). There is, however, research that indicates indirect effects extend out approximately two times the average tree height (Morrison et al. 2002). Based on this research, an estimate of 30 meters is used in non-LSOG forest habitat. In non-forested areas, no indirect effects are estimated since no new edge would be created. Table 4.7.3.6-2 and figure 4.7-6 provide a summary of the total number of LSR acres that would be directly and indirectly affected on Forest Service lands by the pipeline project.

The construction, operation, and maintenance of the proposed pipeline project would affect LSRs on Forest Service lands in several ways. It would remove and fragment LSOG forest habitat that some vertebrate and invertebrate species depend on. It would directly affect individuals of species listed as threatened under the ESA through removal of suitable nesting, roosting, and foraging habitat for the NSO. The indirect effects discussed above would result in the loss of interior LSOG forest habitat and increased predation (see also section 4.6 of this EIS for additional discussion).

TABLE 4.3.7.6-2

Summary of Total LSR Acres Directly and Indirectly (a/) Affected by the Proposed Project

Forest	Direct Effects	Indirect Effects	Total Effects
Umpqua	84	241	325
Rogue River	276	534	810
Total Forest Service	**360**	**775**	**1,135**

Data source: Forest Service GIS data layers
a/ Direct effects include cleared acres (corridor and TEWAs) and modified acres (UCSAs). Indirect effects include 100 meters on each side of the cleared corridor edge in LSOG, and 30 meters on each side of the cleared corridor edge in non-LSOG.

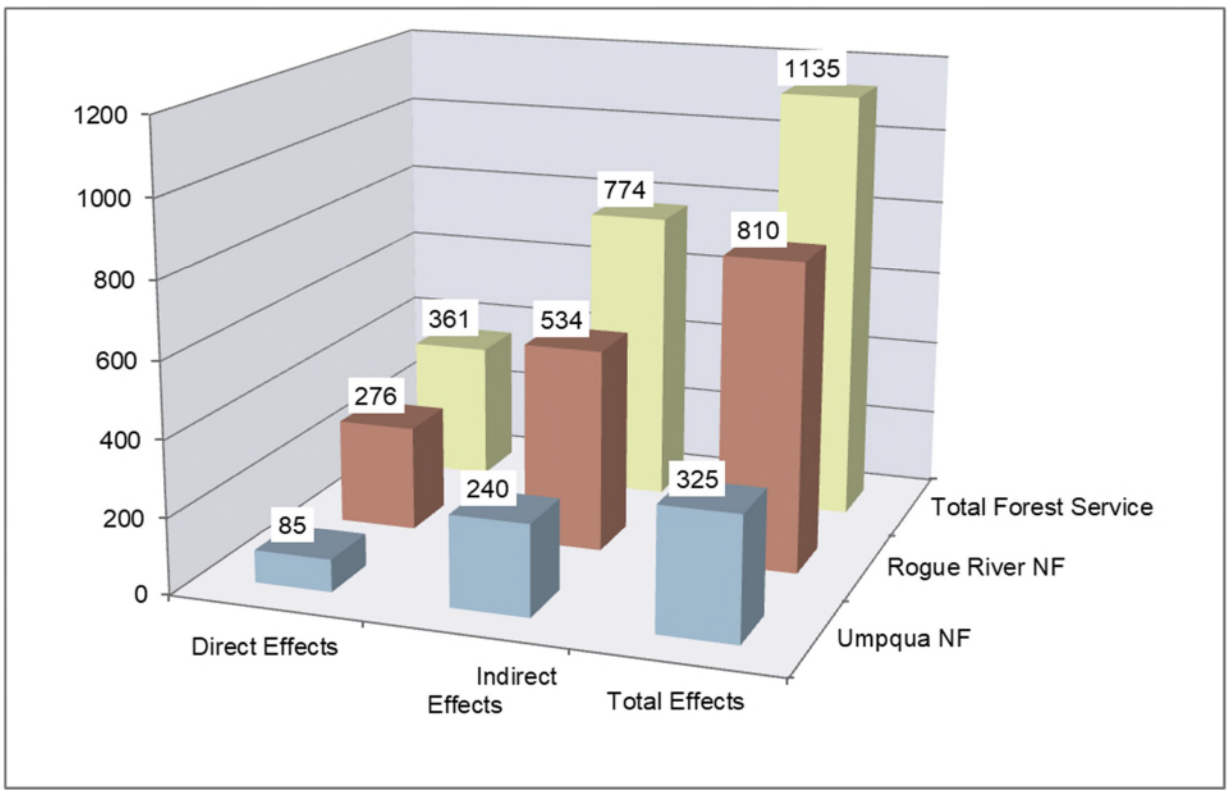

Figure 4.7-6. Summary of Total LSR Acres Directly and Indirectly Affected

The primary mitigation action for the effects of the proposed pipeline on LSRs would add acres to the LSRs. The Forest Service is proposing to accomplish this through reallocation of matrix lands to LSR. Reallocating these acres will require amendments to the Umpqua and Rogue River

National Forest LRMPs.[155] Table 4.7.3.6-3 and figure 4.7-7 display a summary comparison between the LSR acres that would be cleared by the construction of the project and the proposed reallocation of matrix lands to LSR.

TABLE 4.7.3.6-3

Comparison of Total LSR Acres Cleared (a/) by the Project and the Acres of Matrix Reallocated to LSR

	LSR Habitat Affected by Project Construction Clearing			**LSR Mitigation**
Forest	**LSOG Habitat**	**Non-LSOG Habitat**	**Total LSR Clearing**	**Matrix to LSR Reallocations**
Umpqua National Forest	20	48	68	585
Rogue River National Forest	55	151	206	522
Total	**75**	**199**	**274**	**1,107**

Data source: Forest Service GIS data layers
a/ Clearing includes acres in the project corridor and the TEWAs.

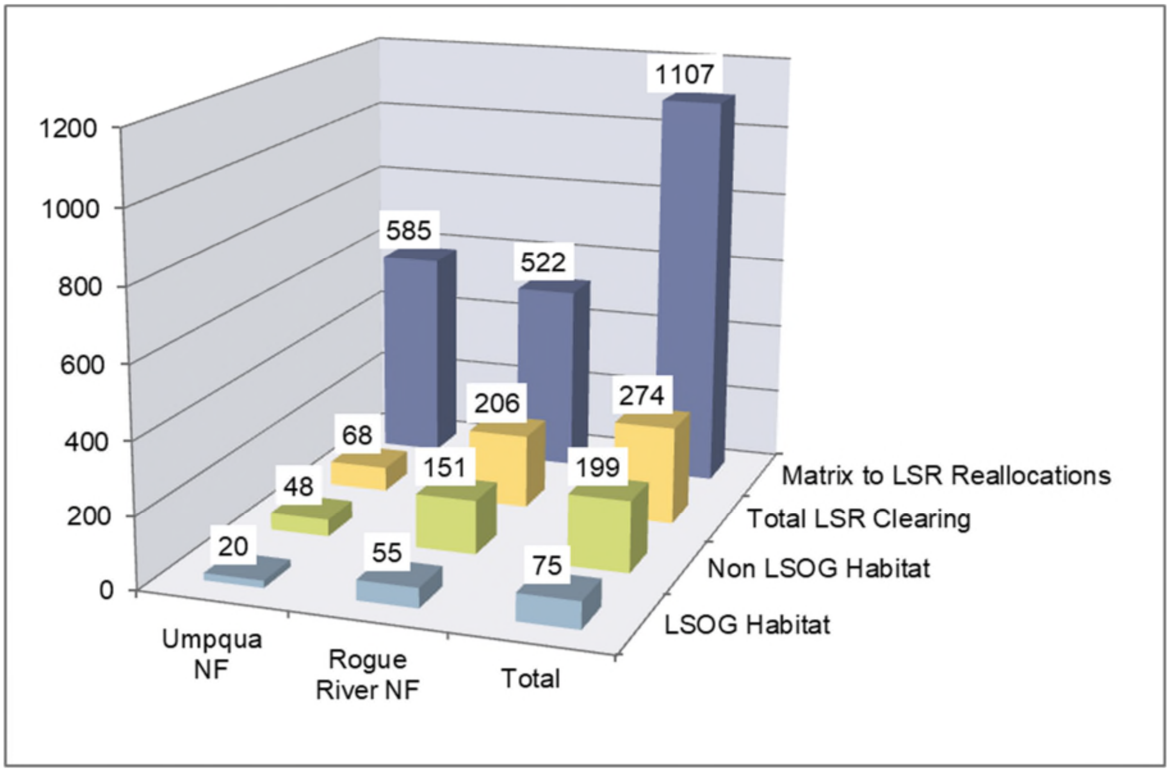

Figure 4.7-7. Comparison of Total LSR Acres Cleared by the Project and Total Acres of Matrix Reallocated to LSR

In addition to the reallocation of matrix lands to LSR, off-site mitigation would also be necessary to ensure that unavoidable adverse impacts are mitigated to meet the requirement that the overall impact would be either neutral or beneficial to the creation and maintenance of late-successional

[155] Evaluations of these proposed amendments and how they relate to the planning requirements in the Forest Service planning rule at 36 CFR 219 (2012 Version) is discussed in Section 4.7 of the DEIS and in appendix F.2.

habitat in LSRs (USDA and USDI Memorandum 2001). A Compensatory Mitigation Plan (CMP) on Forest Service lands has been developed by the agency for the project. A portion of the CMP was developed specifically to compensate for the unavoidable adverse impacts of the project on LSRs, to achieve a neutral or beneficial condition within affected LSRs, and to maintain the long-term integrity of the Forest Service land use plans for LSRs. Under the CMP, unavoidable impacts to LSOG forest habitats within LSRs on Forest Service lands would be compensated for by a set of off-site mitigation projects. These projects are discussed in the sections below (see also appendix F.3 sections 2.1 and 2.2, appendix F.2, and section 4.7.3.4 of this EIS).

Umpqua National Forest LSR 223

In the Umpqua National Forest, the construction of the project would directly affect (acres cleared plus acres modified) approximately 85 acres of LSR 223. A map of the proposed project and LSRs in the Umpqua National Forest is displayed in figure 4.7-8.

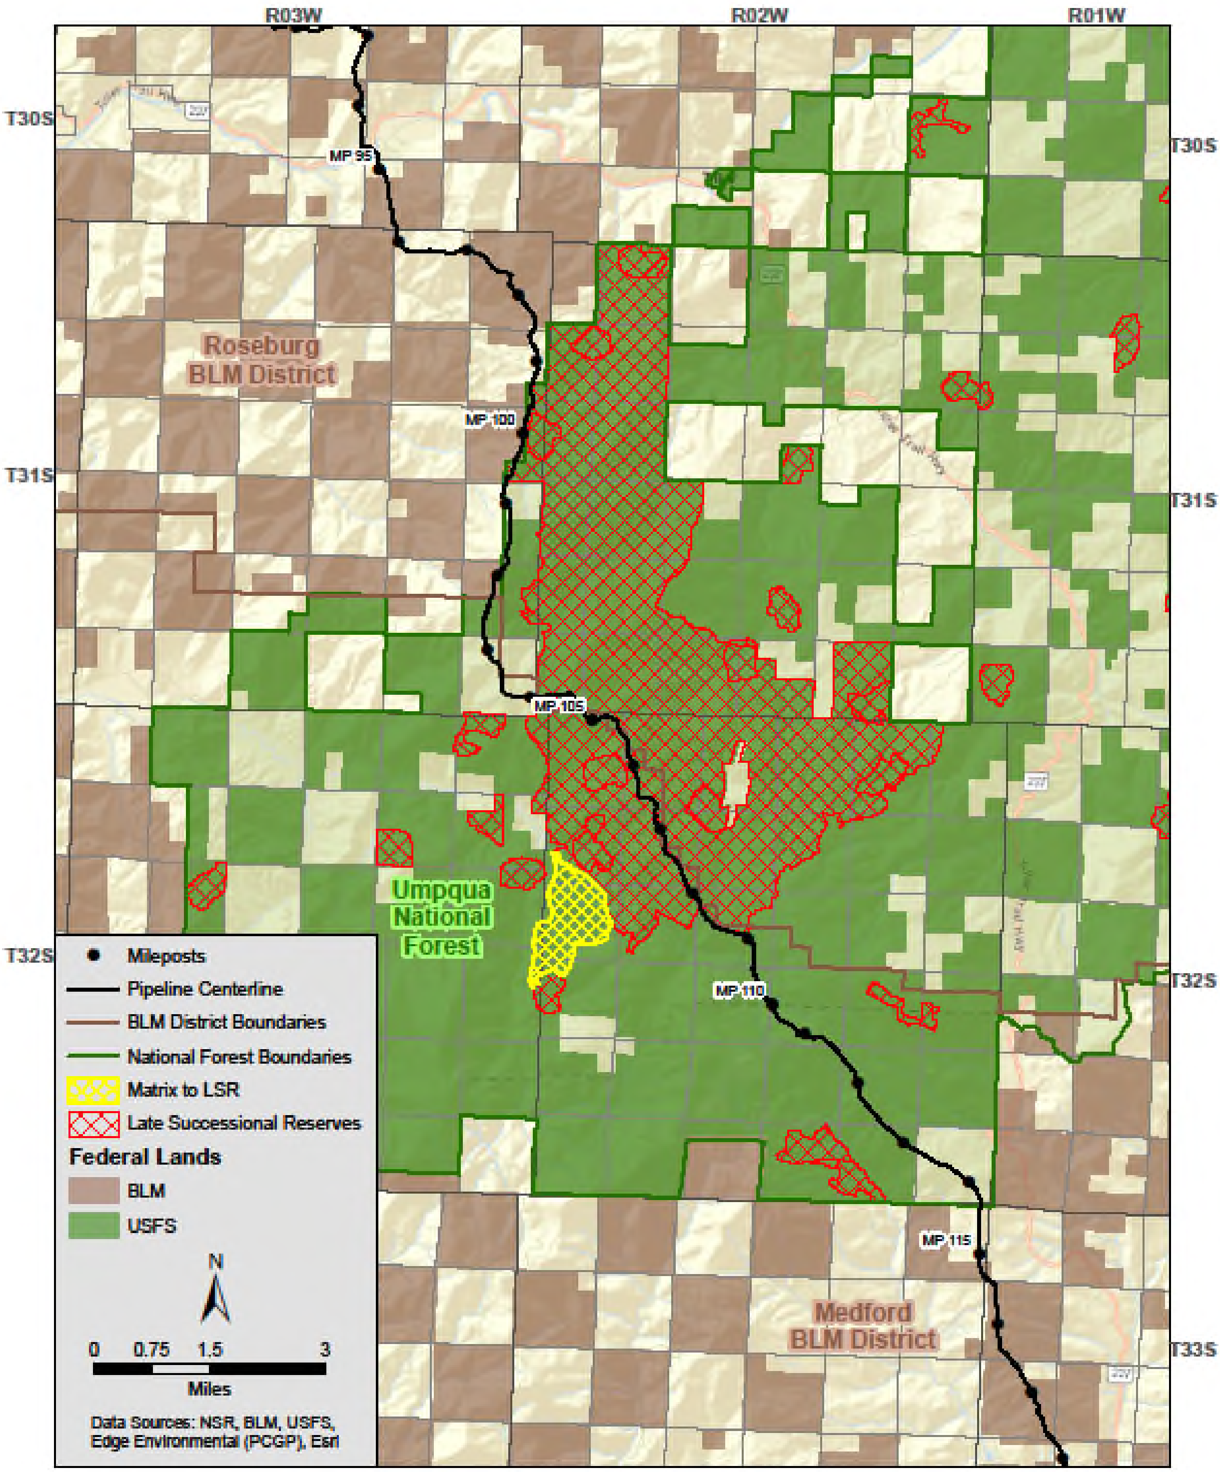

Figure 4.7-8. Map of Proposed Project and LSRs in the Umpqua National Forest

Amendment UNF-4, Reallocation of Matrix Lands to Late Successional Reserves

The Umpqua National Forest LRMP would be amended to change the designation of approximately 585 acres from the matrix land allocation to the LSR land allocation in Sections 7, 18, and 19, T.32 S., R. 2 W., Oregon; and Sections 13 and 24, T. 32 S., R. 3 W., W. M., Oregon (see figure 4.7-8). This change in land allocation is proposed to partially mitigate for the potential adverse impact of the project on LSR 223 in the Umpqua National Forest. This amendment would change future management direction for the lands reallocated from matrix to LSR.

Mitigation Actions

A compensatory mitigation plan has been developed by the Forest Service and submitted to the project applicant to ensure that the goals and objectives of the LRMP related to LSR 223 would be achieved.[156] Mitigation actions include:

- Creation of snags on 190 acres that are below desired snag densities for LSRs.
- Placing coarse woody debris (CWD) on 164 acres in units that are currently below desired levels for CWD.
- Decommissioning 5 miles of roads to reduce fragmentation and develop interior stand habitat over time.
- Thinning approximately 247 acres of overstocked stands to reduce fire risk and accelerate development of LSR characteristics.
- Integrated stand density and fuel break treatments on 898 acres in LSR 233 to restore stand density, species diversity, structural diversity and control the spread and intensity of wildfire within forested stands prone to fire activity.
- Other proposed mitigation actions in LSR 223 include 80 acres of meadow restoration, 301 acres of off-site pine removal, 6 miles of noxious weed treatments, fish passage improvement at two sites, 5 miles of road stormproofing and one water source improvement.

The off-site mitigation actions proposed are consistent with the recommendations in the Late Successional Reserve Assessment (LSRA) for LSR 223. These off-site mitigation actions would accelerate the development of LSOG forest habitat elements to further offset the effects of the project on LSR 223 in the long term. The additional off-site mitigation actions would also increase the effectiveness of the additional LSOG forest habitat added to LSR 223 by improving the quantity, quality, and distribution of high-quality habitat. Figure 4.7-9 displays a map of the proposed mitigation actions.

[156] This mitigation plan has been revised from the previous version based on the changed conditions in LSR 223 as a result of the 2015 Stouts Creek Fire (see Attachment 1 to appendix F.3).

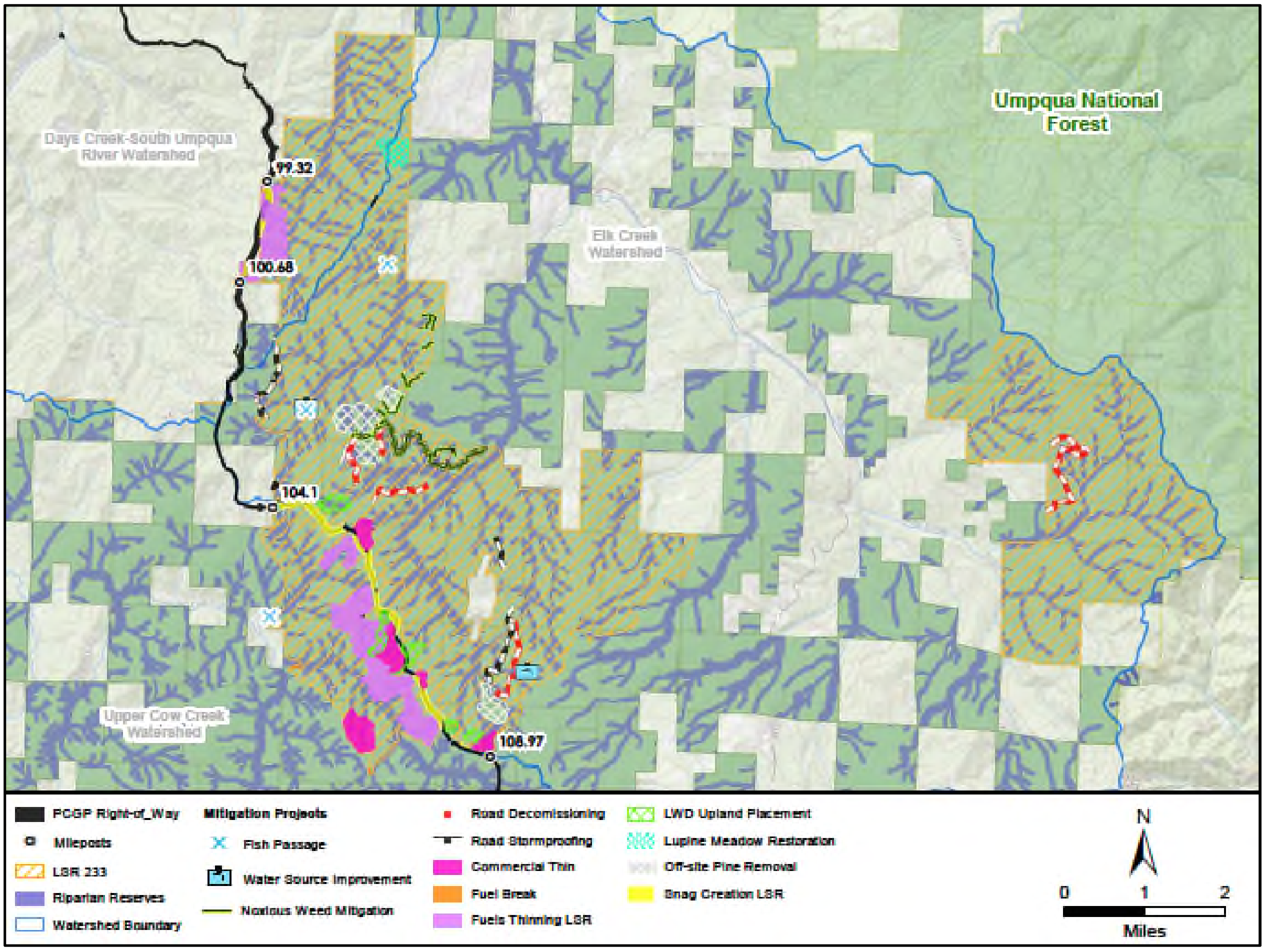

Figure 4.7-9. Proposed Off-Site Mitigation Actions in LSR 223

Assessment of Proposed Amendments and Mitigation Actions Relevant to LSR 223

The Project would clear approximately 68 acres in LSR 223, of which approximately 20 acres are LSOG forest. The area proposed to be reallocated to LSR 223 is approximately 585 acres of matrix lands, of which approximately 296 acres are LSOG forest. This change in land allocation is proposed to partially mitigate for the potential adverse impact of the Project on LSR 223 in the Umpqua National Forest. When acres reallocated from matrix lands to LSR are compared to the acres of LSR that would be cleared by the Project, the proposed amendment would reallocate over eight times more acres to LSR than would be cleared for the Project corridor. A comparison of the total acres affected in LSR 223 and the acres of reallocation are displayed in table 4.7.3.6-4 and figure 4.7-10 below.

TABLE 4.7.3.6-4

Comparison of LSR 223 Acres Affected (a/) by the Project and Acres of Matrix Reallocated to LSR

Umpqua NF LSR 223	Direct Effects: Cleared	Direct Effects: Modified	Indirect Effects	Total Effects	Matrix to LSR Reallocation
LSOG	20	6	166	192	296
Non- LSOG	48	11	74	133	289
Non-Forest	0	0	0	0	0
Total	**68**	**17**	**240**	**325**	**585**

a/ Total effects include cleared acres (corridor and TEWAs), modified acres (UCSAs), and indirect effect acres (100 meters on each side of the cleared corridor edge in LSOG and 30 meters on each side of the cleared corridor edge in non-LSOG).
Data source: USFS GIS Data Layers

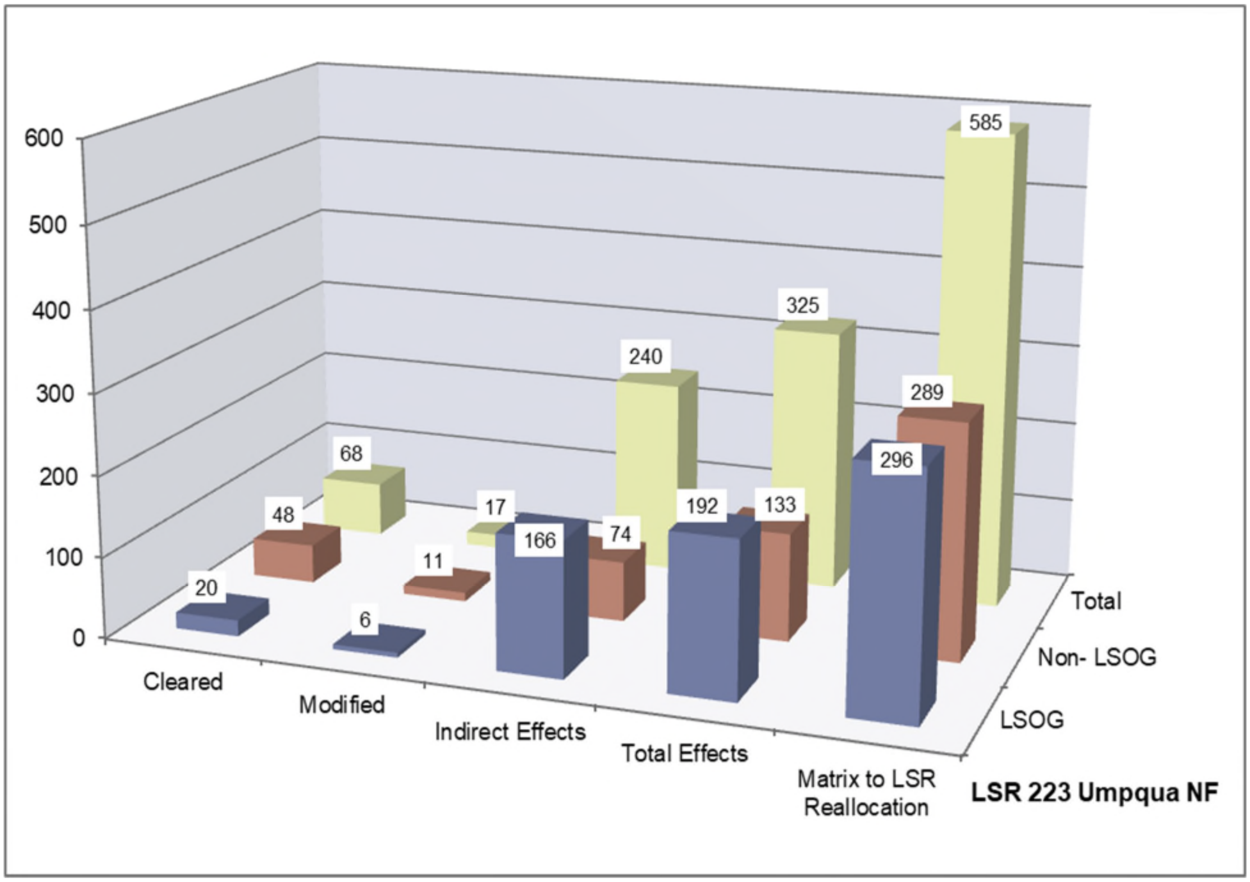

Figure 4.7-10. Comparison of Total LSR 223 Acres Affected by the Project and Acres of Matrix Reallocated to LSR

In addition to the Project impacts on LSR 223 in the Umpqua National Forest there are also potential off-site impacts to LSR 223 from road re-reconstruction that would be necessary to accommodate the trucks that would haul the sections of pipe. These trucks are longer than typical trucks that use forest roads, and some road widening and curve realignment may be necessary to safely allow for this truck traffic. Although this road widening would occur to the extent possible within the existing clearing limits, it is probable that some additional clearing of forest vegetation would be necessary to accommodate the road reconstruction. It is estimated that this would be a maximum of 2.5 acres and would occur along an existing road opening.

Assessment of Functionality of LSR 223 on the Umpqua National Forest and Consistency with LSR Standards and Guidelines

The functionality of LSR 223 relates directly to the goals and objectives for LSRs (see section 1.2 of appendix F.3) and can be measured by the quantity, quality, and distribution of LSOG forest habitat in the LSR and how the proposed project would impact these characteristics.

- Quantity: The overall quantity of LSOG habitat within LSR 223 on the Umpqua National Forest would increase with the proposed LRMP amendment. The project would remove approximately 20 acres of LSOG habitat but the reallocation would add 296 acres of LSOG habitat, for a net increase of 276 acres.

- Quality: The area proposed for reallocation to LSR 223 contains some large blocks of LSOG habitat and it would also be located immediately adjacent to two KOACs, providing further consolidation of LSOG habitat and increased protection of NSO habitat. With the reallocation of matrix to LSR and the consolidating of larger blocks of LSOG habitat, the quality of the LSOG habitat within LSR 223 would be slightly improved. There is also the benefit of the 289 acres of younger (less than 80 years old) stands in the reallocated acres being managed for future LSOG habitat, which would provide the potential for larger blocks of LSOG habitat.

- Distribution: The distribution of LSOG habitat within LSR 223 would remain largely unchanged with the proposed project and the reallocation of matrix to LSR LRMP amendment. To the extent there are minor changes, they would be beneficial due to the location of the proposed reallocation. The reallocation would occur on the southwest edge of the LSR, providing for some additional connectivity with the nearest LSRs to the south and west.

- The off-site mitigation actions would improve the quantity, quality, and distribution of LSOG habitat in LSR 223 by accelerating the development of constituent elements of late-successional habitat, reducing the risk of stand-replacement fire and reducing fragmentation through road decommissioning and stand-density management.

The project design features, the reallocations of matrix to LSR, and the off-site mitigation actions for LSR 223 in the Umpqua National Forest have been designed with the goal of making the overall impact of the Pacific Connector pipeline project either neutral or beneficial to the creation and maintenance of late-successional habitat. These actions combined would maintain or improve the functionality of LSR 223.

Rogue River National Forest LSR 227

The proposed project would cross approximately 13.7 miles of the Rogue River National Forest and, if constructed, would directly affect (corridor plus TEWAs and UCSAs) approximately 276 acres of LSR 227. The proposed project and LSR 227 in the Rogue River National Forest are displayed on figure 4.7-11.

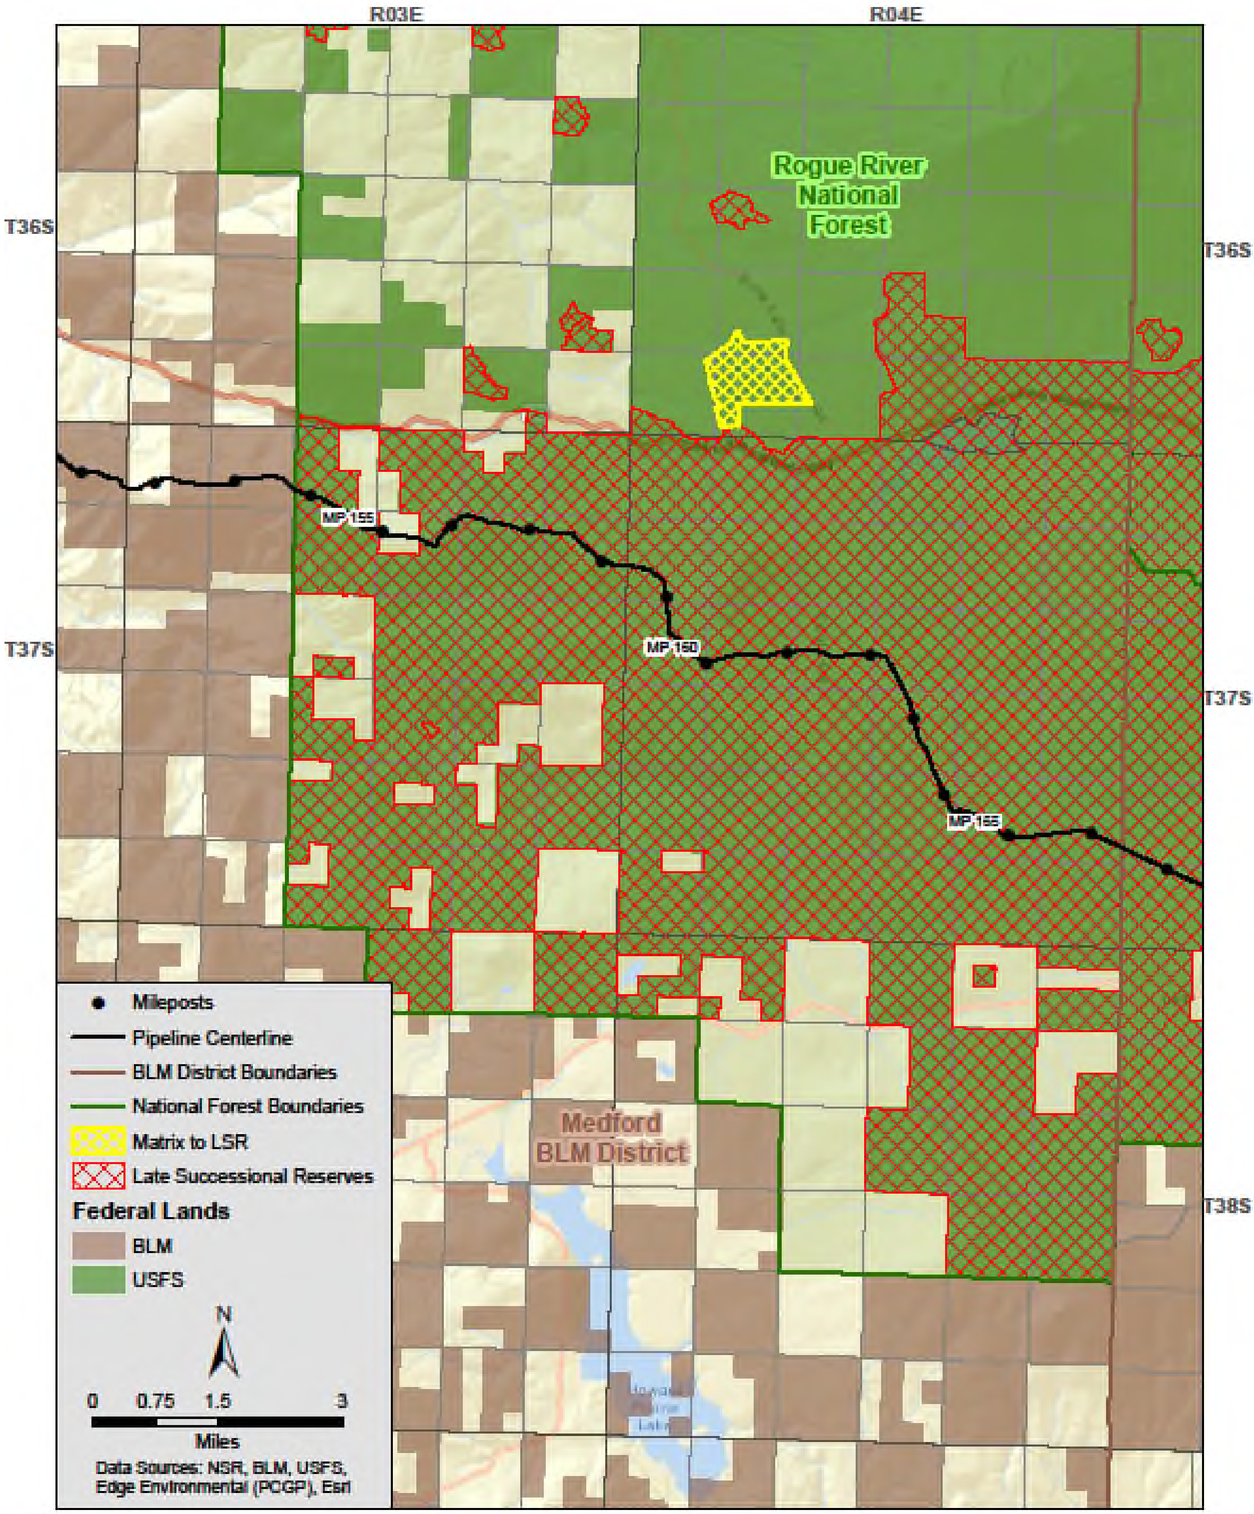

Figure 4.7-11. Map of Proposed Project and LSR in the Rogue River National Forest

Amendment RRNF-7, Reallocation of Matrix Lands to Late Successional Reserves

The Rogue River National Forest LRMP would be amended to change the designation of approximately 522 acres from the matrix land allocation to the LSR land allocation in Section 32, T.36 S., R. 4 E., W. M., Oregon (see figure 4.7-11). This change in land allocation is proposed to partially mitigate for the potential adverse impact of the project on LSR 227 in the Rogue River National Forest. The amendment would change future management direction for the lands reallocated from matrix to LSR.

Mitigation Actions

A compensatory mitigation plan has been developed by the Forest Service and submitted to the project applicant to ensure that the goals and objectives of the LRMP related to LSR 227 would be achieved (see appendix F.3 section 2.2). The lands in the Rogue River National Forest that would be affected by the proposed project are all within LSR 227. The primary objectives for the off-site mitigation actions are to accelerate the development of LSOG forest habitat in LSR 227. Mitigation actions include:

- Creation of snags on 622 acres that are below desired snag densities for LSRs.
- Placing CWD on 511 acres in units that are currently below desired levels for CWD.
- Decommissioning 57 miles of roads to reduce fragmentation and develop interior stand habitat over time.
- Thinning approximately 618 acres of overstocked stands to reduce fire risk and accelerate development of LSR characteristics.
- Other proposed mitigation actions in LSR 227 include placing large woody debris in approximately 1.4 miles of streams to improve fish habitat.

The off-site mitigation actions proposed are consistent with the recommendations in the LSRA for LSR 227. These off-site mitigation actions would accelerate the development of LSOG forest habitat elements to further offset the effects of the project on LSR 227 in the long term. The additional off-site mitigation actions would also increase the effectiveness of the additional LSOG forest habitat added to LSR 227 by improving the quantity, quality, and distribution of high-quality habitat. The proposed mitigation actions are displayed in figure 4.7-12.

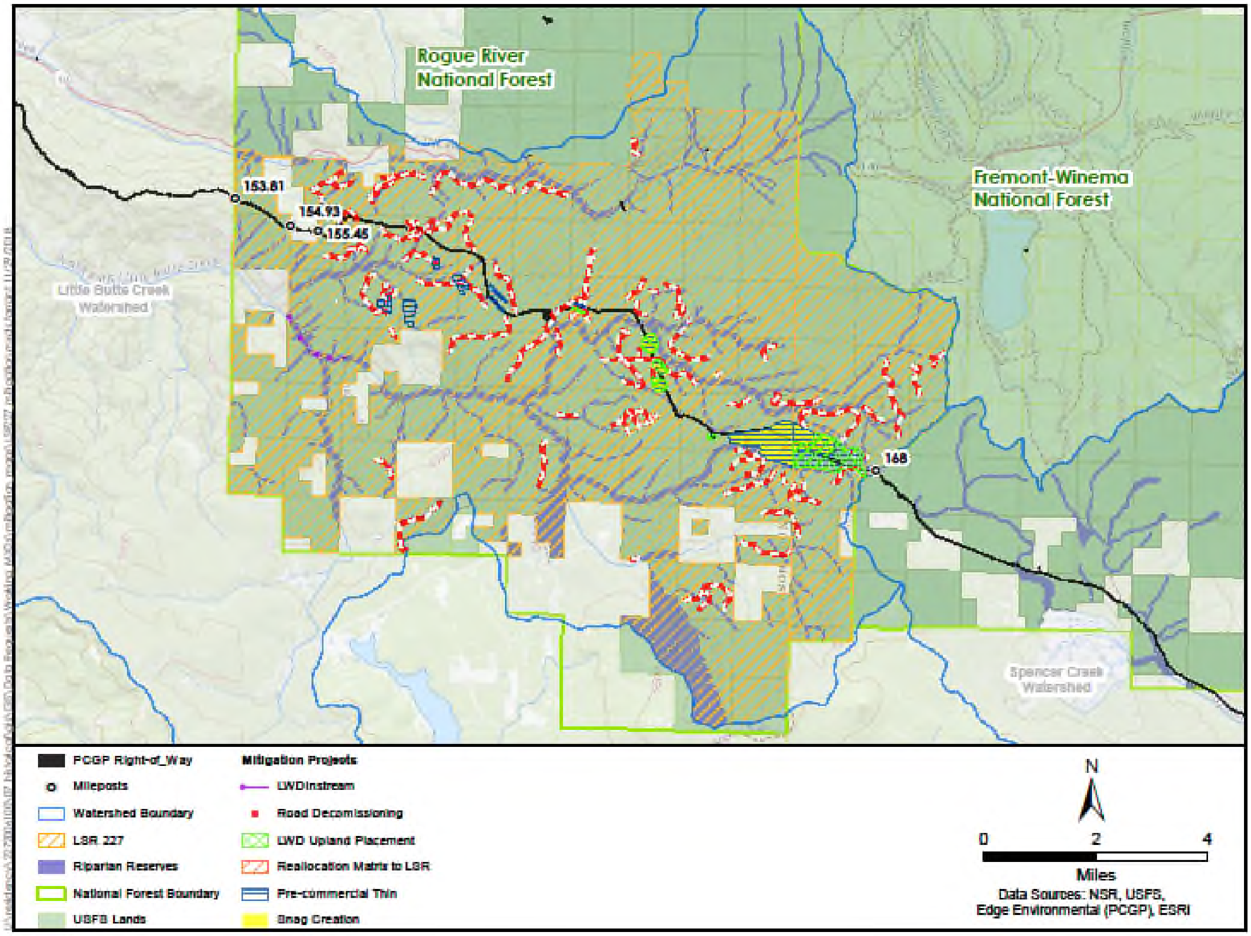

Figure 4.7-12. Proposed Off-Site Mitigation Actions in the Rogue River National Forest

Assessment of Proposed Amendments and Mitigation Actions Relevant to LSR 227

In the Rogue River National Forest, the proposed project would lie entirely within LSR 227. If constructed, the portion of the project on the Rogue River National Forest would be about 13.7 miles long and would clear approximately 206 acres of forest vegetation in LSR 227, of which approximately 55 acres are LSOG forest. The matrix area proposed for reallocation to LSR is approximately 522 acres, of which approximately 237 acres are LSOG forest (see figure 4.7-13). This change in land allocation is proposed to partially mitigate for the potential adverse impact of the project on LSR 227 in the Rogue River National Forest. When acres reallocated from matrix to LSR are compared to the acres of LSR that would be cleared by the project, the proposed amendment would reallocate about 2-1/2 more acres to LSR than would be cleared in the project corridor. When comparing acres of LSOG habitat, the proposed amendment would reallocate over 4 times more acres of LSOG habitat than would be cleared by the project. A comparison of the total acres affected in LSR 227 and the acres that would be reallocated are displayed in table 4.7.3.6-5 and figure 4.7-13 below.

TABLE 4.7.3.6-5

Comparison of Total LSR Acres Affected a/ by the Project and Acres of Matrix Reallocated to LSR

Rogue River National Forest LSR 227	Cleared	Modified	Indirect Effects	Total Effects	Matrix to LSR Reallocation
	Direct Effects				
LSOG	55	21	350	426	237
Non- LSOG	142	49	184	375	284
Non-Forest	9	0	0	9	1
Total	**206**	**70**	**534**	**810**	**522**

a/ Total effects include cleared acres (corridor and TEWAs), modified acres (UCSAs), and indirect effect acres (100 meters on each side of the cleared corridor edge in LSOG and 30 meters on each side of the cleared corridor edge in non-LSOG).
Data source: USFS GIS Data Layers

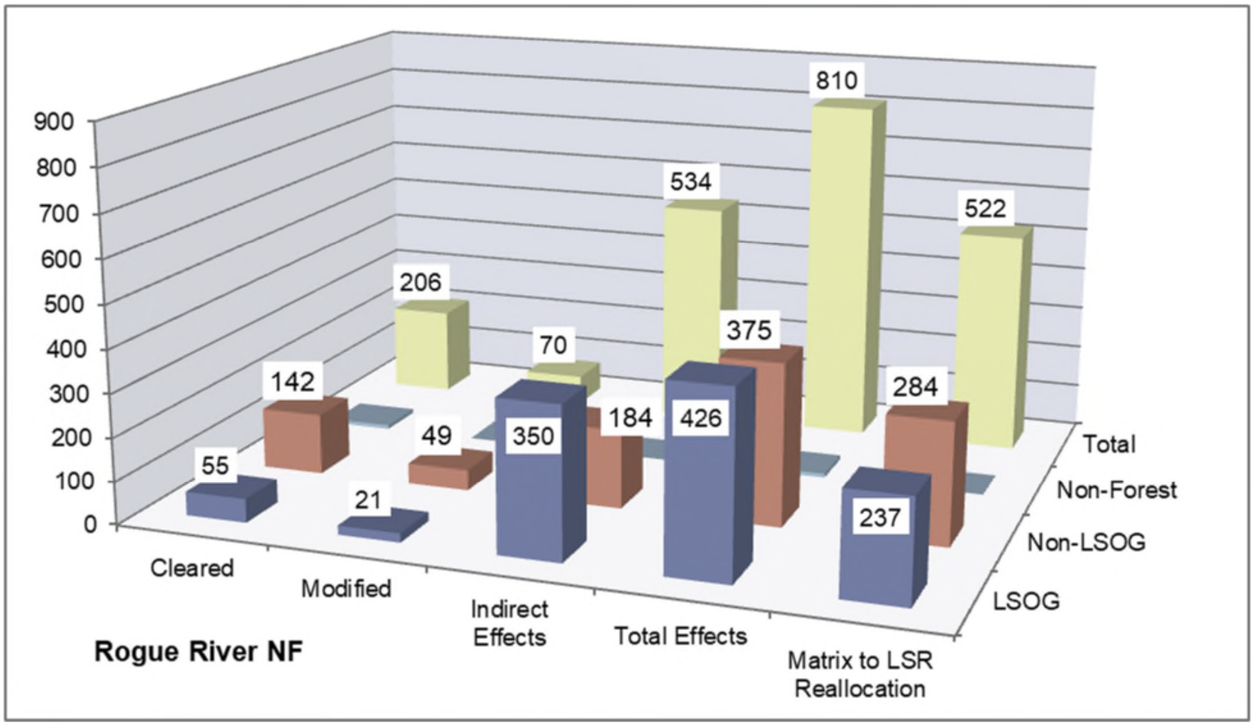

Figure 4.7-13. Comparison of Total LSR Acres Affected by the Project and Acres of Matrix Reallocated to LSR

In addition to the impacts of the pipeline corridor, there are also potential off-site impacts to LSR 227 from road reconstruction that would be necessary to accommodate the trucks that would haul the sections of pipe. These trucks are longer than typical trucks that use forest roads, and some road widening and curve realignment may be necessary to safely allow for this truck traffic. Although this road widening would occur to the extent possible within the existing clearing limits, it is probable that some additional clearing of forest vegetation would be necessary to accommodate the road reconstruction. It is estimated that this would be a maximum of four acres and would occur along an existing road opening.

Assessment of Functionality of LSR 227 on the Rogue River National Forest and Consistency with LSR Standards and Guidelines

The functionality of LSR 227 relates directly to the goals and objectives for LSRs (see section 1.2 of appendix F.3) and can be measured by the quantity, quality, and distribution of LSOG forest habitat in the LSR and how the proposed project would impact these characteristics.

- Quantity: The overall quantity of LSOG habitat within LSR 227 on the Rogue River National Forest would increase with the proposed LRMP amendment. The project would remove approximately 55 acres of LSOG habitat but the reallocation would add 237 acres of LSOG habitat for a net increase of 182 acres.

- Quality: The area proposed for reallocation to LSR 227 contains some large blocks of LSOG habitat. With the reallocation of matrix to LSR and the consolidating of larger blocks of LSOG habitat, the quality of the LSOG habitat within LSR 227 would be slightly improved. There is also the benefit of the 284 acres of younger (less than 80 years old) stands in the reallocated acres being managed for future LSOG habitat that would provide the potential for larger blocks of LSOG habitat.

- Distribution: The distribution of LSOG habitat within LSR 227 would remain largely unchanged with the proposed project and the reallocation of matrix to LSR LRMP amendment. To the extent there are minor changes, they would be beneficial due to the location of the proposed reallocation. The reallocation would occur on the north end of the LSR, providing for some additional connectivity with the nearest LSRs to the north.

- The off-site mitigation would improve the quantity, quality, and distribution of LSOG habitat in LSR 227 by accelerating the development of constituent elements of late-successional habitat, reducing the risk of stand-replacing fire, and reducing fragmentation through road decommissioning and stand-density management.

The Project design features, the reallocation of matrix to LSR, and the off-site mitigation actions for LSR 227 in the Rogue River National Forest have been designed with the goal that the overall impact of the Pacific Connector pipeline project would be either neutral or beneficial to the creation and maintenance of late-successional habitat. These actions combined would maintain or improve the functionality of LSR 227.

4.7.4 Conclusion

Constructing and operating the Project would have both temporary and permanent effects on land use. Some land uses would be permanently converted to industrial use, others (such as affected orchards, vineyards, and forests) would no longer being permitted directly over the pipeline, Other land uses would be converted to more natural conditions than they are currently (as part of the proposed Project-related mitigation sites). Based on the proposed mitigation and minimization measures the Project would not significantly affect land use.

4.8 RECREATION AND VISUAL RESOURCES

4.8.1 Recreation and Public Use Areas

4.8.1.1 Jordan Cove LNG Project

Parks and Other Recreational Use Areas

Land on the North Spit is managed and owned by several public agencies, including the COE, BLM, Forest Service, State of Oregon, and the Port, as well as private entities such as Roseburg Forest Products, D.B. Western, and Southport. The COE manages 245 acres on the Spit, including the North Jetty at the mouth of Coos Bay.

The Jordan Cove LNG Project would be located on the North Spit of Coos Bay, on private land. No recreational activities would be allowed within the facility boundaries. Parks and recreational areas in the general vicinity of the Project site are shown on figure 4.8-1 and discussed in the following sections.

BLM Coos Bay/North Spit Shorelands

The North Spit of Coos Bay is a strip of land between the Pacific Ocean and the waters of Coos Bay. This peninsula area contains both industrial and semi-wild areas. The BLM administers 1,864 acres on the Spit, with 709 acres classified as an Area of Critical Environmental Concern (ACEC) and the remainder designated as Recreation Management Areas (RMAs). BLM (2016a) designated four RMAs within the Coos Bay/North Spit area as part of the Northwestern and Coastal Oregon Record of Decision and Approved Resource Management Plan. The four RMAs are: Bastendorff Beach (a 53-acre Special Recreation Management Area [SRMA]), Coos Head (an approximately 11-acre SRMA), North Spit Boat Ramp (a 5-acre SRMA), and the North Spit Trail System (a 1,505-acre Extensive Recreation Management Area [ERMA]).[157] These SRMA and ERMA areas provide non-motorized and motorized recreation opportunities along the Pacific Coast and in the greater Coos Bay area for use by the local community and regional visitors.

The closest of these RMAs to the Jordan Cove LNG Project is the North Spit Trail System, which is approximately 300 feet from the Trans-Pacific Parkway. The BLM boat launch facility and courtesy dock, which provides access to the Coos Bay estuary and is also part of the SRMA, is approximately 0.16 mile southwest of the LNG terminal site. These four areas include designated roads and trails for OHV use. These roads are also available to hikers and equestrians. The BLM estimated that in a typical year about 2,460 OHVs and approximately 6,150 people traveled on the sand road to the North Jetty. According to the BLM, about 13,100 vehicles visited the boat dock in a single year, and about 420 boats were launched (BLM 2006b). Cross country areas in the Bastendorff Beach, Coos Head, and North Spit Trail System RMAs are available for non-motorized use only.

[157] SRMAs are defined by the BLM as administrative units where recreation opportunities and setting characteristics are recognized for their unique value, importance, and/or distinctiveness, especially as compared to other recreation areas. ERMAs are administrative units that require specific management consideration to address recreation use, demand, and/or related investments (BLM 2016a).

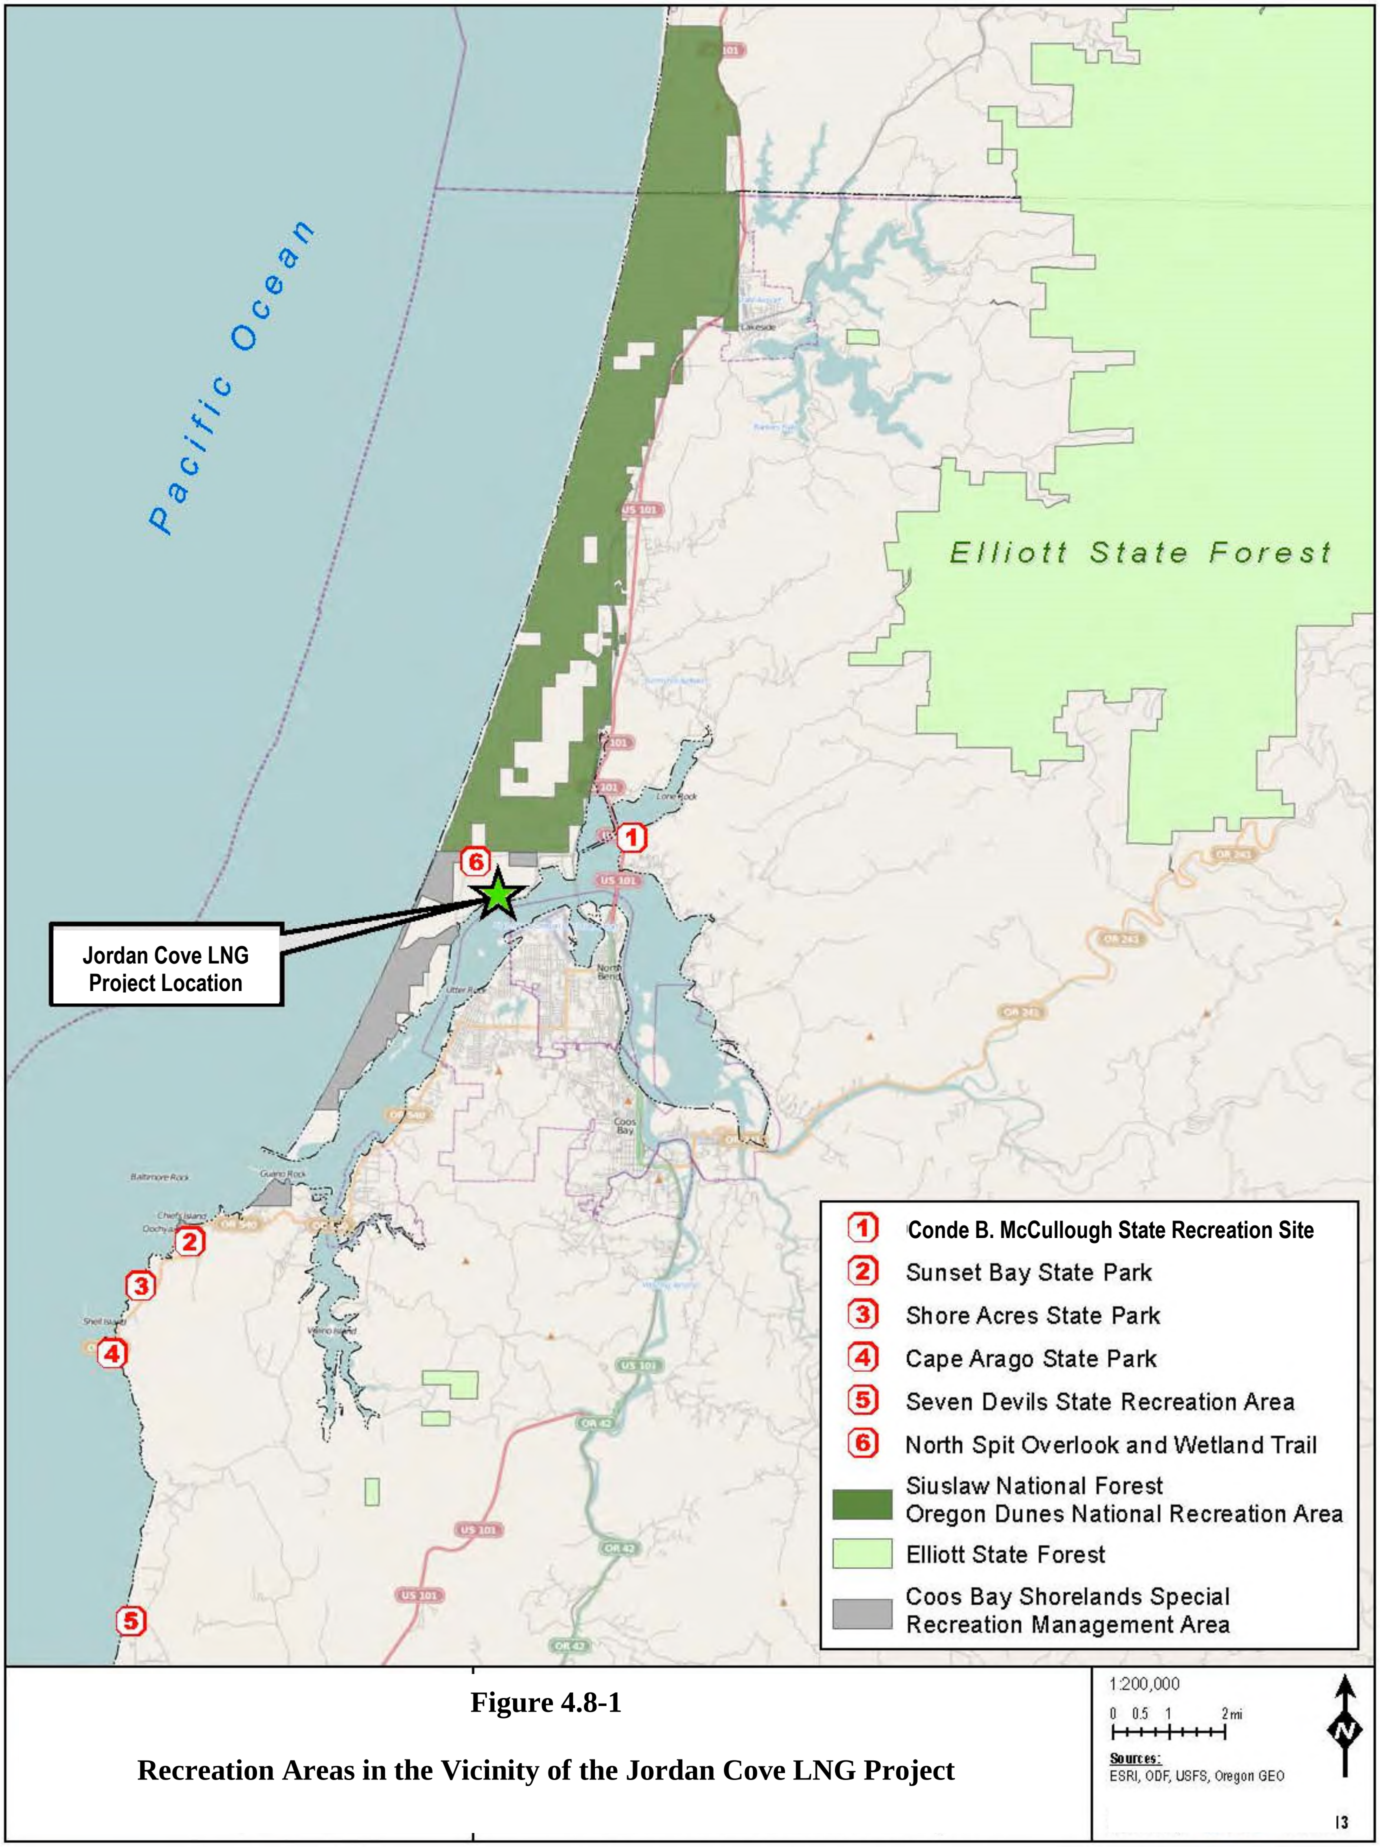

Figure 4.8-1

Recreation Areas in the Vicinity of the Jordan Cove LNG Project

Oregon Dunes National Recreation Area

The Forest Service manages the ODNRA within the Siuslaw National Forest at the north end of the Spit. The ODNRA extends approximately 45 miles along the Oregon Coast from Coos Bay north to Florence. The southern boundary of the ODNRA is about 100 feet north of the Jordan Cove LNG terminal site, across the Trans-Pacific Parkway. The Horsfall Campground is located about 0.5 mile northeast of the LNG terminal site.

The ODNRA contains the largest expanse of coastal sand dunes in North America, as well as a coastal forest and over 30 lakes and ponds. Recreational opportunities at the ODNRA include OHV use, hiking, camping, horseback riding, angling, canoeing, sailing, waterskiing, and swimming. There are approximately 34 miles of designated OHV routes open to all classes of OHVs, and roughly 135 miles of unofficial user-developed routes that are technically closed (Forest Service 2012b). The ODNRA south of Horsfall Road is closed to OHV travel, except along the beach. Day use and overnight camping facilities within the ODNRA are visited by approximately 1.0 to 1.5 million people each year (Forest Service 2009, 2012c). The Forest Service identified 1.6 million visits to the Siuslaw National Forest, including the ODNRA, in 2011, with 23.6 percent of visitors engaging in OHV use, including 18.2 percent of visitors who identified OHV use as their main activity and spent an average of 6.6 hours participating in OHV use per visit (Forest Service 2012c).

National Wildlife Refuges

Two NWRs are located near the North Bank upland wildlife habitat mitigation site (North Bank mitigation site). The 889-acre Bandon Marsh NWR is located adjacent to the North Bank mitigation site, near the mouth of the Coquille River. The lower Coquille River estuary provides important habitat for juvenile and adult anadromous fish species, including coho and Chinook salmon, steelhead, and cutthroat trout (FWS 2018c). The Oregon Islands NWR includes 1,853 rocks, reefs, and islands and extends from Tillamook, Oregon to the Oregon/California border. The refuge also protects two headlands: Coquille Point and Crook Point. Coquille Point, located approximately 5 miles from the North Bank mitigation site, provides a buffer zone between mainland development and the islands, and provides opportunities to watch seabirds and harbor seals, as well as a paved trail and interpretive panels (FWS 2018d).

State of Oregon

Pacific Ocean Beaches

The OPRD controls the Pacific Ocean beaches below the high tide mark on the west side of the Spit, while the ODSL possesses the beach land below mean low tide, including submerged lands (BLM 2005). A survey conducted on behalf of the OPRD found that the 15-mile stretch of beach along the ocean from Ten Mile Creek to the mouth of Coos Bay was visited by an average of 38 people on a weekday, and 60 people on a weekend day (Shelby and Tokarczyk 2002). The main activities of beach visitors in this area include OHV use (54 percent), relaxing (21 percent), walking (16 percent), and recreational activities with dogs (4 percent). Surfing is also a recreational activity in the ocean along the North Spit.

Oregon State Parks and Recreation Areas

Four state parks and two state recreation areas are located within 15 miles of the Project. The closest of these is the Conde B. McCullough State Recreation Site, located approximately 2.4 miles northeast across Highway 101 from the Jordan Cove LNG Project. Located along the southern shore of Haynes Inlet, this narrow shoreline recreation site is largely forested, with a small parking lot near a boat ramp at its eastern end. Only day-use recreation is permitted. The remaining five sites—the William M. Tugman, Sunset Bay, Shore Acres, and Cape Arago State Parks, and the Seven Devils State Recreation Site—are all located more than 8 miles from the Jordan Cove LNG Project. In addition, two state parks are located near the North Bank mitigation site. Bullards Beach State Park is located approximately 0.75 mile west of the North Bank mitigation site. Park facilities include campsites, a horse camp, a hiker/biker camp, and a boat ramp, and also provides access to the historic Coquille River Lighthouse (Oregon State Parks 2018). Face Rock State Scenic Viewpoint is located about 0.2 mile from the North Bank mitigation site. Amenities include picnic tables, restrooms, a viewing scope, and a stairway and trail to the beach.

Oregon State Forests

Elliott State Forest, located in the Coast Range approximately 7.8 miles to the northeast, is the closest state forest to the Jordan Cove LNG Project. Elliott State Forest is a contiguous block of land about 18 miles long (north to south), and about 16 miles wide (west to east) that encompasses approximately 93,000 acres, primarily in Coos and Douglas Counties. Although Elliott State Forest is managed primarily for timber production, recreation uses on the forest include dispersed camping, fishing, OHV use on forest roads and designated trails, horseback riding, hunting, and low amounts of hiking and mountain biking.

North Spit Overlook

The North Spit Overlook and nature trail are located about 0.5 mile west of the Jordan Cove LNG Project, on the north side of the Trans-Pacific Parkway. These facilities are maintained by Weyerhaeuser, a forest products company, to provide the public an opportunity to observe wildlife and birds in the vicinity of its former wastewater lagoon on the North Spit. Typically open to the public for nature studies, birding, walking, and photography, the gate providing access to the overlook and trails has been closed in recent years.

Coos Bay Estuary

Coos Bay estuary spreads nearly 20 square miles, offering many recreational opportunities including boating, fishing, clamming, and crabbing. The Coos Regional Trails Partnership (2004), a loose consortium of federal land management agencies and local economic development entities, developed a brochure that maps Coos Bay's water trails where canoeists and kayakers can enjoy the sloughs, bay islands, and rivers draining into the bay. The water trails closest to the LNG terminal site are approximately one mile northeast in North Slough and Haynes Inlet east of the Central Oregon and Pacific Railroad Bridge that crosses Coos Bay. A separate water trail is identified for Coos Bay east of the Highway 101 bridge. The section of Coos Bay south of the LNG terminal site is not identified as part of the water trail system (Coos Regional Trails Partnership 2004).

Oregon Coast Trail

The Oregon Coast Trail passes within 0.5 mile of the Jordan Cove LNG Project and the meteorological station site, where the trail follows Horsfall Beach Road and joins the Trans-Pacific Parkway. The Oregon Coastal Trail is a 360-mile-long hiking trail that extends south from the Columbia River to the California border. The trail was created by the Oregon Recreation Trails Advisory Council and is managed by the OPRD as part of the state park system. The trail crosses beaches, follows roads, passes through forests, and hugs coastal headlands. The majority of the trail is on the beach, but approximately 1.25 miles north of the Jordan Cove LNG Project, the trail leaves the beach at Horsfall Beach Access Road and becomes an inland trail. After heading east along Horsfall Beach Access Road, the inland trail turns east along the Trans-Pacific Parkway, and then south on U.S. Highway 101 heading into the city of North Bend. The inland trail continues through North Bend on city streets and then continues south to Charleston and then out to Sunset Bay State Park.

Oregon Coast Bike Route

The Oregon Coast Bike Route is a 370-mile-long signed bicycle route that primarily follows U.S. 101 as a shoulder bikeway and passes near the terminal, following U.S. Highway 101 through the Trans-Pacific Parkway/U.S. 101 intersection. In several areas, the route departs from the main highway and follows county roads and city streets. This occurs in North Bend, where bicyclists follow the North Bend Bypass and avoid heavy commercial and truck traffic on U.S. 101 through North Bend and Coos Bay. The bypass passes south of Pony Slough on Virginia Avenue and then turns south on Broadway Street, approximately 1.7 miles south of the Jordan Cove LNG Project. At Newmark Avenue (Cape Arago Highway), the bypass turns west and continues to South Empire Boulevard, where it continues south to Charleston, crossing the South Slough Bridge. Leaving Charleston, the bypass turns south on Seven Devils Road. In Bandon, near the North Bank mitigation site, the route runs along Riverside Drive, Ocean Drive, and Beach Loop Road through historic Old Town.

City of North Bend Parks

There are eight existing parks, one planned park, and a boat ramp in the city of North Bend. Three of these parks and the boat ramp are within 3 miles of the Jordan Cove LNG Project. Simpson Park, located approximately 1.9 miles to the southeast, is mostly forested land for day-use, low intensity recreation. Ferry Road Park, located approximately 1.9 miles to the southeast, across U.S. Highway 101 from Simpson Park and the terminal, is a developed recreation site, with a baseball diamond, a pavilion available for rent from the North Bend Parks Department, and restrooms. Winsor Park, also located approximately 1.9 miles to the southeast, on the east side of U.S. 101, is mostly forested, with an open field for recreational activities. All three parks are located close to the APCO laydown site. The California Street Boat Ramp is located approximately 2.5 miles southeast of the Jordan Cove LNG Project.

City of Coos Bay Parks

Parks operated by the City of Coos Bay Parks Department include John Topits Park, Hollering Place Wayside, Mingus Park, and a series of neighborhood pocket parks. Hollering Place Wayside and Ed Lund Park, one of the neighborhood pocket parks, are the closest of these facilities to the Jordan Cove LNG Project; both are located about 2 miles to the south. Hollering Place Wayside was the location of a pre-European village and also the site of the first European settlement in what would become Coos County. Today, the location offers water views and a place for a picnic. Ed Lund Park includes a children's play area, a large lawn, horseshoe pits, picnic tables and benches, and is the site of many community activities, including the annual Empire Clamboree.

City of Bandon Parks

Three city parks (i.e., Bandon City Park, Kronenberg County Park, and Weber’s Pier) are located approximately 3 miles southwest of the North Bank mitigation site. In addition, private recreation facilities in the vicinity of the North Bank mitigation site include three golf courses north of Bullards Beach State Park, a youth center, and an RV park.

Impacts on Parks and Other Recreational Use Areas

Increased Demand from Construction Workers

The temporary influx of non-local construction workers could potentially increase demand for recreational activities at the parks and other recreational use areas located near the Jordan Cove LNG Project. An estimated average of 802 non-local workers are expected to be employed over the 53-month-long construction phase, with the number of non-local workers expected to peak at 1,568 workers during month 30. Assuming that a portion of the workforce temporarily relocating to the area would be accompanied by family members, temporary increases in population would range from the equivalent of 3.4 percent to 6.6 percent of the combined populations of Coos Bay and North Bend in 2016 (section 4.9). A share of these workers and family members may seek recreational opportunities near the Jordan Cove LNG Project. Demand would primarily be limited to periods when workers are not employed, primarily weekend days, and would be temporary and short term. Given the large amount of public lands in the region and the relatively low levels of current use, this potential short-term increase in demand is not expected to result in significant effects on parks and other recreational areas.

Noise

Construction and operation of the Jordan Cove LNG Project could result in increases in the ambient sound environment for people recreating in the immediate vicinity, including users of the North Spit Overlook, coastal beaches, BLM RMAs, and ODNRA. Noise modeling (discussed in more detail in section 4.12 of this EIS) indicates that expected Project construction noise levels at the closest noise sensitive area (REC 1, which is located about 0.7 mile from the LNG terminal and is representative of the closest areas of federally managed lands on the North Spit) would temporarily result in noise levels increasing from ambient levels of approximately 55 A-weighted decibels (dBA)to 57 dBA.

OHVs that are allowed on the beach and dune trails contribute to the ambient noise levels on the North Spit. The noise limit for OHVs in the ODNRA is 93 dBA at 20 inches from the exhaust outlet (Forest Service 2013). For OHV riders and other people in close proximity, OHV sound levels would exceed the predicted Project's construction and operational noise levels. Distance, topography, coastal winds, and vegetation would help to minimize Project construction and operational noise in the portions of the ODNRA where OHVs are not allowed (between the Trans-Pacific Parkway and Horsfall Beach Access Road).

Recreation Access and Driving for Pleasure:

There may be some conflicts between recreational drivers on the Trans-Pacific Parkway and construction traffic traveling to and from the Jordan Cove LNG Project. Recreational drivers in this context could include recreationists using the Trans-Pacific Parkway to access recreation sites, including the ODNRA, as well as people recreating by driving for pleasure.

Traffic counts conducted in support of the Traffic Impact Analysis prepared on behalf of Jordan Cove (David Evans & Associates, Inc. [DEA] 2017b) counted a total of 232 vehicles passing through the intersection of the Trans-Pacific Parkway and Horsfall Beach Road from 4:30 p.m. to 6:30 p.m. on a Friday afternoon in August 2015. DEA (2017b) estimates that the number of vehicles traveling to and from the Jordan Cove LNG Project would peak in 2021, with 945 workers driving to the site in two staggered shifts each day, and 140 long haul truck trips each day to and from U.S. 101 via the Trans-Pacific Parkway to the site/north laydown yard, and 2 long haul trips each day to and from U.S. 101 via Ferry Road to the south laydown yard. DEA (2017b) assumed that the truck trips would occur throughout the day. Although the number of construction workers employed on-site would be higher in 2022, the number of passenger vehicles traveling to and from the terminal site would decrease with the addition of the temporary workforce housing facility on South Dunes, and external park and ride lots. The addition of construction-related traffic could cause potential delays at key intersections as discussed in section 4.10 during peak hours. Mitigation measures, also discussed in section 4.10, are expected to reduce potential effects, and recreationists could avoid delays by traveling outside of peak commuting hours. Mitigation would likely include staggered work shifts, construction of a dedicated eastbound left-turn lane at the intersection of U.S. 101 at the Trans-Pacific Parkway, and implementation of a temporary signal at the intersection for the duration of construction activities (see section 4.10).

Hunting

Hunting activities are managed by the ODFW. Big game, waterfowl, and fur-bearing animals are hunted in the public areas of the North Spit and within the Siuslaw National Forest during hunting seasons. The influx of Jordan Cove workers to the area could add to the number of people who would hunt on public lands in the region during hunting seasons. However, this potential increase would be temporary and short term. The total construction period would be about 53 months and most construction jobs would last for less than two years. As noted with respect to overall project-related demand for recreation, workers temporarily relocating to the area would have limited time available to hunt, primarily weekend days.

Clamming and Crabbing in Coos Bay

Recreational clamming and crabbing activities occur in Coos Bay near the Jordan Cove LNG Project. Coos Bay was the third most productive clamming estuary in Oregon as of 2008 and an annual average of 15,000 crabbing trips took place between 2008 and 2011 (Ainsworth and Vance 2009; Ainsworth et al. 2012). Sites for clamming include the mud flats on the bay side of the North Spit, the northern reaches of South Slough, in Haynes Inlet and the eastern side of the bay north of the McCullough Bridge. Crabbing takes place from the docks in Charleston and Empire, from boats, and on the bay side of the North Spit.

Dredging in the bay to create the access channel for the Jordan Cove LNG Project could potentially affect recreational clamming and crabbing. Potential effects related to dredging are assessed in section 4.3.2.1 of this EIS, which concludes that dredging of the access channel would only have temporary effects on bay water quality, and increased sedimentation from dredging would be limited in extent. The limited time and extent of dredging siltation is not expected to result in long-term or population wide effects on clams and crabs near the Jordan Cove LNG Project. Further, as mitigation for wetland effects, Jordan Cove would create new eelgrass beds in Coos Bay that could serve as nursery habitat for crabs and Jordan Cove would also create new wetlands at Kentuck Slough.

Wakes from LNG carriers in the Federal Navigation Channel are not expected to cause major shoreline erosion beyond natural waves. Further, due to the relatively low transit speed and the required minimum underkeel clearance distance, propeller wash from LNG carriers is not expected to greatly disturb the channel bottom or affect clam and crab harvest in Coos Bay (see section 4.3.2.1).

Recreational clamming and crabbing that takes place outside the navigation channel would not be directly affected by LNG carrier traffic transiting the waterway to and from the LNG terminal. Effects would be similar to those presently experienced during the passage of other deep-draft ships. However, if crabbing or clamming activities were to occur within the established security zones, those activities may be required to cease, with attending vessels required to temporarily move out of the security zone while the LNG carrier in transit moves by. The requirement for any commercial or recreational boat operating within the security zone near the channel, but not impeding the safe navigation of the LNG carrier in the channel, to move and vacate the security zone area would be up to the Coast Guard on-scene commander and decided on a case-by-case basis. The Coast Guard has informed Jordan Cove that the degree of security zone enforcement would be based on the threat level in effect at the time and the specific perceived threat of any vessel in the security zone. Crab pots outside of the navigation channel should not be affected by LNG carrier traffic in the waterway. Passive equipment, such as crab pots, would be permitted to remain within the security zone while an LNG carrier is present.

Boating and Fishing

Data collected by the Oregon State Marine Board (OSMB) identified approximately 105,000 boat-use days in Coos County in 2013 (Lesser et al. 2014). The data did not identify the share of these trips that originated in Coos Bay, but information collected as part of a similar survey in 2007 indicated that recreational boaters took a total of 31,552 boat trips in Coos Bay for a total of 35,950 activity days. Fishing accounted for 91 percent of these days, sailing for 8 percent, and recreational cruising for 1 percent (OSMB 2008). Sixty-eight percent of the boating activities in Coos Bay in 2007 originated from the Charleston Marina and the Empire ramp, 19 percent at the California Street boat ramp, and 4 percent at the North Spit ramps. Charleston Marina, the Empire ramp, and North Spit ramp are located approximately 7.3 miles, 3.3 miles, and 2.1 miles southwest of the Jordan Cove LNG Project; the California Street boat ramp is about 2.5 miles southeast.

Popular fish species caught by recreational anglers out of Coos Bay include Coho and Chinook salmon. Other recreational catch species include various species of perch, rockfish, flatfish, sturgeon, Pacific herring, and California halibut. Much of the recreational angling for salmon in Coos Bay occurs in late summer and fall. Bank angler access on the North Spit is limited. Boat angling occurs throughout the bay, but angling is limited in some areas at times by exposure to winds.

Jordan Cove proposes to construct the slip and LNG carrier berth structures while the slip is kept isolated from Coos Bay by an earthen berm. The excavation and dredging of the slip would occur in isolation from the bay, with no restrictions placed on recreational boating in the construction site area. Recreational boating would, however, be discouraged around the construction area during the final phase in the slip construction, which would involve removing the earthen berm and connecting the excavated/dredged slip area to the bay. Recreational boating would also be discouraged during excavation of the access channel. Construction would also involve dredging within Coos Bay and would include the excavation of the four submerged areas adjacent to the existing Federal Navigation Channel as part of the Navigation Reliability Improvements. Excavation and dredging activities are expected to occur during the in-water work period from October through February 15. Excavation of the berm and the four submerged areas as part of the

Navigation Reliability Improvements would occur during a single in-water work period. Dredging of the access channel is expected to occur over two in-water work periods.

The Coast Guard and OSMB would provide Notice to Mariners to avoid the affected areas during the construction period. In addition, Jordan Cove would post signs on the shoreline, at the boat ramps and marinas, and on buoys or fixed navigation aids in the bay to notify boaters of the planned construction activity and the duration of the activity. All floating and submerged dredging equipment operating in the bay would be clearly marked with day signals and light signals at night in accordance with the U.S. Inland Rules of the Road. If the signage and notices are not sufficient to prevent recreational boaters from avoiding the construction areas, some form of physical barrier, such as a continuous string of highly visible soft material floats, could be extended across the mouth of the slip or around the construction area. Construction safety inspectors would also be responsible for warning any recreational boaters who enter the construction area.

Potential effects on recreational boaters during construction of the slip, access channel, and the four Navigation Reliability Improvement areas would be temporary and affect a limited area. Coos Bay is extensive (20 square miles or 12,800 acres) and recreational boating opportunities would continue to be available in other portions of the bay during construction, with existing boat ramps remaining open during construction. The construction dredging areas are limited in size and boaters could avoid these areas by moving to the south and east side of the bay.

During construction of the Project, Jordan Cove would have large pieces of equipment brought in via water transport, using the existing Federal Navigation Channel. Jordan Cove anticipates that the terminal would receive approximately 70 water deliveries over a 2-year period. Deliveries would be via a mix of ocean-going vessels and barges. In addition, during construction of the access channel about two barges per day would transport dredged materials from Ingram Yard to the Kentuck project site. The addition of these vessels is not expected to have adverse effects on other bay users, including recreational boaters.

During operation of the Project, recreational boaters would have to avoid LNG carriers in transit within the waterway. Jordan Cove anticipates that up to 120 LNG carriers would visit the LNG terminal each year. Recreational boaters using the bay at the same time that an LNG carrier is in transit within the waterway may encounter delays due to the moving security zone requirements around an LNG carrier, as specified in Jordan Cove's Waterway Suitability Assessment (WSA) and the Coast Guard's Waterway Suitability Report (WSR) and LOR. Jordan Cove estimated that it may take an LNG carrier up to 90 minutes to transit the waterway from the buoy to the terminal at speeds between 4 and 10 knots. Pilots guiding commercial ships in the Federal Navigation Channel currently encounter approximately six recreational boats during the transit into and out of the Port. These numbers are typically lower in winter and on weekdays than during the summer and on weekends. The Coast Guard and OSMB would continue to remind boaters of their obligation not to impede deep draft ships, regardless of the cargo. LNG carriers may take up to 30 minutes to pass resulting in limited potential delays to recreational boaters.

Other Public and Special Use Areas:

The LNG terminal would be approximately 0.9 mile from the Southwest Oregon Regional Airport. Potential effects of the LNG terminal on the airport are addressed in section 4.10.

4.8.1.2 Pacific Connector Pipeline Project

Parks and Recreational Areas or Facilities on Non-Federal Lands

The pipeline route does not cross any non-federal park lands or developed recreational facilities, and construction and operation of the pipeline should not adversely affect park users. However, construction-related activities would temporarily increase traffic on local roads used to access parks, and park users may be able to hear construction noise while workers and equipment move through the area to install the pipeline. In addition, the pipeline route would cross a water trail (i.e., the Haynes Inlet Water Trail) as discussed below. The following sections discuss parks and recreational areas or facilities in the vicinity of the pipeline project.

<u>Oregon State Lands</u>

Oregon Coast Trail

The Oregon Coast Trail is discussed above in section 4.8.1.1. The pipeline route would be within one-quarter mile of the trail where it follows Horsfall Beach road and joins the Trans-Pacific Parkway. Recreational users of the Oregon Coast Trail would be exposed to pipeline construction traffic along the Trans-Pacific Parkway, which is the only access road to the North Spit area and the Jordan Cove Meter Station. Pacific Connector proposes to reduce effects on local traffic by following the measures outlined in its *Transportation Management Plan* (see section 4.10.2). Pipeline construction activities and related traffic could be visible and audible to hikers on the Oregon Coast Trail where it joins with the Trans-Pacific Parkway, but these effects would be temporary, lasting only the duration of pipeline installation in this area. Further, this area is adjacent to a large-scale industrial facility (Roseburg Forest Products), a railroad, and a road. As a result, pipeline construction is not expected to significantly affect trail use or trail user experience.

Coos Bay Estuary

Coos Bay is used for recreational boating, canoeing, kayaking, angling, clamming, and crabbing. As noted above, the Coos Regional Trails Partnership, a consortium of land management agencies and economic development groups, have mapped Coos Bay's water trails for kayakers and other paddlers (Coos Regional Trails Partnership 2004). Portions of one water trail – the Coos Bay Trail – would be crossed by the pipeline alignment. The Coos Bay Trail begins at the California Avenue Boat Ramp, near the south end of the McCullough Bridge (i.e. U.S. Highway 101). The trail heads south through Coos Bay, along the western banks. The pipeline would cross this water trail using trenchless HDD crossing methods at about MP 1.50, with the proposed HDD continuing up into Kentuck Inlet to approximately MP 3.0, where it would end in uplands.

Potential effects on boaters using these areas during or after construction would be limited due to the use of HDD as boating in the vicinity of the HDD path would be allowed to continue during the drilling. HDD operations and pipe stringing would occur in uplands for both the Jordan Cove to North Point HDD, and for the HDD crossing from North Point to Kentuck Inlet. The HDD pipe string would be staged in uplands north of Jordan Cove for the Jordan Cove to North Point HDD, and the pipe string for the North Point to Kentuck Inlet crossing would be staged east of Kentuck Inlet and pulled to the west underneath the bay.

Klamath Wildlife Area

The Klamath Wildlife Area is managed by ODFW to provide habitat for wintering and nesting waterfowl, upland game birds, and a variety of other wildlife. Bald eagles, white pelicans, and ospreys are among the bird species that are present in this area during certain times of the year. The Miller Island Unit, along the Klamath River south of West Klamath, also serves as a recreation spot for fishing, hunting, and boating (ODFW 2017i). The pipeline right-of-way passes within 0.1 mile along the north side of the Miller Island Unit near MP 199.15, but is separated from the Unit by the Klamath River and other industrial areas. Construction in this area would be limited to the ODFW-recommended work period of July 1 through January 31 to avoid affecting wildlife populations supported by the area.

State Parks

There are no Oregon State Parks within 1 mile of the pipeline. Some USGS maps show Camas Mountain State Park near MP 51.7 in Douglas County. However, OPRD records do not show that there is, or historically has been, a state park or any state land ownership at this location (Teal 2006).

County Lands

There are nine county parks located near the pipeline route. Five of these parks are located in Coos County and include three parks accessed by the Coos Bay Wagon Road: Middle Creek Park, Ham Bunch-Cherry Creek Park, and Frona County Park. Middle Creek Park lies approximately 0.5 mile west of the pipeline alignment at about MP 27.5. Middle Creek is an unimproved, day use park. Ham Bunch-Cherry Creek Park, with about eight primitive campsites and fishing on Cherry Creek, is located about 1 mile northwest of the pipeline alignment at MP 28.5. Frona County Park, which offers a primitive group campground and fishing area along the East Fork of the Coquille River, is less than 0.5 mile northwest of the pipeline alignment at MP 29.9 (Coos Bay Net 2006; Coos County Park and Recreation 2006).

The other two parks in Coos County are Rock Prairie County Park and Laverne County Park. Rock Prairie County Park is an unimproved, day use park, located approximately 1.5 miles southwest of the pipeline, near MP 23.26. Laverne County Park is a 350-acre park located approximately 2.5 miles southeast of MP 22. Located on the North Fork Coquille River, Laverne County Park includes 76 campsites (46 RV sites and 30 tent sites), as well as a picnic area, large group area, softball field, playground, and other amenities. Construction is not anticipated to affect park use or associated recreational opportunities.

There are three county parks near the pipeline route in Douglas County: Ben Irving Reservoir, North Myrtle Park, and the Carl C. Hill Wayside. Ben Irving Reservoir, located about 1.5 miles south of the pipeline alignment near the town of Tenmile and State Highway 42 (near MP 55.8), is a large man-made water body used for fishing, boating, and other water related recreation. The day use park has a picnic site and boat launch. The reservoir could be a source of water for pipeline hydrostatic testing (see section 4.3). Project water use would be allowed by the reservoir owner and is not expected to significantly draw down the reservoir or affect boating or other day-use activities. North Myrtle Park is located approximately 1.5 miles north of MP 79 on County Road 15 (North Myrtle Road). This park is a day use park, with a ball field and picnic area. The pipeline would cross the access road to this park. Near Milo, the Carl C. Hill Wayside provides a picnic area and fishing along the South Umpqua River. This day use area is approximately 0.7 mile southwest of the pipeline alignment at MP 94.7, where the pipeline route crosses the South Umpqua River.

In Jackson County, Rogue Elk Country Park provides camping, hiking, and picnicking opportunities. This park is located west on State Highway (SH) 62 (Crater Lake Highway), approximately 2 miles west of the town of Trail. The park, at its closest point, is approximately 0.64 mile from the pipeline. No construction traffic or other related indirect effects are anticipated for park visitors because construction access to the pipeline would be via other roadways.

Although construction-related activities would temporarily increase traffic on local roads used to access the above parks, the five relatively remote county parks (Middle Creek, Ham Bunch-Cherry Creek, Frona, Ben Irving Reservoir, North Myrtle, and Rogue Elk Country) would not be directly affected by construction and operation. The Carl C. Hill Wayside picnic area may experience increased construction traffic and noise due to its proximity to SH 227 and the presence of a large pipe laydown and staging yard. Park visitors would also be able to hear construction activities upriver. The proposed diverted open cut of the South Umpqua River is, however, scheduled to coincide with the low water season of late summer/early fall to minimize effects on boaters and anglers in the area.

Other Non-Federal Public Recreation Areas

Keno Recreation Area

Pacific Power's Keno Recreation Area consists of a developed campground, boat launch, and picnic area along the Keno Reservoir of the Klamath River. Fishing and water sports are common activities at this recreation site near the town of Keno. The pipeline alignment passes less than 0.5 mile north of the reservoir where it would be adjacent to an existing powerline corridor. Recreation and access to the Keno Recreation Area would not be affected by construction and operation activities. While the Keno Reservoir could be a source of water for pipeline hydrostatic testing, this potential use is not expected to significantly draw down the reservoir or affect boating or other day-use activities. Hydrostatic testing is more fully discussed in section 4.3.2.

OHV Controls and Limited Access to the Right-of-Way

Comments received during public scoping expressed concern with the potential for an increase in OHV use where the pipeline right-of-way could create new access points. There was also concern about the effectiveness of control methods proposed by Pacific Connector. The pipeline right-of-way could increase unauthorized OHV, snowmobile, and dispersed motorized access and associated resource access. Pacific Connector's *Recreation Management Plan*[158] describes measures to be employed on both public and private lands to control unauthorized OHV use. Pacific Connector's plan indicates that they would assess the need for OHV control measures primarily where the pipeline right-of-way would intersect roads, OHV trails, or other trails. Various natural and constructed control measures would be installed at appropriate locations in coordination with the appropriate land management agencies or landowner. Potential locations identified by Pacific Connector include the PCT area, the Camel Hump and Obenchain Road areas, Dead Indian Memorial Highway, Forest Road 700, and Clover Creek Road. OHV control measures could include:

- dirt or rock berms, sometimes coupled with erosion control devices;

[158] Appendix S to Pacific Connector's POD filed with the FERC in January 2018.

- strategically placed non-merchantable logs, slash, or tree stumps;
- large rocks or boulders partly buried along the right-of-way;
- signs;
- fencing and locked gates; and
- vegetative screening to disguise the existence of the right-of-way.

Where necessary, OHV control structures would extend out beyond the right-of-way to prevent "drive-around" and would be built at an appropriate height to prevent passage.

Pacific Connector would coordinate with landowners during construction and restoration to finalize site-specific OHV control measures. In addition, following construction, the effectiveness of the site-specific measures would be assessed on a periodic basis, generally in conjunction with revegetation monitoring and in response to identified problems. Pacific Connector would be responsible for monitoring and managing unauthorized OHV use during the full life of the pipeline project and would implement additional measures as necessary.

Federal Parks, Recreation Areas, and Other National Designations

As discussed throughout this EIS, portions of the Pacific Connector pipeline route would cross through parts of three National Forests (Umpqua, Rogue River-Siskiyou, and Fremont-Winema) and four BLM Districts (Coos Bay, Roseburg, Medford, and Lakeview). The proposed route for the Pacific Connector pipeline would not cross any national parks, national monuments, national landmarks, wilderness areas, wildlife preserves, wild and scenic river segments, or reservoirs. The route would, however, cross several federally designated scenic byways, rivers on the national inventory, and national trails, as discussed below. The route would also cross two ERMAs, also discussed below.

National Parks and Monuments

The closest national park to the Pacific Connector pipeline is Crater Lake National Park, located approximately 26 miles northeast of MP 132. The Cascade-Siskiyou National Monument is the closest monument to the pipeline at approximately 10 miles southwest of MP 175. Because of their distance from the pipeline route, no national parks or monuments would be directly affected by the Pacific Connector Pipeline Project. However, indirect effects may include air quality effects on Class I areas (see section 4.12.1), and construction traffic on roads leading to the parks and monuments.

National Scenic Byways

Three National Scenic Byways would be crossed by the Pacific Connector pipeline: the Pacific Coast Scenic Byway (U.S. Highway 101); the Rogue-Umpqua Scenic Byway (State Highway 62); and the Volcanic Legacy Scenic Byway (U.S. Highway 97). Generally, installation of a pipeline across a road may have direct effects through a temporary halt to traffic, and removal of vegetation which may affect visual quality. However, in the case of these three National Scenic Byways, as discussed below, the highways would remain open during pipeline construction and no vegetation would be removed in the vicinity of the crossings.

Following Highway 101 south from Astoria to Brookings, many locations along the Pacific Coast Scenic Byway offer views of the Oregon coast. The pipeline would be installed by conventional construction methods underneath U.S. Highway 101 (at Conde B. McCullough Memorial Bridge) between approximately MPs 1.22 and 1.23 because the highway is elevated at this location. Pipeline construction activities would be staged within existing construction storage yards on both the west and east sides of the highway and would be visible on either side from the highway. There would be no surface disturbance to the highway. Construction access to the staging areas would be via surface streets at Pittum Loop and Chappell Parkway. Temporary short-term traffic interruptions may occur at the intersection of Highway 1 and Ferry Road (approximately 0.23 mile south of construction), when supplies, crews, and heavy equipment traffic are required. Potential effects would be temporary, and once completed, the pipeline would be undetectable to those traveling on U.S. Highway 101, but the right-of-way may be visible in the existing construction storage yard and an old lumber storage yard to the west of Highway 101. Given the current land use of these areas, the right-of-way feature would not be expected to be especially noticeable to those travelling the Pacific Coast Scenic Byway.

Following State Routes 138, 62, and 234, the Rogue-Umpqua Scenic Byway forms a semi-circle route through the Umpqua and Rogue National Forests between the cities of Roseburg and Gold Hill. The pipeline would cross the Rogue-Umpqua Scenic Byway approximately 0.2 mile south of the town of Trail (MP 122.6) on State Highway 62. An HDD would be used to cross under State Highway 62 and the adjacent Rogue River, from MP 122.24 to 122.67; therefore, the pipeline is not expected to affect the Rogue-Umpqua Scenic Byway. A temporary extra work area would be located immediately adjacent to the Scenic Byway, in between the highway and the Rogue River. Temporary short-term traffic interruptions may occur at the intersection of State Highway 62 when supplies, crews, and heavy equipment traffic would be required to service the HDD operations. Pacific Connector would implement traffic control measures while the HDD activities are occurring to ensure safety for the public and construction personnel. The pipeline would not be visible to travelers along the Rogue-Umpqua Scenic Byway following the completion of construction.

The Volcanic Legacy Scenic Byway provides a touring route of south-central Oregon and northeastern California. The Oregon portion of the Volcanic Legacy Scenic Byway begins on U.S. Highway 97, north of Crater Lake, circles Crater Lake, and then continues south on State Routes 62 and 140 through Klamath Falls and into California. The Pacific Connector pipeline would cross the Volcanic Legacy Scenic Byway just south of Klamath Falls (MP 199.6) near where it crosses the Klamath River. Pacific Connector proposes to use an HDD to cross under Highway 97 and the Klamath River between MPs 199 and 200. Effects would be temporary, as travelers on Highway 97 may be able to briefly glimpse pipeline construction activities off in the distance. The HDD under Highway 97 and the Klamath River would be completed within a two-month period. The Pacific Connector Pipeline Project would have no direct effects on the Volcanic Legacy Scenic Byway, and the highway would be kept open to traffic during construction. Following installation, the pipeline would not be visible to travelers using the Volcanic Legacy Scenic Byway and is, therefore, not expected to affect the scenic qualities of this byway.

National Wild and Scenic Rivers and Nationwide Rivers Inventory

Wild and Scenic Rivers

The Rogue River, which the pipeline would cross near the community of Trail, is a designated Wild and Scenic River[159] from the Crater Lake National Park boundary downstream to Prospect, approximately 20 miles north of the pipeline crossing. In addition, an 84-mile section of the Rogue River is designated as Wild and Scenic starting about 7 miles west of the city of Grants Pass and proceeding west toward the town of Gold Beach (NPS 2005). Neither of the designated Wild and Scenic River segments would be crossed or otherwise affected by the pipeline.

Indirect effects could occur if the pipeline crossing were to cause sedimentation that could run downstream and affect water quality of the federally designated Wild and Scenic River portion of the Rogue River. However, the pipeline would cross the Rogue River using an HDD, which would avoid direct effects on this river. Also, while this segment of the Rogue River was found eligible for Wild and Scenic designation by the BLM Medford District (BLM 1995f), its river-related values are only protected on BLM-managed lands (approximately one mile from the pipeline crossing). The pipeline would not cross any protected segments of the Rogue River on BLM-managed lands. The values for which the river was found eligible are not expected to be affected by the pipeline construction and operation.

National Wildlife Refuges, Natural Landmarks, and Wilderness Areas

Sky Lakes Wilderness and Mountain Lakes Wilderness

There are several federally designated Wilderness Areas in the Umpqua, Rogue River, and Fremont-Winema National Forests, but none of them would be crossed by the Pacific Connector pipeline. The pipeline does, however, pass in the general vicinity of two Wilderness Areas: the Sky Lakes Wilderness (113,590 acres), which is located in both the Fremont-Winema and Rogue River National Forests; and the Mountain Lakes Wilderness (23,071 acres), in the Fremont-Winema National Forest. The pipeline would pass approximately 3.7 miles south of the Sky Lakes Wilderness and 1.3 miles south of the Mountain Lakes Wilderness. These wildernesses would not be affected by pipeline construction or operation because of these distances and the intervening forested landscapes.

Round Top Butte National Natural Landmark

Between MPs 134.7 and 137.1 the Pacific Connector pipeline route would pass in close proximity to the east side of the Round Top Butte National Natural Landmark (NNL), which was designated an NNL on June 15, 2011. Geologically, the NNL includes a basaltic butte and volcanic plains. Biologically, the NNL encompasses a unique mixture of grasslands, ponderosa pine, white oak, and buck brush vegetation. The NNL is administered as two parcels: 747 acres managed by the BLM as a Research Natural Area (RNA), and a private preserve managed by The Nature Conservancy.

At its closest point, the pipeline would be about 0.25 mile away from the BLM boundary to the NNL. Where the pipeline would be closest to the NNL boundary, near MP 135.6, it would be located on private land through previously harvested and thinned forest. The pipeline route does

[159] Wild and scenic rivers are designated for preservation under the Wild and Scenic Rivers Act of 1968 (Public Law 90-542), which was enacted by the U.S. Congress to preserve certain rivers with outstanding natural, cultural, and/or recreational values in a free-flowing condition for the enjoyment of present and future generations.

not cross the NNL and would have no direct effects on it. Pacific Connector would minimize the spread of weeds by following its ECRP and its *Integrated Pest Management Plan*.

Klamath Basin National Wildlife Refuges

The Klamath Basin hosts a complex of six NWRs in the Klamath Falls region of Southern Oregon and Northern California. These refuges, managed by the FWS, consist of a variety of habitats including freshwater marshes, lakes, meadows, coniferous forests, sagebrush and juniper grasslands, agricultural lands, and rocky cliffs and slopes. These habitats support diverse and abundant populations of resident and migratory wildlife, with 433 species having been observed on or near the refuges. Each year the refuges serve as a migratory stopover for about 75 percent of the Pacific Flyway waterfowl, with peak fall concentrations of more than 1 million birds. The Pacific Flyway is one of four major migratory routes (Pacific, Central, Mississippi, and Atlantic flyways) used by migratory birds in North America.

The pipeline would pass approximately 3.5 miles north of the Bear Valley NWR, and approximately 3.7 miles north of the Lower Klamath NWR. Between MPs 196 and 199, the pipeline wraps around on the north side of the Klamath River. On the south side of the river, the FWS owns two small 80-acre "out parcels," which are surrounded by State of Oregon lands managed by the ODFW. The two parcels are approximately 0.8 mile to 1.2 miles south of the pipeline. Some USGS topographic maps show old Lower Klamath Refuge boundaries on lands that were withdrawn from consideration in the 1920s (Coles 2006). Pacific Connector confirmed with the FWS in June 2006 that the pipeline would not affect any lands within the Klamath Basin Refuge boundaries.

Construction and operation of the Pacific Connector Pipeline Project should have no direct effects on the Wilderness Areas, Natural Landmarks, and NWRs discussed above because the pipeline would not cross any of these areas.

<u>Inventoried Roadless Areas</u>

The pipeline route and related facilities would not be located in any Inventoried Roadless Areas (IRAs). The nearest IRA is the Brown Mountain IRA, located on the Rogue River National Forest approximately 0.6 mile north of the pipeline route at MP 162.0. On the Fremont-Winema National Forest, the West Boundary IRA is about 2.2 miles northeast of MP 172.25. Construction and operation of the Pacific Connector Pipeline Project would have no direct effects on these IRAs.

<u>National Recreational Areas and Trails</u>

BLM Coos Bay/North Spit RMAs and Forest Service ODNRA

The Pacific Connector pipeline would have no direct effects on the Coos Bay/North Spit RMAs or the ODNRA because it does not cross those areas. From MP 0.00, the pipeline would be installed using an HDD underneath Coos Bay to the southeast, away from the RMAs and ODNRA. During the HDD process, supplies, equipment and crews would need to access the LNG terminal area and the north end of the HDD area. There would be increased traffic volumes on the Trans-Pacific Parkway, which provides access to the North Spit. Travelers may experience increased traffic congestion and short delays, but these effects would be temporary and short term, and access or use of the RMA or ODNRA areas would not be precluded. The *Transportation Management*

Plan prepared by Pacific Connector[160] addresses the potential indirect effects that construction-related traffic may have on recreational users who drive on Highway 101, the Trans-Pacific Parkway, and Horsfall Beach Road to reach the RMAs and ODNRA. This is further discussed in section 4.10.

Recreational users of the Coos Bay/North Spit RMAs and the ODNRA may also be exposed to noise from pipeline construction, as well as from construction of Pacific Connector's Jordan Cove Meter Station. Potential noise effects would be temporary and short-term, and mitigated in part by distance, topography, vegetation, and ambient noise levels from other sources, including non-project related traffic on the Trans-Pacific Parkway, OHVs, and other industries on the North Spit. Noise is more fully discussed in section 4.12.2.

Pacific Crest National Scenic Trail

The Pacific Crest Trail (PCT) is a 2,650-mile-long hiking and equestrian trail stretching from the Canadian border in Washington to the Mexican border in California. With the passage of the National Trails System Act of 1968, as amended, Congress designated the PCT as one of the first scenic trails in the nation (Forest Service 1982). Thousands of hikers, horse riders, cross-country skiers, and snowshoers use the trail each year. Approximately 430 miles of the PCT runs through the Cascade Mountain Range in Oregon. The pipeline route crosses the PCT at approximately MP 167.8.

Trail users can access the trail in several locations near the pipeline route area, including a registered trailhead on the Dead Indian Memorial Highway (County Road 533). This trailhead is about 1.3 miles west of where the pipeline would cross Dead Indian Memorial Highway. The trail can also be accessed using Forest Road 700 or using the Brown Mountain trail accessed by Forest Road 3705.

Installation of the pipeline would affect PCT users for a short duration of time. Pacific Connector proposes to construct the portion of the pipeline across the trail as a "tie-in" to reduce the period when trail users are inconvenienced. Pacific Connector has indicated that it expects that construction of the trail tie-in would be completed within 48 hours or less to minimize effects and the need for trail detours. Pacific Connector has also identified site-specific mitigation measures to reduce potential effects on the PCT in its *Recreation Management Plan*. These measures include the following:

- Provide advance notice of construction to the Forest Service and PCT Association;
- Notify the Forest Service District Ranger 48 hours in advance if any anticipated delays for PCT users would exceed 1 hour;
- Provide at least 7 days advance notice if the PCT needs to be detoured;
- Obtain Forest Service approval and install detailed detour route signs (if needed);
- Plan, if practicable, for PCT disruption outside of the trail's busiest hiking season (mid-July to early August);
- Establish a roughed-in trailhead within 24 hours of crossing completion, with temporary directional signs posted at each end of the crossing;
- Restore the trail to full design standards within 2 weeks of completing the trail crossing (weather permitting);

[160] Appendix Y to Pacific Connector's POD filed with the FERC in January 2018.

- Install standard Nordic ski trail markers as needed post-construction;
- Revegetate the right-of-way using native trees, shrubs, and plants;
- Use a combination of rocks, logs, slash, and gates to deter motorized vehicles and OHVs from gaining access to the PCT, in such a manner as not to adversely affect the area's visual resource qualities, to the extent practicable.

Pacific Connector intends to use a "dog-leg" segment to avoid a perpendicular crossing of the trail and thereby reduce the visibility of the pipeline corridor to trail users (see section 4.8.2.3 for an assessment of visual resources on federal lands). To further reduce potential effects on the PCT and its users, Pacific Connector has "necked down" the construction right-of-way width from the standard 95 feet to 75 feet for approximately 300 feet on either side of the trail.

South Brown Mountain Shelter

The South Brown Mountain Shelter is a small, fully enclosed log cabin about 200 yards off the PCT in Section 32, T.37S, R.5E. The shelter, located in the Rogue River-Siskiyou National Forest near its boundary with the Fremont-Winema National Forest, is used year-round by hikers, cross-country skiers, snowmobilers, and others. The cabin contains a wood stove, primitive storage facilities, and counter spaces. Potable well water is available using a hand pump that is operational from mid-May to late October.

The South Brown Mountain Shelter is approximately 600 feet north of the pipeline route near MP 167.7; and would not be directly affected by construction or operation of the pipeline. Temporary noise from pipeline construction may be audible at the shelter, but visitors would not be able to see the pipeline or related construction activities because of the existing vegetation screening that is located between the shelter and the right-of-way. Distance, topography, and vegetation would reduce pipeline construction noise at the shelter. The effects from pipeline construction noise would be temporary and should not adversely affect users of the shelter.

Brown Mountain Trail

The Brown Mountain Trail is a path for non-motorized users on the Fremont-Winema and Rogue River-Siskiyou National Forests. The trail is linked by two short sections of forest roads and circles Brown Mountain. One access point is near the pipeline at a trailhead on Forest Road 3705, near South Fork Little Butte Creek about a mile north of MP 165.0. In addition to summer recreational activities, cross-country skiing and snowmobiling are popular winter sports along the Brown Mountain multi-use trail system between about MPs 160 and 170. The Brown Mountain Trail and access on Forest Road 3705 are not expected to be affected by pipeline construction or operation.

<u>Other Extensive Recreation Management Areas</u>

Blue Ridge Trail System ERMA.

The Blue Ridge Trail System ERMA is located within the Coos Bay District. Designated for hiking, biking, equestrian, and motorcycle trails, this 1,405-acre ERMA currently supports approximately 12 miles of trails, which connect with a larger network of logging roads that can also be utilized. Timber harvest and management operations occur in this area, with road closures occurring intermittently for logging operations. The pipeline would cross this ERMA from MP 19.92 to MP 22.11 (approximately 2.19 miles) and cross three of the Blue Ridge trails. In addition, Pacific Connector would utilize several existing roads in this ERMA for construction access.

Similar to when logging activities occur in the area, these trail segments would need to be closed during pipeline construction. Construction would also result in increased traffic volumes on existing roads and other users may experience traffic congestion and delays, with access to some trails temporarily affected. Potential construction traffic-related impacts on recreational users are discussed in Pacific Connector's *Transportation Management Plan*. Recreational users may also be exposed to noise during pipeline construction. Potential noise effects would be temporary and short-term, and partially mitigated in some locations by distance, topography, vegetation, and ambient noise levels from other sources, including OHVs. Noise is more fully discussed in section 4.12.2. After construction is complete, Pacific Connector would restore trail segments affected during construction.

In addition, Pacific Connector is proposing to use an existing communications tower located on the top of Blue Ridge, within the ERMA. Pacific Connector would use the tower during operations and Pacific Connector staff and contractors may need to access this existing location intermittently to maintain communications equipment. Impacts to other users are expected to be limited.

Buck Berry Rock ERMA

The Buck Berry Rock ERMA is located within the Medford District. Designated for non-motorized trail systems in a remote setting, this ERMA encompasses 6,504 acres, located north of the community of Trail. This ERMA is approximately 0.5 mile from the pipeline at its closest point, near MP 121 and separated from the proposed route by private lands and SH 227. Construction is not anticipated to have any impacts on this ERMA.

Green Top Mountain ERMA

The Green Top Mountain ERMA consists of 5,316 acres located within the Medford District. Designated for non-motorized trail systems, this ERMA is not located in proximity to any larger communities. This ERMA is approximately 0.3 mile from the Pipeline at its closest point, near MP 138.5. Construction is not anticipated to have any impacts on this ERMA.

Surveyor Mountain ERMA

The Surveyor Mountain ERMA consists of 17,376 acres located within the Lakeview District. This ERMA is a short distance from Klamath Falls and frequented by big game hunters, OHV users, and snowmobilers. From MPs 172 to 178, the pipeline is within one mile of the ERMA, and between MPs 176.1 and 177, the pipeline crosses the ERMA. In this area, the proposed pipeline right-of-way is co-located immediately adjacent to Clover Creek Road (County Road 603), and no new impacts are expected.

Stukel Mountain ERMA

The Stukel Mountain ERMA consists of 9,622 acres located within the Lakeview District. Located close to Klamath Falls, this ERMA attracts OHV users, hikers, and mountain bikers. The Pipeline is approximately 0.4 mile from the ERMA, near MP 212.5, and separated from the ERMA by private lands. Pipeline construction is not expected to have any impacts on this ERMA. Pacific Connector's proposed Stukel Mountain Communication Site is located at an existing communication tower complex on BLM-managed lands within the ERMA. Construction activities at or adjacent to the existing complex would be temporary and short-term lasting a few months with a small crew requiring limited equipment. Communication-related construction and operation activities would be similar to existing activities and operations at the complex with limited impacts on recreation users.

Bryant Mountain ERMA

The Bryant Mountain ERMA consists of 9,093 acres located within the Lakeview District. The Bryant Mountain ERMA has potential for an OHV trail system. The site is close to Klamath Falls and is mostly a contiguous block of BLM land. The Pipeline is approximately 0.4 mile from the ERMA, near MP 228, and separated from the ERMA by private lands. Construction is not anticipated to have any impacts on this ERMA.

<u>Federal Recreational Lakes and Reservoirs</u>

Fish Lake

Fish Lake is located on the Rogue River National Forest near the crest of the Cascades about 2.5 miles away from the pipeline route at about MP 161. The Fish Lake Recreation Area includes Forest Service campgrounds, picnic areas, and a boat ramp, as well as a privately-operated resort with cabins, a trailer park, additional camp sites, food service, and a marina. During the summer the lake supports water related activities, including fishing and boating. During the winter, ice-fishing, cross-country skiing, and snowmobiling are popular in the area. Pacific Connector has identified Fish Lake as a potential source for water that would be used for hydrostatic testing of the pipeline. Water would be potentially withdrawn from two places: one location at the lower end of the lake near the dam; and the other at the upper end of the lake in the vicinity of the Fish Lake Campground and boat ramp. No roads or recreational facilities would be closed because of the hydrostatic test water withdrawals from the lake; however, water trucks would use Forest Service Roads 2800700, 2800706, and 2800800. Use of these roads is addressed in Pacific Connector's *Transportation Management Plan*. Pacific Connector has indicated that after it has selected a construction contractor for the pipeline, it would submit a water withdrawal plan to the Forest Service that would outline measures to minimize effects on recreational users and encumbrances at the lake.

John C. Boyle Reservoir

The John C. Boyle Reservoir is operated by PacifiCorp as part of a FERC-licensed hydropower project. Boat launches and the Topsy Recreation site, operated by the BLM, provide camping, picnicking, fishing, boating and swimming for visitors to this section of the Klamath River approximately 8 miles south of MP 184.31. Recreation and access to the reservoir and recreation site would not be directly affected by construction activities, although construction could cause some temporary delays on Keno Access Road (also known as State Highway 66). Pacific Connector has identified the reservoir as a potential source of water for hydrostatic testing. Use of the reservoir for this purpose would not be expected to significantly or noticeably draw down the reservoir or affect recreational activities. The John C. Boyle Dam is one of four dams on the Klamath River that is planned to be removed as part of the Klamath Economic Restoration Act.

<u>ACECs</u>

North Spit ACEC

The North Spit ACEC is located about 3.5 miles southwest of the Jordan Cove Meter Station, where the pipeline would terminate. The North Spit ACEC would not be directly affected by construction or operation of the Pacific Connector Pipeline Project. Indirect effects could occur as a result of the increased traffic on the Trans-Pacific Parkway that would occur during construction. These potential increases have the potential to cause traffic congestion and short delays but are not expected to preclude access to or use of the ACEC.

Upper Rock Creek ACEC

The BLM's Coos Bay District designated 364 acres in Section 5, T.29S., R.9W., Douglas County, Oregon as the Upper Rock Creek ACEC. The purpose of this ACEC is to maintain, protect, and restore the area's natural systems and botanical values, which include western red cedar and western hemlock, and skunk cabbage, as well as sedge-dominated wetlands. The area also supports the Oregon Natural Heritage Program Coast Range Ecological Cell 108 and provides habitat for marbled murrelet and northern spotted owl. At its closest point, the construction right-of-way is approximately 115 feet south of this ACEC at MP 43.2 and would not directly conflict with the management of the ACEC. Pacific Connector proposes to use North Rock Creek Road, a paved public road located approximately 50 feet from the ACEC, for construction access in this area. Potential effects on wildlife are assessed in section 4.5.1.

4.8.1.3 Environmental Consequences on Federal Lands

Forest Service Potential Wilderness Evaluation

Wilderness Areas, Inventoried Roadless Areas (IRA), and Potential Wilderness Areas (PWA) are discussed together here because they share a set of terminology and interrelated history. A wide range of terms and references have been used by respondents, the courts, and the Forest Service when referring to these topics such as roadless, unroaded, uninventoried roadless, undeveloped areas, and roadless expanse. The terms and definitions as stated below are used in this site-specific analysis. They are based on current law, regulation, agency policy, and the LRMPs, as amended, for the Umpqua, Rogue River, and Winema National Forests.

<u>Wilderness</u>

A Wilderness Area is designated by congressional action under the Wilderness Act of 1964 and other wilderness acts. The Wilderness Act of 1964, Section 2(c) defines wilderness, in part, as:

> *[A]n area of undeveloped Federal land retaining its primeval character and influence, without permanent improvements of human habitation, which is protected and managed so as to preserve its natural conditions and which (1) generally appears to have been affected primarily by the forces of nature, with the imprint of man's work substantially unnoticeable; (2) has outstanding opportunities for solitude or a primitive and unconfined type of recreation; …*

Two Wilderness Areas are in proximity to the pipeline alignment: Sky Lakes Wilderness (113,590 acres) is in both the Winema and Rogue River National Forests and its southern tip is approximately 3.7 miles north of the pipeline alignment at MP 162, and Mountain Lakes Wilderness (23,071 acres), in the Winema National Forest, is approximately 1.3 miles north of MP 172.

No Project activities would occur within or adjacent to a wilderness area. There would be no effects on designated wilderness or wilderness characteristics because the closest wilderness (Mountain Lakes) is over a mile away. Because of this distance, project activities would typically not be seen or heard by anyone recreating in the wilderness. The exceptions could be short duration views of smoke during burning activities. Smoke management mitigation measures would minimize the risk of smoke drifting into the wilderness.

Inventoried Roadless Areas

IRAs were identified in the 2001 Roadless Area Conservation Rule in a set of inventoried roadless area maps, contained in Forest Service Roadless Area Conservation Final Environmental Impact Statement, volume 2, dated November 2000, which are held at the National headquarters office of the Forest Service, or any subsequent update or revision of those maps (36 CFR 294.11). These areas were set aside through administrative rulemaking and have provisions, within the context of multiple use management, for the protection of inventoried roadless areas.

The nearest IRA is the Brown Mountain IRA, located on the Rogue River National Forest approximately 0.6 mile north of MP 162. On the Winema National Forest, the West Boundary IRA is about 2.2 miles northeast of MP 172. No activities associated with the Pacific Connector Pipeline Project would occur within or adjacent to an IRA; therefore, there would be no project-related effects on IRAs.

Potential Wilderness Areas

This is not an official inventory. Official inventories of potential wilderness areas are completed during forest planning. This analysis considers PWAs only for purposes of assessing potential effects of the Pacific Connector pipeline activities on wilderness characteristics. PWAs are not a land designation decision (e.g., does not change current land management allocations), they do not imply or impart any particular level of management direction or protection, they are not an evaluation of potential wilderness (Forest Service Handbook [FSH] 1909.12, Chapter 72), and they are not preliminary administrative recommendations for wilderness designation (FSH 1909.12, Chapter 73). The inventory of PWAs does not change the administrative boundary of any IRA or any congressionally designated wilderness. The original designated management area (*e.g.*, Matrix) would remain the land designation even if areas in the project planning area meet the handbook criteria for PWAs. PWAs are evaluated (regarding making recommendations to Congress for inclusion in the National Wilderness Preservation System) during the development or revision of land management plans, in other words at the forest planning level and not at the project planning level.

PWAs qualify for placement on the inventory if they meet the following criteria (FSH 1909.12, Chapter 71):

1. The area contains 5,000 acres or more.
2. Areas contain less than 5,000 acres, but can meet one or more of the following criteria:
    a. Area can be preserved due to physical terrain and natural conditions.
    b. Areas are self-contained ecosystems, such as an island, that can be effectively managed as a separate unit of the National Wilderness Preservation System.
    c. Areas are contiguous to existing wilderness, primitive areas, Administration endorsed wilderness, or potential wilderness in other Federal ownership, regardless of their size.
3. Areas do not contain forest roads (36 CFR 212.1) or other permanently authorized roads, except as permitted in areas east of the 100th meridian.

Areas may meet either criteria 1 and 3, or criteria 2 and 3. If the criteria in section 71.1 of the FSH are met, criteria in section 71.11 of the FSH (criteria for including improvements) must also be met. This analysis used the following project-specific criteria to delineate areas characterized as undeveloped and roadless, yet included improvements:

- Roads (as defined in 36 CFR 212.1) were excluded per FSH 1909.12, section 71.1. Mapped areas were at least 300 feet from NFS roads. This distance was selected because tree harvest is commonly permitted within 300 feet of open forest roads for personal-use firewood. In addition, danger tree removal occurs at various distances from open forest roads depending on tree height, topographic slope, and other factors.

- Timber harvest areas where logging, as evidenced by stumps, and prior skid trails or roads are substantially unrecognizable, or areas where clearcuts have regenerated to the degree that canopy closure is similar to surrounding uncut areas per FSH 1909.12, section 71.11.

No undeveloped areas greater than 5,000 acres would be crossed by the Pacific Connector pipeline route. All of the undeveloped areas crossed by the pipeline are less than 5,000 acres in size, are not contiguous to existing Wilderness or IRAs, and do not meet the PWA criteria for areas less than 5,000 acres. As a result, the Project would not affect any PWAs.

<u>Other Undeveloped Areas</u>

Other undeveloped areas refer to those areas that do not meet inventory criteria as PWAs, and are not an IRA or designated Wilderness area. There are no forest-wide or management area standards and guidelines specific to other undeveloped areas in the Umpqua, Rogue River, and Winema National Forest LRMPs. All lands, including undeveloped areas, are managed consistent with forest-wide standards and guidelines and by designated LRMP management area allocations. Other undeveloped areas are identified because they may contain special resource values that warrant an evaluation differently than other parts of the project area.

There are approximately 3,747 acres of other undeveloped lands not meeting PWA criteria that would be crossed by the pipeline on NFS lands. Approximately 1,792 acres of these areas are within the Umpqua National Forest[161], and approximately 1,955 acres are within the Rogue River National Forest (see appendix F8 for maps and additional information). The portion of the pipeline route within the Winema National Forest is on or adjacent to existing roads and would not impact "other undeveloped areas." Other undeveloped areas may have intrinsic ecological and social values because they do not contain roads (or the roads are no longer system roads) or evidence of past timber harvest. These values can include intrinsic physical and biological resources (e.g., soil, water, wildlife, recreation, fisheries, etc.), and intrinsic social values (e.g., apparent naturalness, solitude, remoteness).

Human influences have had limited impact to long-term ecological processes within these other undeveloped areas. Disturbances by insects and fire have likely been the factors with the most potential to have affected the area. Opportunities for primitive recreation include camping, hiking, hunting, wildlife watching, and photography. Opportunities for a feeling of solitude, the spirit of adventure and awareness, serenity, and self-reliance are limited by the size and shape of the areas,

[161] This area burned in the 2015 Stouts Creek Fire and as a result there are additional alterations in this area from fire suppression efforts. In addition to the changed vegetation conditions the surrounding landscape has also changed as a result of salvage logging on industrial forest lands immediately to the west of this area.

as well as by distance to roads and topographic screening. The size of the area necessary to feel a sense of solitude varies by individual; however, areas that are long and narrow offer less opportunity for solitude due to less distance from noise at their midpoint. Nearby sounds of roads, timber harvest, and other management activities can often be heard and the activities sometimes seen from within these undeveloped areas because they are all within approximately 1 mile or less of the nearest road from their midpoints.

The Pacific Connector Pipeline Project would directly impact approximately 8 acres of other undeveloped areas on the Umpqua National Forest and approximately 22 acres on the Rogue River National Forest. These impacts include the areas cleared by the right-of-way construction, the TEWAs, and the acres used as UCSAs.

For these other undeveloped areas within the pipeline project area where construction and operation would occur the impacts to soil; water quality; air quality; forage; plant and animal communities; habitat for threatened, endangered, and sensitive species; developed recreation; noxious weeds; and cultural resources are essentially the same as disclosed above for recreation and in other sections of chapter 4 of this EIS and are not reiterated here.

The Pacific Connector Pipeline Project would impact the apparent naturalness and solitude within these areas. Pipeline construction would alter the apparent naturalness on approximately 30 acres of these areas. The increase in the number of visible stumps, and the linear nature of the pipeline corridor clearing would be the most apparent visual change resulting from implementation. The linear nature of the cleared corridor would likely adversely affect the visual recreational experience of anyone using these areas for dispersed recreation. This impact would be long term due to a portion of the right-of-way being maintained as a low vegetation area for the life of the pipeline project. Although the pipeline construction and operation would adversely affect visual resources in these areas, they would not be inconsistent with the standards and guidelines for visual quality in the respective LRMPs.

Activities associated with the construction of the pipeline in and adjacent to these other undeveloped areas would reduce the sense of solitude and remoteness during construction activities. Other sights and sounds of ongoing and previously approved activities in areas adjacent to these other undeveloped areas would continue to have short-term effects on opportunities for solitude and remoteness. Overall, there would be little change to the current availability of solitude or primitive recreation within these areas because only a very small portion (approximately 0.8 percent) would be affected by the Pacific Connector Pipeline Project.

BLM Lands with Wilderness Character

In the fall of 2012, the BLM updated its inventory of lands with wilderness character. These updates were part of the Analysis of the Management Situation process associated with the new RMPs for western Oregon that were approved in August of 2016. The inventory covered BLM lands in the Salem, Eugene, Roseburg, Coos Bay, and Medford Districts, as well as the Klamath Falls Resource Area of the Lakeview District. The results of this most recent inventory were compared to the proposed route, and no areas of overlap were discovered. The proposed pipeline would not impact BLM land with wilderness character.

4.8.1.4 Conclusions

Constructing and operating the Jordan Cove LNG Project would not have direct adverse effects on nearby recreational areas, including the ODNRA and BLM RMAs, but may have indirect effects. As described in the preceding sections, temporary indirect impacts during construction would include construction-related noise and short-term delays to recreationists using the Trans-Pacific Parkway to access recreation sites, including the ODNRA. Indirect impacts during operation include short-term delays for recreational boaters required to avoid LNG carriers in transit within the waterway. Constructing and operating the Pacific Connector Pipeline Project would result in impacts on recreation resources as described in the preceding sections. Based on the proposed construction, mitigation, and operation procedures the Project would not significantly affect recreation resources or areas.

4.8.2 Visual Resources

Procedures for describing the existing visual condition of the landscape and assessing the visual effects of the Project are similar to and generally consistent with methodologies developed by the BLM (1986), Forest Service (1973, 1995b), the FHWA (2015), and the COE (Smardon et al. 1988). This section documents the visual assessment conducted for the Jordan Cove LNG Project and the Pacific Connector pipeline, based primarily on the potential visibility of the Project facilities and their expected visual effects on the landscape.

4.8.2.1 Jordan Cove LNG Project

The Jordan Cove LNG Project would be located almost entirely on privately owned, mostly open, industrial-zoned land on the bay side of the North Spit of Coos Bay. Ingram Yard is generally bordered to the north by the Coos Bay Rail Link and the Trans-Pacific Parkway; to the west are open lands of Henderson Marsh, which is owned by the Port; to the east is the existing industrial Roseburg Forest Products wood chip facility; and to the south are the open waters of the Coos Bay estuary. About 3,000 feet northwest of the LNG terminal is the beach and Pacific Ocean. Topography on the westernmost portion of Ingram Yard is relatively flat where fill material has been covered by brush and grasses. Forested sand dune ridges reaching elevations that exceed 100 feet AMSL cover the eastern portion of Ingram Yard.

North of the access and utility corridor is the Coos Bay Rail Link and the Trans-Pacific Parkway, beyond which are federal lands managed by the BLM and Forest Service. Those federal lands contain forested sand dunes. South of the corridor is the existing industrial Roseburg Forest Products facility.

The South Dunes area is relatively flat open lands that were formerly the location of the Menasha-Weyerhaeuser mill complex and a fish hatchery. Most of the buildings of those facilities have been removed, and what remains is a mixture of roads, railroad tracks, parking lots, grasslands, dunes, and wetlands. The South Dunes area is surrounded on the south and east by the open waters of the Coos Bay estuary, including geographic Jordan Cove on the south and Hayes Inlet on the east. To the west is the Roseburg Forest Products facility. To the north is the ODNRA.

The Roseburg Forest Products facility is mostly paved, with roads and railroad tracks, and includes a dock for mooring ships, a 190-foot-tall loading tower, wood chip piles, two large buildings, two water towers, and several small outbuildings.

Beyond 0.5 mile from the Jordan Cove LNG Project, the existing landscape on the North Spit is characterized by a mix of industrial land uses and open space. Industrial facilities on the north side of Coos Bay on the North Spit include the Southport Forest Products lumber mill, approximately 1 mile southwest of the Jordan Cove LNG Project. The International Marine Contractors and the D.B. Western manufacturing plant facilities are also located on the North Spit approximately 2 miles southwest of the Jordan Cove LNG Project (specifically the terminal site). Undeveloped land separates the Project from these facilities. Most of the rest of the North Spit southwest from the Project consists of the open lands and dunes of the BLM RMAs.

Southward, across Coos Bay from the Jordan Cove LNG Project, are the cities of North Bend and Coos Bay. The smaller community of Glasgow is located on the east side of Haynes Inlet and north side of the Coos Bay estuary, about 4,000 feet northeast of South Dunes. The Kentuck project site proposed for wetland mitigation (see section 4.4) is located approximately 1.5 miles southeast of Glasgow and inland from Kentuck Inlet on Upper Coos Bay. The closest residential developments to the terminal site are approximately 1 mile south, on the opposite side of the bay. The Southwest Oregon Regional Airport is directly across Coos Bay, about 1 mile south of the terminal site.

Once constructed, the largest aboveground structures within the Jordan Cove terminal would be the two LNG storage tanks, which would each be approximately 267 feet wide and 180 feet tall. Dredge materials from the Navigation Reliability Improvement Project would be deposited at the APCO site located on the south side of the Bay, between the Coos Bay Railroad Bridge and the Oregon Coast Highway (also known as U.S. Highway 101).

Viewpoint Selection

A visual assessment was conducted to determine the potential effects on visual resources associated with the Jordan Cove LNG Project. Representative viewing points (also referred to as key observation points [KOPs]) were identified within the terminal viewshed (i.e., the area from which facilities at the terminal would be potentially visible). Generally, visual details become apparent to the viewer when they are seen in the foreground, at a distance of one-half mile or less, but may affect viewers when they are present in the middleground (up to 4 miles from the viewer) depending on the extent of landscape modification noticeable and other visual factors. It is anticipated, however, that views of the Project would be partially or fully screened by existing vegetation, topography, or infrastructure for much of the Project viewshed, and from most areas beyond 2 miles away. Therefore, the visual assessment applies to a viewshed for the Jordan Cove LNG Project that extends to a distance of approximately 2 miles from the LNG terminal in all directions, which was defined using aerial and ground photography, local planning documents, computer modeling, and field reconnaissance. Site visits to document existing visual conditions in the terminal area and to identify potentially affected sensitive viewing locations were conducted in April 2006, May 2013, and August 2017.

Representative viewpoints for use in the assessment were selected based on potential visibility of the proposed Jordan Cove LNG Project site from various distances, the sensitivity of viewing locations, and input from land management agencies (primarily the BLM and Forest Service). The viewpoints consist of locations with concentrations of viewers, such as major roadways or housing developments; visually sensitive land uses, such as parks and recreation areas; culturally sensitive locations, such as historic sites; and places designated as having scenic importance, such as highways and overlooks. Figure 4.8-2 indicates the locations of the 11 viewpoints used for visual assessment of the Jordan Cove LNG Project, and the location of the most prominent features there. The viewpoints are identified as follows:

- Viewpoint-1 North Spit Overlook and Wetland Trailhead
- Viewpoint-2 Trans-Pacific Parkway at Jordan Cove Project Site Entrance
- Viewpoint-3 Horsfall Beach Campground and Day Use Area
- Viewpoint-4 U.S. Highway 101 and Trans Pacific Parkway Intersection
- Viewpoint-5 U.S. Highway 101 on the north side of McCullough Bridge
- Viewpoint-6 U.S. Highway 101 at the southern end of McCullough Bridge
- Viewpoint-7 North Bend, intersection of Meade Avenue and Florida Avenue
- Viewpoint-8 North Bend, intersection of Meade Avenue and Vermont Avenue
- Viewpoint-9 North Bend, Open Space near Washington Avenue
- Viewpoint-10 North Bend, Bike Trail south of the Airport
- Viewpoint-11 BLM North Spit Boat Launch Area

Figure 4.8-2

Key Observation Point Locations for the Jordan Cove LNG Project

Visual Simulations

Computer-generated visual simulations were prepared for 9 of the 11 viewpoints. Visual simulations were not prepared for Viewpoint 4 and Viewpoint 7 because the LNG terminal would be, at most, minimally visible from those locations. Figures K-1 through K-11 in appendix K show the existing conditions (or "before" view) for each viewpoint, and a visual simulation (or "after" view) illustrating the expected appearance of built portions of the Project. The visual impact assessment was based on evaluation of the landscape changes that would result from completed construction and during the operation phase of the proposed facilities.

The visual simulations are the result of an objective analytical and computer modeling process and are accurate within the constraints of available site data, such as site topography, the proposed LNG terminal design, and photography obtained in the field. Existing GIS, a digital elevation model, engineering data, and digital aerial photographs provided the basis for developing three-dimensional digital models of the LNG storage tanks using a real-world coordinate system.

Viewpoint Analyses

The visual assessment for the Jordan Cove LNG Project is based on evaluation of the expected visual effects at the individual representative viewpoints. Because the LNG storage tanks would be the most visible feature of the LNG export terminal, the evaluation for each viewpoint focused on the visibility of the storage tanks.

Viewpoint-1 North Spit Overlook and Wetland Trailhead**—**Viewpoint-1 represents views to the southeast experienced by recreational visitors from the North Spit Overlook and Wetland Trailhead, which are located on private land on the northwest side of the Trans-Pacific Highway approximately 0.4 mile west of the LNG terminal site boundary. As shown in the simulation in figure K-1 in appendix K, there would be an unobstructed view of the LNG terminal from this location. Once the forested sand dune is removed, the LNG storage tanks, ground flares, and surrounding concrete perimeter walls would dominate the view.

Viewpoint-2 Trans-Pacific Parkway at Jordan Cove Project Site Entranc**e—**Viewpoint-2 represents views to the southwest for travelers along the Trans Pacific Parkway to the north of the terminal site. The viewpoint is located approximately 0.25 mile northeast of the northern boundary of the LNG terminal site, and approximately 0.5 mile northeast of the LNG storage tanks. As shown in figure K-2 in appendix K, with the forested sand dune removed, parkway travelers at this location would have an unobstructed view of the ground flares, gas processing area and concrete perimeter walls, and a partially screened view of the LNG storage tanks. Similar conditions would occur at other locations along the Trans-Pacific Parkway where views to the south were not obscured by vegetation.

Viewpoint-3 Horsfall Beach Campground and Day Use Area**—**Viewpoint-3 represents views to the south-southeast experienced by visitors to the sand dune public overlook above the Horsfall Beach Campground/Parking/Staging Area in the ODNRA. The Oregon Coast Trail also passes through this location as it transitions from the beach to Horsfall Beach Road. The viewpoint is located approximately 1.25 mile north of the LNG terminal site boundary, and approximately 1.6 miles northwest of the LNG storage tanks. The simulation indicates that views of the proposed facilities would be partially obstructed, and that the domes of the LNG storage tanks, the ground flares, and the surrounding concrete perimeter walls would be partially visible above the existing tree line (figure K-3 in appendix K). Because of their light color, viewers would be most likely to notice the tops of the LNG storage tanks. Along the Oregon Coast Trail, the LNG terminal would likely be partially visible from 0.5 mile to the east of the intersection of Horsfall Beach Road and the Trans-Pacific Parkway.

Viewpoint-4 U.S. Highway 101 and Trans-Pacific Parkway Intersection**—**Viewpoint-4 represents views to the west for travelers along U.S. 101 approximately 2.2 miles east of the LNG terminal site boundary, near the intersection with the Trans-Pacific Parkway and less than 0.5 mile east of the Conde B. McCullough State Recreation Site (figure K-4 in appendix K). The Oregon Coast Trail is also located along the Trans-Pacific Parkway and U.S. Highway 101 south of the Trans-Pacific Parkway Intersection in this area. Looking southwest, the Trans-Pacific Parkway can be seen in the middleground and the 190-foot-high loading tower at the Roseburg Forest Products chip export facility is barely visible above the trees beyond. The LNG terminal site, which would be obstructed by intervening landform and vegetation, would be located behind and to the right of the loading tower. Figure K-4 is an existing view from this viewpoint. A simulation was not completed because the proposed facilities would be obscured by topography and vegetation from this viewpoint. The Trans-Pacific Parkway/U.S. 101 widening would be visible in the foreground. The LNG terminal would likely be partially visible from the Conde B. McCullough State Recreation Site, located 2.4 miles to the northeast of the LNG terminal, but would be mostly obscured by vegetation and intervening topography. The LNG terminal would be visible along U.S. Highway 101 South in this area, but would be partially obscured by vegetation and intervening topography.

Viewpoint-5 U.S. Highway 101 on the north side of McCullough Bridg**e—**Viewpoint-5 represents views to the west as seen by travelers along U.S. 101 on the north side of McCullough Bridge, and is located approximately 2 miles east of the LNG terminal site boundary. The Oregon Coast Trail is also located along this section of U.S. Highway 101.

In the existing view, the forested sand dune located on the LNG terminal site is visible behind the Coos Bay Rail Link Bridge and the Roseburg Forest Products facility (figure K-5 in appendix K). The simulation shows that the forested sand dune would be removed, and that the LNG tanks and concrete perimeter wall would be visible above the treeline. Views of the LNG terminal facilities would be partially obscured by the existing Roseburg Forest Products facilities.

Viewpoint-6 U.S. Highway 101 at the Southern end of McCullough Bridge**—**Viewpoint-6 represents views to the northwest from the south side of McCullough Bridge, approximately 2 miles southeast of the LNG terminal site boundary and approximately 0.1 to 0.3 mile east of the APCO Dredge Disposal Site. Simpson Park, owned by the City of North Bend Parks, is located adjacent to the viewpoint location to the south. As shown in the simulation (figure K-6 in appendix K), the LNG storage tanks would be visible in the background above the APCO Site dredge material deposits, which are visible in the foreground. APCO Site 1 (approximately 0.1 mile west of the viewpoint location) would be approximately 36 feet tall, and APCO Site 2 (approximately 0.3 mile west of the viewpoint location) would be 48 feet tall. Initially, the dredge deposit areas would appear as an exposed sand dune. After vegetation is established, ground cover on the dredge deposit areas would appear visually similar to the surrounding landscape.

Viewpoint-7 North Bend, intersection of Meade Avenue and Florida Avenue**—**Viewpoint-7 represents views to the northwest from urbanized areas within North Bend, approximately 2 miles southeast of the LNG terminal site boundary. The Roseburg Forest Products facility is visible between and over the residential buildings and vegetation, across Pony Slough and Coos Bay (figure K-7 in appendix K). The forested sand dune that currently exists on the LNG terminal site is visible as a dark green line of vegetation behind the Roseburg Forest Products facility in the background. The view of the proposed facilities from this viewpoint was not simulated, because visibility of the facilities would be limited by the vegetation, residences, and other development. The LNG storage tanks would mostly be obstructed by intervening landforms, vegetation, and the existing Roseburg Forest Products facility.

Viewpoint-8 North Bend, intersection of Meade Avenue and Vermont Avenue**—**Viewpoint-8 represents views to the northwest from an urbanized area within North Bend that is higher in elevation compared to Viewpoint-7. The viewpoint is located approximately 2.25 miles southeast of the LNG terminal site boundary. In the existing view, Pony Slough, the Southwest Oregon Regional Airport, the Coos Bay Rail Link, and Coos Bay are visible between the viewpoint location and the proposed terminal location. The forested sand dune that currently exists on the LNG terminal site is visible as the dark green line of vegetation in the distance (figure K-8 in appendix K). As shown in the simulation, the forested sand dune would be removed and the LNG storage tanks, marine slip, concrete perimeter walls, and LNG vessel (when in port) would be visible from this viewpoint.

Viewpoint-9 North Bend, Open Space Near Washington Avenue**—**Viewpoint-9 represents views to the north from an open space in an urbanized area within the western part of North Bend. A single-family development is proposed (but not approved) for this location along Washington Avenue, which is located just south and uphill from the Church of Jesus Christ of Latter-day Saints, approximately 1.4 miles from the LNG terminal site boundary. As shown in figure K-9 in appendix K, the LNG storage tanks, marine slip, and concrete perimeter walls would be visible above the tree line.

Viewpoint-10 North Bend, Bike Trail South of the Airport**—**Viewpoint-10 represents views from Airport Lane and a bike trail that is located south and uphill from of the North Bend Waste Water Treatment Plant and the Southwest Oregon Regional Airport, near the intersection of Colorado Avenue and Arthur Street. The viewpoint is located approximately 1 mile south of the LNG terminal site boundary. In the existing view, treatment plant and airport structures are present in the foreground and the Roseburg Forest Products facility is visible in the middleground, as is the forested dune on the LNG terminal site (figure K-10 in appendix K). The simulation shows that the LNG storage tanks, marine slip and associated sheet pile walls, and LNG vessel (when in port) would be visible and prominent from this viewpoint.

Viewpoint-11 BLM North Spit Boat Launch Area**—**Viewpoint-11 (figure K-11 in appendix K) represents views to the northeast from the interpretive overlook at the BLM North Spit Boat Launch parking lot, and is approximately 0.75 mile southwest of the LNG terminal site boundary. The topography at this site is flat with low-growing vegetation, allowing views of the existing forested sand dune located on the LNG terminal site to the left of the Roseburg Forest Products facility. The simulation shows that the LNG storage tanks, marine slip, concrete perimeter walls, and the LNG carrier (when in port) would be visible in the near middleground.

Visual Impacts

Short-Term Visual Impacts

Construction of the Jordan Cove LNG Project would be noticeable to recreational users on Coos Bay, in portions of the ODNRA, in portions of the North Spit Overlook, and at the boat launch and other locations within the BLM Coos Bay/North Spit RMA. Some residences in both the cities of

North Bend and Coos Bay would also have views across the bay to the terminal, although for other residences such views would be obstructed by terrain, vegetation, or intervening development. Construction activities would also be noticeable to motorists using the Trans-Pacific Parkway and the Pacific Coast Scenic Byway (U.S. Highway 101). Visual effects from construction activities near the terminal site would include dust plumes, exposed surfaces resulting from clearing and grading, and the presence of construction equipment and personnel activity on the LNG terminal site. Wetland restoration activity at the Kentuck project site might be evident to motorists using local roads and rural residences in the immediate vicinity of the site. These visual effects from construction activity would be temporary and limited to the construction period.

Short-term visual effects during construction of the LNG terminal would include the presence of the workforce housing facility within the South Dunes that would include pre-fabricated housing units and basic utility structures, which would visually resemble a small, dense residential community. The workforce housing facility would be dismantled and all structural elements removed from the site following completion of construction activities, and therefore visual effects resulting from the housing facility would be short term.

Long-Term Visual Effects

Based on the visual simulations, the Jordan Cove LNG Project would be visible to the public and would alter the existing visual character and scenic quality of the site. In addition to installation of the LNG tanks and related facilities, another permanent effect includes the removal of portions of a forested dune located on the eastern portion of the terminal site. This dune is a noticeable topographic feature of the existing landscape, and its removal was incorporated in the simulations whenever applicable.

Based on the visual changes indicated by the simulations for the set of representative viewpoints, the Jordan Cove LNG Project would have a moderate to high visual effect on residential communities in Coos Bay and North Bend to the south of the site. This effect would occur because of proposed landform modifications, including removal of the forested sand dune on the LNG terminal site, and the visibility of proposed industrial facilities on a previously undeveloped site. Moderate visual impacts are anticipated for viewers from hillside residences that would have views of the LNG terminal site that are not screened by topography, vegetation, or intervening development. These viewers would see the proposed development in the context of existing residential, commercial, transportation, and industrial uses in North Bend and Coos Bay that would be visible in foreground to middleground distances. Residences located along the shoreline of Coos Bay south of the regional airport (along Maxwell Road, Seagate Avenue, and Fenwick Street, for example) with unobstructed views of the site would experience a stronger visual effects and reduced scenic quality than would hillside residences, because the proposed facilities would primarily be viewed in the context of a shoreline landscape that currently has sparser development and higher scenic quality than the interior urban areas. Lights associated with the LNG terminal site are not anticipated to create a substantial new source of light or glare that would adversely affect daytime views. Nighttime views in the area include lights associated with the airport, the industrial facilities on the North Spit, and other urban uses. The addition of lights associated with the Jordan Cove LNG Project would be a low to moderate incremental impact when viewed in context of the extent and intensity of current lighting in the area.

The Jordan Cove LNG Project would be visible to recreational users on Coos Bay, in portions of the ODNRA, from the North Spit Overlook, and in portions of the BLM Coos Bay/North Spit

RMAs, including the BLM boat launch. Recreational users with views of the Jordan Cove terminal would notice moderate visual contrast in most locations, but high contrast when the Project is viewed in the foreground (within approximately 0.5 mile of the proposed facilities). The reduction of scenic quality in these areas where the Project creates a high contrast in the foreground would reduce the recreation experience from those viewpoints for some viewers who are sensitive to those changes. When viewed from greater distances, the reduction of scenic quality would generally be less pronounced because the Project would be viewed in the context of the surrounding landscape, which is characterized by other industrial, residential, and commercial developments.

The Project would be noticeable to motorists using the Trans-Pacific Parkway and the Pacific Coast Scenic Byway (also known as U.S. Highway 101). Visual effects on travelers on these roadways would be low to moderate. Intervening landforms and vegetation obstructs views toward the LNG terminal site from many locations along U.S. 101 and the Trans-Pacific Parkway. Travelers on these roadways would potentially experience low to moderate visual effects, because these viewers tend to have lower sensitivity and a shorter duration of view, and because the facilities would be viewed in the context of the surrounding landscape.

Wetland restoration would alter the long-term appearance of the 140-acre Kentuck project site. The site is the location of the former Kentuck Golf and Country Club, an 18-hole golf course that opened for play in the mid-1960s and closed in 2009. Aerial imagery indicates the site is no longer actively maintained and has a vegetative cover of grasses and other low-growing species, with trees and shrubs in some areas around the southern periphery and some visible evidence of remnant golf course features. The Kentuck project site is similar in character to adjacent open pasture areas located in the flat valley bottom land along Kentuck Slough, which is a narrow, linear waterway parallel to Kentuck Lane. Over time, most of the open, grassy area of the site would take on the appearance of freshwater and estuarine wetlands, including some areas of open water. The long-term visual effect of the proposed mitigation action would be to create a more natural-appearing landscape at the Kentuck site, and the change would be relatively subtle. Because the Kentuck project site is in a narrow tributary valley, this visual change would only be evident within the immediate local area, primarily including segments of East Bay Road and Kentuck Lane and a small number of rural residences located in the valley. The long-term landscape change at the Kentuck site is likely to be perceived as a minor, positive visual effect.

A related visual element of the LNG terminal would be the introduction of LNG carriers to the viewshed of the Coos Bay area communities. Traveling between 4 and 10 knots per hour, an LNG carrier would cross through the field of view for shoreline viewers in a few minutes. While LNG carriers are very large vessels, they are relatively close in size to cargo ships that currently transit the bay for the purpose of transporting wood products, which average around 600 feet in length. Because ships of this scale are already a regular occurrence in the waterway, the presence of LNG carriers would not be a new type of visual feature on the waterway.

Proposed Mitigation Measures

Jordan Cove has proposed several measures that would mitigate long-term visual effects of the Project. Jordan Cove has taken measures to minimize impacts on wetlands and estuaries in the siting of the Project, thereby retaining some of the visual characteristics of the site. The LNG terminal location was selected to avoid disturbance of Jordan Lake, which would help to minimize visual effects by preserving an existing, distinctive waterbody in the landscape. However, the size and location of the proposed LNG terminal and associated facilities would cause visual effects from many viewpoints that cannot be effectively mitigated.

The exterior of the LNG storage tanks would be constructed of untreated concrete of a light grey color for cryogenic purposes. While a darker color would help reduce the visibility of the tanks from a distance, such treatment is not generally considered feasible, as dark colors absorb heat, which would increase the temperature of the tank exterior and become problematic for LNG storage control. Jordan Cove evaluated various tank profiles and locations to minimize visual effects, and concluded that the proposed size, profile, and location would be the optimum considering other environmental factors, safety, and reliability. The final landscape design for the site would include provisions to contour and stabilize landforms not affected by construction and to provide some level of screening around the facilities. The use of native plants for restoration and stabilization of the landforms would also be incorporated into the final planting design to the extent practical. Building facades would incorporate the architectural design of existing buildings in the area. The final lighting plan would include hooded or cut-off lighting to minimize light spillage onto adjacent areas. Only lighting required for operation and maintenance, site safety and security, and to meet FAA requirements would be used on the LNG storage tanks and, whenever possible, the light would be localized to minimize off-site effects.

4.8.2.2 Pacific Connector Pipeline

Visual resources along the pipeline alignment vary greatly. The natural landscape features include sandy treed dunes, expansive bay views and temperate rain forest in the Coos Bay area, and rolling steep conifer-forested hillsides in the Coast and Cascade ranges and foothills. Open oak savanna, pasturelands, and rolling hills are common in the viewsheds near Roseburg and east of Medford, with views transitioning to dramatic conifer mountain and volcanic landscapes in the Cascade Mountains. Croplands, pasturelands, rolling sagebrush rangeland, and pine-juniper forests punctuated by westerly views of the Cascades compose a unique scenic landscape in the Klamath Basin at the eastern end of the pipeline.

Culturally modified landscapes include farm and rangelands, small towns, and forest management activities including clearcut timber harvesting. Forested viewsheds are characterized by various aged forest stands that are in various stages of harvest, regeneration, or mature forests. Several viewsheds along the western portion of the pipeline route have very low scenic integrity, including hillsides altered by clearcuts and traversed by logging roads. A few forested areas also include existing utility corridors. Where the pipeline crosses NFS lands within the Umpqua, Rogue River-Siskiyou, and Fremont-Winema National Forests, the forested viewsheds are characterized as ranging from low to high scenic integrity, varying with stages of forest maturity and harvest regeneration. Other forest landscapes and views have been modified by recent wildfires, such as the Stouts Creek Fire in the Umpqua National Forest in 2015.

On BLM and NFS lands, visual resources are managed according to visual resource management guidelines. Most of the pipeline alignment would pass through viewsheds which allow moderate change, as evidenced by active timber management activities. These are areas where alterations of the existing landscape would not significantly alter the existing characteristics of the viewshed. In a few locations, the pipeline would cross federally managed public lands that are designated as having high visual resource sensitivity under the agencies' visual management system. These areas are discussed in detail later in this section.

KOP Selection

A visual assessment was conducted to determine the potential effects on visual resources associated with the pipeline. Representative viewpoint points (also referred to as KOPs) were identified within the viewshed for the pipeline, defined as the area from which the pipeline would be potentially visible. The pipeline viewshed extends to a distance of 5 miles on either side of the pipeline. This distance was defined using aerial and ground photography, local planning documents, computer modeling, and field reconnaissance. Site visits were conducted in April 2006 and updated in May 2013 to document visual conditions along the pipeline route and to identify potentially affected sensitive viewing locations along the proposed route. Based on these site visits, it is anticipated that views of much of the pipeline from within the 5-mile viewshed would be partially or fully screened by existing trees, landforms, or intervening development. Figures 4.8-3 to 4.8-5 show the proposed route as it moves through the various BLM VRM classifications and Forest Service visual quality objective (VQO) classes[162] as well as the KOP locations along the route.[163]

A supplemental visual impact assessment was conducted to determine the potential effects on visual resources associated with the pipeline as it crosses the PCT. The viewshed for the PCT at this crossing is quite limited because of the old-growth forest, dense brush and understory trees, and the pedestrian scale of the characteristic landscape. A detailed visual analysis was undertaken for the PCT crossing site. Several site visits were conducted in the spring of 2015 to document existing visual conditions of the PCT at the pipeline crossing. The Forest Service determined that two new KOPs would be required to accurately simulate the expected future visual conditions as seen from the PCT. Forest Service personnel and the visual analysts established two new KOPs in this pedestrian landscape.

For this supplemental analysis, the new KOPs are numbered sequentially as KOP-P8 and KOP-P9, as shown on figure 4.8-5 (MP 155 to 228). The VQO for the affected landscape along the PCT is Foreground Partial Retention, indicating that human activities should remain visually subordinate to the characteristic landscape. Activities may repeat form, line, color, and texture common to the characteristic landscape, but changes in their qualities of size, amount, intensity, direction, pattern, etc. should remain visually subordinate to the characteristic landscape.

A supplemental visual impact assessment was also conducted for the crossing of the Coos Bay Wagon Road corridor in 2013, to support an analysis of the Modified Blue Ridge Route Alternative, which has been incorporated into the Proposed Route. As a result, KOP-P10 was added to the visual resource analysis, as shown on figure 4.8-3.

As a result of the original and supplemental visual assessments, the complete list of KOPs for the Pacific Connector Pipeline Project is summarized as follows:

- **KOP-P1 ODNRA**, west of MP 0, Horsfall Beach Campground and Day Use Area

[162] The VRM system has four management classes, with objectives ranging from preserving the existing landscape character (Class I) to providing for management activities that require major modification of the existing landscape character (Class IV). The VQO system has five classes, ranging from Preservation (where most management activities are prohibited) to Maximum Modification (where management activities may dominate the landscape). See Section 4.8.2.3 for additional discussion.

[163] The VRM class boundaries shown on figure 4.8-4 are incorrect near KOP-P2. They are based on GIS data which is being corrected at the time of publication. The VRM class near the Trail Post Office KOP is VRM-II.

- **KOP-P10 Coos Bay Wagon Road**, MP 24.37, Sumner-Fairview Road northwest of Fairview
- **KOP-P2 Trail Post Office**, MP 123.0, Town of Trail adjacent to Highway 62
- **KOP-P3 Highway 140**, MP 145.6 near Little Butte Creek
- **KOP-P4 Big Elk Road** (Forest Road 37), MP 161.4, west of Lake of the Woods
- **KOP-P5 Clover Creek Road**, MP 172.2, north of Buck Lake
- **KOP-P6 Clover Creek Road**, MP 176.8, east of Buck Lake and west of Aspen Lake
- **KOP-P7 Clover Creek Road**, MP 170.1, northwest of Buck lake
- **KOP-P8 Pacific Crest Trail**, MP 167.8, south of Brown Mountain
- **KOP-P9 Pacific Crest Trail**, MP 167.8, south of Brown Mountain

Visual Simulations

Photographs of existing visual conditions were used in preparing computerized visual simulations for each KOP. Because the appearance of the pipeline right-of-way would change with time, a series of simulations were prepared to illustrate how the pipeline right-of-way would look at different timeframes following construction. The KOP photo sets are presented sequentially in appendix K as follows:

- Existing Conditions: How the landscape appeared at the time site photography was conducted.
- Post-Construction (Year 0): The pipeline is in place and backfilled. Soils have been re-contoured, water bars constructed, and cull logs, root wads, and boulders have been scattered across the right-of-way. Seedlings of native trees (Douglas-fir and ponderosa pine) have been planted among the woody debris and boulders, except for a 30-foot-wide corridor directly above the pipeline.
- Post-Construction, Site Repair, and Replanting (Year 5): Douglas-fir and ponderosa pine saplings are starting to show among the woody debris, boulders, and water bars. Grasses are growing across the entire right-of-way. There are no trees growing in a 30-foot-wide corridor directly above the pipeline.
- Year 25: Young Douglas-fir and ponderosa pine trees are growing throughout the right-of-way, except for the 30-foot-wide corridor directly above the pipeline, and some of the woody debris (cull logs and root wads) is beginning to deteriorate. The boulders and water bars remain, and maintenance has occurred to keep only low-growing shrubs and grasses in the 30-foot-wide corridor centered directly over the pipeline.

KOP Analyses

Pacific Connector, with guidance from the Forest Service and BLM, initially selected nine points from which to assess visual and aesthetic impacts. Five points were selected based on their proximity to federal lands with high scenic qualities and associated visual management objectives. A tenth KOP was added later to reflect potential visual impacts at the pipeline crossing of the former Coos Bay Wagon Road, a feature of historic interest. These KOPs would also serve as monitoring points for mitigation. Each KOP is described below.

KOP-P1 ODNRA

KOP-P1 represents views experienced by recreational users at the ODNRA, Horsfall Beach Campground and Day Use Area. KOP-P1 is geographically similar to Viewpoint-3 at and is located north of pipeline MP 0.00 with views of both the LNG terminal and pipeline construction areas (figure 4.8-2). From KOP-P1, visual effects associated with the pipeline would be subordinate to concurrent construction at the proposed LNG terminal, as well as activities associated with nearby industrial areas, air and sea port traffic, and urban development in the Coos Bay region. Visual effects of the pipeline from this KOP are therefore negligible overall. No further visual impact assessment is necessary at this location due to complete visual screening of the pipeline alignment by intervening topography. For this reason, there is no photograph/simulation set for KOP-P1 in the figures that follow.

KOP-P10 Coos Bay Wagon Road

The pipeline would cross the route of the historic Coos Bay Wagon Road on private lands at MP 24.37, about 15 miles southeast of Coos Bay and 2 miles northwest of the community of Fairview. The Coos Bay Wagon Road was a historic backcountry route built in the 1870s to connect Coos Bay and Roseburg, Oregon for freight transportation. The Wagon Road fell into disuse after OR 42 was built in the Coquille River valley during the early twentieth century. Local roads developed along the original road alignment continue to be used as an alternative travel route. KOP-P10 is located where the pipeline would cross the Wagon Road route, which is now a two-lane paved road identified locally as the Sumner-Fairview Road. The KOP represents foreground/middle ground views of the pipeline that would be experienced by travelers on the former Wagon Road route.

Figure K-12a in appendix K provides the existing view from the just outside the proposed pipeline right-of-way, and figures K-12a through K-12c show visual simulations for different stages of construction and restoration (note that for this KOP the set of simulations also includes a view of conditions at Year 10 as requested by the BLM). In Year 0, clearing associated with the pipeline would be visible to road users for approximately 0.25 mile, or approximately one-eighth of a mile on either side of the pipeline crossing. While the pipeline clearing might be visible from locations beyond this area, it is not likely to dominate views or affect landscape character. By Year 10, the right-of-way might not be noticeable to most road users because planted vegetation would mask the corridor unless the viewer is directly adjacent to the 30-foot permanently cleared area.

KOP-P2 Trail Post Office

KOP-P2 is located on private land at the U.S. Post Office in the town of Trail, near MP 123.0 and is representative of the view from Crater Lake Highway (State Highway 62). Simulations show the views to the southeast where the pipeline route crosses private land southwest of the Rogue River HDD crossing. Approximately halfway up the hill, the pipeline would leave private land and cross BLM land designated as VRM Class IV. Existing vegetation depicted in the view from KOP-P2 at the pipeline right-of-way consists of a dense evergreen forest of Douglas-fir and ponderosa pine. There are patches of scrub-oak and manzanita at the right-of-way, and a bare patch of soil north (left) of the right-of-way (figures K-13a and K-13b in appendix K). After pipeline construction, the removed vegetation and exposed earth within the cleared right-of-way would create a moderate to high level of contrast in the short term, until vegetation is re-established. After vegetation is established, the level of contrast would be low to moderate (figure K-13b and K-13c).

KOP-P3 Highway 140 near Little Butte Creek

KOP-P3 is located at MP 145.6, at the point where the pipeline would cross under State Highway 140 near Little Butte Creek on private lands, and represents views to the southeast experienced by travelers along Highway 140 (figures K-14a and K-14b in appendix K). This KOP provides a middle ground/background view of BLM lands classified as VRM Class IV located approximately 2.5 miles southeast of KOP-P3. The pipeline right-of-way would be visible in the foreground where it is located adjacent to Highway 140, and then in the middleground/background where it would be located on a hill on BLM land. Initially, contrast levels would be moderate to high, depending upon the angle of view. Contrast would be reduced over time as vegetation is re-established within the right-of-way.

KOP-P4 Big Elk Road (Forest Road 37)

KOP-P4 represents views to the north experienced by travelers along Big Elk Road (Forest Road 37) at MP 161.4 This road provides access for snowmobilers, anglers, hikers, and others travelling to Lake of the Woods. The pipeline crossing location is located in the Rogue River-Siskiyou National Forest in an area designated with a VQO of Foreground Retention. The pipeline would cross the road at this location in a perpendicular manner, and viewers would experience both foreground and middleground views of the cleared pipeline right-of-way when they are adjacent to or near the road crossing. Simulations show the moderate long-term visual effects of the permanently cleared 30-foot-wide right-of-way that would be visible to passing motorists (figures K-15a and K-15b in appendix K).

KOP-P5, KOP-P6, and KOP-P7 Clover Creek Road

The pipeline would generally parallel Clover Creek Road for approximately 18.2 miles between MP 169.5 and MP 187.7. The Forest Service VQO for MPs 170 and 175 is Partial Retention. The series of three simulations in figure K-16 shows the typical visual effects that would occur in timbered landscapes along this segment of Clover Creek Road.

Simulations prepared for KOP-P5 represent a long-distance view of the right-of-way near MP 172.2 from the perspective of motorists along Clover Creek Road. The simulations show that clearing associated with the pipeline right-of-way would be visible in the immediate foreground, foreground, and middleground from this perspective (figures K-16a and K-16b in appendix K). Contrast created by the clearing of the right-of-way would be reduced over time after restoration, which would involve recontouring, reseeding, scattering of slash across the right-of-way, and replanting.

KOP-P6 represents a second view from the perspective of motorists on Clover Creek Road, near Spencer Creek at about MP 176.8 along the pipeline route, on BLM lands, looking uphill. In this location, the pipeline right-of-way would be immediately adjacent to the road, as shown in figures K-16a and K-16b for KOP-P5 and figures K-17a and K-17b for KOP-P6. The clearing would create a “widening” effect. Contrast created by the clearing of the right-of-way would be reduced over time after restoration, which would involve recontouring, reseeding, scattering of slash across the right-of-way, and replanting.

KOP-P7 represents a third view from the perspective of motorists along Clover Creek Road. KOP-P7 is located at MP 170.1, facing due east and downhill from a motorists’ perspective. There is an existing partial-cut timber harvest area on the north (left) side of the road. Simulations for KOP-P7 show an additional long-distance view of the pipeline right-of-way from along Clover Creek Road. As shown on the post-construction simulation, woody debris (cull logs, slash, and root wads) would be left on the right-of-way to discourage OHV use, which would create visual contrasts. The Year 25 simulation shows pine reforestation on the right-of-way, and in this view, the permanently cleared and maintained area directly over the pipeline would be partially to completely screened from view of the road. This simulation shows the extent of high visual effects of the pipeline, over time, in the immediate foreground, foreground, and middleground of Clover Creek Road (figures K-18a and K-18b in appendix K).

KOP-P8 and KOP-P9, Pacific Crest Trail

The pipeline would intersect the PCT at approximately MP 167.8, in the Fremont-Winema National Forest. At this location, the old-growth forest has a VQO of Foreground Partial Retention to maintain the aesthetic quality of the forest for PCT users. Because the pedestrian landscape has very limited sight distance, only immediate foreground (0 to 300 feet) views are possible. The visual simulations presented in figures K-19 and K-20 in appendix K show the anticipated visible impacts of the pipeline right-of-way and construction work space immediately following construction as well as 5 and 25 years following implementation.

Because the pipeline would create a linear opening in old-growth forest, hikers and equestrians would now have immediate foreground (0 to 300 feet) and foreground (0 to ½ mile) views. In the Year 0 simulation, the pipeline is in place and the trench is backfilled. The right-of-way clearing was "necked down" from 95 feet to 75 feet wide for a length of 300 feet each side of the PCT (the immediate foreground zone). Within this 600-foot-long zone at the PCT, all large diameter trees that are right along the edge of the cleared right-of-way have been retained. All stumps have been flush-cut rather than removed in this area of right-of-way so that equipment can drive over them. All shrubs have been mowed to 6 inches in height in this 600-foot-long zone, rather than stripping the right-of-way to bare ground. The only bare earth was the 10-foot-wide ditch zone. On-site shrubs and ground cover plants were dug from the 10-foot-wide ditch zone, heeled-in root balls in a safe storage location, and then transplanted back into the trench zone. The entire 75-foot-wide right-of-way was seeded with native grasses and forbs for a length of 300 feet each side of the PCT. In this 600-foot-long zone, trees were planted in masses outside of the 30-foot-wide mowed area and would be irrigated via a holding tank and drip system. Beyond 300 feet from the PCT, the right-of-way expanded back to 95 feet wide, and the entire right-of-way was seeded with native grasses and forbs. Seedlings of Douglas-fir and Shasta red fir were planted in the right-of-way outside the 30-foot-wide mowed zone, and logs were placed in the right-of-way. At Year 5, Douglas-fir and Shasta red fir trees are growing larger, and grasses and forbs are growing across the entire right-of-way. At Year 25, Douglas-fir and Shasta red fir trees are growing larger and some of the logs are beginning to lose their bark. Maintenance has occurred to keep only low-growing shrubs, forbs, and grasses in the 30-foot-wide corridor centered directly over the pipeline.

KOP-P8 represents a hiker's perspective walking northbound on the PCT, looking ahead from the old-growth forest into the 75-foot-wide cleared right-of-way at approximately MP 167.8 and beyond. This vantage point is located between two large trees and is the first opportunity to see the right-of-way clearing, which extends from 67 feet to 142 feet ahead of the camera position. A hiker is shown in the photographs and simulations to represent human scale (figures K-19a and K-19b).

For a typical hiker or equestrian, the duration of view would be short, because it does not take long to walk or ride a few hundred feet along the PCT. The right-of-way would create an opening that would allow more sunlight into this area. The interpretive sign would call attention to the pipeline and explain the changes in the characteristic landscape. As seen from KOP-P8, the overall visual effect would achieve the Foreground Partial Retention VQO.

KOP-P9 is from a hiker's perspective standing in the middle of the 30-foot-wide cleared area over the right-of-way, looking west from a short distance (48 feet) east of the PCT (figures K-20a and K-20b). The pipeline clearing would extend to the west and then make a dogleg to the northwest, thereby reducing the length of the "tunnel effect" of the right-of-way clearing. If the viewer turned around at this location and looked east, a similar dogleg would be limit the visibility of the right-of-way in that direction. Both of these doglegs reduce the extent of right-of-way clearing that would be visible from the PCT. Duration of view from this vantage point would be longer than for KOP-P8 because the viewer has walked off the trail and stopped to survey the landscape. The right-of-way would create a different viewing experience because of its linear form; however, revegetation with trees, grasses, and forbs, plus placement of logs in the right-of-way, would partially retain the surrounding landscape character. Because of the restoration efforts, the pipeline right-of-way would remain visually subordinate to the characteristic landscape. The interpretive sign would call attention to the pipeline and the changes in the characteristic landscape, causing viewers to stop and look more carefully. As seen from KOP-P9, the overall visual effect would achieve the Foreground Partial Retention VQO.

Visual Impacts

Short-Term Visual Impacts

Construction impacts on visual resources would result from the presence of equipment, materials, and workers along the pipeline right-of-way, at TEWAs and staging areas, and along access roads. Visual effects would also result from the alteration of landforms and vegetation along the right-of-way during construction. Excavation for the pipeline would expose sub-grade soils that would contrast with the color of the existing land surface and the forest canopy. Visual contrast in color, line, and texture between the disturbed, vegetated ground and the adjacent vegetation would be most noticeable in the short term (0-5 years after construction) while the right-of-way is in the process of revegetating. Vehicles, heavy equipment, helicopters, pipeline components, and workers would be visible during site clearing, grading, trenching, pipeline transport, welding, laying in, backfilling, and site/right-of-way cleanup and restoration. Construction equipment and activities would be seen by various viewers close to the sites and pipeline corridor, including adjacent and nearby residents, recreationists on trails and roads, motorists on public roadways and, in some cases, pedestrians. Much of the Pacific Connector pipeline route is in remote locations seldom visited by the public, although visitors in such remote areas may be relatively sensitive to changes in visual quality. Where visible, view durations would vary from brief to extended periods. Construction activities would be most visible for those elements of the pipeline in close proximity to residential neighborhoods and adjacent to major travel corridors, including highways and the PCT; however, these effects would be temporary and would be limited to the construction period. Revegetation and restoration efforts, including placement of slash on the right-of-way in forested areas, would serve to mitigate the visual contrast in color, line, and texture.

Amendments to the Rogue River-Siskiyou and Fremont-Winema National Forest LMPs would be necessary to address consistency with specific standards and guidelines related to VQOs. These amendments would acknowledge the short-term visual effects that would occur that would be inconsistent with current management direction. They would allow for an extended period of time for the areas to recover and meet the VQOs in a reasonable amount of time.

Long-Term Visual Impacts

Pipeline

The landscape setting along the pipeline route is varied, ranging from flat valley floors and agricultural fields, to rolling hillsides covered with oak and madrone woodlands, to steep mountainsides and sharp ridgelines covered with mixed conifer forests. On flat terrain in agricultural settings, the right-of-way would be restored following construction and ranchers/farmers would be allowed to grow shallow-rooted crops over the pipeline. Construction work areas would normally be difficult to distinguish from surrounding areas. Therefore, no long-term visual effects would result from installation of the pipeline in agricultural areas.

In the mountainous terrain, many of the existing landscapes that would be traversed by the pipeline have already been affected by timber harvests, including large clear-cuts. Existing scenic integrity in these areas is low, and the introduction of the pipeline should not create long-term visual contrasts in these settings.

The greatest long-term visual effects would occur where the new right-of-way would create new clearings through forestlands not characterized by large-scale timber harvests. The clearing of the right-of-way would create a sharp-edged linear feature across contiguously forested landscape. The appearance of the corridor would be similar to transmission line corridors. Revegetation and restoration, including replacement of slash in the right-of-way, would be initiated following construction and would mitigate the visual contrast in color, line, and texture. Contrast might also be increased where surface rock or stumps would be scattered across the right-of-way or placed in piles at road crossings to create OHV barriers or habitat features. Over time, contrast would decrease as the right-of-way is revegetated, narrows in width because of revegetation, and becomes more similar in texture and color to the surrounding forest lands. After successful restoration, the cleared area around the right-of-way would be reduced to the 30-foot permanently cleared area, further reducing contrast with the surrounding forested area.

The right-of-way might be noticeable to the casual observer depending on the distance, line-of-sight, topographic, and vegetation conditions at the viewpoint as well as the conditions along the Pipeline right-of-way. The corridor would be most apparent when viewed from a location in-line with the right-of-way, and might not be visible when viewed from a perpendicular location due to vegetative screening. Where it crosses ridges, the cleared right-of-way might be visible as a "notch" in the treeline from perpendicular or near-perpendicular viewpoints. Many forested areas crossed by the pipeline are away or visually screened from roads, trails, and populated areas, and therefore are not immediately visible to viewers.

Aboveground Facilities

The aboveground facilities proposed by Pacific Connector would be long-term structural features on the landscape. A detailed description of the aboveground facilities is provided in chapter 2. The MLV sites are all located within the pipeline ROW, and consist of a 50-foot x 75-foot (0.9 acre) site that would be enclosed by a 7-foot-high, chain-link fence. Five of the MLVs would require a 40-foot-tall tower to be installed within the site. Pacific Connector has attempted to locate MLVs adjacent to existing roads to facilitate access and minimize the length of new access roads, and to set block valves back from crossings in sensitive viewsheds. Where not screened by topography or vegetation, the MLV sites would be visible to roadway travelers. On federal lands, all aboveground piping would be painted with a color approved by the managing federal agency in order to meet visual quality objectives and visual screening would be implemented. The MLVs would all be located within the pipeline right-of-way and therefore, with the mitigation measures applied to federal lands, would have low effects on visual quality of the surrounding area. MLV 13 was previously located adjacent to the Dead Indian Memorial Highway, but has been relocated back from Clover Creek Road and accessed from an existing private road to screen the block valve from view.

The Klamath Compressor Station (MP 228.1) would have visual effects on nearby residents and travelers along Malin Loop Road and Morelock Road (figure 4.8-6). The location is on private land in a rural area that is relatively flat and is currently covered by grasses, sage, and juniper. To reduce visual contrast, the buildings at the compressor station would be painted a color selected to blend as well as possible with the surrounding landscape, and portions of the outward facing sides of the station would be landscaped to reduce potential visual effects on area residences. The station would be surrounded by a 7-foot-tall chain-link fence with screening slats. The station would include exterior lighting to be used only when operations personnel are actively performing nighttime work at the station. Pacific Connector has stated that during operation of the station nighttime work or maintenance activities would generally not be scheduled; therefore, these lights would only be used periodically and possibly for short periods during the winter when daylight working hours are shorter. Pacific Connector has not identified specific lighting arrangements, although standard practice is for outside lights at infrastructure facilities such as compressor stations to be shrouded to direct light to the specific work areas within the station.

Pacific Connector anticipates that communications towers would be required at the compressor meter stations, several automated MLVs, and at leased space on existing communication towers (see chapter 2 for location descriptions). The towers at the meter stations, compressor station, and automated MLVs would be located within the fenced facility sites. The Communication Facilities Plan[164] describes the construction, modification, operation, and maintenance of communication facilities on lands managed by the BLM and the Forest Service.

The proposed communication facilities are not expected to significantly alter or impair the visual setting. Pacific Connector would co-locate communications towers with existing facilities whenever possible, if leased space is available within existing facility sites at the time of construction. If construction of new facilities is required, Pacific Connector would seek to obtain an approximate 100-foot by 100-foot (0.23 acre) area for each of the new tower installations in the immediate vicinity of the existing communication tower facilities. A variance would be needed to allow installation of any new tower under such conditions. Because additional towers are anticipated to be co-located with existing tower facilities, they are not expected to impair the existing visual setting.

Proposed Mitigation Measures

Pacific Connector produced an *Aesthetics Management Plan*[165] that outlined measures to reduce visual impacts along its pipeline route. Generally, these measures include:

- reducing the width of the right-of-way and elimination of TEWAs at sites with high visual sensitivity;
- strategic alignment of the right-of-way where it crosses roads or trails to reduce the visible extent of the corridor (for example, crossing roads or trails at right angles);
- strategic placement of construction debris (slash, stumps, and boulders) in visually sensitive areas;

[164] Appendix D of Pacific Connector's POD filed with the FERC in January 2018.
[165] Appendix A to Pacific Connector's POD filed with the FERC in January 2018.

- place natural barriers where the right-of-way opening is adjacent to trails and roads to prevent potential unauthorized OHV use;
- clear additional timber outside the right-of-way in selected locations to scallop and feather the edges of the clearing, to reduce the hard line of forested lands adjacent to the right-of-way;
- revegetation of the right-of-way after pipeline installation, including planting trees in TEWAs that were cleared of forest or woods and strategic placement of trees to help reduce contrast between the cleared right-of-way and surrounding forest lands;
- planting rows or clusters of trees and shrubs across the right-of-way (outside of the 30-foor permanently cleared corridor) to provide visual screens at specific sensitive trail or road crossings, using native species whenever possible; and
- painting aboveground facilities in color schemes that would blend into the background landscape.

It should be noted that some visual mitigation measures are not shown in the visual simulations. These include opportunities for revegetation with large-sized trees (tree-spade efforts), forest edge scalloping, and/or feathering treatments to decrease stand density contrasts at the right-of-way edges. Therefore, these simulations represent a worst-case scenario at each KOP.

4.8.2.3 Environmental Consequences on Federal Lands

Visual Resources on Federal Lands

Regulatory Setting and Visual/Scenic Management Systems

The responsibility of protecting visual resources on lands owned or under the jurisdiction of the federal government is established by FLPMA, which places emphasis on the protection of scenic resources on public land, and the Forestland and Rangeland Renewable Resources Planning Act (1974) which empowers the Forest Service to manage scenery resources. The National Forest Management Act (1976) required the completion of Forest Plans that established VQOs for the National Forests.

NFS Lands

The Forest Service seeks to manage NFS lands to attain the highest possible quality of landscape aesthetics and scenery commensurate with other appropriate public uses, costs, and benefits. Scenic integrity is defined as "*a measure of the degree to which a landscape is visually perceived to be* "*complete.*" The highest scenic integrity ratings are given to those landscapes that have little or no deviation from the character valued by constituents for its aesthetic appeal. Scenic integrity is used to describe an existing situation, standard for management, or desired future condition" (Forest Service 1995b).

National Forests use a Visual Management System (VMS) to manage visual resources on NFS lands and to analyze visual effects of proposed projects. The VMS has a rating system known as VQO to establish standards for scenery resource management. The VMS was outlined in FSH 462, published in 1974. Since then, scenery management on NFS lands has been updated by Handbook 701, which introduced the Landscape Aesthetics, Scenery Management System (SMS). The SMS utilizes a rating system similar to VMS to evaluate project impacts on visual quality. The SMS is based on the relative scenic quality of each portion of the landscape and its sensitivity based on the visibility from, and uses in, the surrounding areas. The SMS uses Scenic Integrity Objectives to establish the desired conditions for management of an area.

Under the former VMS system, management prescriptions and related VQOs were developed for all NFS lands. VQOs for each national forest crossed by the pipeline are identified in their respective LRMPs. VQOs are management standards that identify five degrees of alteration to the natural landscape based on a landscape's diversity of natural features and the public's concern for scenic quality. Because the aforementioned forest plans have not been amended to use the SMS, both VMS and SMS are used in this EIS section. A crosswalk between the two systems is described in *Landscape Aesthetics: a Handbook for Scenery Management* (Forest Service 1995b), and summarized in table 4.8.2.3-1.

BLM Lands

The BLM has a Visual Resource Management (VRM) system that is comparable to the Forest Service VMS. Based on a matrix of three factors (scenic quality, sensitivity level, and distance), BLM lands are placed into one of four visual resource inventory classes (table 4.8.2.3-2). These classes represent the relative value of the visual resources, Class I (Preserve Character) and Class II (Retain Character) being the most restrictive, Class III (Partially Retain Character) relatively less restrictive, and Class IV (Major Modification of Character) being least respective. The class objectives describe the different degrees of modification, or contrast, allowed to the basic visual elements of the landscape in each class. VRM management classes are then established through the RMP process and adjusted as necessary to reflect the resource allocation decisions made in RMPs.

The Pacific Connector pipeline route would cross 46.9 miles of BLM lands that are classified as VRM Class IV in the 2016 Southwestern Oregon and Northwestern and Coastal Oregon ROD/RMPs. VRM Class IV areas allow high levels of change from projects to the characteristic landscape. Management activities may dominate the view and will be the major focus of viewer attention. The construction, operation, and maintenance of the pipeline would be consistent with the objectives of this class.

TABLE 4.8.2.3-1

Forest Service Crosswalk Between Visual Quality Objectives, Scenic Integrity Objectives, and Scenic Integrity Levels a/

Visual Management System (VMS) 1973 Direction **Visual Quality Objective (VQO)**	**Scenery Management System (SMS) 1995 Direction** **Scenic Integrity Objective (SIO)**	**Definition of Scenic Integrity Levels**
Preservation	Very High	*Unaltered*: Valued landscape character "is" intact with only minute if any visual deviations. The existing landscape character is expressed at the highest possible level.
Retention	High SIO	*Appears unaltered*: Landscapes where the valued landscape character "appears" intact. Visual deviations (human-made structures or activities) may be present but must repeat the form, line, color, texture, and pattern common to the landscape character so completely and at such a scale that they are not evident.
Partial Retention	Moderate SIO	*Appears slightly altered*: Noticeable deviations must remain visually subordinate to the landscape character being viewed.
Modification	Low SIO	*Appears Moderately Altered*: Visual deviations (human-made structures or activities) begin to dominate the valued landscape character being viewed but they borrow valued attributes such as size, shape, edge effect and pattern of natural openings, vegetative type changes or architectural styles outside the landscape being viewed. They should not only appear as valued character outside the landscape being viewed but compatible or complimentary to the character within.
Maximum Modification	Very Low SIO	*Appears Heavily Altered*: Visual deviations (human-made structures or activities) may strongly dominate the valued landscape character. They may not borrow from valued attributes such as size, shape, edge effect and pattern of natural openings, vegetative type changes or architectural styles within or outside the landscape being viewed. However deviations must be shaped and blended with the natural terrain (landforms) so that elements such as unnatural edges, roads, landings, and structures do not dominate the composition.
For Inventory and Scenic Effect Prediction Purposes Only		
Unacceptable Modification UM	Unacceptably Low	*Extremely altered*: Landscapes where the valued landscape character being viewed appears extremely altered. Visual deviations (human-made structures or activities) are extremely dominant and borrow little if any form, line, color, texture pattern or scale from the landscape character. Landscapes of this level of integrity need rehabilitation. This level should only be used to inventory existing integrity. It must not be used as a management objective.

a/ Scenic Integrity Objectives establish desired conditions for management (equivalent to purpose of Visual Quality Objectives under former VMS); Scenic Integrity Levels describe the current condition of the scenic resource.

TABLE 4.8.2.3-2

BLM Visual Resource Management Classes

VRM Class	Definition
Class I Preserve Landscape Character	Manage Visual Resource Management Class I areas in accordance with natural ecological changes. Prohibit activities that would lower the Visual Resources Inventory class of Visual Resource Management Class I areas. The level of change to the characteristic landscape will be very low and will not attract attention. Changes will repeat the basic elements of form, line, color, texture, and scale found in the predominant natural features of the characteristic landscape.
Class II Retain Landscape Character	Manage Visual Resource Management Class II areas for low levels of change to the characteristic landscape. Management activities will be seen but will not attract the attention of the casual observer. Changes will repeat the basic elements of form, line, color, texture, and scale found in the predominant natural features of the characteristic landscape.
Class III Partially Retain Landscape Character	Manage Visual Resource Management Class II areas for low levels of change to the characteristic landscape. Management activities will be seen but will not attract the attention of the casual observer. Changes will repeat the basic elements of form, line, color, texture, and scale found in the predominant natural features of the characteristic landscape.
Class IV Major Modification of Landscape Character	Visual Resource Management Class IV includes all lands that are not designated as Visual Resource Management Classes I, II, or III. Manage Visual Resource Management Class IV areas for high levels of change to the characteristic landscape. Management activities may dominate the view and will be the major focus of viewer attention.

Sensitive Viewsheds on Federal Lands

The federal land managing agencies identified areas they consider possessing sensitive viewsheds along the pipeline route and, as appropriate, developed site-specific amendments to LMPs to ensure compliance with the LMPs if the Project were authorized. Pacific Connector outlined measures it would implement to reduce visual impacts at those areas in its *Aesthetic Management Plan for Federal Lands* (Appendix A to the POD). Table 4.8.2.3-3 lists the sensitive viewsheds on federal land, their visual objective classes, and proposed mitigation measures.

TABLE 4.8.2.3-3

Sensitive Viewsheds on Federal Lands and Proposed Mitigation Measures

MPs	Viewshed Area	Agency/Unit	Visual Class or Objective	Sensitivity Level	Mitigation Methods a/
161.07-161.64	Big Elk Road (FS Road 37) – South Fork Little Butte Valley	Forest Service – Rogue River National Forest	VQO – Foreground Retention	High	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 13
167.49-167.93	PCT	Forest Service – Rogue River National Forest	VQO – Foreground Partial Retention	High	1, 2, 3, 4, 5, 6, 10, 13
156.3 to 156.8 and 157.2 to 157.5	Little Butte Creek	Forest Service – Rogue River National Forest	Middleground Partial Retention	Moderate	1, 2, 6, 12, 13
168.40-169.00	Dead Indian Memorial Highway	Forest Service – Winema National Forest	VQO – Foreground Retention	High	1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13
169.00-174.40 176.15-176.45; 176.60-177.04	Clover Creek Road	Forest Service – Winema National Forest	VQO - Foreground Partial Retention	Moderate-High	1, 2, 3, 4, 5, 6, 7, 8, 10

a/ 1 – Mulch right-of-way and use colorant of dark brownish green for hydro-mulch;
2 – Scallop and feather edges of the right-of-way by removing or cutting some tall trees as directed by land manager;
3 – Transplant trees 15-20 feet tall in clusters spaced 660 feet apart;
4 – Transplant trees in clusters in TEWAs and combine with partly buried boulders;
5 – Bury root wads and boulders in foreground along right-of-way;
6 – Reduce soil compaction according to the ECRP;
7 - Plant 1-2 gallon-sized shrubs and protect them with plant guards;
8 – Construct a berm with boulders to discourage OHV access;
9 – Screen corridor from viewer by leaving trees near roadway and transplanting trees 15-20 feet tall in foreground;
10 – Plant deciduous trees and shrubs such as willow, ceanothus, ribes, huckleberry and chinquapin;
11 – Recontour cut bank to discourage OHV access;
12 – Fund Forest Service tree thinning activities
13 – Necking-down, or narrowing, construction corridor.
b/ This VRM class is inconsistent with figure 4.8-16. The VRM Class shown here is correct.

Visual Resources Specific to Consistency with Federal LMPs

BLM Lands

BLM lands crossed by the Pacific Connector Pipeline Project are VRM Class IV where high levels of change in the landscape character are permitted. The Pacific Connector Pipeline would meet the VRM Class IV standards on all BLM lands.

NFS Lands

Umpqua National Forest

The VQO for all lands crossed by the Pacific Connector Pipeline Project on the Umpqua National Forest is Maximum Modification. The pipeline would be within the VQO standards of Maximum Modification upon completion of corridor restoration and revegetation.

Rogue River National Forest

The Pacific Connector pipeline would meet the VQOs of the Rogue River National Forest LRMP with the following three exceptions:

(1). At the crossing of the Big Elk Road at Pacific Connector pipeline MP 161.4 in Section 16, T. 37 S., R. 4 E., W. M., Oregon.

This location has a VQO of Foreground Retention (Management Strategy 6, Rogue River National Forest LRMP, page 4-72). Standards and guidelines for Foreground Retention where the Pacific Connector pipeline route crosses the Big Elk Road require that VQOs be met within one year after completion of the Project and that management activities not be visually evident. The pipeline project would not meet that standard at that location. Amendment RRNF-2 of the Rogue River National Forest LRMP is proposed at this location to make provision for the Pacific Connector pipeline. This proposed amendment would change the VQO at this location to Foreground Partial Retention (Management Strategy 7, LRMP page 4-86) and allow 10 to 15 years for the amended VQOs to be attained. The Big Elk Road in the vicinity of the Pacific Connector pipeline crossing would be affected by this proposed amendment. This is a site-specific amendment that would apply only to the Pacific Connector pipeline. It does not change VQOs for any other project.

Temporal and Spatial Boundaries of Impacts

This proposed change would affect about 5 acres in the year of construction and approximately 2 acres after 10 years. The 5 acres represents the 75-foot-wide construction right-of-way as seen from Big Elk Road. The 2 acres represents the area seen from Big Elk Road associated with the 30-foot-wide operational permanent easement for the pipeline that would be kept clear of tall trees (more than 15 feet tall) 10 years after right-of-way restoration and revegetation. This would not achieve the Forest Plan goals and objectives of a natural appearing forest at that location one year after construction. Drivers passing the corridor would be able to see it for approximately 15 to 20 seconds. This change would affect only recreation and VQOs in the vicinity of the Big Elk Road–Pacific Connector pipeline intersection. No other LRMP goals and objectives would be affected by this change.

(2). At the crossing of the PCT at Pacific Connector pipeline MP 168 in Section 32, T. 37 S., R. 5 E., W. M., Oregon

This location has a VQO of Foreground Partial Retention (Management Strategy 7, Rogue River National Forest LRMP page 4–86). Standards and guidelines for Foreground Partial Retention require that VQOs be met within three years of completion of the Project, and that activities be visually subordinate to the landscape. The Pacific Connector pipeline would not meet that standard at that location. Amendment RRNF-3 is proposed at this location to change the VQO to Modification (USDA Forest Service Agricultural Handbook 478) and to allow five years for amended VQOs to be attained. The PCT in the vicinity of the Pacific Connector pipeline crossing would be affected by this proposed amendment. This is a site-specific amendment that would apply only to the Pacific Connector pipeline. It does not change VQOs for any other project.

Temporal and Spatial Boundaries of Impacts

This proposed change would affect approximately 5 acres of seen area in the year of construction. The 5 acres would encompass the 75-foot-wide pipeline construction right-of-way seen from the PCT. Vegetation growth and mitigation measures would reduce the seen area to approximately 2 acres after five years. This would not achieve the Forest Plan goals and objectives of a natural appearing forest at that location within 3 years after construction. Hikers and horseback riders passing the corridor would be able to see it for approximately 1 to 3 minutes. This change would affect only recreation and VQOs in the vicinity of the PCT–Pacific Connector pipeline intersection.

(3). Along the ridgetop south of State Highway 140 between Pacific Connector pipeline MPs 156.3 to 156.8 and 157.2 to 157.5 in Sections 11 and 12, T. 37 S., R. 3 E., W. M., Oregon

This location has a VQO of Middleground Partial Retention. Standards and guidelines for Middleground Partial Retention (Management Strategy 9, Rogue River National Forest LRMP Page 4– 112) require that VQOs for a given location be achieved within 3 years of completion of the Project. The Pacific Connector pipeline would not meet this standard at that location. Amendment RRNF-4 of the Rogue River National Forest LRMP is proposed at this location to make provision for the pipeline project. This proposed amendment would allow 10 to 15 years to meet the Middleground Partial Retention standard at this location. Approximately 0.8 mile or 9 acres of the Pacific Connector right-of-way in the Middleground Partial Retention VQO visible at distances of 0.8 to 5 miles from State Highway 140 would be affected by this proposed amendment. This is a site-specific amendment that would apply only to the Pacific Connector pipeline. It does not change VQOs for any other project.

Temporal and Spatial Boundaries of Impacts

This proposed change would affect approximately 9 acres or about 0.8 mile of the pipeline corridor as seen from Highway 140 in the year of construction. For the next 10 to 15 years, the pipeline corridor would remain visually dominant to the surrounding landscape but would become less evident each year. Vegetation growth and mitigation measures would allow the area to meet the assigned VQO of Middleground Partial Retention after 10 to 15 years.

This proposed amendment would not change VQOs, but instead allow more time to meet the VQO of Middleground Partial Retention as seen from Highway 140. To the degree that travelers look up as they are headed west on Highway 140, this location would be visible from a distance of 0.8 to 5 miles for a few minutes. Duration would depend on travel speed but would likely be less than 10 minutes, and would likely not be continuous because of the height of roadside trees and line of sight from the highway. This location would not be visible from other key observation points or travel routes such as the Big Elk Road.

Winema National Forest

The Pacific Connector pipeline would meet the VQO of the Winema National Forest LRMP with the following exceptions:

(1). Where the Pacific Connector right-of-way crosses the Dead Indian Memorial Highway at approximately pipeline MP 168.8 in Section 33, T. 37 S., R. 5 E., W. M., Oregon

This location has visual standard of Foreground Retention. Standards and guidelines for Scenic Management, foreground retention (Winema National Forest [WNF] LRMP 4–103, Management Area 3A, Foreground Retention) requires visual standards for a given location be achieved within one year of completion of the Project. The Pacific Connector pipeline would not meet that standard at that location. Amendment WNF-2 is proposed to allow 10 to 15 years to meet the specified visual standard at this location. This is a site-specific amendment that would apply only to the Pacific Connector pipeline in the vicinity of the Dead Indian Memorial Highway and would not change future management direction for any other project.

Temporal and Spatial Boundaries of Impacts

This proposed amendment would affect about 3 acres of Management Area 3A initially, but over a period of 10 to 15 years, the affected area would decrease to around one-quarter of an acre because of the growth of vegetation at the highway crossing. Installing the pipeline across Dead Indian Memorial Highway would create a corridor that would be visible for about 10 to 15 seconds for travelers along the highway. The area affected by pipeline construction at the crossing would be much less than one percent of Management Area 3A. This is a project-specific amendment that would affect only and recreational experiences in a limited area. This proposed amendment would not change visual standards, but instead allows more time to meet the visual standards of foreground retention as seen the Dead Indian Memorial Highway.

(2). Where the Pacific Connector right-of-way is adjacent to the Clover Creek Road from approximately pipeline MP 170 to 175 in Sections 2, 3, 4, 11, and 12, T. 38 S., R. 5 E., and Sections 7 and 18, T. 38 S., R. 6 E., W. M., Oregon

This location has a visual standard of Foreground, Partial Retention. Standards and guidelines for Foreground Partial Retention (LRMP, page 4–107, Management Area 3B) require that visual standards be met within three years of completion of a project. The Pacific Connector pipeline cannot meet that standard at that location in three years after construction. Amendment WNF-3 is proposed to allow 10 to 15 years to meet the standard of Foreground, Partial Retention at this location. This is a site-specific amendment that would apply only to the Pacific Connector pipeline in the vicinity of the Clover Creek Road and would not change future management direction for any other project.

Temporal and Spatial Boundaries of Impacts

The Winema National Forest LRMP would be amended to allow 10 to 15 years to meet the VQO for Scenic Management, Foreground Partial Retention from MPs 170 to 175. This change would potentially affect approximately 50 acres and 6 miles of corridor as seen from the Clover Creek Road. This is a site-specific amendment that would apply only to the Pacific Connector pipeline in the vicinity of Clover Creek Road and would not change future management direction for any other project. Over a period of 10 to 15 years, the affected area would decrease to about 29 acres because of changes in vegetation. Initially, the affected area would be visually evident for the entire 5 miles on NFS lands adjacent to the Clover Creek road. Over time, this would become less visually evident because of the ingrowth of vegetation and mitigation measures adopted by the Pacific Connector pipeline. At an average speed of 40 mph, the 5-mile-long area affected by this amendment would be visible for approximately 10 to 12 minutes.

4.8.2.4 Conclusion

Constructing and operating the Jordan Cove LNG Project would result in substantial short-term and long-term changes to the existing landscape within the viewshed of the Project. As described in the preceding sections, the LNG tanks and related facilities at the terminal would be visible from a range of viewpoints within the surrounding area and the visual effects were assessed to be low to high dependent on the user and viewpoint location. Jordan Cove attempted to optimize design factors for the LNG tanks and has adopted various measures to mitigate for the visibility of the Project facilities, including use of landform contouring and stabilization, vegetative screening, architectural treatments, and use of hooded lighting. However, based on the size and location of the proposed LNG facilities we conclude that the Jordan Cove LNG portion of the Project would significantly affect visual resources for some views and viewing locations.

Constructing and operating the Pacific Connector Pipeline Project would result in short-term and long-term visual effects as described in the preceding sections. However, Pacific Connector's proposed procedures and mitigation measures are expected to result in reduction of the long-term visual contrast in color, as well as line and texture created by clearing of the pipeline right-of-way. Measures such as structure co-location, painting, landscaping, and screening are expected to limit the visual effects of the associated aboveground Project facilities. Based on the proposed construction, operation, and minimization measures, the Project, excluding the LNG facility, would not significantly affect visual resources.

4.9 SOCIOECONOMICS

This section addresses the potential effects of Project construction and operation on the following components of the social and economic environment: population, housing, the local economy and employment, infrastructure and public services, recreation and tourism, other commercial activities, and environmental justice. The following discussion is divided into two main sections that address the Jordan Cove LNG Project and Pacific Connector Pipeline Project separately. Both projects would involve construction and operation activities in Coos County. Potential impacts to Coos County are discussed separately by Project, with the combined impacts of both Projects discussed in section 4.9.2.

4.9.1 Jordan Cove LNG Project

4.9.1.1 Population

The closest cities to the Jordan Cove LNG Project are North Bend and Coos Bay. These two cities had estimated 2017 populations of 9,800 and 16,615, respectively (see table 4.9.1.1-1). The total estimated population of Coos County in 2017 was 63,310.

TABLE 4.9.1.1-1

Population by State, County, and Community

State/County/Community	2000	2010	2017	2010 to 2017 Net Change	2010 to 2017 Percent Change
Oregon	3,421,399	3,831,074	4,141,100	310,026	8.1%
Coos County	62,779	63,043	63,310	267	0.4%
City of Coos Bay	15,374	15,967	16,615	648	4.1%
City of North Bend	9,544	9,695	9,800	105	1.1%

Source: Portland State University 2012, 2017a, 2017b

As described previously, Jordan Cove estimates that construction of the Jordan Cove LNG Project and associated facilities would take place over a roughly 5-year period. Following an initial 9-month period of site clearing, construction of the Jordan Cove LNG Project would occur over a 53-month construction period. Jordan Cove's estimated construction workforce would average 1,023 workers over the 53-month construction period, with projected employment expected to peak in month 30 with an estimated 1,996 workers employed on site (ECONorthwest 2017a). Construction would require workers in highly skilled crafts, such as pipefitters, ironworkers, electricians, carpenters, and management staff, including safety specialists. Jordan Cove anticipates that the workers hired will already have these skills, having gained experience in other related industries, including the oil and gas and power industries.

Jordan Cove estimates that an average of 221 workers would commute daily from their normal place of residence to the Project site, leaving an estimated average of 802 workers temporarily relocating to the Project vicinity. A portion of this workforce would be accompanied by family members, resulting in the total estimated addition of an average of 901 people (workers and family members) to the Project vicinity. The addition of 901 people would be equivalent to approximately 3.4 percent of the combined populations in the cities of Coos Bay and North Bend in 2017 (26,415), and approximately 1.4 percent of the total county population (63,310) (table 4.9.1.1-1).

At the peak of construction, an estimated total of 1,752 people would temporarily relocate to the Project vicinity (ECONorthwest 2017a). This temporary increase would be equivalent to about 6.6 percent of the combined populations of Coos Bay and North Bend and 2.8 percent of the county total (table 4.9.1.1-1). These estimated peak population increases would be temporary and short term. Very few, if any, of the temporary construction workers relocating to the Project area are expected to stay permanently. Impacts associated with construction-related population increases are discussed throughout this section.

In the first full year of operations, Jordan Cove would directly employ 200 workers in Oregon, 180 at the Jordan Cove LNG Project and 20 at the company office in Portland. Unlike construction, once the Project is operating, the employees would live permanently near their workplaces. Workers would either be hired locally or permanently relocate to the area. ECONorthwest (2017a) estimated that about 40 percent of the operating workforce at the Jordan Cove LNG Project would be hired locally, with the remaining 60 percent relocating to Coos County from out-of-state or elsewhere in Oregon. Assuming an average household size of 2.74, this would result in the addition of 296 new residents, which would be equivalent to about 1.1 percent of the combined populations in the cities of Coos Bay and North Bend in 2017.

Crime

We received several comments on the Project that expressed concern that the temporary influx of construction workers and the development of "man-camps" would result in increases in crime, drug and alcohol use, prostitution, human trafficking, and domestic violence, as well as other criminal activities. Local tribal members also expressed concern about the potential for increased crime to disproportionally affect Native Americans and suggested that staff consider natural resource development impacts on crime in North Dakota and Wyoming. Based on this concern and to assess the Project's potential impact on crime rates, we reviewed existing published literature that considers the link between crime and natural resource development, as well as (based on historical patterns) the potential for disproportionate impacts on tribal communities. Most of the research into the link between natural resource development and crime focuses on "boomtowns," where large-scale resource development, especially oil and gas extraction, has resulted in rapid population growth that has weakened existing social ties in the affected communities (O'Connor 2017). Some might consider the introduction of a workforce to construct the Project as analogous to a "boomtown"; however, the number of individuals that are expected to temporarily migrate to the Project area would, as described above, result in a minor increase in the local population.

Based on official crime statistics and interviews with law enforcement officers, studies in North Dakota and Wyoming found that the crimes that increased the most during boom periods included traffic-related crimes (e.g., driving under the influence), felony and simple assault, disorderly conduct, drug-related crimes, thefts, burglaries, and domestic violence (Archbold 2015; Archbold et al. 2014; Jacquet 2005; Jayasundara et al. 2016). Police officers in North Dakota attributed the increase in domestic violence calls to housing shortages and cramped living quarters and stated that violent crimes in their jurisdictions were not increasing to the extent that local, regional, and national media outlets reported (Archbold 2015). Some articles (Harvard 2015; Adler and Hillstrom 2015; Gillette 2016; Briody 2017; Deer and Nagle 2017; Nienaber 2017) have focused on the Bakken Oil Field in North Dakota, near the Fort Berthold Indian Reservation. These articles focus on links between semi-permanent worker camps and negative impacts on female Native

American populations. The influx of large numbers of well-paid male oil workers at the North Dakota camps coincided with increases in sex trafficking, rape, and physical violence.

Other studies found inconclusive links between crime and increased oil and gas activity or only minor increases in crime (Ruddell et al. 2014; Kowalski and Zajac 2012; Luthra et al. 2007; Price et al. 2014). A recent study in North Dakota found few significant relationships linking increased drilling to increases in crime and concluded that the impact of drilling is localized, with different counties experiencing different levels and types of crime-related impacts (O'Connor 2017).

The experiences of oil- and gas-related boomtowns in North Dakota and Wyoming have limited applicability when considering the potential for increased crime in the Project area. As discussed above, temporary construction-related increases in population would range from about 3.4 percent (average) to 6.6 percent (peak) of the combined populations in the cities of Coos Bay and North Bend in 2017. These numbers would, however, be higher when pipeline construction workers employed in Coos County are added to the total (see section 4.9.2.1). This population increase would be temporary, and we conclude that attempts to estimate related increases in crime would be speculative, but were they to occur such increases would likely be commensurate with the relative increases in population.

4.9.1.2 Housing

In 2015, Coos County had an estimated total of 30,482 housing units[166], with a rental vacancy rate of 6.7 percent and 660 housing units available for rent. In addition, an estimated 1,462 units were identified for seasonal, recreational, or occasional use. In the cities of North Bend and Coos Bay, an estimated 124 and 172 housing units, respectively, were available for rent, with an additional 26 and 230 units identified for seasonal, recreational, or occasional use (U.S. Census Bureau 2017a, 2017b).

A housing analysis and action plan completed for Coos County in 2018 (czbLLC 2018) found limited affordable housing units available for rent or purchase in Coos County, with very little new construction over the past decade and existing units being converted to vacation and seasonal use. The study identified a deficit of affordable rental units for almost all income groups, including low-income households. In addition, the study noted that anecdotal examples exist of newcomers being unable to find quality housing at a reasonable price (czbLLC 2018).

ECONorthwest (2017b) identified 23 hotels and motels in Coos County, with a combined total of 1,442 rooms. More than half of these rooms (776 or 54 percent) were located in the cities of Coos Bay and North Bend, with a further 34 percent (496 rooms) located in Bandon, about 30 miles south of the site. There were also at least 26 smaller lodging establishments (less than 15 rooms) in Coos County, with an estimated total of 214 rooms (ECONorthwest 2017b). The number of rooms available for rent by construction workers would vary by season. Average occupancy data for Coos County compiled from January 2011 through July 2017 indicate that average monthly occupancy rates range from about 38 percent in January to 78 percent in July and 80 percent in August (ECONorthwest 2017a). Applying these percentages to the estimated total supply of hotel, motel, and inn rooms in Coos County (1,656) suggests that on average 1,025 rooms would likely

[166] The Census Bureau defines a housing unit as a house, apartment, mobile home or trailer, group of rooms, or single room occupied or intended to be occupied as separate living quarters. Data are 5-year estimates (2011 to 2015) from the U.S. Census American Community Survey. Estimates are annual totals based on 5 years of data (U.S. Census Bureau 2017a, 2017b).

be available for rent in January, with 330 rooms potentially available in August. It should also be noted that occupancy rates vary during the week, and tend to be higher during weekends.

Jordan Cove identified 39 recreational vehicle (RV) parks and campgrounds in Coos County, with a combined total of approximately 2,206 managed spaces (ECONorthwest 2017b). In addition to these identified designated camping facilities, camping is also allowed outside of designated facilities on some public land. This "dispersed camping," as it is known, is common throughout Coos County. As with hotels, demand for RV spaces is highly seasonal and the highest demand is usually on weekends.

As described previously, Jordan Cove proposes to build a workforce housing facility at the South Dunes site to address concern that demand for rental housing by construction workers will have a negative impact on the availability and cost of rental housing for local residents. Units would be added in phases beginning with approximately 200 units in the fall of year 2, and peaking at up to 700 units (depending on demand) in early year 3, with the number of units on-site gradually reduced starting in the latter half of year 4.

Potential housing options for relocating workers include rental housing (houses, apartments, and mobile homes), hotels and motels, and RV parks and campgrounds, as discussed above. In addition, construction workers commonly rent extra bedrooms in existing owner- or renter-occupied homes. Finally, workers would also have the option to stay in the Workforce Housing Facility.

ECONorthwest (2017a) estimated that during an average month 147 workers would seek rental housing, 337 workers would seek hotel and motel rooms, RV or campground spaces, or individual room rentals; with 311 workers expected to reside at the workforce housing facility. During peak construction, they estimated that 274 workers would seek rental housing, 588 workers would seek hotel and motel rooms, RV or campground spaces, or individual room rentals; and 693 workers would be expected to reside at the workforce housing facility.[167]

For rental housing, the estimated average demand for 147 units and peak demand for 274 units would be equivalent to approximately 22 percent and 42 percent of the total 660 units estimated to be available for rent in Coos County. However, as noted above, potential shortages of rental housing have been identified in Coos County (czbLLC 2018). Average and peak demand for other types of housing units (337 and 588 units, respectively) would exceed the estimated available supply of hotel and motel rooms in Coos County in August (330 rooms). However, a share of this demand would also likely be met by RV and campground spaces and individual room rentals in existing owner- or renter-occupied housing. Construction-related demand would result in lower vacancy rates and upward pressure on rental/room rates. Other visitors seeking temporary accommodation near the terminal site may be temporarily displaced during peak season, especially on summer weekends. These estimates also assume, as described above, that about one-third of the workers temporarily relocating to the area would be housed at the workforce housing facility, thereby reducing demand for other types of housing in the Project vicinity. Construction workers associated with the Pacific Connector pipeline would also be seeking temporary housing in Coos

[167] These estimates developed on behalf of Jordan Cove are "likely housing choices based on information provided by contractors, union PLA documents, comparable Oregon projects, JCEP, and estimates by ECONorthwest" (ECONorthwest 2017a, p. 16). In addition to the above, they assumed that a handful of non-local construction workers (7 to 13) would seek to purchase housing.

County. The combined impact of housing demand from LNG terminal and pipeline workers is discussed below in section 4.9.2.2.

In 2024, the first full year of operations, Jordan Cove would directly employ 180 workers in Coos County. ECONorthwest (2017a) estimated that about 40 percent of the operating workforce (72 workers) at the LNG terminal would be hired locally, with the remaining 60 percent (108 workers) relocating to Coos County from out-of-state or elsewhere in Oregon. Many of the relocating workers would likely buy homes, while others would choose to rent. Estimates from the U.S. Census Bureau's American Community Survey indicate that Coos County's existing housing for sale (480 units) and for rent (660 units) currently exceeds this potential demand (U.S. Census Bureau 2017b). However, as noted above, the 2018 Coos County housing analysis and action plan identified potential shortages of rental housing, as well as anecdotal evidence of newcomers to the area being unable to find quality housing at a reasonable price (czbLLC 2018).

4.9.1.3 Property Values

Numerous stakeholders expressed concern about the Project's impact on property values. The nearest residences to the Jordan Cove LNG Project are located across the bay in the cities of North Bend and Coos Bay, more than a mile from the site. The proposed terminal site is located near other industrial uses and the Southwest Oregon Regional Airport. Real estate property values are dependent on a number of factors, including, but not limited to, location, lot size, property condition, proximity to public services and infrastructure, and market trends. Staff has repeatedly attempted to address property value concerns; however, due to the lack of independently prepared, peer-reviewed studies regarding natural gas export terminal facility impacts on property values, we are not able to determine what, if any, impact the Project would have on property values. A property's value is ultimately determined by the amount a purchaser is willing to pay, and we are not aware of any conclusive evidence linking natural gas terminal infrastructure to a decrease in property value.

Studies that assess the impact of LNG export terminals on property values are limited. However, a study conducted by the Argonne National Laboratory (Clark and Nieves 1994) examined the economic impacts of eight types of "noxious" facilities on local wages and property values. The study examined the effects of 262 facilities, 11 of which were LNG facilities. The study concluded that the presence of five of the eight types of "noxious" facilities has a significant negative effect on property values and a positive effect on wages. However, the study concluded that the presence of an LNG facility did not have a significant positive or negative effect on either wages or property values (Clark and Nieves 1994).

More recently, Davis (2011) assessed the impact of 92 large power plants that opened in the U.S. between 1993 and 2000. Using the hedonic price method, Davis estimated impacts to housing values and rents within 2 miles of each new facility and found "modest declines" of 4 to 7 percent, with somewhat larger decreases within 1 mile.

For Jordan Cove, ECONorthwest (2006) reviewed property values within 1 mile of existing LNG "peak storage" facilities in Newport and Portland, Oregon. Using data from the Lincoln County Tax Assessors Office, ECONorthwest found that property values around the Newport LNG plant were not depressed and 25 homes within 0.5 mile and overlooking the facility had above average market values. They also argue that the presence of many other industrial and commercial properties around the Portland LNG facility, including the second-largest industrial employer in the city, suggest that the presence of this facility has not discouraged other businesses from locating in the area (ECONorthwest 2006).

4.9.1.4 Economy and Employment

Coos County had a total estimated civilian labor force of 26,521 in 2016 (Oregon Employment Department 2017). The average annual unemployment rate in Coos County in 2016 was higher than the statewide average, 6.5 percent versus 4.9 percent. State and local government and retail trade were the two largest sectors in the county in 2015 based on employment (U.S. Bureau of Economic Analysis 2016a). The median household income in Coos County in 2015 was $38,934 (U.S. Census Bureau 2016).

Jordan Cove estimates that construction of the Jordan Cove LNG Project would cost about $7.3 billion over the 53-month construction period, with an estimated $2.99 billion expected to be spent in Oregon (ECONorthwest 2017c).

Using IMPLAN economic modeling software, ECONorthwest (2017c) estimated the total (direct, indirect, and induced) regional economic impacts of Project construction (table 4.9.1.4-1). Direct impacts are those that happen at the initial source of the economic activity, in this case the project construction sites. Indirect impacts are generated by the expenditures on goods and services by suppliers who provide goods and services to the construction project. Indirect effects are often referred to as "supply-chain" impacts because they involve interactions among businesses. Induced impacts are generated by the spending of households associated either directly or indirectly with the Project. Workers employed during construction, for example, will use their income to purchase groceries and other household goods and services. Workers at businesses that supply the facility during construction or operation will do the same. Induced effects are sometimes referred to as "consumption-driven" impacts. Spending associated with the Project produces multiplier spending effects for other sectors of the state economy as businesses respond to supply-chain and consumption-driven demands for goods and services.

TABLE 4.9.1.4-1

Regional Economic Impacts of Construction of the Jordan Cove Project in Oregon

Impact Type	Output b/	Value Added b/	Labor Income b/	FTE Jobs b/	Average Number of Jobs per Year c/
Total Direct Impacts	$7,300	na	$1,235	4,527	1,023
Local Impacts (State of Oregon) a/					
Direct	$2,990	$1,027	$967	3,531	798
Indirect	$1,743	$992	$776	14,107	3,194
Induced	$1,725	$982	$571	13,435	3,042
Total d/	**$6,458**	**$3,001**	**$2,314**	**31,073**	**7,034**

Notes:
FTE – full-time equivalent; na – not applicable
a/ Local impacts in this context are impacts that would occur within the state of Oregon. Direct impacts are the share of the total direct impacts expected to occur in Oregon.
b/ Impacts are presented for the entire 53-month construction period. Output, value added, and labor income are expressed in millions of dollars.
c/ Average number of jobs per year based on 53 months of construction.
d/ Totals may not sum due to rounding.
Source: ECONorthwest 2017c

Total impacts are estimated in terms of economic output, value added, labor income, FTE jobs, and average jobs per year. Economic output represents the dollar value of goods and services produced, and serves as a broad measure of economic activity. Value added represents the net contribution of industries to the local economy and consists of revenues less intermediate inputs. Labor income is the sum of employee compensation and proprietary (self-employed) income. FTE jobs represent employment for 2,080 hours per year; FTE jobs do not necessarily translate into the number of affected workers. Two jobs that last 6 months each, for example, count as one FTE job.

As stated in section 4.9.1.1, Jordan Cove estimated that they would employ an annual average of 1,023 workers over the 53-month-long construction period, with a peak of 1,996 employees during month 30. Total direct employment over the 53-month construction period was estimated to be equivalent to 4,527 FTE jobs, with the equivalent of 3,531 FTE jobs expected to be filled by Oregon workers. Construction of the Jordan Cove LNG Project would be a union project, with Jordan Cove requiring the major contractor to sign a project labor agreement with the key signatory unions to the National Construction Agreement. Union locals believe they can supply the majority of skilled crafts workers from within Oregon. ECONorthwest (2017a), in an analysis prepared on behalf of Jordan Cove, assumed that almost four-fifths of all construction workers, managers, and staff for the Jordan Cove LNG Project would come from Oregon. In addition, ECONorthwest (2017a) estimated that Project construction would support a total of 14,107 indirect and 13,435 induced FTE jobs in Oregon over the life of the Project (table 4.9.1.4-1).

During the first full year of operations, Jordan Cove would directly employ 200 workers in Oregon, 180 for the LNG terminal, and 20 for the company office in Portland, with total labor compensation (including benefits and payroll taxes) expected to exceed $44.8 million. This direct employment in conjunction with facility expenditures on Oregon sourced goods and services would support additional economic activity in Coos County and elsewhere in Oregon. Using expenditure data provided by Jordan Cove, ECONorthwest (2017d) estimated that annual Project operation would support total (direct, indirect, and induced) employment of 1,602 FTE jobs in Oregon in 2024, with total associated labor compensation of approximately $132.3 million. Viewed in 2017 dollars, total compensation would be about $111.3 million or $69,477 per FTE job (ECONorthwest 2017d). Indirect and induced impact estimates developed by ECONorthwest (2017c, 2017d) are based on the share of construction and operation expenditures that Jordan Cove estimates would occur in Oregon. Changes in actual levels of in-state spending would result in changes to the indirect and induced impact estimates.

No commercial enterprises would be displaced by the Project, and construction and operation of the terminal would not result in the loss of local business revenues or taxes.

4.9.1.5 Tax Revenues

Total revenues for Coos County were approximately $52.3 million in fiscal year 2016. Tax revenues accounted for $10.5 million of this total, with 96 percent of tax revenues generated by property taxes (Coos County 2017). Other sources of revenue included intergovernmental transfers (state and federal funds); licenses, fees, and permits; charges for services; and timber sales on county forestlands (table 4.9.2.5-1). The LNG terminal would contribute to the fiscal health of local communities through a local Community Enhancement Plan (CEP) in Coos County. Construction and operation of the Jordan Cove LNG Project would also generate state and local tax revenues, including revenues from payroll taxes.

4.9.1.6 Public Services

Law Enforcement and Fire Protection

Coos County is served by one sheriff's office, seven police departments, and 17 fire departments. To minimize potential impacts, Jordan Cove would reimburse Coos County to cover any costs associated with public safety during construction and operation. Jordan Cove has also committed to building and funding the SORSC within the Jordan Cove LNG Project site. In addition, a continuously manned Jordan Cove Fire Station would be located on-site and Jordan Cove would be responsible for funding additional security measures to protect LNG carrier marine traffic.

Jordan Cove would also be responsible for funding additional security measures outlined in the Coast Guard's WSR and LSR to protect LNG carrier marine traffic to and from the terminal within the waterway; this would include escort boats operated by the County Sheriff's department.

Medical Facilities

Coos County is served by three hospitals. The Southern Coos Hospital is designated a critical access hospital as well as a full-service, general acute care hospital. It is ranked as a Level 4 Trauma Center (Southern Coos Hospital & Health Center 2017). The Coquille Valley Hospital in Coquille is ranked as a Level 4 Trauma Center (Coquille Valley Hospital 2017). The Bay Area Hospital in the city of Coos Bay is the closest to the Jordan Cove LNG Project site, approximately 6 miles away. This facility is rated a Level 3 Trauma Center (Bay Area Hospital 2017). In addition, North Bend Medical Center is a regional health care cooperative with five locations and more than 70 providers in the Coos Bay area (North Bend Medical Center 2017).

During construction, Jordan Cove would provide on-site medical facilities and personnel to provide care for the project workforce both at the site and at the Workforce Housing Facility. Care would include first aid, emergency response, and treatment of common illnesses. Potential construction injuries requiring treatment could range from scrapes and bruises through broken bones and injured limbs, concussion, and wounds requiring stitches, with injured parties requiring off-site treatment for more severe injuries should they occur.

During plant operation, Jordan Cove would have a licensed nurse practitioner on staff with offices located in the Operations Building. The primary functions for the nurse practitioner would be to assess routine employee needs, manage employee wellness programs to reduce the need for emergency visits, and handle triage of any job-related injuries that might occur within the Project site. Additionally, to address public concern, Jordan Cove signed an MOU with the State of Oregon that requires it to equip the Bay Area Hospital according to State policies for all hospitals in treating burns.[168] Other potential injuries that might occur are expected to be similar to those already treated at the hospital and by the North Bend Medical Center.

Schools

Coos County has six school districts, with total enrollment of 10,051 in the 2016-17 school year (Oregon Department of Education 2017). The Coos Bay School District operates five schools, serving about 3,100 students (Oregon Department of Education 2017). The North Bend School

[168] Memorandum of Understanding and Agreement No. 14-008 By and Between Jordan Cove Energy Project and the State of Oregon for LNG Emergency Preparedness. Filed July 1, 2014, in FERC Docket No. CP13-483.

District operates four schools serving about 4,400 students (Oregon Department of Education 2017). In addition, there are four private schools in North Bend serving approximately 250 students (ECONorthwest 2017a). The Bandon School District #54 has three schools, serving about 697 students (Bandon School District 2018).

As described previously, numerous non-local workers are expected to temporarily relocate to the Project area during construction, but very few are expected to be accompanied by family members. ECONorthwest (2017a) estimated that 57 households would temporarily relocate to the Project area during Project construction. Assuming an average household size of approximately 2.74 persons, including 0.55 school-aged children, would result in the addition of an estimated 31 students to Coos County schools. This addition would be equivalent to 0.3 percent of total county enrollment in 2016-17, or 0.4 percent of the combined enrollment in the Coos Bay and North Bend School Districts.

Assuming the same average household size as above, Project operation would result in the potential addition of 59 students to Coos County schools. This addition would be equivalent to 0.6 percent of total county enrollment in 2016-17, or 0.8 percent of the combined enrollment in the Coos Bay and North Bend School Districts.

Utilities

Constructing and operating the terminal facilities would require connection to and use of public electric, water, waste disposal, and communications systems/utilities. Jordan Cove has indicated that there is sufficient electric power on the North Spit to serve existing customers and meet Project needs during construction. Liquefaction operations would be powered directly by gas-fired combustion turbines and would not require externally sourced electric power from the grid. The SORSC and low load remote instrumentation would be connected to the local grid.

Solid waste generated during Jordan Cove LNG Project's construction would be collected on-site and items that cannot be reused or recycled would be hauled to licensed landfills by authorized waste haulers and disposal companies. Sanitary waste would either be collected and taken off-site for disposal by a licensed contractor, or treated prior to discharge to the IWWP, and any solid waste would be disposed of off-site by a licensed contractor. All waste generated by the workforce housing facility would be handled in a similar manner.

During operation of the terminal, sanitary waste water would be treated on-site and effluent sent to the IWWP. Solid waste would either be recycled or hauled from the site and disposed of by private licensed waste disposal companies without the need for city or county resources.

4.9.1.7 Recreation and Tourism

Recreation and Tourism

Approximately 1 million people visited Coos County in 2016, staying on average 2.6 nights (Dean Runyan Associates 2017). An estimated 43 percent of these nights were spent in hotels or motels, which accounted for approximately 70 percent of visitor spending. Travel-related spending in Coos County in 2016 totaled about $265.3 million, and supported an estimated 3,280 jobs (approximately 10.2 percent of total county employment), $76.6 million in earnings, and an estimated $9 million in local and state tax revenue.

Commenters during public scoping expressed concern that the Project could negatively affect the local economy by harming the recreation and tourism sectors. Potential effects on tourism could also occur during the summer when construction workers would likely compete with visitors to Coos County for accommodations. Potential combined demand for hotel and motel rooms, RV or campground spaces, and individual room rentals would exceed the estimated available supply of hotel and motel rooms in Coos County in August, even with the workers camp in place. However, as discussed in section 4.9.1.2, a share of this demand would also likely be met by RV and campground spaces and individual room rentals in existing owner- or renter-occupied housing. Construction-related demand would result in lower vacancy rates and upward pressure on rental/room rates. Other visitors seeking temporary accommodation near the terminal site may be temporarily displaced during peak season, especially on summer weekends. This could result in reduced demand for some recreation outfitter/guide services, as potential clients seek recreation opportunities elsewhere.

4.9.1.8 Other Commercial Activities

Commercial Fishing

Coos Bay was the third most important port in Oregon in terms of commercial fish harvested in 2015, accounting for about 10 percent of the total catch by volume. Pacific shrimp constituted almost two-thirds (64 percent; 13.3 million pounds) of the Coos Bay catch in volume and one-half (48 percent) of its catch in value. The other major catches by volume were groundfish (3.2 million pounds), albacore tuna (1.2 million pounds), and sardine (1.4 million pounds) (The Research Group 2016). An estimated total of $54.7 million in total personal income was generated by the fishing industry in the Coos Bay area in 2014, including income from both landed fish and revenue returned from distant water fisheries (The Research Group 2015).

Almost 200 commercial fishing vessels operate in Coos Bay on average per month from March to October, with just over 100 based in Coos Bay for the entire year (ECONorthwest 2017b). The actual number of commercial fishing vessels traveling through Coos Bay might be greater due to some transient travel to deliver products, buy ice, or seek other services. A fisherman's market cooperative and a small commercial fishing fleet are located in Charleston (located a few miles south of the Project area near the mouth of the bay). The Charleston Marina provides infrastructure and services to locally-based and visiting commercial fishing vessels (Oregon International Port of Coos Bay 2018a).

As described previously, numerous cargo ships (vessels and barges) would deliver materials to the terminal site during construction and, once in operation, the site would be called upon by up to 120 LNG carriers per year. Fishing boats would avoid cargo ships and barges similar to how they currently deal with commercial deep-draft ship and barge traffic into and out of the Port. Coos Bay pilots have indicated they typically encounter about two commercial fishing boats when they guide deep-draft commercial ships through the navigation channel (ECONorthwest 2017b).

During LNG carrier transit in the waterway to the terminal, fishermen would be required to move out of the security zone, which would result in delays in transit. The LNG marine traffic would overlap with the portion of the navigation channel used by the ocean-going fishing fleet from Charleston for about 2 miles. There may be slight delays resulting from meeting situations between an LNG carrier and a commercial fishing vessel, because of the security and safety zones or other conditions imposed by the Coast Guard. Jordan Cove has indicated that the impact on boats at any point in the channel would last about 20 to 30 minutes, the same as when other deep-draft vessels use the channel.

Commercial Ship Traffic

According to the Oregon International Port of Coos Bay (2018b), the Port is a major deep-draft coastal harbor moving more than 1.5 million tons of cargo each year. In 2017, 47 deep-draft vessels and 34 tugs and barges docked at Coos Bay port facilities.

The existing Coos Bay channel is wide enough to accommodate only one deep-draft ship in one direction. The Coast Guard, as part of its Waterway Suitability Report (WSR) and LOR, requires Jordan Cove to develop a Transit Management Plan to outline how conflicts with other commercial vessels would be avoided.

Ships associated with the construction and operation of the terminal could be affected by or affect other commercial ship traffic. Because the navigation channel can only accommodate one deep-draft transit, Project-related vessels may need to wait for the channel to clear. Conversely, other commercial ship traffic may need to wait for Project-related vessels to clear the channel, resulting in delays in transit. These potential impacts would be temporary and similar to those associated with existing deep-draft vessels calling at the Port.

Other Industries

There are several industrial enterprises located in proximity to the terminal site including the Southwest Regional Airport, Roseburg Forest Products, the Southport Lumber Company (Southport Lumber), and D.B. Western. The Southwest Oregon Regional Airport is addressed in section 4.10. Jordan Cove would temporarily lease land from Roseburg Forest Products for a staging area (i.e., a “laydown area”) during construction of the Jordan Cove LNG Project. Also, two warehouses located on the Roseburg Forest Products site would be removed during site preparation.

Southport Lumber operates a sawmill about a mile southwest of the terminal site. This facility includes a barge slip at about NCM 6.3 and a rail spur. The D.B. Western factory and berth is located at NCM 5.6, about 2 miles south of the terminal site. Based on the distances to the terminal site, impacts on these facilities are not expected. However, access to these facilities, as well as the Roseburg Forest Products facility, by road and water could be affected by Project-related vehicle traffic on the Trans-Pacific Parkway and vessel traffic in the navigation channel. Project-related effects on the Trans-Pacific Parkway and related mitigation plans are further discussed in section 4.10. Mitigation would likely include staggered work shifts, construction of a dedicated eastbound left-turn lane at the intersection of U.S. 101 at the Trans-Pacific Parkway, and implementation of a temporary signal at the intersection for the duration of construction activities (see section 4.10). Impacts on commercial ship traffic are discussed in the preceding section.

4.9.1.9 Environmental Justice

EO 12898, Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations, requires federal agencies to consider if impacts on human health or the environment (including social and economic aspects) would be disproportionately high and adverse for minority and low-income populations and appreciably exceed impacts on the general population or other comparison group.

As described below and consistent with our understanding of EO 12898, we reviewed the Project to determine if resulting impacts would be disproportionately high and adverse for minority and low-income populations and appreciably exceed impacts on the general population or other comparison group. Our area of analysis for the LNG terminal consisted of a 3-mile radius centered on the LNG terminal site. Our comparison groups for this analysis consisted of the general population in Coos County and the State of Oregon.

In comments provided on the draft resource reports prepared for this Project, the EPA requested that the FERC conduct appropriate public outreach to ensure that the public and Native American tribes are informed about the Project and the possible impacts on their communities and trust resources. The EPA also stated that it considers children, the disabled, the elderly, and those with limited English proficiency to be potential environmental justice communities due to their unique vulnerabilities. In several different filings with the FERC, the Confederated Tribes of Coos, Lower Umpqua, and Siuslaw Indians (Coos Tribe) stated that the Jordan Cove LNG Project would be within their ancestral lands. The Coos Tribes indicated that this EIS should address adverse environmental and cultural impacts on low-income and minority populations, and consider protection of cultural resources of importance to the tribes. Cultural resources are discussed further in section 4.11.

Review Methodology

Based on guidelines provided by the CEQ (1997) and EPA (1998), we used a three-step approach to conduct our review. These steps were:

1. Determine the presence of minority and/or low-income populations.
2. Determine if the Project would result in high and adverse human health or environmental effects.
3. Determine if high and adverse human health or environmental effects would fall disproportionately on minority and/or low-income populations.

Environmental Justice and Vulnerable Populations

Guidelines provided by the CEQ (1997a) and EPA (1998) indicate that a minority community may be defined as one where the minority population comprises more than 50 percent of the total population or comprises a meaningfully greater share of total population than the share in the general population. Minority communities may consist of a group of individuals living in geographic proximity to one another, or a geographically dispersed set of individuals who experience common conditions of environmental effect. Further, a minority population exists if there is “more than one minority group present and the minority percentage, as calculated by aggregating all minority persons, meets one of the above-stated thresholds” (CEQ 1997a, p. 26).

Minority populations identified by the U.S. Census include Black or African American, American Indian and Alaska Native, Asian, Native Hawaiian and Other Pacific Islander, and Other Race, which are considered races, and as well as persons of Hispanic or Latino origin, which is considered an ethnicity.

The CEQ and EPA guidelines indicate that low income populations should be identified based on the annual statistical poverty thresholds established by the U.S. Census Bureau. Like minority populations, low income communities may consist of individuals living in geographic proximity to one another, or a geographically dispersed set of individuals who would be similarly affected by the proposed action or program.

We used the EPA's Environmental Justice Mapping and Screening Tool (EJSCREEN) to assess the potential presence of environmental justice communities in the vicinity of the Jordan Cove LNG Project site. In accordance with EO 12898, EJSCREEN provides information on low income and minority populations. The tool also provides summary information for four other factors: less than high school education; linguistic isolation; individuals under age 5; and individuals over age 64, which are considered potential indicators of vulnerable populations. Data for the six demographic variables assessed in EJSCREEN are presented in table 4.9.1.9-1. Review of EJSCREEN indicated that there are no residents within 1 mile of the Jordan Cove LNG Project site.

TABLE 4.9.1.9-1

Demographic Indicators

Selected Variables a/	**North Bend**	**Coos Bay**	**3-Mile Radius**	**Coos County**	**Oregon**	**United States**
Total Population	16,062	9,583	12,156	62,775	3,939,233	316,515,021
Percent of Total						
Minority Population	19	18	19	14	23	38
Low Income Population	37	46	43	44	36	34
Linguistically Isolated Population	1	1	0	1	3	5
Population with Less Than High School Education	7	12	10	11	10	13
Population under Age 5	6	6	6	5	6	6
Population over Age 64	19	21	17	23	15	14

a/ Data are originally from the American Community Survey 2011-2015 five-year estimates compiled by the U.S. Census Bureau.
Source: EPA 2018b

The data presented in table 4.9.1.9-1 indicate that the minority share of the population in the cities of North Bend and Coos Bay and within 3 miles of the site is higher than the Coos County average. Minority shares in all four areas are, however, lower than the statewide average. The data also indicate that the share of the population considered low income by EJSCREEN in the city of Coos Bay, within 3 miles of the site, and in Coos County is higher than the statewide average. The data also indicate that the share of the population over age 64 is higher than the state average in North Bend, Coos Bay, within 3 miles of the site, and in Coos County as a whole.

Coos County has a higher percentage of Native Americans (2.5 percent) than the state of Oregon (0.9 percent) as a whole. This is also the case with the cities of Coos Bay and North Bend, where Native Americans constitute 2.5 percent and 1.9 percent of the total population, respectively (U.S. Census Bureau 2018).

Larger and more populated geographic areas may have the effect of "masking" or "diluting" the presence of concentrations of minority and/or low income populations (CEQ 1997a; EPA 1998). Data were, therefore, also reviewed at the census tract level to identify the potential existence of minority and/or low-income communities within a 3-mile radius of the LNG terminal site (figure 4.9-1). A total of 10 census tracts are fully or partially located within 3 miles of the LNG terminal site. Data were reviewed at the census tract level for the minority and low-income variables identified in table 4.9.1.9-1 using EJSCREEN. The resulting shares of the population were compared to two benchmark areas – Coos County and the state of Oregon – to identify potential environmental justice and/or vulnerable populations within 3 miles of the LNG terminal site.

Four of the 10 census tracts (03, 04, 05.04, 07) had minority populations that were higher than the county share (14 percent). The minority share for these four census tracts ranged from 17 percent to 26 percent, substantially lower than the 50 percent measure identified in CEQ (1997a) and EPA (1998) guidelines, and less than the state average (23 percent) in all but one case.

The share of the population considered low income by EJSCREEN is higher than the state average (36 percent) in Coos County (44 percent) (table 4.9.1.9-1). The low income share of the population was higher than the county average in one of the 10 census tracts (05.04), and higher than the state average in 6 of the 10 census tracts. The low income share in the six census tracts ranged from 37 percent to 55 percent.

The share of total population with less than a high school education was higher than the state average in 5 of the 10 census tracts. Almost all of the census tracts (9 out of 10) had larger shares of their population over age 64 than the state average, while two tracts also had larger shares of total population below age 5. The share of the population identified as linguistically isolated was below the state average in all 10 census tracts.

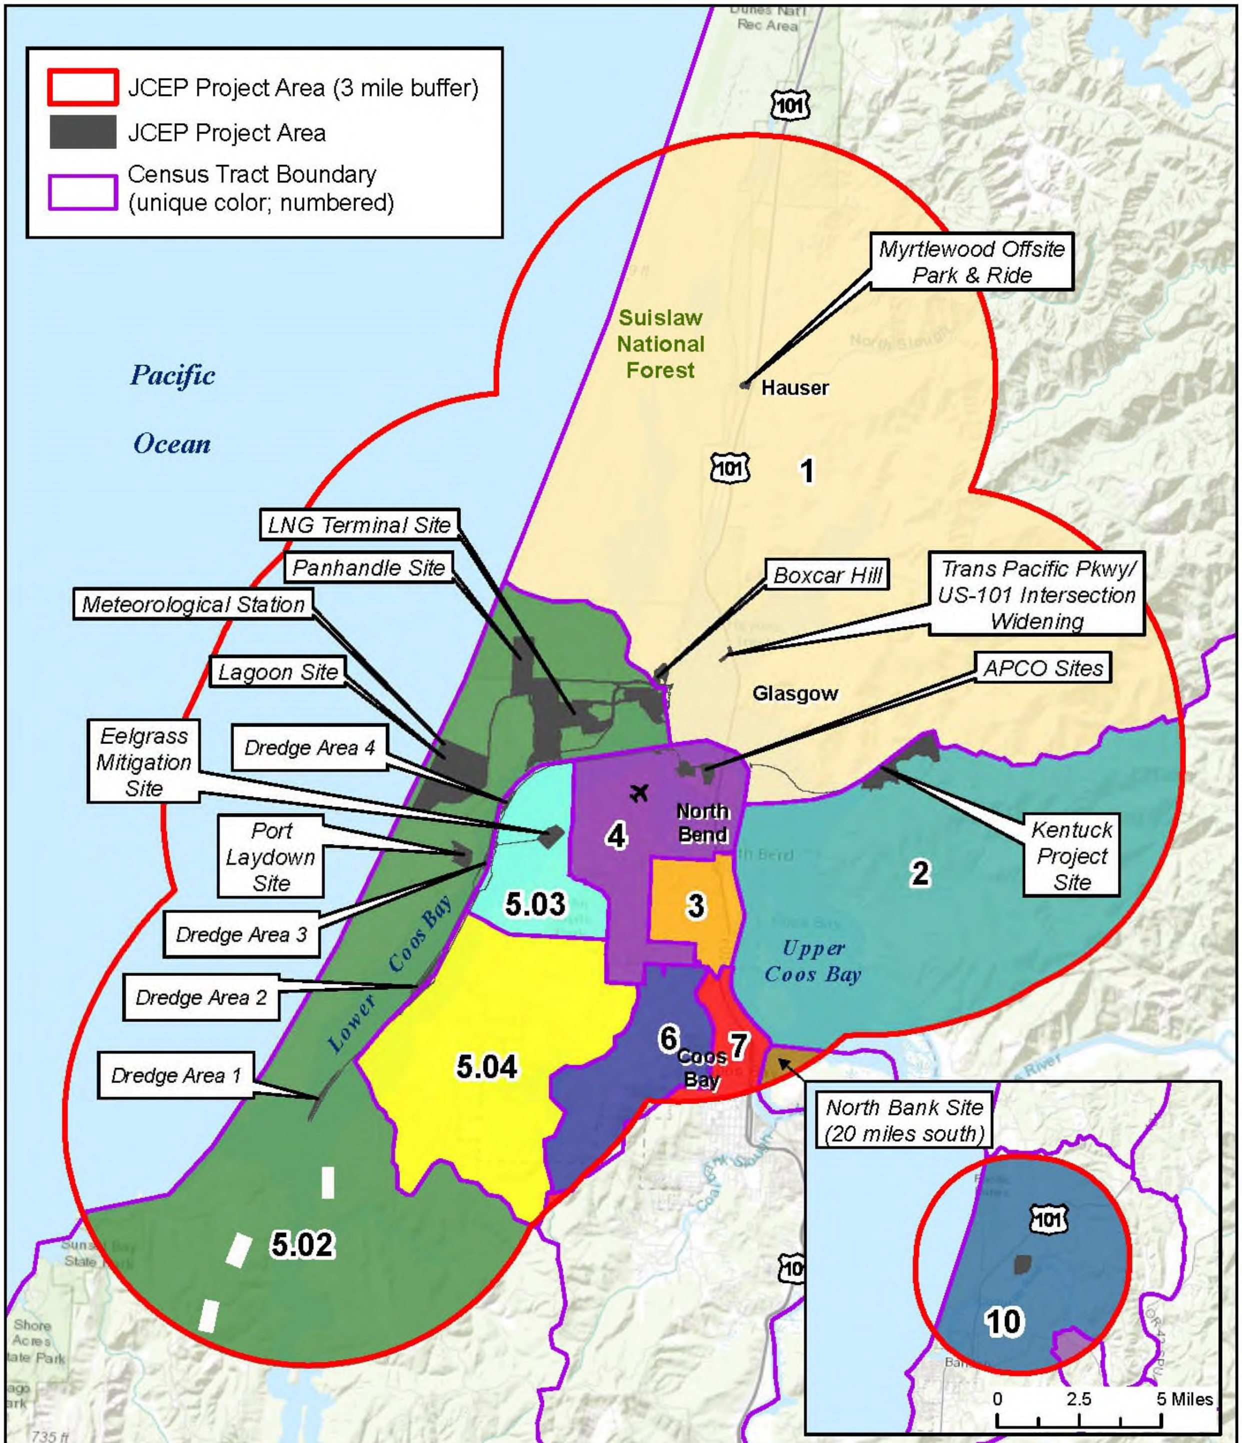

Figure 4.9-1

2010 Census Tracts in the Jordan Cove Project Area

High and Adverse Impacts

The impacts of constructing and operating the Project on the natural and human environments are identified and discussed throughout the environmental analysis section of this document. As described in the numerous environmental resource-specific discussions, we conclude that with two exception, the Project would not significantly impact the environment or have high and adverse effects on human health or the environment. Constructing and operating the LNG terminal would result in a significant impact on the visual character of Coos Bay. Additionally, the combined demand for housing from LNG terminal and pipeline workers would result in a significant impact on housing in Coos County.

Disproportionate Impacts on Environmental Justice Populations

Low-income communities are present in the vicinity of the LNG terminal site. However, none of the potential low-income populations are located within 1 mile of the LNG terminal site (there are no residents within 1 mile of the site) and the potential for these populations to be disproportionately affected relative to other populations within 3 miles of the site is low. Increased demand for rental housing would affect the market as a whole, but would likely be more acutely felt by low-income households who are spending a large share of their income on housing.

Tribal populations are a minority population with the potential to be disproportionately affected by construction and operation of the terminal as a result of their unique relationship with the surrounding environment. Government-to-government consultations between the FERC and Indian tribes are still ongoing and are discussed in detail in section 4.11 of this EIS. Issues raised by the tribes are summarized in section 4.11.1.3 and explicitly recognized in the related environmental analysis sections of this document. An assessment of the potential effects of the Project on tribal uses of those resources or the tribal members themselves has been requested by FERC staff to be presented in a forthcoming ethnographic study (see section 4.11.3.1).

4.9.2 Pacific Connector Pipeline Project

4.9.2.1 Population

Population data for the four counties that would be crossed by the pipeline are summarized in table 4.9.2.1-1. The pipeline route mainly passes through sparsely populated rural areas, with population densities in 2017 ranging from 11.4 people per square mile in Klamath County to 77.9 people per square mile in Jackson County. Estimated population in the affected counties in 2017 ranged from 63,310 in Coos County to 216,900 in Jackson County.

TABLE 4.9.2.1-1

Population by State and County

State/County	Population 2000	Population 2010	Population 2017	Percent Change in Population 2010-2017	Persons per Square Mile 2017
Oregon	**3,421,399**	**3,831,074**	**4,141,100**	**8.1%**	**43.1**
Coos County	62,779	63,043	63,310	0.4%	39.7
Douglas County	100,399	107,667	111,180	3.3%	22.1
Jackson County	181,269	203,206	216,900	6.7%	77.9
Klamath County	63,775	66,380	67,690	2.0%	11.4
Total a/	**408,222**	**440,296**	**459,080**	**4.3%**	**29.9**

a/ This row is the sum of the four counties that would be crossed by the pipeline.
Sources: Portland State University 2012, 2017a; U.S. Census Bureau 2017c

As described previously, Pacific Connector estimates that construction of the pipeline would occur over a 4-year period, with an average monthly workforce of 885 people over this period. The construction workforce is expected to peak at approximately 4,242 workers in June of Year 3, dropping to 4,027 the following month. The construction workforce would be distributed over seven construction spreads.

Based on Pacific Connector's initial estimates, monthly employment for pipeline construction is assumed to average 241 workers in Coos County, 194 workers in Douglas County, 361 workers in Jackson County, and 89 workers in Klamath County. ECONorthwest (2017a) assumed that approximately 64 percent of the average pipeline workforce would temporarily relocate to the affected counties for the duration of their employment, with about 5 percent of the total expected to be accompanied by their families. Assuming an average household size of 2.74 persons, estimated temporary increases in population would range from 0.1 percent (Douglas, Jackson, and Klamath Counties) to 0.3 percent (Coos County) of their respective county populations in 2017.

Peak construction workforces would include an estimated 1,002 workers in Coos County, 1,350 workers in Douglas County, 1,524 workers in Jackson County, and 366 workers in Klamath County. ECONorthwest (2017a) assumed that approximately 78 percent of the peak workforce would temporarily relocate to the affected counties, with 1 to 2 percent of workers expected to be accompanied by their families. Assuming an average household size of 2.74 persons, estimated temporary increases in population would range from 0.4 percent (Klamath County) to 1.3 percent (Coos County) of their respective county populations in 2017. These estimated population increases and associated impacts would be temporary and short term, with very few if any of the temporary construction workers relocating to the project area expected to stay permanently. Impacts associated with construction-related population increases are discussed throughout this section.

Construction of the Pacific Connector pipeline in Coos County would coincide with Jordan Cove LNG Project construction. Based on the above analyses, the combined temporary increase in population (workers and family members) associated with both projects would average 1,076 workers over the life of the Project. Assuming LNG terminal and pipeline construction activities in Coos County begin at the same time, construction workforces could potentially peak at the same time, resulting in a temporary combined increase in population of approximately 2,555 workers. These potential additions would be equivalent to approximately 1.7 percent (average) and 4.0 percent (peak) of the total estimated population in Coos County in 2017.

Operating the pipeline would require an estimated permanent staff of 15 employees, consisting of six operations technicians in Coos Bay, Coos County, five employees in the Medford pipeline office in Jackson County, and four employees at the compressor station near Malin in Klamath County. Employees are expected to live within driving distance of their work location and are not expected to affect population levels or trends in the counties along the pipeline route.

Crime

We received several comments on the Project expressing concern that a temporary influx of construction workers would result in increases in crime, drug and alcohol use, prostitution, human trafficking, domestic violence, and other criminal activities. Potential increases in crime related to an influx of construction workers is discussed in section 4.9.1.1. As discussed in section 4.9.1.1, increases in crime, were they to occur, would likely be commensurate with the relatively small increases in population (discussed above).

4.9.2.2 Housing

In 2015, the four counties that would be crossed by the pipeline had an estimated total of 204,107 housing units, with almost half of this total (91,782 units) located in Jackson County. An estimated 3,927 of these units were identified as vacant and available for rent. Available rental units ranged from 660 in Coos County to 1,436 in Jackson County. In addition, an estimated 7,138 units were identified for seasonal, recreational, or occasional use, ranging from 1,164 units in Douglas County to 2,335 units in Klamath County. ECONorthwest (2017b) also identified an estimated total of 9,640 hotel, motel, and small inn rooms in the four counties, along with 9,237 sites in managed RV parks and campgrounds (table 4.9.2.2-1).

TABLE 4.9.2.2-1

Housing

Geographic Area	Housing Units 2011-2015 a/				Hotels and Motels b/		Managed RV Parks and Campgrounds Number of Sites
	Total Housing Units	Rental Vacancy Rate	Units Available for Rent	For Seasonal, Recreational, or Occasional Use c/	Number of Facilities	Number of Rooms	
Coos County	30,482	6.7%	660	1,462	49	1,656	2,206
Douglas County	49,018	5.5%	834	1,164	40	1,990	2,800
Jackson County	91,782	4.3%	1,436	2,177	91	4,457	2,498
Klamath County	32,825	9.4%	997	2,335	37	1,537	1,733
Project Area Total	**204,107**	**5.7%**	**3,927**	**7,138**	**217**	**9,640**	**9,237**

a/ Data are 5-year estimates from the U.S. Census American Community Survey. Estimates are annual totals based on 5 years of data.
b/ Hotel and motels include commercial hotels, inns, and motels, as well as smaller inns and bed and breakfast establishments (B&Bs), with data obtained from STR, Inc. (commercial hotels, inns, and motels) and internet searches (smaller inns and B&Bs) (ECONorthwest 2017b).
c/ Housing units for seasonal, recreational, or occasional use are generally considered to be vacation homes. They are not included in the estimated number of housing units available for rent.
Source: ECONorthwest 2017b, U.S. Census Bureau 2017a, 2017b

Hotel and motel occupancy rates in the Project area follow a seasonal trend, with occupancy rates tending to be higher in the summer (June through September) and lower in the winter (November through February). During peak tourist season (July and August), average hotel and motel occupancy rates are around 80 percent in Coos, Jackson, and Klamath Counties and close to 75 percent in Douglas County (ECONorthwest 2017b). Occupancy rates for RV parks in the pipeline project area are not published, but tend to be more seasonal than those of hotels and motels, largely because RV parks tend to cater to tourists and RV driving is difficult during the rainy season and winter months (ECONorthwest 2017b).

Estimated average and peak housing demand by non-local construction workers is shown by housing type and county in table 4.9.2.2-2. Estimated average and peak demand is compared with estimated supply by housing type and county in table 4.9.2.2-3. Viewed as a portion of available rental housing, peak demand for rental housing would range from 6 percent (Klamath County) to 24 percent (Coos County) and 25 percent (Douglas County) of estimated available units. As discussed in section 4.9.2.1, the 2018 Coos County housing analysis and action plan identified a shortage of affordable rental housing (czbLLC 2018). Similarly, despite Census estimates that almost 1,000 housing units in Klamath County are currently available for rent, a recent newspaper editorial indicated that Klamath Falls and Klamath County are also facing a housing shortage (H&N View 2019).

TABLE 4.9.2.2-2

Estimated Housing Demand by Pacific Connector Construction Workers

	Rental Housing (Apartments, Houses, Mobile Homes) a/,b/		Hotels and Motels, RV and Campground Spaces, and Individual Room Rentals a/	
Geographic Area	**Average**	**Peak**	**Average**	**Peak**
Coos County	59	157	92	624
Douglas County	48	207	74	845
Jackson County	88	239	138	949
Klamath County	22	57	34	228

a/ Estimated demand by housing type is based on ratios estimated by ECONorthwest (2017a) adjusted to account for subsequent changes in Pacific Connector's construction schedule and workforce estimates.
b/ Assumes that 10 percent of individual workers would share a rental unit with another construction worker.

TABLE 4.9.2.2-3

Estimated Housing Demand by Pacific Connector Construction Workers as a Share of Estimated Supply

	Rental Housing (Apartments, Houses, Mobile Homes)		Hotels and Motels and RV and Campground Spaces a/b/	
Geographic Area	**Average**	**Peak**	**Average**	**Peak**
Coos County	9%	24%	2%	16%
Douglas County	6%	25%	2%	18%
Jackson County	6%	17%	2%	14%
Klamath County	2%	6%	1%	7%

a/ Percentages represent estimated demand as a share of the total estimated supply of hotel and motel rooms and RV sites, not the share that would normally be available for rent. Percentages do not include special living situations, such as bedrooms in single-family homes that home owners may rent to construction workers

Peak demand for hotels and motels, RV and campground spaces, and individual room rentals would range from about 7 percent of the total supply of hotel and motel rooms and RV spaces in Klamath County to 18 percent of the total in Douglas County. Total supply in this context refers to the total number of units and is not adjusted to account for seasonal occupancy rates. During peak season (July and August), peak demand would exceed the normally available supply of hotel and motel rooms in Coos (330 rooms), Douglas (511 rooms), and Jackson (833 rooms) Counties. A share of this demand would, however, also likely be met by RV and campground spaces and individual room rentals in existing owner- or renter-occupied housing.

During peak tourist season (July to September), short-term accommodations in some communities, especially those in Coos, Douglas, and Jackson Counties, would experience lower vacancy rates and upward pressure on rental rates. The availability of short-term housing, especially at hotels, motels, and RV parks, could become limited in the immediate pipeline vicinity, and workers and others seeking temporary accommodation in those areas may pay higher rents or have to commute farther than desired. Additionally, during peak construction worker demand, tourists would likely be displaced, particularly during summer weekends. Visitors seeking outdoor recreational opportunities do, however, have a wide range of destination choices in southern Oregon and would be likely to recreate elsewhere in the region if they were interrupted by pipeline construction at a particular location.

These potential issues would be exacerbated in Coos County, where the Pacific Connector Pipeline Project construction would coincide with Jordan Cove LNG Project construction, resulting in higher levels of demand for temporary housing. The following discussion addresses the combined demand from both projects and assumes that housing demand would peak for both projects during the same month. Combined, estimated average and peak demand for hotel and motel rooms, RV or campground spaces, or individual room rentals would be for 429 and 1,212 units, respectively, equivalent to 11 percent and 31 percent of the total supply of hotel and motel rooms and RV spaces in Coos County. These peak levels of demand would exceed the share of hotel and motel rooms and RV spaces that are usually vacant and available for rent during the summer, resulting in increased competition for temporary housing among workers, as well as the potential displacement of tourists and other visitors who would be unable to find temporary accommodation in Coos County.

For rental housing, the combined estimated average and peak demand would be for 207 and 432 units, respectively, equivalent to approximately 31 percent and 65 percent of the total 660 units estimated to be available for rent in Coos County. As noted in section 4.9.2.1, potential shortages of rental housing have been identified in Coos County (czbLLC 2018). Increased demand from Project-related construction workers would likely reduce vacancy rates and place upward pressure on rental rates, resulting in the potential displacement of other existing or potential residents seeking rental accommodation.

Operation of the pipeline would require 15 permanent employees and would have no noticeable effect on the local housing markets.

4.9.2.3 Property Values

We received numerous comments concerning the potential effect of the pipeline on property values. These comments included concerns that the pipeline would negatively affect sales prices and result in an inability to sell one's property. Concern was also expressed that a decrease in property values would result in reduced property tax revenues for the affected counties.

A number of studies have sought to determine whether the presence of a pipeline affects property values using a range of statistical techniques including paired sales and other sales comparisons, linear regression and hedonic price modeling, and descriptive statistics. These studies include two national case studies conducted by the Interstate Natural Gas Association of America (Allen, Williford & Seale, Inc. 2001; Integra Reality Resources 2016), two case studies that evaluated the effects of the South Mist Pipeline Extension in Clackamas and Washington Counties, Oregon (Fruits 2008; Palmer 2008), and studies from Arizona and Nevada (Diskin et al. 2011; Wilde et al. 2014). These studies suggest that natural gas pipelines dos not necessarily negatively affect the value of that property. The effect a pipeline may have on a property's value depends on many factors, including the size of the tract, the values of adjacent properties, the presence of other utilities, the current value of the land, and the current land use. Subjective valuation is generally not considered in appraisals, but may affect individual decisions when a property is offered for sale. Purchase decisions are often based on the purchaser's plans for the property, such as occupancy, use for agriculture, future residential development, or commercial/industrial development. If the presence of a pipeline interferes with a purchaser's plans, the potential buyer may decide against acquiring the property. However, each potential purchaser has different criteria and differing capabilities to purchase land. Therefore, based on our review of available studies and our understanding of property valuation, we conclude that the likelihood of the pipeline resulting in a long-term decline in property values and a related decrease in property tax revenues is low.

4.9.2.4 Economy and Employment

The four counties that would be crossed by the pipeline had a total combined estimated labor force of 203,614 in 2016. Labor force estimates by county ranged from 26,521 in Coos County to 101,776 in Jackson County (table 4.9.2.4-1). Annual unemployment rates in 2016 ranged from 5.8 percent in Jackson County to 6.5 percent in Coos and Klamath Counties and were higher than the state average (4.9 percent) in all four counties. Table 4.9.2.4-1 also presents average per capita income and median household income by county, and identifies the two largest economic sectors based on total employment data compiled by the U.S. Bureau of Economic Analysis (2016a). Average per capita income in 2015 (the most recent year available) was lower than the state average ($43,783) in all of the affected counties. Median household income was also below the state median ($54,074) in 2015 in all four counties.

TABLE 4.9.2.4-1

Employment and Labor Statistics for the Pacific Connector Pipeline Project Area

State/ County	Civilian Labor Force 2016 a/	Unemployment Rate (%) 2016 a/	Per Capita Income ($) 2015	Median Household Income ($) 2015	Two Largest Economic Sectors 2015 (By Percent of Employment) b/
Oregon	2,055,114	4.9	$43,783	$54,074	Health Care and Social Assistance (12%); Retail (11%)
Coos	26,521	6.5	$38,475	$38,934	State and Local Government (16%); Retail Trade (12%)
Douglas	45,891	6.4	$35,977	$41,696	Health Care and Social Assistance (12%); Retail (12%)
Jackson	101,776	5.8	$40,698	$44,855	Health Care and Social Assistance (15%); Retail Trade (13%)
Klamath	29,426	6.5	$35,216	$42,384	State and Local Government (13%); Health Care and Social Assistance (13%)

a/ Labor force and unemployment data are annual averages.
b/ Employment by economic sector is summarized in more detail in table 4.9.2.4-2.
Sources: Oregon Employment Department 2017; U.S. Bureau of Economic Analysis 2016a, 2016b; U.S. Census Bureau 2016, 2017c

All four counties were identified as distressed on Business Oregon's Temporary Distressed List for January 2017 (Business Oregon 2017). A county is considered distressed by Business Oregon based on an index calculated from four composite factors (unemployment rates, per capita personal income, changes in covered payroll by worker, and changes in employment). Twenty-three of Oregon's 36 counties were identified as distressed in January 2017.

Similar to the analysis prepared for the Jordan Cove LNG Project (see section 4.9.1.4, above), ECONorthwest (2017c) used IMPLAN to estimate the total (direct, indirect, and induced) regional economic impacts of pipeline construction and operation. Pacific Connector estimates that constructing the pipeline and related facilities would cost about $2.46 billion, with an estimated $1.4 billion expected to be spent in Oregon (ECONorthwest 2017c). ECONorthwest (2017c) estimated that total direct employment over the 24-month construction period would be equivalent to 2,854 FTE jobs, with the equivalent of 1,712 FTE jobs expected to be filled by Oregon workers. [169] Total direct labor income during pipeline construction would be approximately $926 million; with $544 million of this total expected to be paid to Oregon workers (table 4.9.2.4-2).

Constructing the Project would also support an estimated total of 4,102 indirect and 6,344 induced FTE jobs, with an estimated average of 2,051 indirect and 3,172 induced FTE jobs supported each year. In addition, Project construction would support total (direct, indirect, and induced) output, value added, and labor income of $2.8 billion, $1.3 billion, and $1.1 billion, respectively (table 4.9.2.4-2).

TABLE 4.9.2.4-2

Regional Economic Impacts of Construction of the Pacific Connector Pipeline Project in Oregon

Impact Type	Output b/	Value Added b/	Labor Income b/	FTE Jobs b/
Total Direct Impacts	$2,460	na	$926	2,854
Local Impacts (State of Oregon) a/				
Direct	$1,400	$578	$544	1,712
Indirect	$591	$313	$241	4,102
Induced	$820	$467	$272	6,344
Total d/	$2,811	$1,359	$1,056	12,159

Notes:
na – not applicable.
a/ Local impacts in this context are impacts that would occur within the state of Oregon. Direct impacts are the share of the total direct impacts expected to occur in Oregon.
b/ Impacts are presented for the entire construction period. Output, value added, and labor income are expressed in millions of dollars.
c/ Pacific Connector revised its construction workforce estimates in a November 2018 filing with the FERC, increasing the length of the construction period and the total number of FTE workers. These changes would likely result in an increase in direct impacts in Oregon, with smaller potential increases in indirect and induced impacts.
d/ Totals may not sum due to rounding.
Source: ECONorthwest 2017c

In the first full year of operations, Pacific Connector would directly employ 15 workers in Oregon, with total labor compensation (including benefits and payroll taxes) of approximately $3.1 million. This direct employment in conjunction with facility expenditures on Oregon sourced goods and services would support additional economic activity in Coos, Douglas, Jackson, and Klamath Counties and elsewhere in Oregon. Annual Project operation is estimated to support total (direct, indirect, and induced) employment of 180 FTE jobs in Oregon in 2024, with total associated labor compensation of approximately $11.3 million. Viewed in 2017 dollars, total compensation would be about $9.5 million or $53,200 per FTE job (ECONorthwest 2017d).

As noted with respect to the Jordan Cove LNG Project, indirect and induced impact estimates developed by ECONorthwest (2017c, 2017d) are based on the share of construction expenditures that Pacific Connector estimates would occur in Oregon. Changes in actual levels of in-state spending would result in changes to the indirect and induced impact estimates.

[169] Pacific Connector revised its construction workforce estimates in a November 2018 filing with the FERC, increasing the length of the construction period and the total number of FTE workers. These changes would likely result in an increase in direct impacts in Oregon, with smaller potential increases in indirect and induced impacts.

4.9.2.5 Tax Revenues

The Pacific Connector pipeline would generate federal, state, and local tax revenues during both the construction and operation phases of the Project. Federal tax revenues would be generated from federal income tax on Project-related earnings. There is no sales and use tax in Oregon, but state tax revenues would be generated through income and lodging taxes. Local tax revenues would be generated from property taxes.

Federal lands generate revenues for local counties through 25 percent fund/Secure Rural Schools payments and Payment in Lieu of Taxes (PILT) payments. Secure Rural Schools payments are discussed below in section 4.9.3.2. The PILT program is designed to compensate local governments for lost property tax revenue associated with federal lands. Annual PILT payments to the four affected counties in Fiscal Year 2018 ranged from $649,640 in Coos County to $1,864,853 in Jackson County (U.S. Department of the Interior 2018).

Total revenues for the four counties that would be crossed by the pipeline in fiscal year 2016 ranged from $44.0 million in Klamath County to $149.3 million in Jackson County (table 4.9.2.5-1). The intergovernmental revenue category identified in table 4.9.2.5-1 includes payments from the federal and state governments to the counties. These revenues include PILT payments, which help local governments maintain public services such as firefighting and police protection, public schools and roads, and search-and-rescue operations.

TABLE 4.9.2.5-1

Revenues for the Counties Crossed by the Pacific Connector Pipeline, FY 2016

Revenue Type	Coos County	Douglas County	Jackson County	Klamath County
Property Taxes	$10,150,562	$9,628,905	$41,248,304	$12,527,141
Other Taxes	$373,677	NR	NR	$1,470,964
Intergovernmental Revenues a/	$29,188,456	$40,276,259	$82,404,563	$23,682,220
Licenses, Fees, and Permits	$4,311,496	$1,571,451	$4,257,881	$1,499,150
Charges for Services	$2,132,755	$10,899,007	$18,775,415	$3,877,796
Timber Sales	$5,081,975	NR	NR	NR
Interest on Investments	$239,689	$1,762,954	$2,417,455	$729,486
Other Revenue	$849,807	$5,056,629	$168,413	$206,158
Total	**$52,328,417**	**$69,195,205**	**$149,272,031**	**$43,992,915**

NR – not reported
Sources: Coos County 2017; Douglas County 2016; Jackson County 2016; Klamath County 2016

During construction, Pacific Connector estimates that the pipeline would generate approximately $91 million in federal income tax based on an estimated construction payroll of $537 million and an average federal income tax rate of 17 percent. The estimated construction payroll would also generate approximately $40.1 million in state income tax, assuming an average state income tax rate of 9 percent. Temporary workers associated with pipeline construction would generate approximately $374,000 in state lodging taxes, as well as an estimated $1.9 million in local lodging taxes that would be distributed across the four counties. Pacific Connector also estimates that personal property taxes on approximately $728 million worth of equipment and materials either purchased in or brought into Oregon would generate about $10.9 million in tax revenues.

During operation, Pacific Connector estimates that the pipeline would generate approximately $518,000 in annual federal taxes based on estimated labor income during the first year of operation, as well as an estimated $233,000 in annual state income taxes. Pacific Connector would also pay property taxes based on the value of the installed pipeline and associated aboveground facilities and the number of pipeline miles in each county. ECONorthwest estimated pipeline property taxes based on 2016 tax rates and the number of pipeline miles in all taxing jurisdictions crossed by the pipeline. Over the initial 20 years of operations, the pipeline is expected to generate approximately $4.7 million in average annual property taxes in Coos and Douglas Counties and approximately $5.3 million in average annual property taxes in Jackson and Klamath Counties (ECONorthwest 2017d). Property tax payments would vary over time due to pipeline depreciation and changing tax rates.

The Pacific Connector pipeline would not involve federal land disposal, acquisition, or exchange and is, therefore, not expected to affect existing PILT or 25 percent fund/Secure Rural Schools payments to the affected counties.

4.9.2.6 Local Infrastructure and Public Services

Law Enforcement and Fire Protection

The pipeline route crosses four counties, each with its own Sheriff's office, employing a combined total of almost 400 officers. In addition, 23 municipalities have their own police departments, with a combined total of more than 350 officers. There are more than 30 municipal fire departments and approximately 40 RFPDs in the four counties that would be crossed by the pipeline, with a combined total of approximately 1,750 firefighters. As discussed in section 4.9.2.1, estimated temporary increases in population during peak construction would range from 0.4 percent of the existing total in Klamath County to 1.3 percent in Coos County. This relatively minor and short-term influx of non-local workers and their families during the peak construction period is not expected to adversely affect existing law enforcement or fire-fighting capabilities.

The USDOT is mandated to provide pipeline safety, and the USDOT pipeline standards are published in 49 CFR Parts 190-199. Part 192 of 49 CFR specifically addresses natural gas pipeline safety issues. Part 192 requires that each operator must establish and maintain liaison with appropriate fire, police, and public officials to learn the resources and responsibilities of each organization that may respond to a natural gas pipeline emergency and to coordinate mutual assistance. The operator must also establish a continuing education program to enable customers, the public, government officials, and those engaged in excavation activities to recognize a gas pipeline emergency and report it to appropriate public officials. Pacific Connector would provide the appropriate training to local emergency service personnel before the pipeline is placed in service. No additional specialized local fire protection equipment is expected be required to handle pipeline emergencies. Pipeline safety is discussed further in section 4.13 of this EIS.

Pacific Connector has developed an *Emergency Response Plan Concept Paper*, a *Fire Prevention and Suppression Plan*, and a *Safety and Security Plan.*[170] Pacific Connector would be responsible for the cost of implementing these plans. Pacific Connector does not anticipate that

[170] Pacific Connector's Overburden and Excess Material Disposal Plan and a Sanitation and Waste Management Plan are included as Appendices Q and W, respectively, in its POD filed with the FERC on January 23, 2018.

implementation of these plans would require additional medical or other public service personnel (including additional police or fire fighting capabilities).

Pacific Connector has indicated that in the event of a pipeline accident, the party deemed responsible for the accident would ultimately be responsible for paying all costs for emergency response, containment, damages, remediation, and repairs for the public and private property affected. In the event of an accident, Pacific Connector would provide emergency support to completely respond to the accident.

Medical Facilities

There are nine hospitals in the four counties that would be crossed by the Pacific Connector pipeline, with a combined total of almost 900 beds (table 4.9.2.6-2). These include four Level III Trauma System Hospitals that can receive helicopter transport and three level IV Trauma Hospitals (table 4.9.2.6-1).

TABLE 4.9.2.6-1

Hospitals in the Counties Crossed by the Pacific Connector Pipeline

County	Hospital	Town	Trauma Level a/	Staffed Beds	Occupancy Rate 2016
Coos	Bay Area Hospital	Coos Bay	III	129	50.1
Coos	Coquille Valley Hospital	Coquille	IV	17	36.1
Coos	Southern Coos Hospital and Health Center	Bandon	IV	19	6.7
Douglas	Lower Umpqua Hospital	Reedsport	NA	16	18.0
Douglas	Mercy Medical Center	Roseburg	III	129	60.1
Jackson	Asante Ashland Community Hospital	Ashland	IV	37	33.9
Jackson	Providence Medford Medical Center	Medford	III	138	54.5
Jackson	Asante Rogue Medical Center	Medford	III	307	74.5
Klamath	Sky Lakes Medical Center	Klamath Falls	NA	100	52.8

a/ Trauma hospitals differ from other hospitals in that they guarantee the immediate availability of surgeons, anesthesiologists, physician specialists, nurses, ancillary services, and resuscitation life-support equipment 24 hours a day and are dedicated to the care of trauma patients. Trauma facilities in Oregon are designated as Level I, II, III, or IV, with Level I and II centers offering the highest level of care (Oregon Health Authority 2018).
Source: Oregon Association of Hospitals and Health Systems 2018

As discussed above, estimated temporary increases in population during peak construction are expected to be short-term and range from 0.4 percent of the existing total in Klamath County to 1.3 percent in Coos County. If construction employment for the terminal and pipeline were to peak in Coos County at the same time, the combined temporary increase in population would be equivalent to about 4.0 percent of the existing total. Existing medical facilities are expected to be adequate to handle issues resulting from the temporary influx of non-local employees working on pipeline construction. Therefore, we conclude that constructing and operating the pipeline is not expected to have significant adverse effects on emergency services or regional hospitals.

Schools

There are 33 school districts within the four counties that would be crossed by the Pacific Connector pipeline, with a total combined enrollment of almost 64,000 students. Enrollment by county in the 2016-2017 school year ranged from about 9,500 students in Klamath County to almost 30,000 students in Jackson County.

As discussed in section 4.9.2.1, Pacific Connector anticipates that approximately 5 percent of the average workforce relocating to the potentially affected counties would be accompanied by family members, with just 1 to 2 percent of the peak non-local workforce expected to be accompanied by family. Assuming an average household size of approximately 2.74 persons, including 0.55 school-aged children, the temporary relocation of these households would result in the addition of 2 (Klamath County) to 10 students (Jackson County) to county schools. These additions would be equivalent to 0.1 percent of current enrollment or less for all counties and are not expected to noticeably affect existing school facilities and programs. Construction of the pipeline would coincide with terminal construction, resulting in a combined (pipeline and terminal) addition of an estimated 38 students to Coos County schools, which would be equivalent to about 0.4 percent of total county enrollment in 2016-2017.

Operation of the pipeline would require an estimated permanent staff of 15 employees, consisting of 6 operations technicians in Coos Bay (Coos County), 5 employees in Medford (Jackson County), and 4 employees near Malin (Klamath County). Assuming that these employees would all be hired from elsewhere, their permanent relocation along with their families to the area would not be expected to noticeably affect enrollment in local public schools.

Utilities

All four counties crossed by the Pacific Connector pipeline route have existing public utilities already in place, including water, sewers and sanitation, electricity, natural gas and propane, telephone, and cable. Some of those services are provided by county governments or municipalities, and some by private companies.

Construction of the pipeline would have only minor, temporary effects on local community utilities, services, and infrastructure. Pacific Connector would need to hook up to local utilities, including electric power and telephone lines, at its compressor station, three meter station locations, and new communications towers and buildings. Pacific Connector would also use electric power and telephone lines at its contractor yards, where existing power and telephone lines are available. Other than water required for pipeline hydrostatic testing and dust control during construction, Pacific Connector has stated that its Project would not require public water or sewer services. The pipeline would not require wastewater treatment or the construction or expansion of wastewater facilities and existing stormwater drainage systems.

Pacific Connector developed an *Overburden and Excess Material Disposal Plan* and a S*anitation and Waste Management Plan* as part of its POD.[171] During construction, trash and food waste would be collected on a daily basis and removed from the pipeline ROW. Excess rocks, overburden, large slash, and timber would be removed to established disposal areas. Following construction, all construction-related debris, including mats, skids, rope, and excess padding, would be removed by qualified solid waste disposal companies to appropriate licensed landfills or recycling facilities.

[171] Pacific Connector's *Overburden and Excess Material Disposal Plan* and a S*anitation and Waste Management Plan* are included as Appendices Q and W, respectively, in its POD filed with the FERC on January 23, 2018.

4.9.2.7 Recreation and Tourism

Recreation

A recent report by the Outdoor Industry Association (2017) estimated that outdoor recreation and related expenditures in Oregon generated an estimated $16.4 billion in consumer spending and $749 million in state and local tax revenues, supporting 172,000 jobs and $5.1 billion in wages and salaries (Outdoor Industry Association 2017). This included money spent on gear, vehicles, trips, and travel-related expenses.

Concern was expressed by commenters that the proposed pipeline crossing of the Rogue River would affect recreation-related businesses in the nearby community of Trail in Jackson County. The Rogue River is well known for its salmon and steelhead fishery, and this section of the river is popular for recreational floating using rafts and inflatable kayaks. Visitors spend money on outfitter and guide services, bait, and equipment rentals, as well as lodging, restaurants, transportation, and other local goods and services. Pacific Connector proposes to cross the Rogue River using HDD technology, which would avoid direct effects on the river and its fisheries (see chapter 2 and section 4.3) and reduce potential direct effects on recreationists.

Concern was expressed during public scoping that the pipeline would have negative effects on the communities of Shady Cove and Trail by disrupting traffic along SH 62, which parallels the Rogue River and connects these communities to Crater Lake. Viewed as a share of current traffic, the average expected increase in vehicles would range from 1.1 percent to 2.4 percent of estimated totals, with the peak estimated increase ranging from 2.4 percent to 5.0 percent (table 4.9.2.7-1). Pacific Connector developed a Transportation Management Plan to reduce conflicts between construction traffic and recreational users of local roads (see Appendix Y to Pacific Connector's POD filed with the FERC on January 23, 2018). Transportation issues related to pipeline construction are more fully addressed in section 4.10.2.

TABLE 4.9.2.7-1

Estimated Construction Traffic Impacts on SH62 near Shady Cove and Trail

SH 62 Location Description	Milepost	2015 AADT	Estimated Increase in AADT	
			Average a/	Peak b/
1.83 miles north of SH 234	15.46	7,900	1.1%	2.4%
0.05 mile south of Brophy Way	18.35	5,500	1.6%	3.4%
0.03 mile north of Indian Creek Road in Shady Cove	19.81	6,200	1.4%	3.0%
0.02 mile north of Rogue River Drive in Shady Cove	20.11	6,400	1.4%	2.9%
Northern city limits of Shady Cove	21.10	4,200	2.1%	4.4%
0.05 mile south of Tiller-Trail Highway (SH 227)	22.37	3,700	2.4%	5.0%

a/ Based on an estimated average of 89 construction-related vehicle round trips per day.
b/ Based on an estimated peak of 187 construction-related vehicle round trips per day.
AADT – average annual daily traffic
Source: Oregon Department of Transportation 2017.

Tourism

Travel spending in the four potentially affected counties in 2016 was approximately $1,187 million, ranging from $141 million in Klamath County to $548 million in Jackson County (table 4.9.2.7-2). Travel spending generated earnings of approximately $334 million and supported approximately 13,760 jobs in the four-county area in 2016. Travel-related employment as a share of total county employment ranged from 4.5 percent (Jackson County) to 10.2 percent (Coos County) (Dean Runyan Associates 2017).

TABLE 4.9.2.7-2

Travel Spending, Earnings, and Employment, 2016

State/County	Travel Spending ($ million)	Earnings ($ million)	Employment	
			Jobs	Percent of County Total (2016) a/
Oregon	11,300	3,100	109,500	Na
Coos	265.3	76.6	3,280	10.2
Douglas	233.2	68.1	3,130	6.1
Jackson	547.9	142.8	5,440	4.5

Project Area Total	**1,187.4**	**333.9**	**13,760**	**Na**

a/ This percentage represents travel-related employment for 2016 as a percent of total employment.
Source: Dean Runyan Associates 2017

As discussed in section 4.9.2.2, during periods of peak demand by pipeline workers and tourists (July to September), short-term housing accommodations in some communities, especially those in Coos, Douglas, and Jackson Counties, would experience lower vacancy rates and upward pressure on rental rates. At peak demand for lodging by construction workers has the potential to temporarily displace tourists at some locations, particularly during weekends of the summer season. As noted in section 4.9.2.2, visitors seeking outdoor recreational opportunities have a wide range of destination choices in southern Oregon and would be likely to recreate elsewhere in the region if they were interrupted by pipeline construction at a particular location. However, this temporary displacement could result in reduced demand for some recreation outfitter/guide services, as potential clients seek recreation opportunities elsewhere.

4.9.2.8 Other Commercial Activities

Commercial Fishing

Commercial and recreational fisheries are discussed in section 4.5 of this EIS and section 4.9.1.8 discusses the commercial fishing industry in Coos Bay. There are no commercial fisheries for vertebrate fish species in the Coos Bay estuary.

Fish are not harvested commercially in the rivers and streams crossed by the pipeline. However, fish such as salmon and steelhead that spawn in affected rivers are commercially harvested in coastal areas off Oregon, Washington, and California, as well as British Columbia and Alaska. A 2009 study estimated that Rogue River salmon commercially harvested off the Northwest coast support annual economic benefits of approximately $1.36 million (ECONorthwest 2009). Constructing the pipeline would affect waterbodies that provide habitat for aquatic resources that are commercially harvested. However, short-term construction-related effects on streams and rivers are not expected to adversely affect the spawning of fish that are commercially harvested from the ocean; as effects such as sedimentation and turbidity would be reduced through the use of erosion control devices. Potential effects resulting from the pipeline crossing waterbodies and mitigation of those effects are discussed in section 4.3, and effects on aquatic resources in stream habitats are evaluated in section 4.5 of this EIS.

Commercial Oyster Farms

Commercial oyster beds are located in South Slough, Haynes Inlet, and Upper Coos Bay, including two commercial oyster operations in the northern portion of Coos Bay near the pipeline crossing: Clausen Oysters and Coos Bay/North Bend Oyster Company. Both companies lease land from the Port of Coos Bay and Coos County and cultivate non-native Pacific and Kumamoto oysters and native Olympia oysters (DeKrey 2017). A study conducted for Pacific Connector estimated that Clausen Oysters had an annual yield of 10 to 13 million oysters, with the potential for gross wholesale revenues of about $2.25 million annually. The same study estimated that Coos Bay/North Bend Oyster Company had an annual yield of 7 to 8 million oysters, with the potential for gross wholesale revenues of about $1.25 million annually. Annual operational costs for both companies were estimated to be approximately 50 percent of gross sales (HDR 2015).

The pipeline would be installed via HDD beneath an active oyster lease area operated by Clausen Oysters. The use of an HDD would generally result avoid impacts on Haynes Inlet and this oyster lease area. Appendix I.2 to Resource Report 2 (i.e., the *Drilling Fluid Contingency Plan*) outlines the measures that would be used during construction to avoid and minimize potential disturbance to oyster populations during construction. However, commercial oyster beds could be affected by an inadvertent release of HDD drilling fluids in the immediate vicinity. Contingency plans would be implemented that would reduce the chance of a frac-out spill being substantial and also result in timely clean up, if needed. This is discussed further in section 4.5 of this EIS.

Other Industries

The pipeline would cross mostly rural areas, avoiding densely populated or urban areas, and not result in the displacement of any businesses. Constructing and operating the pipeline would, however, temporarily and permanently affect forested and agricultural lands and associated businesses. The pipeline would cross about 82.8 miles of mature forested lands and 58.8 miles of recently harvested forested lands. Land ownership of forested lands includes privately-owned timberland, state lands, NFS lands, and BLM lands. Approximately 1,050 MMBF of timber was harvested in the four affected counties in 2016, with an annual average harvest from 2011 to 2016 of 1,047 MMBF (Oregon Department of Forestry 2017). During Project scoping, private timber companies expressed concern about impacts on their operations. The Seneca Jones Timber Company identified a number of concerns, including potential competition between Pacific Connector and private timber companies for the use of ridge tops for access and equipment placement; possible restrictions related to forest yarding or the hauling of heavy equipment over the installed pipeline; and potential increases in the cost of local aggregate materials. Timber harvesting and the mitigation of effects related to the pipeline are discussed in more detail in section 4.7.

Pacific Connector has indicated that it will require a total of approximately 650,00 cubic yards of aggregate to construct the pipeline and associated facilities spread over 2 years, with an estimated 325,000 cubic yards required each year. Using information from DOGAMI, Pacific Connector estimates that this annual demand would be equivalent to approximately 8 percent of the suitable aggregate produced in the four potentially affected counties. In their assessment, they assume that half of the total aggregate (8 million cubic yards) produced in the four counties would be suitable for use in pipeline construction. Therefore, we conclude that pipeline construction is unlikely to result in a measurable decrease in the availability of aggregate or a substantial price increase.

Pipeline construction would affect agricultural land. The majority of the potentially affected land is pasture and cropland used for livestock forage and to grow hay, alfalfa, and food crops. A very small portion of the construction ROW would cross land in orchards, groves, vineyards, and nurseries. Following construction, a smaller area of agricultural land would be retained within permanent easements or acquired for pipeline operation. This area would include the permanent pipeline corridor, surface facilities, and maintenance ROW. The vast majority of these lands could be restored and returned to their original condition and use after the pipeline is installed. Therefore, although impacts could last for several years, most potential effects on agricultural operations would be temporary and short-term in nature. One exception is deep-rooted crops, such as orchards and vineyards, which could not be planted directly over the pipeline. Owners of orchards crossed by the pipeline would lose a percentage of their trees and potential future income. Potential impacts on agriculture are discussed further in section 4.7.

For both temporary and permanent effects, Pacific Connector would negotiate with landowners and provide compensation for timber/crop losses or land taken out of use as a result of pipeline construction.

4.9.2.9 Environmental Justice

Review Methodology

The methodology used for the terminal environmental justice assessment is summarized in section 4.9.1.9. The same methodology was used for the following pipeline assessment.

Environmental Justice and Vulnerable Populations

The Pacific Connector pipeline would cross a mostly rural region. The population in all four counties is predominantly White, with persons of Hispanic or Latino origin making up the largest share of the non-White population in all four counties, and statewide (table 4.9.2.9-1).

TABLE 4.9.2.9-1

Race and Ethnicity in Counties Crossed by the Pacific Connector Pipeline a/

Geographic Area	Total	Percent of Total						
		White b/	Hispanic or Latino	Black or African American b/	American Indian and Alaska Native b/	Asian b/	Other Race b/, c/	Two or more races b/
Coos County	62,775	85.8	5.9	0.6	2.5	1.2	0.4	3.5
Douglas County	107,194	88.8	5.2	0.3	1.3	0.8	0.1	3.5
Jackson County	208,363	82.4	11.8	0.6	0.6	1.0	0.4	3.3
Klamath County	65,972	79.7	11.6	0.8	3.1	1.1	0.3	3.5
Oregon	3,939,233	77.2	12.3	1.8	0.9	3.9	0.5	3.3

a/ Data are American Community Survey 2011-2015 five-year estimates compiled by the U.S. Census Bureau.
b/ Non-Hispanic only. The federal government considers race and Hispanic/Latino origin to be two separate and distinct concepts. People identifying Hispanic or Latino origin may be of any race. The data summarized in this table present Hispanic/Latino as a separate category.
c/ The "Other Race" category presented here includes census respondents identifying as "Native Hawaiian and Other Pacific Islander" or "Some Other Race."
Source: U.S. Census Bureau 2018

Data for the six demographic variables assessed in EJSCREEN are presented by county in table 4.9.2.9-2. These variables include low-income and minority populations, along with four other indicators considered by EJSCREEN to be potential indicators of vulnerable populations. These data indicate that the share of the population considered low income by EJSCREEN is higher than the statewide average in all four counties. The data also indicate that the share of the population over age 64 exceeds the state average in all four counties (table 4.9.2.9-2).

TABLE 4.9.2.9-2

Demographic Indicators

Selected Variables a/	Coos County	Douglas County	Jackson County	Klamath County	Oregon
Total Population a/	62,775	107,194	208,363	65,972	3,939,233
Percent of Total					
Minority Population	14	11	18	20	23
Low Income Population	44	43	42	44	36
Linguistically Isolated Population	1	1	1	1	3
Population with Less Than High School Education	11	11	11	12	10
Population under Age 5	5	5	6	6	6
Population over Age 64	23	23	19	19	15

a/ Data are originally from the American Community Survey 2011-2015 five-year estimates compiled by the U.S. Census Bureau.
Source: EPA 2018b

Data were also reviewed using EJSCREEN for the 34 census block groups that would be crossed by the pipeline. The share of the population considered minority by EJSCREEN is lower than the state average (23 percent) in all four counties, ranging from 11 percent to 20 percent (table 4.9.2.9-2). None of the census block groups in Coos, Douglas, or Jackson Counties had minority populations that exceeded the state average. Five census block groups in Klamath County had minority populations that exceeded the state average, including one where the minority population was more than 50 percent of the total. The share of the population considered low income by EJSCREEN is higher than the state average (36 percent) in all four counties, ranging from 42 percent to 44 percent (table 4.9.2.9-2). Slightly more than half (19 out of 34) of the census block groups that would be crossed by the pipeline had low income populations that exceeded the state share.

The share of the population considered linguistically isolated by EJSCREEN is lower than the state average (3 percent) in all four counties (1 percent in each) (table 4.9.2.9-2). Two census block groups, both in Klamath County, had linguistically isolated populations that exceeded the state average, with linguistically isolated populations of 8 and 11 percent versus the statewide average of 3 percent. The share of the population with less than high school education was slightly higher than the state average (10 percent) in all four counties, ranging from 11 percent to 12 percent (table 4.9.2.9-2), with the shares in 14 of the 34 census block groups also exceeding the state average. The populations in the census block groups crossed by the Pacific Connector pipeline tend to be older than the state average, as suggested by the county averages (table 4.9.2.9-2), with the share of the population over 64 exceeding the state average in 27 census block groups. Only 7 of the census block groups crossed by the pipeline route had populations below age 5 that exceeded the state average.

High and Adverse Impacts

The impacts of constructing and operating the Project on the natural and human environments are identified and discussed throughout the environmental analysis section of this document. As described in the numerous environmental resource-specific discussions, we conclude that the

Project would not significantly impact the environment or have high and adverse effects on human health or the environment. As discussed elsewhere in this section, the combined impact of housing demand from LNG terminal and pipeline workers does, however, have the potential to cause short-term housing impacts in Coos County.

Disproportionate Impacts on Environmental Justice Populations

The Pacific Connector pipeline route mostly crosses rural regions with low population densities, and avoids towns and cities. Pacific Connector has indicated that they sought to find the shortest, buildable route between Coos Bay and Malin, Oregon, where the pipeline would terminate. Along the way, the pipeline route mostly follows ridges through the mountains. Unlike discrete facilities whose impacts are generally concentrated in one location, a pipeline establishes or expands a narrow corridor often over long distances passing near communities with a mosaic of social and economic characteristics. The preceding review suggests the presence of potential environmental justice or vulnerable populations in several of the census block groups that would be crossed by the Pacific Connector pipeline. Construction and operation of the pipeline are not expected to result in high and adverse human health or environmental effects on any nearby communities and the likelihood that these potential environmental justice and vulnerable populations will be disproportionately affected relative to other populations in the census tracts crossed by the pipeline is low.

As noted in section 4.9.1.9, government-to-government consultations between the FERC and Indian tribes are still ongoing and FERC staff has requested an assessment of the potential effects of the Project on tribal uses of those resources or the tribal members to be presented in a forthcoming ethnographic study (see section 4.11.3.1).

4.9.3 Environmental Consequences on Federal Lands

Potential socioeconomic effects of the pipeline on federal lands would be primarily related to timber harvesting, recreation, and transportation. These are discussed in sections 4.7, 4.8, and 4.10, respectively.

4.9.3.1 Financial Efficiency Analysis

The Forest Service directs that projects involving timber sales include a financial efficiency analysis that compares the anticipated costs and revenues that are part of Forest Service monetary transactions (Forest Service 2002). Pacific Connector prepared a financial efficiency analysis that assesses the net present value of costs and benefits that would accrue to the federal government as a result of construction and operation of the pipeline project. This analysis was prepared in general accordance with direction contained within the Forest Service Handbook.

The analysis is limited to those costs and revenues that would result from the direct use of federal assets (land, timber, and roads) and can be directly quantified based on existing fee schedules. The analysis does not include government administrative revenues that would be generated from the fees charged to process the project application and monitor the ROW. In addition, the analysis does not include non-market economic costs or benefits that are not part of federal monetary transactions.

Costs and benefits were projected over a 50-year time period, where appropriate, and discounted using a real discount rate of 4 percent. The analysis identifies two sources of direct government revenue: (1) Pacific Connector's payment for timber that would need to be cut, and (2) Pacific Connector's rental payments for construction access and the pipeline ROW. The analysis also identifies three sources of government costs: (1) the value of lost timber productivity along the new ROW, (2) the value of non-merchantable trees that would need to be cut prematurely (lost timber growth), and (3) the incremental cost of future maintenance for existing roads that Pacific Connector may upgrade above their existing federal maintenance level (Levy 2008). The present values of these projected revenues and costs are summarized in table 4.9.3.1-1. The projected net present value of the Pacific Connector Pipeline Project based on this analysis is $7.77 million in 2015 dollars (table 4.9.3.1-1).

TABLE 4.9.3.1-1

Financial Efficiency Analysis of the Pacific Connector Pipeline Project

Category	Timing	Present Value in 2015 (2010$ millions)
Revenues		
Timber Revenue a/	2021 to 2022	5.25
Temporary Use Permit and Right-of-Way Revenue b/	2021 to 2073	2.67
Costs		
Lost Timber Productivity c/	2021	-0.004
Lost Timber Growth d/	2021	-0.058
Incremental Road Maintenance e/	2023 to 2073	-0.083
Net Present Value		7.77

a/ Timber revenue was calculated based on the pond value of the estimated timber volume, less the costs of logging and hauling the timber to the mill, slash disposal, and road work. Timber volumes and other values used in this estimate are based on preliminary estimates prepared by Pacific Connector.
b/ This analysis assumes that Temporary Use Permits would be required for construction for 2 years and the ROW would be required for 50 years. Revenues are estimated based on the federal 2020-2023 Linear ROW Rental Schedule values per acre for the affected counties. The analysis assumes that Pacific Connector would make a one-time payment, rather than make annual payments over the life of the project.
c/ Lost timber productivity was estimated based on the soil expectation value of the lands that would be permanently lost to timber production and is based on an average soil expectation value of $14.30 per acre.
d/ Lost timber growth accounts for the value of non-merchantable trees that would be cleared in the ROW. This value is based on the projected value of these trees at merchantable age. Premature harvest of these trees represents foregone revenue for the federal government and is, therefore, counted as a cost here.
e/ Non-design improvements, such as turn-outs, widening, or blading/grading, to existing roads on NFS and BLM lands would likely be necessary as part of this project and may change the maintenance level of the existing road (by, for example, adding base and gravel to an existing road surface of native materials) and, as a result, impose an incremental maintenance cost on the government. This analysis assumes that all roads on federal lands used by Pacific Connector for construction access would be upgraded from native materials to gravel and, therefore, result in costs at the upper end of the range of possible outcomes. Incremental cost increases are assumed to be $343 per mile per year.
Source: Levy 2008

This analysis does not, however, as noted above, account for other costs and benefits that are not assigned monetary values by the federal government. Other potential impacts (not valued) to federal lands include impacts on recreation, the PCT, grazing, LSRs, and Riparian Reserves (Levy 2008). While no monetary value is assigned to these potential impacts, they are considered in detail elsewhere in this document.

4.9.3.2 Secure Rural Schools and Community Self-Determination Act

Prior to 2000, in states with national forests and certain BLM lands, 25 percent of the returns to the U.S. Treasury from revenue-producing activities, such as timber sales, were returned to each state for distribution back to counties having acreage within a national forest. Those payments were called the "25 percent fund payments" and were dedicated by law to roads and schools. In October 2000, the *Secure Rural Schools and Community Self Determination Act of 2000* was enacted to stabilize federal payments to states in response to declining federal receipts. The legislation was authorized for implementation for fiscal years 2001 through 2006, and has subsequently been reauthorized, most recently in May 2018 (Forest Service 2018). As mentioned above, the Pacific Connector pipeline would not involve federal land disposal, acquisition, or exchange and is, therefore, not expected to affect existing 25 percent fund/Secure Rural Schools payments to the affected counties.

4.9.3.3 Mitigation of Impacts on Federal Lands

No mitigation of impacts on federal lands specifically related to socioeconomics is currently being considered.

4.9.4 Conclusion

Construction and operation of the Project would result in impacts on socioeconomic resources as described in the preceding sections. Temporary impacts during construction would include increased demand for law enforcement and fire protection, and medical services. These potential construction-related impacts would be temporary and short term. In addition, constructing the Project would provide direct employment for local workers, support jobs and income elsewhere in the local and state economies, and generate tax revenues for local, state, and federal agencies. However, when the combined effects of the Jordan Cove LNG Project and Pacific Connector Pipeline Project are taken into consideration collectively, construction of the Project has the potential to cause significant affects to short-term housing in Coos County. These impacts could include potential displacement of existing and potential residents, as well as tourists and other visitors. Tourists and other visitors could also be displaced during peak construction in Douglas and Jackson counties as Project-related demand for hotel and motel rooms would likely exceed the normally available supply. With the applicant's proposed construction and operations procedures and mitigation measures in place, construction and operation of the LNG terminal and pipeline facilities are not expected to result in significant impacts on socioeconomic resources or services, with the exception of housing availability.

4.10 TRANSPORTATION

4.10.1 Jordan Cove LNG Project

4.10.1.1 Marine Traffic

Marine traffic in Coos Bay includes deep-draft cargo ships that call at the Port; tugs and barges; and commercial and private fishing and recreational boats. In 2015, 42 deep-draft cargo ships called at the Port, down from about 200 calls per year in the mid-1990s. Nearly 200 commercial fishing vessels operate in Coos Bay from March to October, with just over 100 based in Coos Bay year-round. There is also some transient travel from other commercial vessels through Coos Bay delivering products, buying ice, or seeking other services. Barges, commercial fishing boats, and recreational boats are all shallow-draft vessels that can move out of the navigation channel to avoid deep-draft cargo ships when necessary.

All deep-draft cargo ships servicing Coos Bay use the existing navigation channel. They enter and exit the Port under the control of a Coos Bay Pilot. According to ECONorthwest (2017b), the Coos Bay Pilots Association typically encounters an average of six recreational boats and two commercial fishing boats during the transit of each deep-draft vessel through the Federal Navigation Channel.

The LNG terminal would receive approximately 70 water deliveries over a 2-year period. Deliveries would be via a mix of ocean-going vessels and barges. During construction, Jordan Cove would also use barges to transport dredge materials from the LNG terminal access channel and slip for fill at the Kentuck project site, resulting in an estimated 225 barge deliveries over a 4- to 5-month period. The addition of these vessels, about 25 trips per month, would not adversely impact other bay users, such as other commercial ship traffic, fishing vessels, or recreational boaters. Transits would be scheduled with the pilots and follow normal procedures in use for commercial vessel traffic. Jordan Cove would consult with the Coast Guard regarding other requirements for construction equipment ships and barges (see appendix B).

As described in chapter 2, Jordan Cove anticipates that LNG carriers would call on the terminal up to 120 times per year. Travel time from the offshore buoy at the beginning of the navigation channel to the terminal is estimated to be about 90 minutes at typical speeds of 4 to 10 knots. Coos Bay pilots would not pilot an LNG carrier through the Federal Navigation Channel under severe weather conditions, or when the volume of other ship traffic in the channel is so heavy that transit to the LNG terminal could be unsafe.

The Federal Navigation Channel can accommodate only one-way deep-draft vessel traffic (i.e., only one vessel at a time, see chapter 2). An LNG carrier would be unable to use the channel when another deep-draft commercial ship is in transit in Coos Bay, and would instead be held either at the buoy outside the bay or in the marine slip at the Jordan Cove LNG terminal until the other deep-draft ship has completed its transit.

Impacts on fishing and recreational boats in Coos Bay resulting from Project-related ship traffic would be similar to those from current deep-draft cargo ship traffic in the Federal Navigation Channel. In general, as a deep-draft vessel enters the channel, other boats move out of its way, and boats in the ocean near the mouth of the channel defer entering the channel until the larger ships have passed. The escort boats accompanying each LNG carrier would facilitate moving other boats out of the way in a timely manner. As they currently do for other commercial cargo ship traffic, the Coast Guard and OSMB would remind recreational boaters of their obligation to not impede deep-draft vessels transiting in the Federal Navigation Channel. Interactions between deep-draft cargo ships and other boats rarely occur in Coos Bay. The likelihood of a collision between an LNG carrier and another boat would be extremely low because of the mitigation measures imposed by the Coast Guard's WSR, including the implementation of a TMP, and a security zone around LNG carriers in the waterway (typically around 500 yards in size). While an LNG carrier is moored at berth at the terminal, a security zone would be established around the slip. This security zone would not extend as far as the Federal Navigation Channel and would not affect vessels transiting through the channel.

The addition of approximately 70 water deliveries via a mix of ocean-going vessels and barges during the two-year construction period and 120 LNG carriers per year transiting to and from the Jordan Cove LNG terminal during its operation would increase the total number of deep-draft vessels calling at Coos Bay. This increase in marine traffic combined with current deep-draft vessel traffic would be less than historic ship traffic through the channel. Therefore, based on this historic capacity, current traffic practices in the bay, and the implementation of Coast Guard shipping measures, we conclude that some marine traffic might be temporarily inconvenienced, but the passage of LNG carriers and other Project-related marine traffic through the channel would not significantly affect other boats in Coos Bay.

4.10.1.2 Motor Vehicle Traffic

As described in chapter 2, the construction work force would use public roads and highways (U.S. Highway 101 and the Trans-Pacific Parkway) to deliver supplies and access LNG terminal site workspaces.

On behalf of Jordan Cove, DEA prepared a *Traffic Impact Analysis* for the Jordan Cove LNG Project (DEA 2017b) based on a Project study area established by ODOT, Coos County, and the City of North Bend.[172] The 14 intersections that comprise the study area are governed by operational targets or standards established by the applicable jurisdiction (City of North Bend, Coos County, and/or ODOT). The existing conditions (August 2017) analysis performed by DEA found that all study area intersections met the applicable mobility targets during both midweek AM and PM analysis hours. All intersections but one also met the applicable LOS mobility targets during both Friday PM and midday Saturday analysis hours.[173] The exception, the westbound left turn from Ferry Road to U.S. 101, was identified as operating at level of service (LOS) E and, therefore, exceeding the applicable "LOS D" mobility target established by the City of North Bend).[174]

The DEA analysis assessed impacts for four analysis hours, which coincide with peak workforce shift changes. The DEA construction phase analysis assumed two work shifts, with start times staggered by one hour, with only one shift occurring during peak analysis hours. The analysis,

[172] This report was filed as part of Jordan Cove's response to FERC's January 3, 2018 Environmental Information Request.
[173] LOS is measured as a function of control delay at intersections, with six established targets ranging from LOS A, where there is little or no delay, to LOS F, where there is delay of more than 50 seconds at unsignalized intersection, or more than 80 seconds at signalized intersections.
[174] Project construction and operation would not add any traffic to the westbound left turn from Ferry Road to U.S. 101 and, therefore, this intersection is not discussed further.

therefore, looked at only half the proposed workforce, with the other half of the workforce assumed to travel outside of peak analysis hours. The use of two staggered work shifts is intended to reduce construction impacts and assumed to be in place in all the construction-related analyses.

The DEA study analyzed impacts for two construction phases—(1) just before the proposed workforce housing and Park and Ride (PnR) lots are active; and (2) when the construction workforce would be at its peak with the proposed housing and PnR lots also at peak usage—and the first year of operations.

For the first construction phase, the study found that the intersection of U.S. 101 at the Trans-Pacific Parkway would fail to meet operational targets during the midweek PM and Friday PM analysis hours if no mitigation were provided, with construction-related traffic resulting in significant vehicle queuing and delays. To address this failure, Jordan Cove would construct a dedicated eastbound left-turn lane (approximately 600 feet in length) and implement a temporary signal at the intersection for the duration of construction activities.

This intersection would also fail to meet operational targets during the second construction phase evaluated in the DEA study. In addition, U.S. 101 at Hauser Depot Road was predicted to fail to meet operational targets during the midweek PM and Friday PM analysis hours, with estimated traffic volumes exceeding intersection capacity resulting in traffic congestion and delays. Jordan Cove would mitigate this impact by implementing manual flagging of the intersection during the PM hours when the construction workforce would be leaving the Myrtlewood Off-site Park and Ride lot.

The DEA analysis of the first year of operation found that all intersections meet the applicable mobility targets.[175]

In summary, the DEA (2017b) study indicates that Project-generated trips during peak construction would result in operational impacts at two study area intersections if no other mitigation were provided. In addition to staggered work shifts (assumed in the analysis), the *Traffic Impact Analysis* recommended the following strategies and mitigation measures:

- U.S. 101 at Trans-Pacific Parkway – construct a dedicated eastbound left-turn lane and employ temporary signalization of the intersection.
- Hauser Depot Road at U.S. 101 – employ manual flagging at the intersection during the PM hours when the workforce is leaving the Myrtlewood Off-site Park and Ride lot.
- Use PnR lots to bus workers not residing at the North Spit housing facility to the Project site.

The Traffic Impact Analysis recommends that Jordan Cove enter into development agreements with ODOT, Coos County, and the City of North Bend to allow the various entities to work through different scenarios should they occur during construction. Such development agreements would provide the framework to allow for timely identification and development of response actions or

[175] The one exception would be the westbound turn from Ferry Road to U.S. 101, which currently fails to meet operational targets. As noted above, operation of the project would not add any traffic to this intersection.

mitigation for unforeseen scenarios that develop during construction. We concur with these findings. Therefore, **we recommend that:**

- **<u>Prior to construction</u>, Jordan Cove should file documentation that it has entered into development agreements with ODOT, Coos County, and the City of North Bend, as recommended in the *Traffic Impact Analysis* report.**

During construction of the LNG terminal slip, excavated material would be transported by truck to upland sites. The excavated material truck haul route would be on Jordan Cove or Roseburg Forest Products owned land and would not cross the Trans-Pacific Parkway. The haul trucks and other equipment using the haul road would consist of large off-road vehicles common for large civil infrastructure or mining projects. The only potential conflict would be with Roseburg chip truck traffic, when the Jordan Cove excavated material trucks cross Jordan Cove Road. This potential impact would be mitigated by construction of a temporary traffic overpass that would segregate traffic traveling to and from the Roseburg Forest Products facility from large, off-road haul trucks and equipment.

4.10.1.3 Railroad Traffic

The existing Coos Bay rail line would be used for the delivery of sheet piling. Over the first year 16 deliveries of sheet piling would occur. However, Jordan Cove has indicated that pending further analysis, additional use of the rail line may be necessary. All rail shipments would be off-loaded at an existing rail spur at the Roseburg Forest Products yard, which runs into the construction laydown area. No new rail construction is anticipated for the purpose of transporting materials and equipment to the site. Rail deliveries would be coordinated with Roseburg Forest Products and Coos Bay Rail Link to minimize impacts on their operations.

4.10.1.4 Air Traffic

The Southwest Oregon Regional Airport is located in the city of North Bend, directly across Coos Bay and less than 1 mile from the LNG terminal site. The airport is owned and operated by the Coos County Airport District and provides commercial passenger services to the region. The Coast Guard also has five helicopters based at the airport. The number of fixed wing aircraft based at the Southwest Oregon Regional Airport has ranged from 51 to 68 for the past 20 years, with 51 aircraft based at the airport in 2010.

Commercial passenger service to and from the airport is currently provided by United Airlines, with one flight daily to and from San Francisco, four days a week. United Airlines also provides seasonal twice-a-week roundtrip flights to and from Denver. Federal Express and Ameriflight operate cargo services out of the airport.

During operation of the Jordan Cove LNG Project, LNG carriers in the Federal Navigation Channel would cross he airport approach pathway. Jordan Cove has indicated that aircraft would be delayed by about 13 minutes for each passing vessel, consisting of a 10-minute advance notice period, and 3 minutes of actual time during which airspace would be potentially obstructed. LNG carrier transit times could also be adjusted to avoid conflict with air traffic, if the need arises.

Comments during public scoping requested that the EIS evaluate the potential impact of thermal plumes from the Jordan Cove LNG terminal on airport operations. Jordan Cove commissioned a thermal plume study for the previously proposed LNG terminal in 2013 (TRC Environmental

Corporation 2013) which showed that the combustion turbines that were part of the previously proposed South Dunes Power Plant were identified as the main potential source of thermal plumes from the terminal. The South Dunes Power Plant is not part of the current proposal and therefore the LNG terminal would not general thermal plumes.

Title 49 CFR §193.2155 of the USDOT's regulations requires that an LNG storage tank be at least 1 mile from the end of an airport runway, or 0.3 mile from the nearest point on a runway, whichever is longer. This issue is discussed further in section 5.1.13, Reliability and Safety.

4.10.2 Pacific Connector Pipeline Project

4.10.2.1 Access Roads

Pacific Connector would use a variety of vehicles including standard pick-up trucks, earth-moving equipment, tractor trailers, and pipe-stringing (and other materials/equipment) trucks to construct the pipeline. These vehicles would traverse Project-area roadways and access workspaces via existing and new construction access roads. Equipment and materials would be transported from various laydown areas and storage yards to the pipeline right-of-way and associated construction workspaces. Most construction equipment would remain on the right-of-way during construction.

As described previously, existing roads, including federal and state highways, as well as local, private, and BLM and Forest Service roads, would be used to access workspaces and move construction equipment, materials, and personnel (see table D-2 in appendix D).

Major state and federal highways that would be affected by the pipeline include:

- U.S. Highway 101 (MP 1.2) and State Highway 42 (MP 51.5) in Coos County;
- I-5 (MP 71.2) and State Highway 227 (MP 94.7) in Douglas County;
- State Highway 62 (MP 122.6), Butte Falls Highway (132.5), and State Highway 140 (MP 145.6) in Jackson County; and
- State Highway 66 (MP 191.5), U.S. Highway 97 (MP 199.6), and State Highway 39 (MP 208.8) in Klamath County.

The pipeline would be installed in Coos Bay under U.S. Highway 101. State Highways 42, 140, 66, and 39 would be crossed with conventional road bores. Pacific Connector proposes to use direct pipe technology to cross under I-5. State Highway 62 and U.S. 97 would be crossed with HDDs. Highway 227 and the Butte Falls Highway would be crossed with open cuts. Smaller roads would also typically be crossed with open cuts.

Constructing the pipeline would temporarily impact Project-area roads and their users. Temporary impacts include increased road traffic, traffic delays, and road wear. To facilitate construction of the pipeline, some existing roads would be improved. Improvements would generally occur on smaller roads and would include widening, base improvement (gravel), and the installation of pullout/passing spaces. Minor improvements (i.e., filling potholes, grading to remove ruts, and/or limbing to remove overgrowth) would be needed in some areas to accommodate oversized and heavy construction equipment. In other cases, roadway improvements would require reconstruction to make the roads usable for access to the construction right-of-way. Pipeline-stringing trucks would haul 40- to 80-foot lengths (joints) of pipe, which would often require travel outside an existing road footprint. Widening access roads would be necessary to accommodate the potential for the stringing trucks to "walk" outside of the existing road footprint. In some circumstances, it may also be necessary for oncoming traffic to pull off of the existing road footprint to pass.

To reduce impacts on affected roads and users, Pacific Connector would implement the measures described in its TMP.[176] These measures include:

- Obtain all necessary permits from ODOT, BLM, Forest Service, and the counties to cross and/or use roads, and implement all permit stipulations.
- Notify landowners or managers 7 days in advance of planned road work. In cases where there are unforeseen changes to the schedule, provide a minimum 48-hour notice.
- Use flaggers, signs, lights, barriers, and other common traffic control measures.
- Maintain at least one lane of traffic with detours around the construction by plating over the open portion of the trench or by other suitable methods. Where road closures are necessary, limit closures to 24 hours, post signs in advance, provide access for emergency vehicles, and evaluate alternate access for local residents.
- Keep roads free of mud and other debris that may be deposited by construction equipment. Ensure track-driven equipment crosses roads on tires or construction pads to minimize road damage. Repair any roadways damaged by construction activities.

In addition to its use of public roads, Pacific Connector would construct 10 new TARs and 15 new PARs (table 4.10.2.1-1). Eight of the TARs and 12 of the PARs would be located on non-federal land . After the pipeline is installed, unless specifically requested by the landowner, the TARs would be removed, and the land restored to its original use. Most of the new PARs would be located within Pacific Connector's permanent pipeline easement and would provide access during construction as well as for operations and maintenance activities while the Pacific Connector pipeline is in service.

TABLE 4.10.2.1-1

Proposed New Temporary and Permanent Construction Access Roads

Total PAR		**3,810**		

TAR = Temporary Access Road; PAR = Permanent Access Road; MP = milepost
a/ All or portions of the PARs are located within the permanent pipeline easement. Estimated total disturbance from TAR = 3.8 acres, total disturbance from PAR = 2.2 acres.

4.10.2.2 Additional Traffic on Local Roads

Pacific Connector assumes that approximately 80 percent of workers would travel each morning to a construction yard, and then make the return trip in the evening. These workers would then be transported from the contractor yard to and from construction workspaces on crew buses. The remaining 20 percent of the workforce would drive their own vehicles to construction workspaces using local roads and highways, with 30 percent of this total expected to carpool with approximately two workers per vehicle. The 20 percent of the workforce using their own vehicles would make two to three daily trips from the contractor yards to various construction locations.

Pacific Connector estimates that between three and four pipe-stringing trucks would make approximately two roundtrips per day between the pipe storage yards and pipeline work sites for the duration of project construction. Three water trucks and three dump trucks would make up to six roundtrips per day to deliver materials and equipment to the right-of-way and control fugitive dust. Another five fuel/lube/maintenance trucks and five equipment trucks would make approximately one roundtrip per day between the storage yards and work sites. Based on these assumptions, average heavy truck traffic during mainline construction is estimated to include 53 vehicle round trips per day along each construction spread. The routes taken by these vehicles would vary depending on the location of construction activities.

Based on these assumptions, construction-related peak vehicle round trips per day would range from 461 to 1,657, including crew buses and heavy vehicle trips (table 4.10.2.2-1).[177]

[177] These estimates are based on five construction spreads as initially identified by Pacific Connector. Pacific Connector has since indicated that they would use eight construction spreads. Increases in the number of spreads would reduce the number of workers traveling to any one location.

TABLE 4.10.2.2-1

Estimated Peak Vehicle Round Trips per Day by Pipeline Spread

Vehicle Type/Journey	Spread a/,b/				
	1	**2**	**3**	**4**	**5**

Heavy Vehicle Trips e/	53	53	53	53	53
Total Traffic f/	**1,179**	**1,657**	**828**	**520**	**461**

a/ The spreads initially identified by Pacific Connector are as follows:
Spread 1: Coos Bay (Coos County) to Camas Valley (Douglas County)
Spread 2: Camas Valley to Milo (Douglas County)
Spread 3: Milo (Douglas County) to Shady Cove (Jackson County)
Spread 4: Shady Cove (Jackson County) to Keno (Klamath County)
Spread 5: Keno to Malin (Klamath County)
b/ Pacific Connector has indicated they now plan to use eight construction spreads, which would reduce the number of workers traveling to any one location.
c/ Personal vehicles are assumed to make between two and three trips per day between work sites and contractor yards.
d/ Worker vans are assumed to be 15-passenger crew vans.
e/ Heavy vehicle traffic includes pipe-stringing, water, dump, material, and fuel/lube/maintenance trucks making between one and six trips per day between work sites and contractor yards.
f/ Totals may not sum due to rounding.

Other trips not included in the estimates in table 4.10.2.2-1 include workers building the aboveground facilities, inspectors, and surveyors traveling to and from various work sites.

4.10.2.2 Operations

Operating the pipeline would require a permanent staff of about 15 employees. Project-related traffic during operations would be minimal, occurring on a sporadic rather than regular basis, and would have negligible effects on traffic volumes on roads in the Project area.

4.10.2.3 Off-Highway Vehicles

Commenters raised concerns during public scoping that the pipeline right-of-way could be used to increase unauthorized OHV, snowmobile, and dispersed motorized access to adjacent lands. OHV use is discussed in section 4.8, Recreation and Visual Resources.

4.10.3 Environmental Consequences on Federal Lands

4.10.3.1 Roads Crossed

The pipeline would cross multiple roads on BLM and NFS lands. Some roads would be crossed at more than one location. The pipeline would be placed within the right-of-way of a number of roads. Open cuts would be used to cross all of the roads on BLM and NFS lands.

4.10.3.2 Roads Used for Access

Pipeline construction would require the use of many miles of existing roads on federal lands, or existing private roads on which federal land-managing agencies hold an easement. The BLM and NFS roads are of varying conditions, and some roads would require improvements to surfacing, brushing, drainage maintenance, and other work to accommodate oversized and heavy construction equipment. In most cases, the potentially affected roads are single-lane forest roads designed and built primarily for the removal of timber using conventional log trucks. Pacific Connector's pipe-stringing trucks would be hauling 40- to 80-foot-long sections of pipe to the right-of-way. These vehicles would be approximately 100 feet long. Because of the size of these and other vehicles that would use these access roads, some minor improvements (straightening, widening, cut and fill, and/or culvert improvements) may be required. In some circumstances, it may also be necessary to construct turnouts for oncoming traffic to "pull out" of the existing road footprint for passing purposes. All road maintenance, reconstruction, and improvements undertaken by Pacific Connector and their contractors would conform to BLM and Forest Service requirements. No maintenance or improvements would be allowed on any road not authorized for use and approved for improvements.

Pacific Connector would construct one new TAR on BLM land. This road would be approximately 0.3-mile-long and would disturb less than approximately 1 acre of land. One TAR would be constructed on NFS lands. This road would also be approximately 0.3 mile long and disturb less than approximately 1 acre of land (table 4.10.2.1-1). These roads would provide access during construction and would be restored to preconstruction conditions following completion of construction; which would result in a short-term impact.

Pacific Connector would construct three new PARs on BLM land, totaling about 600 feet (see table 4.10.2.1-1). Construction of these new roads would permanently impact approximately one-third of an acre. These roads would provide access during construction and for operations and maintenance activities while the Project is in service. No new PARs would be built on NFS land.

Construction activities at proposed federal road crossings would also affect public access, as well as use by permittees, contractors, and cost share users. Pacific Connector's TMP identifies the roads on federal lands that would be used during Project-related timber extraction activities, and pipeline construction and operations, and specifies the standards that would be utilized where improvements on federal roads are necessary.

As discussed in section 4.10.2.3, Pacific Connector's TMP outlines measures Pacific Connector would implement to maintain public access on roads used for construction access or crossed by the construction right-of-way during pipeline construction.

4.10.3.3 OHV Use on Federal Lands

Federal land managers have raised concerns that the pipeline right-of-way could be used to increase unauthorized OHV, snowmobile, and dispersed motorized access to federal lands. Locations where unauthorized access could be exacerbated by the pipeline right-of-way include the area around the PCT; the Camel Hump area; the Obenchain area; along the Clover Creek Road (on NFS land); and various points on BLM lands. In the Obenchain area, four-wheel-drive vehicles have caused extensive resource damage. The Camel Hump and Obenchain areas are located within the Jackson Access and Cooperative Travel Management Area, which encompasses both private and BLM lands, and is generally closed to motorized use from mid-October through April. In the area along the Clover Creek Road, the pipeline would closely parallel the road for 18 miles (on public and private lands); thus, the pipeline right-of-way could potentially turn into an OHV thoroughfare without appropriate barriers and mitigation.

OHV controls were addressed in Pacific Connector's *Recreational Management Plan*. The general measures Pacific Connector would use to limit OHV access to its right-of-way on federal lands would be the same as those discussed for non-federal lands above.

4.10.4 Conclusion

Constructing and operating the Project would not significantly affect marine, railroad, or air traffic. With the proposed mitigation measures mentioned in previous sections in place, the Project would also not significantly affect motor vehicle traffic.

4.11 CULTURAL RESOURCES

Cultural resources are locations of human activity, occupation, or use. According to the FERC's Office of Energy Projects' "Guidelines for Reporting on Cultural Resources Investigations for National Gas Projects," cultural resources include any prehistoric or historic archaeological site, district, object, cultural feature, building or structure, cultural landscape, or Traditional Cultural Property (TCP). Generally, cultural resources are considered to be historic properties[178] under the NHPA if they are at least 50 years old and meet the criteria for listing on the NRHP (36 CFR Part 60.4). Adverse effects to historic properties are typically considered significant impacts under NEPA; however those impacts may be mitigated to less-than-significant levels. It should be noted that consulted Indian tribes have pointed out that their definition of cultural resources is more expansive than that above and may include natural resources or features. As discussed in subsection 4.11.1.3 below, while resources and issues of concern to Indian tribes that do not meet the above definition of cultural resources are described in this section, the reader is referred to the corresponding section of this EIS for a more detailed discussion.

The regulations for implementing Section 106 of the NHPA, at 36 CFR 800.9, encourages the integration of the Section 106 compliance process with the NEPA process; and we have done this in this section below of the EIS. This section is broken into several subsections. The subsections mirror the Section 106 compliance process. The steps of the process, as outlined in 36 CFR 800 are: 1) consultations; 2) identification of historic properties; 3) assessment of effects; and, 4) the resolution of adverse effects. Our first subsection below is a summary of consultations initiated by the FERC staff, and communications the applicants had with various consulting parties, including other federal agencies, SHPO, and interested Indian tribes. Next, we define the APE, and summarize the results of literature reviews and site file searches, and the results of cultural resources inventories conducted by the applicants' consultants. Then we discuss the Unanticipated Discovery Plan (UDP) produced by the applicants for this Project, and reviews by consulting parties. Lastly, we reach conclusions about the status of our compliance with the NHPA. Appendix L includes a cultural context for the Projects, a brief summary of archaeological research in southern Oregon, detailed listings of consultations with SHPO and Indian Tribes, and detailed listings of identified cultural resources in the APEs of the Project, anticipated impacts on those resources, and proposed methods to address those effects.

Section 101(d)(6) of the NHPA states that properties of traditional religious and cultural importance to Indian tribes may be determined eligible for the NRHP. In carrying out our responsibilities under Section 106 of the NHPA, the FERC staff consulted with Indian tribes that may attach religious and cultural importance to properties in the APE. On behalf of all the federal cooperating agencies, as the lead federal agency, the FERC staff conducted government-to-government consultations with Indian tribes that may be interested in the Projects, and may have concerns about potential impacts on cultural resources and historic properties, including traditional religious and cultural properties. Consultations with Indian tribes are detailed below.

[178] Historic properties include any prehistoric or historic district, site, building, structure, or object, and properties of traditional religious or cultural importance to Indian tribes listed on or eligible for listing on the NRHP, as defined in 36 CFR 800.16(l).

Section 106 of the NHPA requires the FERC to take into account the effect of its undertakings[179] (including authorizations under Sections 3 and 7 of the NGA) on historic properties and afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. Jordan Cove and Pacific Connector, as non-federal applicants, are assisting the FERC in meeting its obligations under Section 106 by providing data, analyses, and recommendations in accordance with 36 CFR 800.2(a)(3) and the FERC's regulations at 18 CFR 380.12(f). The FERC remains responsible for all findings and determinations under the NHPA.

As the lead federal agency for the Project, the FERC will address compliance with Section 106 on behalf of all the federal cooperating agencies in this EIS.[180] However, the federal land-managing agencies still have separate obligations regarding cultural resource management under other federal laws and regulations, including, but not limited to, the Antiquities Act of 1906, Section 110 of the NHPA, Archaeological and Historic Preservation Act of 1974, Archaeological Resources Protection Act of 1979, FLPMA, and the Native American Graves Protection and Repatriation Act.

4.11.1 Consultations

To identify historic properties potentially affected by the Projects and in accordance with Section 106, FERC, on behalf of all of the federal cooperating agencies, consulted with the Oregon SHPO,[181] interested Indian tribes, and other consulting parties prior to making our determinations of NRHP eligibility and Project effects. We also consulted with the SHPO, interested Indian tribes, and other consulting parties to determine the resolution of adverse effects on historic properties that cannot be avoided. All correspondence related to these consultations can be found in the Commission's administrative record. A detailed listing of communications and comments received from Indian tribes are included in appendix L. Our consultations are ongoing and will be updated in the final EIS.

Consultations began with the issuance of the NOI on June 9, 2017. The NOI was sent to a wide range of stakeholders, including other federal agencies such as the ACHP, U.S. Department of the Interior Bureau of Indian Affairs (BIA), BLM, COE, Forest Service, Reclamation, and NPS; state and local government agencies, such as the Oregon SHPO; affected landowners; regional environmental groups and non-governmental organizations; and Indian tribes that may have an interest in the project area. The NOI contained Section 106-specific text initiating consultations with the SHPO and soliciting their views and those of other government agencies, interested Indian tribes, and the public on the Project's potential effects on historic properties.

[179] "Undertaking means a project activity, or program funded in whole or in part under the direct or indirect jurisdiction of a Federal agency, including those carried out by or on behalf of a Federal agency; those carried out with Federal financial assistance; those requiring a Federal permit, license or approval; and those subject to state or local regulation administered pursuant to a delegation or approval by a Federal agency," as defined in 36 CFR 800.16(y). The Projects are undertakings.

[180] Pursuant to 36 CFR 800.2(a)(2), the EPAct, and the May 2002 Interagency Agreement on Early Coordination of Required Environmental and Historic Preservation Reviews.

[181] In all cases, the SHPO refers to the staff of the Oregon State Historic Preservation Office within the Oregon State Parks and Recreation Department, including the State Archaeologist.

4.11.1.1 Consultations with the SHPO

Throughout the planning process, the FERC staff have consulted with and the applicants have communicated with the Oregon SHPO regarding the Projects. While not specific to the current application, FERC consultations and applicant communications regarding previous versions of the Projects occurred between 2006 and 2015 and informed our current consultations. Those efforts were summarized in the relevant FEISs prepared for Docket Nos. CP07-441-000, CP07-444-000, CP13-483-000, and CP13-492-000. Consultations between the FERC and the SHPO after September 2015, related to Docket Nos. CP17-494-000 and CP17-495-000, are summarized in table L-1 in appendix L. Communications between the SHPO and the applicants after September 2015 are summarized in tables L-2 and L-3 in appendix L.

4.11.1.2 Consultations with Indian Tribes

The unique and distinctive political relationship between the United States government and Indian tribes is defined by treaties, statutes, executive orders, judicial decisions, and agreements. These have resulted in differentiating tribes from other entities that deal with, or are affected by, the federal government. This relationship has given rise to a special federal trust responsibility, involving the legal obligations of the United States government toward Indian tribes and the application of fiduciary standards of due care with respect to Indian lands, tribal trust resources, and the exercise of tribal rights. Indian tribes are defined in 36 CFR 800.16(m), as: "an Indian tribe, band, nation, or other organized group or community, including a Native village, Regional Corporation, or Village Corporation, as those terms are defined in Section 3 of the Alaska Native Claims Settlement Act (43 U.S.C. 1602), which is recognized as eligible for the special programs and services provided by the United States to Indians because of their special status as Indians."

The FERC acknowledges that it has trust responsibilities to Indian tribes, and so, on July 23, 2003, it issued a "Policy Statement on Consultations with Indian Tribes in Commission Proceedings" in Order 635. That policy statement included the following key objectives:

- The Commission will endeavor to work with Indian tribes on a government-to-government basis, and will seek to address the effects of proposed projects on tribal rights and resources though consultations; and
- The Commission will ensure that Tribal resources and interests are considered whenever the Commission's actions or decisions have the potential to adversely affect Indian tribes or Indian trust resources.

The FERC contacted Indian tribes that may attach religious or cultural significance to sites in the region or may be interested in potential Project impacts on cultural resources. We identified Indian tribes that historically used or occupied the Project area through basic ethnohistorical sources, such as the *Handbook of North American Indians* (Suttles 1990), communications with the SHPO and the Oregon Legislative Commission on Indian Services, information provided by the applicants, and scoping responses to our June 9, 2017 NOI, including letters from interested Indian tribes.

Indian tribes identified in the region are: the Burns Paiute Tribe, Confederated Tribes of the Lower Umpqua, Coos, and Siuslaw Indians (CTCLUSI), Coquille Indian Tribe (CIT), Cow Creek Band of Umpqua Tribe of Indians (Cow Creek Tribe), Fort Bidwell Paiute Tribe, Confederated Tribes of the Grand Ronde Community of Oregon (Grand Ronde Tribes), Hoopa Valley Tribe, Karuk

Tribe, Klamath Tribes, Modoc Tribe of Oklahoma, Pit River Tribe, Confederated Tribes of Siletz Indians (Siletz Tribes), Tolowa Dee-ni' Nation (formerly Smith River Rancheria), and Yurok Tribe.

A context that identifies Indian tribes that historically used or occupied the area affected by the Project, as well as details of the FERC consultations and the applicants' communications with Indian tribes, can be found in appendix L.

FERC Staff Consultations with Indian Tribes

Similar to consultations with SHPO, government-to-government consultations between the FERC and Indian tribes related to previous versions of the Projects occurred between 2006 and 2015 and were documented in the FEISs produced for Docket Nos. CP07-441-000, CP07-444-000, CP13-483-000, and CP13-492-000.

Consultations between the FERC and Indian tribes after September 2015, related to Docket Nos. CP17-494-000 and CP17-495-000, are listed in table L-4 in appendix L. Consultations between FERC staff and Indian tribes are still ongoing. Tribal consultation efforts were initiated with an e-mail sent on May 9, 2017 to tribes inviting them to participate in a telephone conference call about the Projects. This was followed by the NOI issued by the FERC on June 9, 2017, requesting comments about the Projects. On April 5, 2018, the FERC staff sent out letters to individual Indian tribes. In response to those letters, the CTCLUSI, Coquille Tribe, Grand Ronde Tribes, Karuk Tribe, and Yurok Tribe requested meetings with the FERC staff. Additional meetings and telephone conference calls have occurred between the FERC staff and some of the above tribes to discuss specific concerns about the Projects (see table L-4 in appendix L).

Comments from Native American Individuals

Besides government-to-government consultations between the FERC staff and leaders of interested Indian tribes, various other tribal members and individual Native Americans commented about the Projects during scoping and in response to our notice of applications. Communications between Native American individuals and organizations and the FERC under Docket Nos. CP17-494-00 and CP17-495-000 are listed in table L-5 in appendix L. Of these communications, 26 were letters from Native American individuals submitted as motions to intervene.

In addition to the above letters, several individuals identifying themselves as Native Americans spoke at our public scoping sessions for the Projects. Gary Jackson, who identified himself as a member of the Cow Creek Tribe, spoke at the public scoping session held on June 28, 2017 in Roseburg. Dale Ann Frye Sherman Yaqui and Margaret Robbins, who identified themselves as members of the Yurok Tribe, spoke at the public scoping session held on June 29, 2017 in Klamath Falls. Also at the Klamath Falls session, Monique Sonoquie identified herself as Chumash and Apache residing at the Yurok reservation in California; Mirinda Hart identified herself as Wylocki-Wintu from the Round Valley Confederation of Tribes in California; Anna Powell identified herself as a member of the Hoopa Valley Tribe in California; and Della Sanchez and Taylor Tupper identified themselves as members of the Klamath Tribes. Concerns voiced during the scoping meetings were similar to those identified in the letters from tribal members and Native American individuals listed in table L-5 in appendix L.

Applicants' Communications with Indian Tribes

Jordan Cove and Pacific Connector have also conducted their own, separate Native American contact programs, as part of their investigation efforts. Communications between the applicants and Native Americans informed their current efforts. Those were discussed in the FEISs produced for previous iterations of the Projects under Docket Nos. CP07-441-000, CP07-444-000, CP13-483-000, and CP13-492-000. Current contacts between the applicants and Indian tribes since September 2015 and regarding the current application are listed in tables L-6 and L-7 in appendix L of this EIS.[182] Tribes were provided the opportunity to review research designs and reports. They also participated in cultural resources investigations and monitored surveys and subsurface testing. The applicants have executed a Cultural Resources Protection Agreement (CRPA) with the CTCLUSI.

4.11.1.3 Issues Raised by Indian Tribes

This section summarizes the comments received from consulted Indian tribes. Tribes raised a wide variety of topics, not necessarily limited to historic properties considered under Section 106. In general, issues of concern, outside of the NHPA process, raised by Indian tribes included:

- Indian trust assets;
- traditional lifeways;
- water quality;
- aquatic species/fisheries;
- wildlife;
- forestry and wildfires;
- air quality and climate change;
- aesthetics;
- geologic hazards and general safety of the Project;
- environmental justice and socioeconomics; and
- cumulative impacts of the Project.

We summarize tribal concerns raised in consultations with the FERC, below, by individual tribe. However, where a tribal concern for a resource not considered under Section 106 was discussed, the reader is referred to the corresponding section of this EIS for a more detailed description of those resources, and where applicable, the impacts of the Project on those resources under NEPA.

Confederated Tribes of Coos, Lower Umpqua, and Siuslaw Indians

In several different filings with the FERC, the CTCLUSI indicated that they consider the geographic area of Coos Bay to be a Traditional Cultural Property (TCP), "Q'alay ta Kukwis schichdii me." The Tribe has issued two resolutions (Resolution No. 2006-097 and Resolution No. 2015-049) mentioning the TCP. The CTCLUSI also began the process of nominating the TCP to the NRHP. The nomination has been approved by the Oregon State Advisory Committee on Historic Preservation and forwarded to the SHPO. It is anticipated to be accepted or denied NRHP-listing by the NPS in June 2019. There are no federal laws that would prevent a project from crossing a TCP. However, there are regulations (36 CFR 800) and an NPS bulletin (Parker and King 1998) that provide guidance about evaluation of significance, assessing impacts, and mitigating effects on TCPs.

[182] These communications were documented in Jordan Cove's and Pacific Connector's September 2017 applications to the FERC and their subsequent responses to staff's multiple environmental information request since January 2018.

The CTCLUSI are concerned that Project-related activities at the terminal (Ingram Yard) and South Dunes area, such as drilling, grading, dredging, and vibro-compaction, may impact buried village sites and Indian graves documented in the Tribes' database of cultural resources. In its January 29, 2018 letter to the FERC staff, the CTCLUSI stated that a pre-contact shell midden deposit was found deeply buried in Coos Bay during geotechnical testing for improvements to the Navigation Channel. Survey reports submitted to the FERC by the applicants, including a September 12, 2018 summary memo by Archaeological Investigations Northwest, Inc. (AINW; Hulse 2018) describing the results of a cultural resources survey conducted for the Coos Bay marine waterway modifications, did not identify any deeply buried shell middens in Coos Bay, as described by CTCLUSI. Jordan Cove's consultants have recommended monitoring of construction by professional archaeologists and Tribal representatives. Any cultural resources or human remains uncovered during monitoring would be handled according to the Project's UDP. In addition, Jordan Cove has executed a CRPA with the CTCLUSI that provides for Tribal monitoring of construction activities.

As articulated in its July 10, 2017 letter to the FERC, the CTCLUSI are concerned that traditional activities of its members in the Project area, including the gathering of traditional plants, harvesting of shell fish, fishing, and hunting, may be restricted by the proposed projects. It should be noted that Jordan Cove's proposed upland facilities would be located on private lands where access to the public has already been limited since the Luse family sold its ranch on the North Spit in 1883 (Beckham 2015).[183]

Jordan Cove agreed to hire a professional ethnographer to conduct research to more clearly document religious and cultural properties important to the CTCLUSI that may be located within the APE, including the TCP reported by the CTCLUSI in the Jordan Cove area. A draft ethnographic study was filed with the FERC on April 4, 2018 (Deur 2018); however, the FERC staff has requested revisions to the document. The revised ethnographic study is expected to address what natural resources are important to the Tribes, such as traditionally gathered plants, fisheries, and hunted species that may still exist in the Project area. The CTCLUSI indicated that they are funding their own independent ethnographic study of the Coos Bay area. However, more recently, Jordan Cove has convened a Native American Working Group, and offered individual tribes financial support for them to produce their own ethnographic studies of the Project area.

In the EIS, we address effects on upland vegetation and timber in section 4.4, terrestrial wildlife in section 4.5.1, and aquatic resources in section 4.5.2. Since the U.S. government never executed a treaty with the CTCLUSI, the Tribes do not have treaty-protected or special fishing or hunting privileges on ceded lands.

The CTCLUSI also expressed concerns about crime, sexual exploitation of women, and negative impacts on the native communities of the Coos Bay area as a result of the operation of a "man-camp" (South Dunes Temporary Workers Housing Complex) during terminal construction; similar to the impacts of man-camps of the Bakken oil fields of North Dakota (see Harvard 2015; Adler

[183] William Luse, the son of H.H. Luse, who established a sawmill at Empire in 1855, was once married to a Coos woman, and was involved in the Indian community at Jordan Cove. The Luses acquired the properties of the Henderson, Barnett, Crawford, and Jordan families, which included Coos members. The lands were consolidated into a large ranch on the North Spit. As long as the Luses owned this land, Indian occupation of the North Spit would have been allowed, but this changed once the property was sold to the Oregon Southern Improvement Company.

and Hillstrom 2015; Gillette 2016; Briody 2017; Deer and Nagle 2017; Nienaber 2017; Finn et al. 2016). We discuss this issue in section 4.9, Socioeconomics, of this EIS.

In its July 10, 2017 letter to the FERC, the CTCLUSI requested to be a cooperating agency in the preparation of our EIS. However, on October 25, 2017, the CTCLUSI filed a motion to intervene in the proceeding. It is Commission policy that intervenors cannot also be cooperating agencies. As such, the CTCLUSI's request to be a cooperating agency cannot be granted.

Also in its July 10, 2017 letter, the CTCLUSI requested a meeting between FERC staff and the Tribal Council as part of our government-to-government consultations. Tribal leaders met directly with the Chair of the Commission at FERC headquarters in Washington, D.C., and representatives of the CTCLUSI met face-to-face with Commission staff in Oregon on March 22 and June 28, 2017, and July 17, 2018. We consider those meetings, our NOI, our letters to the CTCLUSI, and letters from the Tribes to the Commission to constitute government-to-government consultations.

The CTCLUSI believe that the Project may have negative impacts on Coos Bay's tourism and fishing industries. Effects on fisheries are discussed in section 4.5.2 of the EIS, and we discuss the tourism industry in section 4.9.

The CTCLUSI are also concerned about potential safety risks that may be caused by earthquakes related to seismic movements along the CSZ, and that an earthquake-triggered tsunami could hit the North Spit. The CSZ is discussed in section 4.2, and there is a tsunami impact assessment in section 4.1 of the EIS.

The CTCLUSI would like an assessment of potential health impacts on Tribal members and the general community of Coos Bay. This includes Project-related impacts on water quality and air quality. Jordan Cove will arrange for on-site medical professionals to provide basic care for terminal construction workers, reducing the potential influx of patients to the local medical facilities. Further, Jordan Cove signed a MOU with the State of Oregon that requires Jordan Cove to equip the Bay Area Hospital according to state policies for all hospitals in treating burns. The EIS addresses water quality effects in sections 4.3.1 and 4.3.2, while air quality effects are discussed in section 4.12.1.

The CTCLUSI raise concerns about the clearing of forest, and the potential for Project-caused wildfires. Effects on forested lands and the potential for wildfires are discussed in in section 4.4.

In a letter to the FERC dated January 22, 2018, the CTCLUSI stated that Jordan Cove was not providing advance notification of geotechnical investigations in a timely manner and did not provide the Tribes with detailed work plans. Jordan Cove responded to these issues in a letter to the FERC dated January 25, 2018, detailing the geotechnical investigation work plan and notifications provided to the Tribes. In addition, the CRPA contains procedures for notifications to the CTCLUSI concerning future geotechnical investigations proposed by Jordan Cove.

According to their January 29, 2018 letter to the FERC, the CTCLUSI would like to be engaged in the discussion of impacts on the Projects' viewshed. This section discusses indirect impacts on cultural resources through visual and audible intrusions. Section 4.8.2 of the EIS includes a visual assessment. The Tribes also requested that the cumulative impact assessment in the EIS include the Channel Modification Project; which it does.

Coquille Indian Tribe

On November 8, 2017, the Coquille Tribe requested to be a cooperator in the production of this EIS. We accepted that request in a letter to the Tribe dated April 4, 2018. On July 16, 2018, the FERC staff met in-person with the Coquille Tribe at Coos Bay.

The Coquille Tribe requested that this EIS address potential indirect impacts on Indian trust assets, such as the Coquille Forest. Although Jordan Cove has stated that there are no Indian trust assets "directly adjacent to the APE," the pipeline route is in close proximity to three parcels of the Coquille Forest which are held in trust by the BIA and managed by the Coquille Tribe. There should be no direct impacts on lands held in trust by the Coquille Tribe. The proposed pipeline right-of-way would be as close as 65 feet upslope of the three parcels of the Coquille Forest. Indirect impacts on the Coquille Forest would be similar to other forested lands, which are discussed in section 4.4 of this EIS.

In a February 26, 2019 e-mail to FERC staff, the Coquille Tribe provided a list of important traditional-cultural plant and animal species. The Tribe noted that plant species provided much of the sustenance, shelter, and safety for their ancestors. Some of the most important traditional cultural plant species that are found on the Coquille Forest and other Tribal lands include: trees, including their bark and wood (Port Orford cedar, western red cedar, Sitka spruce, big leaf maple, myrtle, red alder, madrone, Pacific yew); the wood, buts, and berries of shrubs (elderberry, willows, hazel, vine maple, rhododendron, azalea, manzanita, ocean spray, Labrador tea, huckleberry, salal, thimbleberry, salmonberry, Oregon grape); the roots and fibers of flowers and vines (yarrow, camas, tiger lily, columbine, various Lomatium and Brodiaeas, iris, trailing blackberry, yurba buena, beargrass), various wet meadow/riparian species (cattail, tule, various sedges and ferns, skunk cabbage, various mosses); and marine/estuary species (eelgrass, giant kelp bull kelp, sea lettuce, surfgrass). The upland vegetation in the Project area and wetlands are discussed in sections 4.4 and 4.3 of this EIS, respectively. Some traditionally used plants are also considered special status species, and are discussed in section 4.6.

The Coquille Tribe noted that animals (including fish and birds) provided food and raw materials for shelter, technologies, economies, and ceremonial purposes. The Tribe provided a list of some of the animal species that are culturally important to them: terrestrial mammals (deer, elk, coyote, cougar, bear, bobcat, raccoon, beaver, squirrel), marine/estuary species (Lamprey, all available salmon species, shellfish, crab, sea mammals, rockfish, lingcod, sculpin, halibut, flounder, perch, herring, greenling, candlefish, snails, mussels, barnacles, chiton, sea urchin, abalone, dentalium, other seasonally available estuary species); and birds (eagles, hawks, owls, cormorant, kingfisher, herons, osprey, flicker, woodpeckers [particularly pileated], grebe, cormorant, crows and ravens, and colorful neo-tropical species). Wildlife and aquatic species are discussed in section 4.5 of this EIS. As with the culturally significant plant species listed above, some traditionally important animals are also considered special status species and are discussed in section 4.6.

Cow Creek Band of Umpqua Tribe of Indians

In a letter to the FERC dated October 20, 2017, the Cow Creek Tribe stated that the Pacific Connector pipeline route would cross about 122 miles of the Tribe's aboriginal territory or ceded lands. The Tribe is concerned about potential Project-related impacts on cultural resources, and is also concerned about river and stream crossings and impacts on water quality and aquatic resources.

As of September 2018, Pacific Connector has identified 79 archaeological sites along the pipeline route within the historic aboriginal territory or ceded lands of the Cow Creek Tribe, from about MP 42 to MP 168. The FERC has determined that 59 of those sites are listed or eligible for the NRHP or are unevaluated; the remaining 20 sites were found not eligible for listing on the NRHP. The Cow Creek Tribe has reviewed previously filed cultural resources inventory and evaluation reports, and treatment plans. The Tribe also monitored previous archaeological investigations in their territory. There is additional cultural resource work to be done for the Projects, including additional investigatory work and consultations. However, we expect that Pacific Connector should execute an agreement with the Cow Creek Tribe, similar to the CRPA with the CTCLUSI described above, to continue Tribal monitoring of future archaeological investigations. In addition, the FERC will require Pacific Connector to provide future reports of cultural resources investigations, and new treatment plans, to the Cow Creek Tribe for review.

Proposed waterbody crossings of the Pacific Connector pipeline route are listed by milepost in table H-3 of appendix H of this EIS. This EIS addresses impacts on waterbodies in section 4.3.2 and impacts on aquatic species in section 4.5.2. The 1853 treaty with the Cow Creek Tribe did not specify the reservation of fishing, hunting, or gathering rights for Indians in lands ceded by the Tribe.

Confederated Tribes of the Grand Ronde Community

In its motion to intervene, filed with the FERC on November 15, 2017, the Grand Ronde Tribes stated that they have maintained a deep connection to the resources and sacred places of their treaty homelands. The Tribes are interested in protecting, enhancing, and restoring tribal culture and natural resources affected by the Projects. Salmon and lamprey have particular cultural significance to the Tribes. In addition, the Grand Ronde Tribes have concerns about other aquatic resources, including ESA federally listed bull trout, and Oregon Conservation Strategy species rainbow trout, cutthroat trout, and Umpqua chub. Birds of concern include federally listed marbled murrelet and northern spotted owl, and state-sensitive common nighthawk, flammulated owl, great gray owl, Lewis's woodpecker, purple martin, white-headed woodpecker, and yellow breasted chat. Other upland mammals that hold the Tribes' attention include American marten, fisher, California myotis, fringed myotis, hoary bat, red tree vole, ringtail, and Sierra Nevada red fox. Reptiles of interest include the federally listed Oregon spotted frog, and state-listed Del Norte salamander, northern red-legged frog, southern torrent salamander, California mountain kingsnake, and western pond turtle.

This EIS discusses aquatic species in section 4.5.2, upland wildlife in section 4.5.1, and ESA protected and other special status species in section 4.6. The FERC will additionally produce a BA that addresses impacts on federally listed species protected under the ESA, and submit this BA to the FWS and NMFS. The 1853 treaty with the Rogue River Tribes and 1854 treaty with the Upper Umpqua Tribes did not specify the reservation of fishing, hunting, or gathering rights for Indians on lands ceded by the Tribes.

The Grand Ronde Tribes stated that their ancestors once occupied the region between MPs 50 and 175 along the Pacific Connector pipeline route. As of 2015, Pacific Connector's consultants recorded 81 archaeological sites along that segment of the proposed pipeline route. Of those, 42 sites were either found to be eligible for the NRHP or are unevaluated; the remaining 39 sites were found not eligible for listing on the NRHP. In a January 16, 2018 letter to the FERC commenting on Pacific Connector's Resource Report 4, the Grand Ronde Tribes requested a reassessment of isolated finds, which do not "accurately reflect the historic land use of the landscape, but is a consequence of many years of cultural resource surveys being undertaken in a piecemeal fashion." In addition, the Grand Ronde Tribes suggested revisions to Pacific Connector's UDP. Pacific Connector has provided the Grand Ronde Tribes with copies of cultural resources investigations reports for their review.

In its May 4, 2018 letter to the FERC, the Grand Ronde Tribes re-asserted their deep connections with the resources and sacred places of their ancestral homelands in southern Oregon, including Usual and Accustomed areas ceded by treaties with the U.S. government. The Tribes requested a study be done to identify sacred places, gathering places, locations of burials, and other places of cultural significance to the Tribes. In response to an earlier request from the FERC staff, the applicants filed with the FERC on April 4, 2018 a draft ethnographic study (Deur 2018). However, in a May 4, 2018 environmental information request to Pacific Connector, the FERC staff asked that the document be revised. The revised ethnographic study is expected to address natural resources that are important to the Tribes, such as traditionally gathered plants, fisheries, and hunted species that may still exist in the Project area. However, more recently, Pacific Connector has convened a Native American Working Group, and offered individual tribes financial support for them to produce their own ethnographic studies.

On July 20, 2018, the FERC staff held a telephone conference call with representatives of the Grand Ronde Tribes. That call discussed the FERC's NEPA process, and our process for complying with the NHPA.

On September 19, 2018 the Grand Ronde Tribes provided the FERC staff with a comment letter regarding the cultural resource studies completed to date and the Tribal Working Group proposed by the applicants. The Tribes noted they were, to date, yet to receive complete materials documenting cultural resource surveys from the applicant for the Tribes' review. Concerns were expressed for a lack of consideration of historic properties of religious and cultural significance to Indian tribes. The Grand Ronde Tribes have apprehensions about the proposal for the Tribal Working Group.

In a letter to the FERC dated October 5, 2018, the Grand Ronde Tribes requested an in-person government-to-government meeting with the FERC staff at their Tribal headquarters. We have been unable to schedule such a meeting to date due to travel considerations and ex parte rules, but continue efforts to establish a meeting with the Tribes.

Karuk Tribe

The Karuk Tribe, in comments to the FERC dated July 5, 2017, raised concerns about potential Project-related impacts on water quality and the salmon fishery in the Klamath River. Since the U.S. government never executed a treaty with the Karuk Tribe, and did not set aside an officially designated reservation for the Tribe, the Karuk Tribe does not have special fishing or hunting privileges on ceded lands that are federally protected as treaty rights.

The Karuk Tribe believes that the Pacific Connector pipeline may contribute sediment to and increase the water temperature of streams crossed. We address impacts on waterbodies in section 4.3.2 of this EIS. Likewise, this EIS discusses aquatic resources in section 4.5.2.

The Karuk Tribe also claims that in the case of a break of the Pacific Connector pipeline, waterbodies would be polluted. However, the pipeline would transport natural gas in gaseous form (not liquid) and, in the unlikely event of an incident and release, natural gas, which is lighter than air, would dissipate into the atmosphere and would not contaminate waterbodies. The Karuk Tribe believes that the Jordan Cove export terminal would include a 420-megawatt power plant. This is not so, as the current proposal has eliminated the power plant.

In their May 3, 2018 letter to the FERC, the Karuk Tribe requested a meeting with staff to discuss the Projects. Again, the Tribe mentioned its concerns about the pipeline crossing of the Klamath River, and its potential impacts on the salmon fishery and the lifeways of the Tribe. The FERC staff met in-person with representatives of the Karuk Tribe in Happy Camp, California, on July 18, 2018.

Klamath Tribes

The Klamath Tribes provided comments about the Project to the FERC in filings on June 7 and 26, September 1, and October 20, 2017, and May 3, 2018. The Klamath Tribes assert that the Pacific Connector pipeline route would cross ceded lands that contain cultural resources of importance to the Tribes, and that former villages and graves may be impacted by construction of the pipeline.

As of 2015, Pacific Connector's consultants have identified 10 pre-contact archaeological sites along the pipeline route in Klamath County. Eight of those sites were evaluated as eligible for the NRHP or are unevaluated. It should be noted that members of the Klamath Tribes participated in Pacific Connector's cultural resources surveys. Pacific Connector has provided the Klamath Tribes with copies of all previous cultural resource reports, for their review. If the Projects are authorized by the FERC, and any unanticipated sites or human remains are found during construction, Pacific Connector would follow the procedures outlined in its UDP, that was previously reviewed by the Klamath Tribes.

The Klamath Tribes requested the opportunity to assist in the drafting of a revision of Pacific Connector's Historic Property Management Plan (HPMP). A draft HPMP was filed with the FERC by Pacific Connector on October 5, 2018; it is unclear if the applicants made that document available to the Klamath Tribes for their review.

The Klamath Tribes are also concerned about water quality, the pipeline route crossings of the Rogue and Klamath River, and the potential for the Projects to impact fish species that are important to the Tribes. The 1864 treaty with the Klamath Tribes stated that the Tribes hold "…*the exclusive right of taking fish in the streams and lakes, included in said reservation, and of gathering edible roots, seeds, and berries within its limits*…." However, the Pacific Connector pipeline route does not cross the Klamath Reservation. Pacific Connector proposes to cross under the Rogue River and Klamath River using HDDs, to avoid impacts on those rivers and their associated fisheries. The pipeline would also cross 17 streams or creeks that form part of the Klamath River headwaters in Klamath County. Pacific Connector would use dry methods (flumes or dams) to cross other streams. Erosion controls that would be implemented at stream crossings would limit turbidity and sedimentation. These stream crossing would not result in significant long-term impacts on the fishery resources associated with the Klamath River system. See sections

4.3.2 and 4.5.2 in this EIS for more details about impacts on waterbodies and aquatic resources, respectively, and proposed mitigation measures.

The Klamath Tribes raised concerns about impacts on regional air quality, and the Project's potential contributions to global warming. Air quality is discussed in section 4.12.1 of this EIS.

The Klamath Tribes are also concerned about the potential for the Projects' facilities to be impacted by earthquakes and landslides. Section 4.1 of this EIS discusses geological hazards, including measures that would be implemented to reduce impacts from earthquakes and landslides.

The issue of "man camps" and tribal community safety in those settings has also been raised by the Klamath Tribes. There are no proposed worker housing camps along the Pacific Connector pipeline route. Instead, workers would be dispersed along spreads and find housing in RV camps, rental houses and apartments, and hotels, as discussed in the socioeconomic section of this EIS.

The Klamath Tribes cite EO 12898 as requiring the study of impacts of the Projects on Environmental Justice communities, including Indian Tribes. Although the FERC is an independent regulatory agency excluded from compliance with Executive Orders, in order to address this tribal and general public concern, we analyze in section 4.9 of this EIS whether the Projects would have disproportional environmental impacts on minority and low-income populations.

Tolowa Dee-Ni' Nation

The Tolowa Dee-Ni' Nation, in its letter dated December 6, 2018 to the FERC, described the Nation's "strong opposition [to] and concern" regarding the proposed Project. The Nation noted they cannot support the Project based on the proximity of the pipeline to the headwaters of the Rogue River and the perceived potential for pipeline leaks to impact the waters of the river. As noted elsewhere in this section, the pipeline would transport natural gas in gaseous form which, in the event of a release, would dissipate into the atmosphere and would not contaminate waterbodies. The pipeline would cross under the Rogue River with an HDD, and Pacific Connector would use dry methods to cross other headwater streams. Those techniques, as explained in section 4.3 of this EIS, would reduce impacts on waterbodies and their associated fisheries.

Yurok Tribe

The Yurok Tribe, in its letter dated July 6, 2017 to the FERC, and in its motion to intervene filed October 26, 2017, stated that Pacific Connector's proposed crossing of the Klamath River could have potential impacts on tribal trust fish species, including ESA-listed coho salmon, Chinook salmon, steelhead, green sturgeon, and Pacific lamprey. Disruption of fish habitat may have negative impacts on the Yurok Tribal economy that depends in part on a commercial salmon fishery. In addition, the Tribe states that the Klamath Riverscape is a district listed on the Yurok Tribe Register of Historic Properties. Pacific Connector's consultants should review the Klamath Riverscape to determine what effects, if any, the Projects would have on it.

When the Klamath Reservation in California was created in 1855 for the Yurok and Hupa people, their rights to fish in the rivers running through the reservation were federally protected. In a 1993 opinion issued by the Solicitor for the U.S. Department of the Interior, it was stated that the entitlement of the Yurok and Hoopa Valley Tribes was limited to 50 percent of the harvest of Klamath-Trinity Basin salmon (Leshy 1993). The Pacific Connector pipeline route does not cross through the Klamath-Trinity Basin of California. The pipeline route would cross the Klamath River in Klamath County, Oregon, within the traditional territory of the Klamath Tribes, where Pacific Connector would use an HDD. The HDD would limit impacts on the Klamath River and its fishery resources.

Impacts on federally listed aquatic species are discussed in section 4.6 of this EIS, together with proposed mitigation measures. The FERC will produce a BA and EFH Assessment that will be reviewed by the NMFS and FWS.

In their May 4, 2018 letter to the FERC, the Yurok Tribe requested a meeting with staff to discuss the Projects. On July 18, 2018, the FERC staff met in-person with representatives of the Yurok Tribe in Klamath, California.

4.11.1.4 Communications with Other Agencies

The BLM, Forest Service, Reclamation, COE, EPA, FWS, and NMFS are federal cooperating agencies in the production of this EIS, and consulting parties with regard to the Section 106 compliance process. The federal land-managing agencies previously provided the FERC with their opinions on NRHP eligibility and pipeline effects for sites on federal land. Comments related to cultural resources received by the FERC from other federal agencies between 2012 and 2015 for Docket Nos. CP13-483-000 and CP13-492-000 are discussed in section 4.11.1.3 of our September 2015 FEIS for those projects. Communications between the FERC and other federal agencies related to cultural resources issues for Docket Nos. CP17-494-000 and CP17-494-000 are discussed below.

In response to our June 9, 2017 NOI for these Projects, the EPA filed comments, dated July 10, 2017. One of its comments was that the EIS should discuss compliance with the NHPA, including consultations with the SHPO. In addition, the document should discuss Project-related impacts on tribal, cultural, or other treaty resources. We address EPA's issues in this section.

The ACHP wrote a letter to the FERC dated January 25, 2018, in response to the January 22, 2018 letter from the CTCLUSI to the FERC about geotechnical testing. The ACHP stated that, in general, their agency has "interpreted geotechnical testing as part of project planning for undertakings and not, in and of itself, subject to review by federal agencies under Section 106." They requested that the FERC respond to the Tribes and clarify the purpose of the geotechnical investigations and the place of those investigations in the FERC's Section 106 compliance process. The FERC staff agrees with the ACHP position that geotechnical investigations are considered part of the pre-planning process and not subject to Section 106 compliance. It is FERC practice that pre-construction geotechnical investigations be conducted without FERC review or approval and are not considered to be cultural resource studies or part of the Section 106 process (see FERC 2017). As such, the applicants do not need permission from the FERC to conduct pre-planning geotechnical work, and these activities do not constitute part of the FERC's undertaking. However, the applicants may need permits from other federal agencies, such as the COE, for those activities.

Jordan Cove's Communications with Other Agencies

Jordan Cove sent email communications to the COE, SHPO, ODEQ, and ODE on May 19 and November 16, 2017, providing a context for the geotechnical work proposed at the APCO site and about sampling at Kentuck Slough, respectively. Project Activity Updates were also provided to the same agencies via email on September 3, 2017 for September 2017; October 2, 2017 for activities scheduled in October; October 13 and 27 and November 9, 2017 for activities in November; December 1, 2017 for activities scheduled for December 2017; and December 14 and 20, 2017 for activities scheduled for January and February 2018. Details of these communications can be found in appendix L.

Pacific Connector's Communications with Other Agencies

Communications between Pacific Connector and federal agencies between 2006 and 2009 were summarized in section 4.10.1.3 of our May 2009 FEIS produced for Docket Nos. CP07-441-000 and CP07-444-000. Communications between Pacific Connector and federal agencies between May 2009 and September 2015 were listed in table 4.11.1.3-2 of our September 2015 FEIS for Docket Nos. CP13-483-000 and CP13-492-000.

On February 24, 2017, Pacific Connector sent an email to the BLM requesting a review of the list of cultural resource sites located along the pipeline route on BLM lands. On February 29, 2017, the Forest Service called Historical Research Associates, Inc. (HRA) to discuss heritage properties on NFS lands that may be affected by the Pacific Connector Project. On May 26, 2017, Pacific Connector sent an email to the COE, ODE, and ODEQ regarding geotechnical testing to support the proposed HDD under Coos Bay. We detail Pacific Connector's communications since 2015 with other federal and state agencies in appendix L.

4.11.2 Area of Potential Effect

As stated in our NOI, we define the direct APE as all areas subject to ground disturbance, including the construction right-of-way, temporary extra work spaces, contractor/pipe storage yards, disposal areas, aboveground facilities, and new or to-be-improved access roads. An indirect APE was also established by the applicants for each project based on each viewshed.

4.11.2.1 Jordan Cove LNG Project

In the case of the Jordan Cove Project, the direct APE includes the footprint of all potential ground-disturbing actions. Specifically, this includes the South Dunes Site, Ingram Yard, Access and Utility Corridor, Meteorological Station, Industrial Wastewater Pipeline, Trans-Pacific Parkway/U.S. 101 Intersection, the planned mitigation sites (Kentuck, Eelgrass, Lagoon, Panhandle, and North Bank), Boxcar Hill laydown and parking area, Roseburg Forest Products and Port laydown sites, APCO Sites 1 and 2, Myrtlewood Off-site Park and Ride, and hydraulic dredge pipelines in Coos Bay. We agree with the definition of the direct APE, provided in Jordan Cove's application to the FERC. The Jordan Cove Project facilities are described in more detail in chapter 2 of this EIS.

The indirect APE is defined to include all areas potentially subjected to the introduction of visual, atmospheric, or audible elements that diminish the integrity of a historic property's significant historic features. Jordan Cove's consultants conducted a windshield survey for a 2-mile radius around the proposed LNG terminal. The existing Boxcar Hill Campground and RV Park was noted in this area. Also found in the indirect APE was a house in the Shorewood area at the northern mouth of Haynes Inlet, the Hilltop House restaurant and Bay Bridge Motel on the north side of the McCullough Bridge, and residential neighborhoods in the City of North Bend (Bowden et al. 2017). The consultants concluded that no historic properties would have a view of the aboveground components of the LNG terminal. As such, the indirect APE was recommended to be the same as the direct APE. We agree with this definition. Section 4.8.2 of this EIS includes a visual impact assessment of the LNG terminal facilities. Section 4.12.2 of this EIS discusses noise impacts related to the construction and operation of the terminal.

The direct APE, which is the same as the indirect APE for the Jordan Cove Project, is depicted in Figure 1-1 of the 2017 survey report (Bowden et al. 2017) filed with Jordan Cove's application to the FERC.

4.11.2.2 Pacific Connector Pipeline Project

Pacific Connector defined the direct APE as all geographic areas that will potentially experience ground disturbances from the construction, operation, and maintenance of the pipeline. The construction right-of-way for the pipeline represents the majority of the direct APE and encompasses the temporary construction right-of-way, permanent easement, TEWAs, USCAs, and MLVs. Areas where elements of the Project extend outside the pipeline corridor generally consist of contractor and pipe storage yards, rock source and disposal sites, hydrostatic discharge sites, new and improved access roads, cathodic protection, and aboveground facilities, including communication towers. We agree with this definition of the direct APE. The Pacific Connector Project facilities are described in more detail in chapter 2 of this EIS.

Pacific Connector defined the indirect APE to include all geographic areas that would potentially experience visual intrusions or changes as a result of the construction, operation, and maintenance of the pipeline. The pipeline will not produce sufficient noise or odors to warrant consideration of audible or atmospheric/olfactory indirect effects in establishing the indirect APE. Section 4.12.2 of this EIS discusses noise impacts related to the construction and operation of Pacific Connector's facilities. Since the pipeline will be buried, the aboveground components of the project will be related to the associated aboveground facilities and the permanent easement itself, which will be maintained as a 50-foot-wide cleared corridor on the landscape. To identify the indirect APE, Pacific Connector's consultants reviewed the pipeline route for instances where the cleared easement may be noticeably visible, considering 1) current heavily vegetated landscapes with adjacent significant topographical differences and 2) landscapes that are relatively unencumbered by modern intrusions. This analysis determined that locations where the indirect effects APE diverges from the direct APE are limited to locations where the permanent easement traverses a steep, heavily vegetated area, then turns sharply so that the permanent easement could be seen directly from a location outside of the direct APE. The SHPO, in a letter to Pacific Connector's consultants dated January 22, 2016, concurred with the methodology for defining the indirect APE. We agree. Section 4.8.2 of this EIS includes a visual impact assessment of the proposed pipeline right-of-way.

Appendix A of the 2017 pipeline addendum survey report (Derr et al. 2017), filed with Pacific Connector's application with the FERC, contains maps that depict the direct and indirect APEs.

4.11.3 Results of Investigations

Archaeological, historical, and ethnographic contexts of the Project area can be found in the numerous survey reports completed for the Project since 2005. A brief historical summary of archaeological studies in the region can be found in appendix L. Studies conducted specifically for the Projects are described and listed below.

4.11.3.1 Ethnographic Studies

On April 4, 2018, the applicants filed a first draft Ethnographic Report (Deur 2018). The FERC staff and several interested Indian tribes reviewed that draft, and the FERC staff, in environmental information requests dated May 4 and October 23, 2018, requested that the applicants revise the ethnographic report. In a filing on November 2, 2018, the applicants declined to revise the ethnographic report, claiming that it is not required for purposes of compliance with Section 106 of the NHPA. This is not true. The regulations for implementing Section 106 at 36 CFR 800.2(c)(2)(ii) require consultations with Indian tribes to identify sites of religious and cultural importance to tribes, in keeping with Section 101(d)(6) of the NHPA. Further, section 6.1 (8) of the FERC staff's guidelines (FERC 2017) directs applicants to produce and file an "ethnographic analysis to identify any living Native American groups or other groups with ties to the project area to identify properties of traditional, religious, or cultural importance to Tribes and other groups." In addition, several interested Indian tribes requested the additional data we asked for in the revision request. In order to meet our obligations under Sections 101 and 106 of the NHPA, **we recommend that**:

- **<u>Prior to construction of facilities and/or use of any staging, storage, temporary work areas, or new or to-be-improved access roads</u>, Jordan Cove and Pacific Connector should file with the Secretary a revised Ethnographic Report describing sites of religious and cultural significance to Indian Tribes and other tribal information as outlined in the FERC staff's October 23, 2018 environmental information request #14, for the review of interested Indian tribes and the FERC staff, and for written approval by the Director of OEP.**

4.11.3.2 Jordan Cove LNG Project

Since 2005 surveys have been conducted for Jordan Cove to identify cultural resources within the LNG terminal direct APE. Table 4.11.3.2-1 lists the surveys that cover Jordan Cove's proposed facilities. More detailed summary descriptions of the surveys are included in appendix L of this EIS.

TABLE 4.11.3.2-1

Cultural Resources Surveys of Jordan Cove's Proposed LNG Terminal Facilities

Facility or Use Area a/	Survey Reports	Inventory Status
Access Channel (Coos Bay)	Byram 2006a, Rose et al. 2014, Punke, et al. 2018, Punke 2018	Survey Complete
Marine Slip (Ingram Yard) including LNG Vessel Berth, Tug Berth, and Emergency Lay Berth	Stubbs 1975, Barner 1978, Simmons 1983, Byram 2006a, Byram 2006b, Rose et al. 2014, Byram and Shindruk 2014; Punke et al. 2018, Punke 2018	Requires Additional Geoarchaeological Deep Testing of High Probability Area
Rock Apron (Ingram Yard & Coos Bay)	Hulse 2018	Survey Complete

TABLE 4.11.3.1-1 (continued)

Cultural Resources Surveys of Jordan Cove's Proposed LNG Terminal Facilities

Facility or Use Area a/	Survey Reports	Inventory Status
Material Offloading Berth (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Punke et al. 2018, Punke 2018	Survey Complete
Haul Road (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Punke et al. 2018, Punke 2018	Survey Complete
LNG Loading Platform and Transfer Pipeline (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Punke et al. 2018, Punke 2018	Survey Complete
LNG Storage Tanks (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Liquefaction Processing Area (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Refrigerant Storage Area (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Gas Processing Area (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Utilities (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Flare Area (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Secondary Terminal Entrance (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Punke et al. 2018, Punke 2018	Survey Complete
Laydown Area (Ingram Yard)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Fire Station and Ancillary Buildings at west end of Access and Utility Corridor (north of Roseburg Forest Products)	Byram 2006a, Byram 2006b, Punke et al. 2018, Punke 2018	Survey Complete
Access and Utility Corridor (north of Roseburg Forest Products)	Barner 1977, Simmon 1984, Byram 2006a, Byram 2006b, Byram 2008, Byram and Shindruk 2012, Punke et al. 2018, Punke 2018	Survey Complete
Laydown Areas (Roseburg Forest Products)	Byram 2006a, Byram 2006b, Rose and Davis 2013	Survey Complete
Temporary Dredge Slurry and Water Return Pipelines (Roseburg Forest Products & South Dunes)	Byram 2006a, Byram 2006b, Byram 2008; Bowden et al. 2009	Survey Complete
Truck Haul Route (Ingram Yard and Roseburg Forest Products)	Simmons 1983, Byram 2006a, Byram 2006b, Macfarlane and Skinner 2013, Punke et al. 2018, Punke 2018	Survey Complete
Laydown Area (South Dunes) and Temporary Workforce Housing Complex (South Dunes)	Stubbs 1975, Barner 1978, Byram and Purdy 2007, Byram and Shindruk 2012, Olander et al. 2009, Bowden et al. 2009, Ragsdale et al. 2013, Bowden et al. 2017; Punke 2018	Survey Complete
SORSC (South Dunes)	Byram and Purdy 2007, Bowden et al. 2017	Survey Complete
Administration Building (South Dunes)	Byram and Purdy 2007, Bowden et al. 2017	Survey Complete
Industrial Wastewater Pipeline Replacement and new Water Line (Trans-Pacific Parkway)	Simmons 1984, Lange 1984, Langer 1986, Byram 2009, Byram and Shindruk 2012, Byram and Rose 2013, Rose and Johnson 2014	Survey Complete
Port Laydown Site (North Spit – south of Southport facility)	Darby 2005, Byram and Purdy 2008	Survey Complete
Box Car Hill Laydown Area (North Spit – east side of Causeway)	Langer 1986, Byram 2009, Derr et al. 2017	Partially surveyed/Requires additional survey
Meteorological Station and Access Road (Lagoon)	Goodwin 2014	Survey Complete

TABLE 4.11.3.1-1 (continued)

Cultural Resources Surveys of Jordan Cove's Proposed LNG Terminal Facilities

Facility or Use Area a/	Survey Reports	Inventory Status
Channel Improvement Areas 1-4 (Coos Bay)	AINW 2017; Hulse 2018	Survey Complete
Temporary Dredge Line from Channel Improvement Areas to APCO sites (Coos Bay)	AINW 2017; Hulse 2018	Survey Complete
Temporary Dredge Line to Eel Grass Mitigation Site (Coos Bay)	Bowden et al. 2017	Survey Complete
Eel Grass Mitigation Site (Coos Bay – north of airport)	Byram 2013; Bowden 2018	Survey Complete
Temporary Dredge Line to Kentuck Slough Mitigation Area (Coos Bay)	Bowden et al. 2017	Partially surveyed/Requires additional survey
Trans-Pacific Parkway Causeway and U.S. Highway 101 Intersection Improvements (north of McCullough Bridge)	Simmons 1984, Byram 2006a, Byram 2009, Byram 2013, Goodwin 2014	Survey Complete
APCO Sites 1 and 2 (North Point of North Bend)	Byram 2017, Bowden et al. 2017; Punke and Bowden 2018	Survey Complete
Kentuck Slough Wetland Mitigation Area (Kentuck Slough)	Bowden et al. 2009, Byram and Walker 2010, Ragsdale et al 2013, Bowden et al. 2017, Derr et al. 2017; Bowden 2018	Partially surveyed/Requires additional survey
Myrtlewood RV Park Off-Site Parking Lot (Hauser)	Bowden et al. 2017	Survey Complete
Lagoon Habitat Mitigation Site	N/A	Unsurveyed
Panhandle Habitat Mitigation Site	N/A	Unsurveyed
North Bank Habitat Mitigation Site	N/A	Unsurveyed

a/ Facilities derived from Table 1.4-1 and Figure 1.1-1 of Resource Report 1 attached to Jordan Cove's application to the FERC, and Table 4.2-2 filed November 2, 2018.

Areas that still require additional survey include the dredge slurry lines in Coos Bay; the Boxcar Hill Laydown and Parking Area; and the Lagoon, Panhandle, and North Bank habitat mitigation sites.

Geoarchaeological deep testing and shovel probing have been conducted in Ingram Yard, the Access and Utility Corridor, and the South Dunes area (Punke et al. 2018; Punke 2018a and 2018b), as well as at both APCO sites (Punke and Bowden 2018). A possible piece of archaeological bone material was found in a shovel probe at the South Dunes area. No other archaeological evidence was uncovered by the geoarchaeological studies. However, buried surfaces suitable for human habitation were identified beneath the fill layers at tested areas and may include unrecorded archaeological resources. The geoarchaeological studies identified "high probability areas." Additional geoarchaeological deep testing has been recommended in the high probability area within Ingram Yard, which is yet to be completed. Jordan Cove has indicated that supplemental shovel and auger testing is ongoing and will be provided in a new, comprehensive survey report to be submitted in late 2018 or early 2019. Additionally, Jordan Cove's consultants recommended that archaeological monitoring of construction activities within the high probability areas at the terminal site and the APCO sites be conducted (Punke 2018a and 2018b; Punke and Bowden 2018).

Appendix L summarizes the identified and reported resources that are within or adjacent to the direct APE. We concur with all SHPO determinations of NRHP eligibility and effects. For those resources where SHPO concurrence has not yet been requested (pending additional investigations) or is pending SHPO response, the recommended NRHP eligibilities and effects are preliminarily used for this analysis.

To date, no historic properties have been identified within the APE for the Jordan Cove LNG terminal. One NRHP-listed resource, McCullough Bridge, is avoided by the Project. Jordan Cove's consultants have recommended that construction be monitored by qualified professional archaeologists in the vicinity of sites 35CS221 and 35CS227 at the Ingram Yard and South Dune area respectively; and at site BAC-2014-1 near the intersection of Highway 101 with the North Spit Causeway. Jordan Cove's consultants also recommended that sites 35CS324, 35CS325, 35CS326, 35CS327, and 35CS328, near the Kentuck project site be avoided or tested to assess their NRHP eligibility. In a November 2, 2018 filing, Jordan Cove indicated it would conduct phase II testing in 2019 to determine the NRHP eligibility of site 35CS227. Additionally, the reported site leads require additional testing and/or monitoring during construction. Similarly, the TCP, *Q'alay ta Kukwis schichdii me*, requires further consultation.

4.11.3.3 Pacific Connector Pipeline Project

Pacific Connector hired cultural resources management consultants HRA to coordinate its cultural resources investigations and has conducted surveys of the APE since 2006, as applicable to the various past iterations of the Project. Table 4.11.3.3-1 lists the surveys, including those that cover Jordan Cove's proposed facilities.

TABLE 4.11.3.3-1

Cultural Resources Surveys Conducted for the Pacific Connector Project

Title	Reference	Type	Subsurface Detail	Project Component(s) Surveyed
Pacific Connector Gas Pipeline Project Cultural Resources Survey, Coos, Douglas, Jackson, and Klamath Counties, Oregon	Bowden et al. 2009	Pedestrian and subsurface	Shovel probe, test units	Portions of pipeline corridor and some TEWAs (including co-located aboveground facilities), UCSAs, quarries, laydown areas, and access roads outside the pipeline corridor.

Cultural Resources Surveys Conducted for the Pacific Connector Project

Title	Reference	Type	Subsurface Detail	Project Component(s) Surveyed
Pacific Connector Gas Pipeline Project Cultural Resources Survey: 2013 Cultural Resources Addendum #2	Ragsdale et al, 2013	Pedestrian and subsurface	Shovel probe, deep testing, test units	Portions of pipeline corridor, some TEWAs.
Pacific Connector Gas Pipeline Project Cultural Resources Survey: Phase II Evaluation of Site 35DO1284	Willis et al. 2013	Subsurface	Test units	Portion of pipeline corridor and one TEWA in pipeline corridor.
Pacific Connector Gas Pipeline Project Cultural Resources Survey, Coos, Douglas, Jackson, and Klamath Counties, Oregon. 2014-2015 Cultural Resources Addendum	Derr et al. 2015	Pedestrian and subsurface	Shovel probes, deep testing	Portions of pipeline corridor, some TEWAs, and one laydown area.
Pacific Connector Gas Pipeline Project Cultural Resources Survey, Coos, Douglas, Jackson, and Klamath Counties, Oregon. 2017 Cultural Resources Addendum.	Derr et al. 2017	Pedestrian, intertidal/boat, windshield, and subsurface	Test units	Portions of pipeline corridor and some TEWAs and access roads outside the pipeline corridor.
Pacific Connector Gas Pipeline Project Cultural Resources Survey, Coos County, Oregon: 2018 Cultural Resource Addendum 1	Derr et al. 2018	Pedestrian and subsurface	Shovel probes	Portion of pipeline corridor and some TEWAs and access roads outside the pipeline corridor.

As of April 2018, Pacific Connector indicated that approximately 221 miles of the direct APE for the pipeline route (96 percent) was covered by cultural resources surveys. A total of 1,557 work spaces (97 percent) have been surveyed. Surveys has been completed for 26 pipe yards and 16 rock source and disposal sites. All 35 hydrostatic test water discharge sites have been surveyed. About 498 miles (85 percent) of roads has been surveyed.

Access to unsurveyed portions of the 229-mile-long proposed pipeline corridor has either been denied or is pending. The pipeline crossings of Coos Bay/North Point, North Point/Kentuck Slough, Coos River, South Umpqua/I-5, Rogue River, and Klamath River are considered to have potential for buried cultural resources that could be impacted by the proposed HDD technology at these locations. Geoarchaeological deep testing has been conducted at the Klamath River crossing (Derr et al. 2015). Additional deep testing is planned to be conducted at the remaining above HDD crossings when access is obtained.

Survey of work spaces is also partially complete. Forty-one TEWAs (2.6 percent of the total number of TEWAs) remain to be surveyed. One UCSA (0.3 percent of the total number of UCSAs) requires survey.

A total of 17 pipe yards and rock source and disposal sites (34 percent) remain to be surveyed. One hundred and forty-eight access roads, totaling about 81 miles (15 percent) of proposed access roads, need to be surveyed. Lastly, three TARs (30 percent) require survey.

With the exception of the Klamath Compressor Station and new communication towers, all of the proposed aboveground facilities are within the pipeline corridor and/or are co-located with other facilities. Those aboveground facilities within sections of the pipeline corridor that have not yet been surveyed are MLV #2 and MLV #9. This area is 8 percent of the total area of MLVs not co-located with other aboveground facilities. Additionally, the Harness Mountain Communication Tower has not been surveyed. This area is less than 7 percent of the total area of communication towers not co-located with other facilities. Pacific Connector plans to survey this area once specific construction plans are finalized and access to the area is granted. The Klamath Compressor Station was surveyed as part of a previous iteration of the application (Bowden et al. 2013), however the design of the station has changed in the current application (CP17-494 and CP17-495; filed September 21, 2017). As such, a portion of this Project component requires survey. Pacific Connector planned to survey the additional acreage in 2017; however, the results have not yet been submitted to the FERC.

Of the 18 locations identified by Pacific Connector's consultants as having potential to convey indirect effects from viewshed changes related to the pipeline, only five appeared to contain potentially historic features based on a desktop analysis. Only these five areas in the indirect APE were recommended for survey. Surveys have not yet been conducted at the following five locations in the indirect APE: 1) east of Haynes Inlet (MP 5.5R); 2) west side of Kentuck Slough (MP 6.3R); 3) 13674 Sitkum Lane, Myrtle Point (MP 29.5); 4) near Dora Cemetery (MP 29.5): and 5) 2378 Upper Camas Road, Camas Valley (MP 49.5). Other areas of the indirect APE either have no potential to affect historic-period resources because no potential historic properties appear to be present, or historic-period resources are entrenched within a modern viewshed and significant impacts are therefore not expected.

The inventories for the Pacific Connector Project identified 158 archaeological and historic architectural sites (see appendix L); 120 sites are along the proposed pipeline route, and 38 sites are along access roads, within TEWA or UCSA, rock source or disposal areas, or yards. Thirty-seven of these sites are located on federal lands (one is on private and federal lands). In addition to the identified sites, 129 isolated finds were also recorded. Two of these require additional investigations (HRA-724i and HRA-727i). After consulting with the SHPO, we determined that the remaining 127 isolated finds are not eligible for the NRHP and require no further work.

Of the 125 sites on non-federal land (including one site that is on private and federal land), 26 have been evaluated as not eligible for the NRHP and require no further work. The Oregon SHPO has concurred with these recommendations and we agree (see appendix L). Seventy-nine sites are outside the APE or can be avoided. Six sites were previously recorded by other investigators and not relocated by Pacific Connector's consultants. The remaining sites are either NRHP-eligible or unevaluated.

Avoidance plans can be found in the draft HPMP filed with the FERC on October 5, 2018. The HPMP is subject to revision based on ongoing consultations between Pacific Connector, tribes, SHPO, and cooperating agencies. However, not all unevaluated, potentially NRHP-eligible, and NRHP-listed sites that can be avoided by the Project have avoidance plans; therefore, the draft HPMP still needs further revision.

Forty-three sites are unevaluated and cannot be avoided, so they need additional investigations, either survey or testing. The unevaluated sites requiring additional work are listed in in appendix L.

Twenty sites, listed in appendix L, have been determined to be eligible for or listed on the NRHP and cannot be avoided. Data recovery excavations are recommended as mitigation for these sites.

In most cases, the applicants prepared treatment plans for these sites, which were reviewed and accepted by appropriate interested Indian tribes, federal land management agencies, the Oregon SHPO, and the FERC staff.

4.11.3.4 Federal Lands

The Jordan Cove LNG Project would not directly affect any federal lands. The proposed Pacific Connector pipeline route, however, would cross federal lands administered by the BLM, Forest Service, and Reclamation. In total, 38 sites were identified on federal lands or are otherwise managed by one of these federal agencies. Thirty-three of the sites are on BLM lands (three of which extend onto private lands and therefore have dual land ownership), four are on NFS lands, and one is managed by Reclamation. We have included a table in appendix L listing all sites on federal lands.

Of the 33 sites on BLM lands, 10 are not eligible for the NRHP and require no further work. Ten of the 33 sites are treated as NRHP-eligible or are unevaluated and can be avoided. Eight of the sites on BLM lands require additional work, either additional survey or testing, prior to their evaluation for eligibility to the NRHP. Five BLM sites (35DO1104, 35DO1105, 35DO1106, 35DO1110, and 35DO1117) have been determined eligible for the NRHP and cannot be avoided by the Project. Pacific Connector's consultants have recommended that data recovery investigations be conducted to mitigate adverse effects at the unavoidable eligible sites.

Two of the four sites on NFS lands were evaluated as not eligible for the NRHP and require no further work. One Forest Service site (35DO1426) is unevaluated, but can be avoided. The remaining site (35DO1107) on NFS lands is eligible for the NRHP and cannot be avoided. Pacific Connector produced a treatment plan to mitigate adverse effects at 35DO1107, which the Forest Service found acceptable.

The Klamath Project, managed by Reclamation, is eligible for the NRHP. The Pacific Connector pipeline route would cross 16 features associated with the Klamath Project. Pacific Connector proposes to bore under the Klamath Project canals. However, neither Reclamation nor the SHPO have commented to date on this method of reducing impacts on the canals.

4.11.4 Unanticipated Discovery Plans

Jordan Cove included a draft UDP (August 2017) as Appendix B.4 in Resource Report 4 of its September 2017 application to the FERC in Docket No. CP17-495-000. Jordan Cove has stated that it developed its UDP in communications with certain Indian tribes (see appendix L). The Oregon SHPO, as well as the CTCLUSI, Coquille Tribe, Grand Ronde Tribes, and Klamath Tribes, provided Jordan Cove with comments on the plan, and Jordan Cove indicated that it would address those comments. A revised and final version of the UDP has not yet been submitted to the FERC.

Pacific Connector included a copy of its August 2017 draft UDP as Appendix B.4 of Resource Report 4, attached to its September 2017 application to the FERC and as an appendix to the draft HPMP submitted in October 2018 in response to a request by the FERC staff. Pacific Connector has indicated that the CTCLUSI, Coquille Tribe, and the Klamath Tribes commented on the draft UDP. Review of the draft UDP by the SHPO has not yet been completed. As such, a revised and final version of the UDP based on tribal and SHPO review has not yet been submitted to the FERC.

We cannot find the UDPs acceptable until we see final versions that address comments from Indian tribes and the SHPO.

4.11.5 Compliance with the NHPA

We have not yet completed the process of complying with Sections 101 and 106 of the NHPA. Additional consultations, investigations, and/or plans remain necessary.

For the Jordan Cove LNG Project, the planned Lagoon, Panhandle, and North Bank habitat mitigation sites still require surveys. Jordan Cove's consultants recommended that construction be monitored by qualified professional archaeologists in the vicinity of sites 35CS221 and 35CS227 at the Ingram Yard and South Dune area, respectively; and at site BAC-2014-1 near the intersection of Highway 101 with the North Spit Causeway. In a November 2, 2018 filing, Jordan Cove indicated it would conduct phase II testing at site 35CS227 in 2019. Jordan Cove's consultants also recommended that sites 35CS324, 35CS325, 35CS326, 35CS327, and 35CS328, which may be impacted by the dredge slurry line in Coos Bay to the Kentuck project site, should be avoided or tested to assess their NRHP eligibility.

For the Pacific Connector Pipeline Project, about 23 miles (totaling 793 acres) of proposed pipeline route, 41 TEWAs (totaling about 28 acres), 17 pipe yards rock source and disposal sites (totaling about 211 acres), and 148 access roads (totaling about 81 miles) remain to be inventoried. Where access has been denied, Pacific Connector would need a Certificate from the Commission in order to use eminent domain to conduct remaining surveys and other investigations. Forty-three sites are unevaluated and cannot be avoided, so they may be impacted by the Pacific Connector Pipeline Project. Those sites need additional investigations, either survey or testing.

The ethnographic study of the Projects and the identification of traditional cultural resources is also incomplete. We have recommended that the applicants file a revised Ethnographic Report.

Twenty historic properties may be affected by the Pacific Connector Pipeline Project. Those sites require treatment to mitigate impacts. To resolve adverse effects at affected historic properties, the FERC will produce a MOA for the current undertaking, to be circulated among the consulting parties. The MOA would stipulate that the treatment plans should be implemented; with the written permission of the FERC and federal land-managing agencies, as applicable. It would also allow for phased surveys and testing investigations, in areas were access was previously denied. However, the MOA cannot be drafted until after the Commission authorizes the Projects. If the Commission should deny the Projects, no adverse effects on historic properties would occur.

To ensure that the Commission's responsibilities under the NHPA and its implementing regulations are met, **we recommend that:**

- **Jordan Cove and Pacific Connector should <u>not begin construction of facilities and/or use</u> any staging, storage, or temporary work areas and new or to-be-improved access roads <u>until</u>:**
  - **a. Jordan Cove and Pacific Connector each file with the Secretary:**
    1. **remaining cultural resources inventory reports for areas not previously surveyed;**

2. **site evaluations and monitoring reports, as necessary;**
3. **final HPMP with avoidance plans;**
4. **final UDP; and**
5. **comments on the cultural resources reports and plans from the SHPO, applicable federal land managing agencies, and interested Indian tribes.**

b. **FERC affords the ACHP an opportunity to comment on the undertaking; and**

c. **FERC staff reviews and the Director of OEP approves all cultural resources reports and plans and notifies Jordan Cove and Pacific Connector in writing that treatment plans may be implemented and/or construction may proceed.**

All materials filed with the Commission containing location, character, and ownership information about cultural resources must have the cover and any relevant pages therein clearly labeled in bold lettering: "CUI//PRIV - DO NOT RELEASE."

4.11.6 Conclusion

We have not yet completed the process of complying with Sections 101 and 106 of the NHPA. Additional cultural resource inventories, evaluations, and associated reports are to be completed, as are a final ethnographic study, HPMP, and UDP. Consultations with tribes, SHPO, and applicable federal land-managing agencies have also not been concluded. As such, the Project would result in an adverse effect under Section 106 of the NHPA and a significant impact under NEPA. However, should the Project be approved by the Commission, an MOA would be developed with the goal of resolving adverse effects under Section 106. It is expected that the resolution of adverse effects through an MOA and implementation of treatment plans would mitigate impacts at affected historic properties to a less-than-significant finding under NEPA.

4.12 AIR QUALITY AND NOISE

4.12.1 Air Quality

Construction and operation of the proposed Projects would affect local and regional air quality. The term "air quality" refers to relative concentrations of pollutants in the ambient air. The subsections below summarize applicable federal and state air quality regulations and describe well-established air quality concepts that are applied to characterize air quality and to determine the significance of increases in air pollution. This includes metrics for specific air pollutants known as ambient air quality standards (AAQS), regional designations to manage air quality known as Air Quality Control Regions (AQCRs), and efforts to monitor ambient air concentrations.

Air quality impacts are spatially dependent, and therefore this section is divided into subsections as follows:

- Impacts in the Coos Bay area associated with the Jordan Cove LNG Project and marine vessels on the waterway are discussed in section 4.12.1.3.
- Impacts associated with the Pacific Connector pipeline—for which the key air pollution sources are emissions from construction and operation of the compressor station in Klamath County—are discussed in section 4.12.1.4.
- Environmental consequences on federal lands are summarized in section 4.12.1.5.

4.12.1.1 Regulatory Setting

Regulatory requirements for air quality—aside from the requirement that the overall project not contribute to a degradation in air quality that results in an exceedance of the national ambient air quality standards (NAAQS)—depend upon the equipment that is proposed to be constructed and the associated emissions. Sources of air pollution at the Jordan Cove LNG Project and in the associated waterway include the following:

- five direct-drive combined cycle combustion turbines, each rated at 524.1 million Btu per hour (MMBtu/hr), to power refrigeration compressors;
- one thermal oxidizer, rated at 110 MMBtu/hr for the gas conditioning system;
- one auxiliary boiler rated at 296.2 MMBtu/hr;
- one enclosed marine flare rated at 0.74 MMBtu/hr;
- one multipoint ground flare rated at 2.13 MMBtu/hr;
- two diesel black-start engines each rated at 4,376 hp;
- two backup engines each rated at 1,073 hp;
- three fire water pump engines each rated at 700 hp;
- two 160,000 cubic meters (m^3) capacity LNG storage tanks;
- fugitive emission sources (valves, flanges, and other equipment); and
- LNG carriers and support vessels.

Regulatory requirements for air quality applicable to the Pacific Connector Pipeline Project depend in part upon the equipment that is proposed to be installed at the compressor station and the associated emissions. Sources of air pollution at the compressor station would include:

- three General Electric PGT25/DLE 1.5 natural gas–fired combustion turbines, each with a maximum site rating of 28,290 hp, and a maximum heat input rate of 194.7 MMBtu/hr at 0°F (the air permit would limit operation to only two turbines at a time; the third is solely for reliability to maintain maximum throughput for the pipeline at times when one of the two operating units is offline for maintenance);
- one 6.28 MMBtu/hr gas-fired hot water boiler;
- one 1,090 kilowatt (kW) natural gas–fired spark-ignition standby generator, limited to no more than 100 hours per year of operation; and
- ancillary activities (fugitive venting, blowdowns, and condensate tank).

Air emission sources for the Jordan Cove LNG Project and the Pacific Connector Pipeline Project are regulated at the federal and state level. Applicable federal and state air quality regulations are summarized below.

Federal and International Air Quality Requirements

Applicable and potentially applicable federal air quality regulations include:

- New Source Review (NSR)/Prevention of Significant Deterioration (PSD) preconstruction permit requirements;
- General Conformity;
- Title V Operating Permit requirements;
- New Source Performance Standards;
- National Emissions Standards for Hazardous Air Pollutants (HAP);
- Chemical Accident Prevention; and
- Mobile Source Regulations.

<u>NSR/PSD Preconstruction Permit Requirements</u>

The federal NSR preconstruction permit program is administered by ODEQ under OAR 340-224 and includes two components: Nonattainment NSR (NNSR), which applies to "major" stationary sources located in nonattainment areas, and PSD, which applies to "major" stationary sources located in attainment or unclassifiable areas. Because existing air quality is classified as "attainment" or "unclassifiable" for all NAAQS pollutants, only PSD regulations are applicable to the Jordan Cove LNG Project. The Project as originally designed was considered a "major" PSD source, and a PSD permit application was submitted to ODEQ in March 2013. However, the current Project design no longer includes the previously proposed South Dunes Power Plant facility, and as a result it no longer qualifies as a major PSD source. A Type B state-only NSR application was submitted to ODEQ in September 2017.

Criteria pollutant emissions from the Pacific Connector Pipeline Project compressor station would be well below major source thresholds. Although GHGs are above previously identified major source thresholds, the Supreme Court made a ruling on June 23, 2014 (*Utility Air Regulatory Group [UARG] v. EPA [No. 12-1146])* that effectively disallowed the triggering of NSR/PSD based on the significance of GHG emissions alone. Therefore, the Pacific Connector Pipeline Project is not expected to trigger NSR/PSD.

General Conformity

For proposed activities that are not covered by NSR/PSD permits—such as construction activities—General Conformity requirements can apply in areas designated as "nonattainment" or "maintenance" with respect to the NAAQS. However, as there are no such areas within the vicinity of the Jordan Cove LNG Project or along construction routes, these requirements do not apply.

Approximately 325 feet of the Pacific Connector pipeline in construction spread 5, between MPs 199 and 200, would be located within the particulate matter with a diameter of less than 10 microns (PM_{10}) maintenance area. Federal regulations at 40 CFR 93 Subpart B require a General Conformity analysis for PM_{10} maintenance areas when emissions of PM_{10} exceed 100 tons per year (TPY). Estimated emissions for this 325-foot length of construction in the PM_{10} maintenance area are presented in table 4.12.1.1-1 and are far below the General Conformity applicability threshold; therefore, the General Conformity requirements do not apply to the Pacific Connector Pipeline Project.

TABLE 4.12.1.1-1

Estimated Construction PM_{10} Emissions in Klamath Falls PM_{10} Maintenance Area (tons) from the Pacific Connector Pipeline Project

Pollutant	PM_{10}
Total Spread 5 nonroad engine emissions (42.5 miles)	2.48
Total Spread 5 fugitive dust emissions (42.5 miles)	26.573
Total Spread 5 PM_{10} emissions	29.053
PM_{10} maintenance area total emissions (300 feet)	**0.039**

Title V Operating Permit

Facilities that have the potential to emit at least 100 TPY of any criteria pollutant, 10 TPY of any individual HAP, or 25 TPY of any combination of HAPs are required to obtain Title V Operating Permits, which are implemented by ODEQ under OAR 340-218. Because the Jordan Cove LNG Project's emissions of oxides of nitrogen (NO_x), carbon monoxide (CO), PM_{10}, and particulate matter with a diameter of less than 2.5 microns ($PM_{2.5}$) would each exceed that threshold for criteria pollutants, it will be required to apply for a Title V Operating Permit. For new sources (such as the ones proposed here), applications for these permits are due one year after the source commences operation. Oregon requires Title V facilities to obtain a Standard ACDP permit prior to construction; see the discussion of state air permitting requirements below.

Facilities that trigger PSD permitting, such as this one, are required to obtain Title V Operating Permits, which are implemented by ODEQ under OAR 340-218. The Pacific Connector Pipeline Project would therefore be required to apply for a Title V Operating Permit. For new sources (such as the ones proposed here), applications for these permits are due one year after the source commences operation.

The Title V Operating Permit will help ensure that the facility continues to comply with all applicable air regulations after it is built. These permits require periodic monitoring to ensure compliance with the permit, annual certification of compliance with all applicable air pollution regulatory requirements, and public comment on permit issuance/renewal and on significant modifications to the permit.

New Source Performance Standards

All new sources of air pollution in specific source categories are required to comply with applicable New Source Performance Standards (NSPS) regulations (40 CFR 60), which establish maximum emission limits for criteria pollutants (and their precursors) and also incorporate monitoring, reporting, and recordkeeping requirements. NSPS regulations that are applicable to the Project are discussed below.

The natural gas–fired turbines at the Jordan Cove LNG Project are subject to NSPS Subpart KKKK, which limits emissions of NO_x from the turbines.

The auxiliary boiler is subject to NSPS Subpart Db, which applies to steam-generating units rated at greater than 100 MMBtu/hr heat input. The auxiliary boiler would be subject to the Subpart Db emission limit for NO_x but would be exempt from the Subpart Db emission limits for sulfur dioxide (SO_2) and particulate matter because it would burn only natural gas.

The two diesel black-start generators, two diesel backup generators, and three diesel fire pump engines are subject to NSPS Subpart IIII, which requires that new or modified stationary engines meet the same emissions standards that manufacturers of comparable nonroad engines are required to comply with. Jordan Cove has proposed to install engines that meet EPA Tier 2 emission standards for the diesel generators, and EPA Tier 3 emission standards for the diesel fire pump engines.

New large storage tanks containing liquids that can emit significant amounts of volatile organic compounds (VOCs) - i.e., where the equilibrium partial pressure exerted by the VOC exceeds 3.5 kilopascals (kPa) - are subject to NSPS Subpart Kb. However, the two largest constituents in LNG that exert partial pressure are methane and ethane (both of which are negligibly photochemically reactive and therefore exempt from the definition of VOC). The remaining VOC constituents in LNG, such as butane, propane, and heavier compounds, have an equilibrium partial pressure of less than 3.5 kPa at the storage temperature, and therefore the LNG storage tanks are not subject to NSPS Subpart Kb.

Certain equipment at crude oil and natural gas production facilities can be subject to NSPS Subpart OOOOa. However, Jordan Cove has determined that none of its proposed facilities or equipment would qualify as affected sources under Subpart OOOOa.

With respect to the Pacific Connector Pipeline Project, the gas-fired combustion turbines located at the Klamath Compressor Station would be new and subject to NSPS Subpart KKKK (and are therefore specifically exempted from NSPS Subpart GG for stationary combustion turbines, as per 40 CFR 60.4305(b)). They would be required to meet an NO_x emission standard of 25 parts per million (ppm) by volume, dry basis, corrected to 15 percent oxygen (ppmvd @ 15 percent O_2) or approximately 1.2 pounds NO_x per megawatt hour generated.

The potential spark-ignition emergency generator at the compressor station would be manufactured after June 12, 2006, and therefore would be subject to NSPS Subpart JJJJ, which requires that NO_x emissions be no higher than 2.0 grams per horsepower per hour (g/hp-hr) = 160 ppmvd @ 15% O_2 and that CO emissions be no higher than 4.0 g/hp-hr = 540 ppmvd @ 15% O_2.

New large storage tanks containing liquids that can emit significant amounts of VOCs—i.e., where the equilibrium partial pressure exerted by the VOC exceeds 3.5 kPa—are subject to NSPS Subpart Kb. While the design of the Klamath Compressor Station has not been finalized, a condensate storage tank is likely to be installed. The potential applicability of NSPS Subpart Kb will be determined once the final storage tank specifications are known.

Certain equipment at crude oil and natural gas production facilities can be subject to NSPS Subpart OOOOa. The fugitive emissions at the Klamath Compressor Station would qualify as an "affected facility" under Subpart OOOOa, and the centrifugal compressors may be subject as well if they are equipped with wet seals. If any pneumatic controllers are installed, they may also be subject to Subpart OOOOa if they have a natural gas bleed rate of greater than 6 standard cubic feet per hour. Storage tanks may be subject to Subpart OOOOa if they have potential VOC emissions of 6 TPY or more; however, the condensate storage tank is unlikely to have potential emissions meeting this threshold. The extent to which NSPS Subpart OOOOa is applicable will be determined once the design of the Klamath Compressor Station is finalized.

National Emissions Standards for Hazardous Air Pollutants

New and existing sources of air pollution are required to comply with applicable National Emissions Standards for Hazardous Air Pollutants (NESHAP), many of which are also incorporated by reference into Oregon's regulations at OAR 340-244-0220. NESHAPs exist for the following source types included at the Jordan Cove LNG Project terminal:

- Stationary Combustion Turbines (40 CFR 63, Subpart YYYY); Stationary Reciprocating Internal Combustion Engines (40 CFR 63, Subpart ZZZZ); and
- Industrial, Commercial, and Institutional Boilers at Area Sources (40 CFR 63, Subpart JJJJJJ).

For natural gas–fired turbines, the requirements of Subpart YYYY were stayed per 40 CFR 63.6095(d), and therefore, there are no applicable requirements. For the engines, compliance with NSPS Subpart IIII satisfies the requirements of 40 CFR 63 Subpart ZZZZ, and therefore, there are no additional applicable requirements. For the auxiliary boiler, the requirements of Subpart JJJJJJ do not apply because it would burn only natural gas.

NESHAPs exist for the following source types included at the Pacific Connector compressor station:

- Stationary Combustion Turbines (40 CFR 63, Subpart YYYY); and
- Stationary Reciprocating Internal Combustion Engines (40 CFR 63, Subpart ZZZZ).

For natural gas–fired turbines, the requirements of Subpart YYYY were stayed per 40 CFR 63.6095(d), and therefore there are no applicable requirements. For the engines, compliance with NSPS Subpart JJJJ satisfies the requirements of 40 CFR 63 Subpart ZZZZ, and therefore there are no additional applicable requirements.

Chemical Accident Prevention Provisions

LNG facilities are subject to safety regulations developed by the USDOT (49 CFR 193) and the U.S. Department of Homeland Security (33 CFR 127). The EPA's Chemical Accident Prevention Provisions (40 CFR 68, which were developed in accordance with Section 112(r) of the Clean Air

Act (CAA) and referenced by Oregon regulations at OAR 340-244-0230) can also apply to owners or operators of stationary sources producing, processing, handling, or storing toxic or flammable substances. However, the EPA's General Counsel has clarified that Section 112(r) and the associated regulations do not apply to LNG stored at terminals because the material is either being transported or stored incident to transportation (EPA 2006).

Aside from LNG, which would be stored incident to transportation, the Project would not be storing hazardous or flammable substances in excess of any thresholds identified in 40 CFR 68, and therefore, those regulations do not apply. However, with regard to the storage of any small quantities of hazardous substances that are not being transported or stored incident to transportation, the 112(r)(1) general duty clause does apply:

> *The owners and operators of stationary sources producing, processing, handling or storing [hazardous] substances have a general duty in the same manner and to the same extent as section 654, title 29 of the United States Code, to identify hazards which may result from [accidental] releases using appropriate hazard assessment techniques, to design and maintain a safe facility taking such steps as are necessary to prevent releases, and to minimize the consequences of accidental releases which do occur.*

Mobile Source Regulations

International Maritime Organization (IMO) Standards for Ships – The IMO has officially designated waters off North American coasts as "Emission Control Areas" (ECAs) under Annex VI, which means that stringent international emission standards will apply to ships operating in these areas. Effective in 2015, the sulfur content in marine fuels used in these waters is required to contain no more than 0.1 percent sulfur (or else vessels can install control equipment to reduce emissions from fuels with higher sulfur contents to equivalent levels). In November 2011, IMO's Marine Environment Protection Committee adopted amendments that exempted boiler-propelled vessels "that were not originally designed for continued operation on marine distillate fuel or natural gas" (such as LNG carriers) from the fuel sulfur requirements until at least 2020 (IMO 2011). However, Jordan Cove has indicated that they would require vessels calling on the LNG terminal to meet the fuel sulfur requirements. In addition, diesel engines installed on vessels manufactured in 2016 or later are required to control NO_x emissions to levels that are approximately 80 percent lower than currently allowable levels ("Tier 1") when operating in ECAs (which in most cases will mean that NO_x control equipment will need to be installed). The IMO regulations also include requirements pertaining to emissions from shipboard incinerators.

EPA Requirements for Marine Diesel Engines – All marine diesels larger than 37 kW that have been manufactured in the United States since January 1, 2004, are required to meet federal emissions standards identified in 40 CFR 94 or 40 CFR 1042; the newest engines are subject to the most stringent requirements ("Tier 4"). Although most engines on existing LNG carriers were not manufactured in the United States, some of the newer engines installed on tugs and other local support vessels may be subject to these regulations, and the Project's emissions calculations reflect the use of "Tier 4" diesel engines in the tugboats.

EPA Requirements for Land-Based Engines and Vehicles – The EPA has promulgated extensive regulations reducing emissions from new on-road vehicles and construction equipment, which has resulted in substantial emissions reductions over time in spite of increased equipment/vehicle populations and usage.

EPA Regulations on Fuels – Any diesel oil or gasoline sold in the United States that is used in or intended for use in marine engines or land-based engines is subject to federal regulations (40 CFR 80). Non-road, locomotive, and marine diesel sold in the United States must have a sulfur content no greater than 15 ppm (0.0015 percent) by weight. Although these requirements do not apply to diesel fuel (or boiler fuel) obtained by LNG carriers outside the United States, diesel fuel used by tugboats, support vessels, and construction equipment would need to meet these criteria. Gasoline is required to have a sulfur content of no more than 80 ppm per gallon, or more than 30 ppm on average for any given refinery or importer.

State Air Quality Requirements

In addition to the rules identified above, ODEQ has state-specific air quality requirements. Those that would be directly applicable to the Jordan Cove LNG Project and/or the Pacific Connector Pipeline Project, and those that may potentially be applicable are discussed below.

Oregon Construction Permit

Oregon requires that facilities subject to Title V Operating Permits obtain a Standard ACDP in accordance with OAR 340-216 prior to construction. As part of this permit, Plant Site Emission Limits are required to be obtained for all regulated pollutants, as per OAR 340-222-0020, and an air quality impact analysis must be conducted in accordance with OAR 340-216. Since the Jordan Cove LNG Project terminal is subject to the Title V Operating Permit regulations, an ACDP is required. Oregon also requires that facilities subject to NSPS regulations with emissions greater than 10 TPY obtain an ACDP, including Plant Site Emission Limits and an air quality impact analysis. The Pacific Connector Pipeline Project is subject to this requirement.

A Standard ACDP identifies all applicable requirements, identifies plant site emission limits (PSELs), and includes testing, recordkeeping, and reporting requirements sufficient to determine compliance with the PSEL. A Type B state-only NSR application for a Standard ACDP was submitted to ODEQ in September 2017.

Air Quality Impact Analysis

Oregon's ACDP regulations cross-reference air quality analysis regulations in OAR 340-225-0050(1) and (2) and OAR 340-225-0060. These regulations are therefore applicable. With respect to the requirement for projects to demonstrate compliance with the NAAQS and PSD increments, ODEQ allows projects to show that their own impacts are below significant impact levels. Projects that cannot demonstrate impacts less than the significant impact levels must show that (a) modeled impacts from the proposed source and other PSD increment-consuming sources are less than PSD increments, and (b) those impacts plus background concentrations are less than the NAAQS. The Project's ACDP permit application demonstrates that the applicable requirements of these regulations are met. More details about the air quality impact analysis are provided under the "Operational Air Impacts and Mitigation" subheadings below.

General Emission Standards

Under OAR 340-226, sources that are not already subject to NSPS requirements (as identified above) or other new source standard and have the potential to emit at least 1 TPY of any criteria pollutant must meet the requirements for Typically Achievable Control Technologies (TACT). Emission limits that meet TACT would be typical of the emission rates achieved by other recently installed emission units of a similar type and size. The use of dry low emission technology and good combustion practices in the Pacific Connector compressor turbines would meet or exceed TACT for gas-fired turbines of this size.

Visible Emission and Nuisance Requirements

State visible emissions and nuisance abatement regulations are codified in OAR 340-208. Both construction and operation phases of the Projects would be subject to visible emission limits stated in terms of opacity. Either Project may not emit contaminants causing opacity to equal or exceed 20 percent in any period or periods aggregating more than 3 minutes in any hour. In addition, no person may create an observable deposition of particulate matter on another person's property (OAR 340-208-540).

This regulation prohibits nuisances and requires that reasonable precautions be taken to minimize fugitive dust emissions in Special Control Areas (which include areas within 3 miles of the corporate limits of any city having a population of 4,000 or more). The LNG Project site is within three miles of North Bend, Oregon, which has a population of approximately 10,000.

Given that visible emissions from the combustion of gaseous fuels are typically far below 20 percent opacity and that the only fugitive dust emissions are likely to be those associated with construction, the Jordan Cove LNG Project is anticipated to meet these regulations.

4.12.1.2 Existing Conditions

Climate

Jordan Cove LNG Project

Climatic conditions, such as ambient temperature, cloud cover, and wind, can significantly change how emissions of pollutants impact local air quality. The State of Oregon is divided into nine climate zones as established by the National Climatic Data Center (NCDC). The Jordan Cove LNG Project and the waterway used by the LNG marine traffic lies in the southern part of Zone 1–The Oregon Coast. The climate of the Project area is characterized by wet winters, relatively dry summers, and mild temperatures year-round. Terrain features include the coastal plain, which extends from less than a mile to a few tens of miles in width, numerous coastal valleys, and the Coast Range, whose peaks range from 2,000 to 5,500 feet above sea level. The National Weather Service (NWS) maintains a climate station at the Southwest Oregon Regional Airport in Coos County, located across Coos Bay approximately 1 mile south of the Project site. Climate data from this station should be representative of conditions in the area of the Jordan Cove LNG Project.

The heaviest precipitation in this zone occurs mainly during the winter months when moist air masses move off the Pacific Ocean onto land. Normal annual precipitation (as measured at the Southwest Oregon Regional Airport) is approximately 65 inches, with normal annual snowfall of approximately 1 inch. The highest monthly precipitation values occur during the months of November, December, and January.

The mean maximum temperature in North Bend/Coos Bay is approximately 60°F, the mean minimum temperature is approximately 46°F, and the mean temperature is approximately 53°F. Temperatures of 90°F or higher occur less than once per year, on average, and freezing temperatures are infrequent, with killing frosts being even less frequent. The growing season (period between minimum temperature occurrences of 28°F) averages approximately 303 days.

Strong winds occur occasionally, usually in advance of winter storms. These winds can exceed hurricane force and have been known to cause significant damage to structures and vegetation. Such events, however, are typically short-lived, and last less than one day. Partly cloudy skies are prevalent during the summer. Winter skies are likely to be cloudy. As a result of the persistent cloudiness, total solar radiation is relatively low in this zone.

Pacific Connector Pipeline Project

As identified above, the State of Oregon is divided into nine climate zones as established by the NCDC. The pipeline runs from Zone 1 (the Oregon Coast; as described in section 4.12.1.1) through Zone 3 (Oregon Southwestern Valleys) to Zone 7 (the South Central Oregon climate region; NCDC 1994). The primary source of air pollutants associated with Project operation is the proposed Klamath Compressor Station, which lies in Zone 7. The region surrounding the Klamath Compressor Station receives an annual average of 14.2 inches of precipitation per year.[184] Average daily temperature is 50.4°F from the same station and reporting period. The prevailing wind direction is from the west at an average daily speed of 6.3 miles per hour (mph).[185]

The air temperature extreme in Klamath Falls ranges from -10°F to 100°F. For the period 1997 to 2008, an air temperature below 0°F was recorded on average 1.3 days per year (Western Regional Climatic Center [WRCC] 2012). Hourly meteorological data for Klamath Falls were obtained from the NCDC for the most recent five-year period (2008 to 2012) (NCDC 2013). During the 2008–2012 period, ambient air temperature at or below 0°F occurred for 84 hours for an average of approximately 17 hours (0.7 day) per year.

Existing Air Quality

Existing air quality is typically characterized relative to EPA's NAAQS, which exist for seven pollutants:

- oxides of sulfur (measured as SO_2)
- CO
- oxides of nitrogen (measured as nitrogen dioxide, NO_2)
- ozone
- PM_{10}
- $PM_{2.5}$
- lead and its compounds (measured as lead)

[184] Based on data from the Western Regional Climatic Center at the Klamath Falls 2 SSW weather station for the period January 1981 through December 2010.
[185] As recorded at the Klamath Falls Airport Weather Station, from November 1997 to December 2008.

These pollutants are referred to as "criteria pollutants" because EPA is required to periodically identify air quality criteria which reflect the latest scientific knowledge (including knowledge regarding the health impacts on children, asthmatics, and the elderly), and revise the NAAQS accordingly. The CAA requires EPA to set both primary NAAQS (which are established to be protective of human health, allowing an adequate margin of safety) and secondary NAAQS (established to be protective of public welfare, which includes effects on wildlife, crops, vegetation, and buildings). Emissions of other non-criteria pollutants are also regulated by EPA and state/local environmental agencies, even though NAAQS are not developed for them.

The EPA, and state and local agencies, have established a network of ambient air quality monitoring stations to measure concentrations of criteria pollutants across the United States. All areas of the United States are classified as being "attainment," "unclassified," or "nonattainment" with respect to the NAAQS. "Nonattainment" areas, where criteria pollutant concentrations exceed the NAAQS, are required to develop plans to meet the standards by specified deadlines, and after meeting the standards are classified as "maintenance areas" (a subcategory of attainment areas, for areas previously designated as nonattainment). Coos County is part of the Southwest Oregon Interstate AQCR and is designated as "attainment" (criteria pollutant concentrations are below the NAAQS) or "unclassifiable" for all of the NAAQS. The NAAQS and the ambient concentrations of criteria pollutants at the nearest ambient air monitoring stations are shown in table 4.12.1.2-1. The monitoring stations selected (Portland for SO_2, CO, and NO_2; Eugene for PM_{10}; and Cottage Grove for ozone and $PM_{2.5}$) are located between approximately 65 and 165 miles from the Jordan Cove LNG Project. These were the closest available stations for each respective pollutant.

TABLE 4.12.1.2-1

Existing Air Quality Concentrations for Criteria Air Pollutants Near the Jordan Cove LNG Project

Air Pollutant	Averaging Period	Primary NAAQS	Secondary NAAQS	State AAQS	Nearest Ambient Monitoring Site(s)	Monitor Value g/	Background as Fraction of NAAQS
SO_2 (µg/m^3)	1-Hour a/	197	NA	197	Portland	10.5	0.05
	3-Hour b/	NA	1,300	1,300		21.0	0.02
	24-Hour b/	365	NA	260		5.3	0.02
	Annual	80	NA	52		0	0.00
CO (µg/m^3)	1-Hour b/	40,000	NA	40,000	Portland	2,740	0.07
	8-Hour b/	10,000	NA	10,000		2,100	0.21
NO_2 (µg/m^3)	1-Hour c/	188	NA	188	Portland	54.5	0.29
	Annual	100	100	100		17	0.17
Ozone (ppm)	8-Hour d/	0.070	0.070	0.070	Cottage Grove	0.061	0.87
PM_{10} (µg/m^3)	24-Hour b/	150	150	150	Eugene	53	0.35
$PM_{2.5}$ (µg/m^3)	24-Hour e/	35	35	35	Cottage Grove	22	0.63
	Annual f/	12.0	12.0	12		8.2	0.68

a/ NAAQS applies to the 3-year average of the annual (99th percentile) of the daily max.1-hour avg. concentration.
b/ NAAQS is not to be exceeded more than once per calendar year.
c/ NAAQS applies to the 3-year average of the annual (98th percentile) of the daily max. 1-hour avg. concentration.
d/ NAAQS applies to the 3-year average of the annual 4th highest daily max. 8-hour avg. concentration.
e/ NAAQS applies to the 3-year average of the annual 98th percentile 24-hour concentration.
f/ NAAQS applies to the 3-year average of annual concentrations.
g/ For 1-hr SO_2, 1-hr NO_2 ,8-hr ozone, and 24-hour $PM_{2.5}$ the values in this column are the 3-year (2013–2015) averages that the NAAQS applies to. For other pollutants the annual values shown in this column represent the maximum concentrations seen in 2013-2015 and the shorter-term values are high second-high concentrations.

In addition to the NAAQS identified in table 4.12.1.2-1, states are allowed to set more stringent ambient air quality standards. While Oregon has adopted state AAQS that match the NAAQS in most cases, it has set more stringent AAQS for SO_2, as shown in table 4.12.1.2-1.

Each of the criteria pollutants in table 4.12.1.2-1, except ozone, are emitted directly; ozone can also be emitted directly by a few sources but is predominantly a result of reactions between NO_x—predominantly NO_2 and nitrogen oxide (NO)—and VOCs in the air, particularly in the warmer months. For this reason, emissions inventories often refer to NO_x and VOCs as criteria pollutants as well.

In addition to the criteria pollutants, other types of air pollutants include "air toxics" (as defined by ODEQ 340-246)—which include but are not limited to chemicals designated as HAPs by EPA. Air toxics are a set of chemicals and chemical classes that often have carcinogenic, mutagenic, or other especially hazardous properties; most are subsets of criteria pollutants (i.e., several air toxics exist in the form of particulate matter and/or can be classified as VOCs). Ambient air quality standards do not typically exist for these pollutants; ODEQ regulations identify "ambient benchmarks" for some, but not all, and existing monitoring stations do not monitor all of these chemicals either. Aggregate impacts of air toxics are often assessed in terms of the lifetime cancer risk and respiratory hazard index, which are calculated based on conservatively determined cancer risk factors and reference exposure levels. EPA's latest National Air Toxics Assessment (for calendar year 2014) shows that regionally, the lifetime cancer risk associated with ambient air toxics concentrations in Coos Bay and the surrounding area is 30 in a million or less, and the respiratory hazard index is approximately 0.50 or less (EPA 2018c). A respiratory hazard index of less than 1 means that ambient air toxics are unlikely to cause adverse respiratory health effects over a lifetime of exposure.

The term "greenhouse gases" (GHG) refers to the gases and aerosols that occur in the atmosphere both naturally and as a result of human activities, such as the burning of fossil fuels. The primary GHGs are CO_2, methane, and nitrous oxide. GHGs are non-toxic and non-hazardous at normal ambient concentrations, and there are no applicable ambient standards or emission limits for GHG. However, unlike criteria pollutants and air toxics, GHG concentrations have been increasing over time and are continuing to increase. Elevated levels of GHGs are the primary cause of warming of the climatic system.

Emissions of GHGs are typically quantified and regulated in units of carbon dioxide equivalents (CO_2e). The CO_2e takes into account the global warming potential (GWP) of each GHG. The GWP is the measure of a particular GHG's ability to absorb solar radiation as well as its residence time within the atmosphere. The GWP allows comparison of global warming impacts between different gases; the higher the GWP, the more that gas contributes to climate change in comparison to CO_2. Thus, CO_2 has a GWP of 1, methane has a GWP of 25, and nitrous oxide has a GWP of 298.[186]

The Pacific Connector pipeline would pass through predominantly rural areas in Coos, Douglas, Jackson, and Klamath Counties. The Klamath Compressor Station would be located within an agricultural area approximately 1.8 miles northeast of Malin in Klamath County. The areas through

[186] These GWPs are based on a 100-year time period. We have selected their use over other published GWPs for other timeframes because these are the GWPs the EPA has established for reporting of GHG emissions and air permitting requirements. This allows for a consistent comparison with these regulatory requirements.

which the pipeline would pass and in which the compressor station would be located all attain all ambient air quality standards (see section 4.12.1.1), with the exception that approximately 325 feet of pipeline in construction spread 5, between MPs 199 and 200, would be located within the Klamath Falls PM_{10} maintenance area (i.e., an area that currently attains the PM_{10} standard, but was formerly designated as a nonattainment area). The compressor station would be located approximately 14 miles to the southeast of the southeast corner of the nonattainment area. (An additional 4.3 miles of pipeline would be located within the Klamath Falls nonattainment area for the 2006 24-hour $PM_{2.5}$ standard. However, the 2006 $PM_{2.5}$ standard was superseded by the 2012 $PM_{2.5}$ standard, for which the entire pipeline route is in attainment.)

Background air quality data near the compressor station are presented in table 4.12.1.2-2. For SO_2, CO, and NO_2, the nearest active monitors are located in Boise, Idaho for SO_2 and CO (280 miles to the northeast), and in Eureka, California for NO_x (165 miles to the southwest). Because of these great distances, the nearest monitors are not considered to be representative of the ambient air quality near the compressor station location. Therefore, background concentrations are based on values predicted by NW AIRQUEST (2018) Criteria Pollutant Design Value maps and lookup tables. The background concentrations shown for PM_{10} and $PM_{2.5}$ represent the worst-case values recorded by monitors in Klamath, Jackson, and Lane Counties, which respectively are closest to the eastern, central, and western portions of the pipeline. Wildfires in 2014-2015 caused elevated $PM_{2.5}$ near Klamath Falls, resulting in an exceedance of the 24-hour 98th percentile 3-year average for 2013-2015. The ODEQ submitted an exceptional event demonstration in April 2017 requesting that the EPA exclude $PM_{2.5}$ data affected by the wildfire events. The EPA has concurred that a portion of the August 2015 data was affected by an exceptional event, but no formal regulatory action has been taken to exclude the data.

TABLE 4.12.1.2-2

Existing Air Quality Near Proposed Klamath Compressor Station

Air Pollutant	Averaging Period	Most Stringent AAQS	Background Concentration	Background Based On
SO_2 (µg/m³)	1-Hour a/	197	1.0	Design values for 2009-2011 estimated using NW AIRQUEST (2018)
	3-Hour b/	1,300	1.0	
	24-Hour b/	260	0.8	
	Annual	52	0.5	
CO (µg/m³)	1-Hour b/	40,000	942	Design values for 2009-2011 estimated using NW AIRQUEST (2018)
	8-Hour b/	10,000	708	
NO_2 (µg/m³)	1-Hour c/	188	8.1	Design values for 2009-2011 estimated using NW AIRQUEST (2018)
	Annual	100	1.3	
Ozone (ppm)	8-Hour d/	0.070	0.065	Data from Jackson County (Medford) for 2013-2015
PM_{10} (µg/m³)	24-Hour b/	150	71	Data from Jackson County (Medford) for 2013 (no record)
	Annual	50	-	
$PM_{2.5}$ (µg/m³)	24-Hour e/	35	40 g/	Data from Jackson County (Medford) for 2013-2015
	Annual f/	12.0	11 g/	

µg/m³ = microgram per cubic meter
a/ AAQS applies to the 3-year average of the annual (99th percentile) of the daily max.1-hour avg. concentration.
b/ AAQS is not to be exceeded more than once per calendar year.
c/ AAQS applies to the 3-year average of the annual (98th percentile) of the daily max. 1-hour avg. concentration.
d/ AAQS applies to the 3-year average of the annual 4th highest daily max. 8-hour avg. concentration.
e/ AAQS applies to the 3-year average of the annual 98th percentile 24-hour concentration.
f/ AAQS applies to the 3-year average of annual concentrations.
g/ May include data deemed part of the “exceptional event” due to wildfires in the region during 2014 and 2015.

4.12.1.3 Jordan Cove LNG Project Impacts

Construction Air Quality Impacts

During construction, a temporary reduction in ambient air quality may result from emissions and fugitive dust generated by construction equipment. Fugitive dust emission levels would vary in relation to moisture content, composition, and volume of soils disturbed. Fugitive dust and other emissions from construction activities generally do not result in a significant increase in regional pollutant levels, although local pollutant levels could increase temporarily.

Construction air pollutant emissions include exhaust and crankcase emissions from construction equipment, vehicles that transport workers and materials, and vessels that transport equipment and construction materials. Emissions of criteria pollutants from construction activities by year are shown in table 4.12.1.3-1. Emissions would occur over the duration of construction activity, which is anticipated to last five years. The construction emission totals during year 5 including emissions from commissioning and startup of the LNG Project facilities.

Construction tasks for which emissions were estimated include the following broad categories of activity:

- **Site Preparation:** Includes demolition, clearing, and removal of vegetation or existing structures on site; construction of an MOF and TMBB for delivery of construction materials; topsoil removal, cut/fill, and grading of the site; dredge spoil placement; soil improvement to stabilize it against settling and seismic events;
- **Underground Structures:** Includes installation of pilings for the LNG Project structures and marine slip; laying storm drains, utility lines, fire water piping, process piping, and duct banks; construction of all foundations, including the LNG storage tanks, process equipment, and pipe racks; and site restoration, road paving, and landscaping;
- **Marine Facilities:** Includes derrick barges for dredging of the slip basin and access channel; land-based construction equipment to construct the slip face and install armoring; installation of a sheetpile retaining wall; installation of pilings for marine structures, and installation of LNG carrier loading facilities;
- **Marine Waterway Modification:** Includes excavation of submerged areas adjacent to the shipping channel;
- **LNG Storage Tank Construction:** Includes construction of outer concrete foundation, walls, and roof; construction of interior steel plate floor, walls, and roof; hydrostatic pressure testing of the inner tank and pneumatic testing of the outer tank; and installation of insulation, including expanded perlite between the wall liner and inner tank wall;
- **Aboveground Structures:** Includes installation of all process facilities, including both pre-fabricated modules and structures built onsite; installation of aboveground piping; and installation of electrical wiring and instrumentation; and
- **Miscellaneous Construction:** Includes various construction tasks not listed above, including the operation of an on-site concrete batch plant.

TABLE 4.12.1.3-1

Estimated Emissions from Terminal Construction Activities, By Year (tons)

Year	CO	NO_x	SO_2	VOC	PM_{10}	$PM_{2.5}$	HAP	GHG (as CO_2e)
Year 1	120	351	0.35	23	268	39	7.4	53,397
Year 2	184	404	0.43	32	310	100	11.0	66,708
Year 3	199	269	0.33	31	192	87	11.3	52,768
Year 4	81	43	0.08	10	18	17	3.7	13,615
Year 5 (plus commissioning emissions)	85	72	20.94	71	209	68	4.1	925,856
Total	**669**	**1,139**	**22.13**	**167**	**997**	**311**	**37.5**	**1,112,344**

To mitigate construction-related emissions, all construction equipment would be maintained in accordance with manufacturers' recommendations and engine idling time would be minimized. As required by federal regulations, construction equipment would combust diesel fuel with no more than 0.0015 percent sulfur, and vessels would combust fuel that complies with International Convention for the Prevention of Pollution from Ships and EPA standards for sulfur content. Additionally, Jordan Cove would implement the following measures to mitigate construction emissions from mobile and temporary stationary sources:

- reduce use, trips, and unnecessary idling of heavy equipment.
- maintain and tune engines per manufacturer's specifications to perform EPA certification levels, where applicable, and to perform at verified standards applicable to retrofit technologies. Employ periodic, unscheduled inspections to limit unnecessary idling and to ensure that construction equipment is properly maintained, tuned, and modified consistent with established specifications.
- prohibit any tampering with engines and require continuing adherence to manufacturer's recommendations.
- use construction equipment engines that incorporate modern pollution control technology. If practicable, lease new, clean equipment meeting the most stringent of applicable federal or state standards.

To mitigate fugitive dust emissions during construction, Jordan Cove would spray water or use dust suppressants on disturbed soil and access roads. The frequency and methodology of dust suppression would depend on the specific construction activities, terrain, soil conditions, and weather conditions. Additionally, Jordan Cove would implement the following measures to mitigate construction emissions due to fugitive dust:

- use of large off-road equipment for excavation and hauling operations to complete the work in the shortest time and least number of trips;
- stabilization of open storage piles and disturbed areas by covering and/or applying water or chemical/organic dust palliative where appropriate. This applies to both inactive and active sites, during workdays, weekends, holidays, and windy conditions. Installing wind fencing, and phase grading operations, where appropriate, and operate water trucks for stabilization of surfaces under windy conditions;

- pre-wetting of material before excavation in selected areas;
- use of wheel-washing stations to prevent trackout of materials onto public roads;
- use of street sweepers to clean any materials inadvertently tracked onto public roads near the project site; and
- when hauling material and operating non-earthmoving equipment, prevent spillage by covering loads, limiting fill height in trucks, and training operators in the proper hauling and loading of material.

The effect of construction emissions on ambient air quality would vary with time due to the construction schedule, the mobility of the sources, and the variety of emission sources. Fugitive dust and other emissions due to construction activities generally do not pose a significant increase in regional pollutant levels; however, local pollutant levels would increase during the construction period. Based on the duration and scope of construction activities, we determine that construction of the Project would impact local air quality. However, construction emissions would not have a long-term, permanent effect on air quality in the area.

Operational Air Quality Impacts

Operational emissions from the Project include those from the Jordan Cove LNG Project sources, fugitive emissions from evaporative losses, and emissions from the LNG carriers and tugboats (including emissions in the waterway). These emissions are summarized in table 4.12.1.3-2 for routine operation. Commissioning emissions are included in year 5 of the construction emissions in table 4.12.1.3-2.

TABLE 4.12.1.3-2

Estimated Emissions During Operation of the Jordan Cove LNG Project (tons per year)

Source	CO	NO_x	SO_2	VOC	PM_{10}	$PM_{2.5}$	HAP	GHG (as CO_2e)
Combustion Turbines	97.82	81.99	35.19	32.72	112.26	112.26	5.06	1,292,706

Fugitive Emissions	0	0	0	7.98	0	0	1.77	13,116
Aggregate Insignificant Emissions	1.0	1.0	1.0	1.0	1.0	1.0	--	--
LNG Carriers a/	36.68	48.68	9.5	9.47	3.31	3.31	--	14,653
Tugs	17.68	9.51	2.6	1.00	0.32	0.32	--	3,736
Total	**208.26**	**214.98**	**68.71**	**80.04**	**123.83**	**123.83**	**8.13**	**1,969,795**

a/ Values are based on 120 vessel calls per year, assuming worst-case emissions (i.e., vessel type with the highest emissions) for each pollutant. Emissions estimated at 2.2 nautical miles from the Oregon coastline.

Commissioning and Start-Up Emissions: Commissioning of the Jordan Cove LNG Project is planned to occur during year 5 of construction. Table 4.12.1.3-2 includes estimated commissioning and operating emissions from all of the terminal stationary sources in year 5, including compressor turbines and duct burners, startup/shutdown emissions, auxiliary boiler, thermal oxidizer, flares, emergency engines, and fugitive emissions.

Routine Operation: The following sources are expected to operate continuously during routine operation:

- five combustion turbines for the refrigeration compressors;
- one thermal oxidizer;
- flare pilot flames for the enclosed marine flare and multipoint ground flare;
- two LNG storage tanks; and
- fugitive emission sources (valves, flanges, and other equipment).

Intermittent Operation: The following sources or activities would only operate intermittently. The auxiliary boiler would provide high-pressure steam if none of the LNG trains are operating, and the other intermittent sources would only operate during startup or shutdown events, planned maintenance, process upsets, readiness testing, or emergency situations:

- combustion turbine startup and shutdown events;
- one auxiliary boiler;
- one enclosed marine flare;
- one multipoint ground flare;
- two diesel black-start engines;
- two backup engines;
- three fire water pump engines; and
- up to 120 LNG carriers per year, with one tugboat attending each carrier.

The Jordan Cove LNG Project would remain below PSD major source thresholds for emissions of all criteria pollutants, HAP, and GHG, but would be a Title V major source for emissions of NO_x, CO, PM_{10}, and $PM_{2.5}$. As described above, a Type B state-only NSR application was submitted to ODEQ in September 2017.

For the criteria pollutants, dispersion modeling of the combined impacts of the terminal and LNG carriers/tugs was conducted using version 16216r of EPA's preferred dispersion model (AERMOD). Secondary formation of PM was also accounted for in accordance with EPA guidance, by adding the expected secondary formation of $PM_{2.5}$ from NO_x and SO_2 emissions to the modeled result for direct $PM_{2.5}$ impacts. For the permitting of just the stationary sources, regulations state that if worst-case impacts from worst-case project emissions are below the "significant" levels identified in OAR 240-200-0020 Table 1 (which are well below the NAAQS standards in table 4.12.1.2-1 and the PSD increments in 4.12.1.3-2), there is no need to quantitatively model impacts from other nearby sources as well. The ACDP permit application showed that 1-hour SO_2 impacts, as well as short-term and annual impacts for NO_2, $PM_{2.5}$, and PM_{10}, were above "significant" levels. Therefore, multisource modeling was conducted which incorporated emissions from eight other nearby facilities (RFP, Westrum Funeral Services, Bandon Concrete, Southport Forest Products, Allweather Wood, LTM Incorporated, Coastal Cremation and Funeral Services, and Georgia-Pacific Wood Products). The multisource modeling also included emissions from LNG carriers/tugs. Results are shown in table 4.12.1.3-3.

TABLE 4.12.1.3-3

Maximum Combined Impacts of Jordan Cove LNG Project, Marine Vessels, and Nearby Major Sources

Air Pollutant	Averaging Period	Maximum Cumulative Impact	Class II Increment	Maximum Cumulative Impact + Background	AAQS
SO_2 (µg/m^3)	1-Hour	30.1	NA	33.2	199
NO_2 (µg/m^3)	1-Hour	132.3	NA	148.3	188
	Annual	4.1	25.0	6.0	100
PM_{10} (µg/m^3)	24-Hour	9.3	30.0	44.3	150
	Annual	1.4	17.0	1.4	NA
$PM_{2.5}$ (µg/m^3)	24-Hour	8.3	9.0	18.2	35.0
	Annual	1.7	4.0	8.4	12.0

µg/m^3 = microgram per cubic meter

For all pollutants, the combined impacts at the points of highest concentration are below the applicable NAAQS and the PSD increments. Impacts on the distant Class I areas[187] are discussed in section 4.12.1.5. Therefore, we conclude that based on the maximum predicted impacts of the LNG terminal and LNG carriers, in addition to nearby major sources, there would be no significant impacts on regional air quality.

4.12.1.4 Pacific Connector Pipeline Project Impacts

Construction Air Quality Impacts

Construction of the pipeline and compressor station would result in a temporary increase in emissions due to the combustion of fuel in vehicles and equipment, dust generated from soil disturbance, and general construction activities (e.g., painting and welding). Pipeline construction spread activities would occur in sequence or in assembly-line fashion along the right-of-way with one crew following the next from clearing until final cleanup. Emissions from any given stage of construction would therefore be spread out along the construction corridor due to the sequence/assembly-line nature of the work, rather than being concentrated in a specific stationary location. As work proceeds, there are often small periods between job tasks when work at a specific location on the right-of-way is delayed such as between trenching and pipe stringing or pipe stringing and welding. As the work crews move along the corridor, the construction equipment would produce emissions and these emission sources would move along the corridor as work progresses. Local residents nearby to construction may notice a localized increase in dust (i.e., directly around the Project area) from construction activities; however, Pacific Connector would spray water on the right-of-way, and may use Dustlock®, in addition to water, for dust control. Pipeline construction crews would move quickly down the right-of-way in a linear fashion, and few locations would see sustained construction for significant lengths of time.

Pacific Connector estimated total pollutant emissions from the entire duration of construction activities, as detailed in table 4.12.1.4-1. Helicopters may be used during logging for right-of-way clearance; however, their use is uncertain and, due to the limited scope and duration of the activity, the associated emissions were not quantified.

[187] Areas designated as "Class I" include international parks and various national wilderness areas and parks above specified sizes.

TABLE 4.12.1.4-1

Estimated Emissions from Construction of the Klamath Compressor Station and Pacific Connector Pipeline (tons)

Source	CO	NO_x	SO_2	VOC	PM_{10}	$PM_{2.5}$	HAP	GHG (as CO_2e)
Compressor Station – Fugitive Dust on Unpaved Roads	0	0	0	0	4.67	0.47	0	0

Pipeline (Spread 4) – Construction Equipment Exhaust	9.10	23.56	1.52	2.79	2.82	2.73	2.34	9,082
Pipeline (Spread 5) – Construction Equipment Exhaust	8.06	20.11	1.33	2.50	2.46	2.39	2.09	8,003
Total	**54.78**	**139.17**	**9.13**	**17.14**	**324.26**	**180.95**	**14.24**	**54,688**

Emissions from construction equipment have been reduced over time as a result of the federal regulations for mobile engines and fuels, and measures would be taken by Pacific Connector to minimize fugitive dust. The predominant source of PM is fugitive dust (for which emissions estimation procedures have typically largely over-predicted emissions compared to what is seen in ambient measurements) (Watson and Chow 2000; Countess Environmental 2001). Pacific Connector would implement the following measures to mitigate the air emissions during pipeline construction:

Fugitive Dust Source Controls:

- Limit drop heights of soil excavation activities.
- Water the right-of-way, laydown areas, and temporary roads at least daily in areas of active construction, if necessary.
- Control project-related traffic speeds on dirt access roads and on linear facility rights-of-way.
- Ensure that speeds on the construction right-of-way would not exceed 15 mph where fugitive dust can be generated.
- Water gravel or dirt access roads in areas of heavy traffic, as determined necessary to control fugitive dust.
- Decrease speed limits when excessive winds prevail and where sensitive areas such as public roads may be adjacent to access roads or the right-of-way.
- Maintain speed limit signs for the duration of the construction activities and place them where access roads intersect the construction right-of-way.

- Water temporarily stockpiled soils to create a semi-hard protective layer to minimize wind erosion, if necessary.
- Ensure that wind erosion BMPs will be in place during forecasted high wind (greater than 25 mph) weather advisories (see the ECRP).

Mobile and Stationary Source Controls:

- Reduce use, trips, and unnecessary idling of heavy equipment.
- Maintain and tune engines per manufacturer's specifications to perform EPA certification levels, where applicable, and to perform at verified standards applicable to retrofit technologies. Employ periodic, unscheduled inspections to limit unnecessary idling and to ensure that construction equipment is properly maintained, tuned, and modified consistent with established specifications.
- Prohibit any tampering with engines and require continuing adherence to manufacturer's recommendations.
- Use construction equipment engines that incorporate modern pollution control technology. If practicable, lease new, clean equipment meeting the most stringent of applicable federal or state standards.

The impacts on ambient air quality from construction of the Klamath Compressor Station and Pacific Connector pipeline would vary with time due to the construction schedule, the mobility of the sources, and the variety of emission sources. Fugitive dust and other emissions due to construction activities generally do not pose a significant increase in regional pollutant levels; however, local pollutant levels would increase during the construction period. Based on the duration and scope of construction activities, we conclude that construction of the Project would impact local air quality. However, construction emissions would not have a long-term, permanent effect on air quality in areas adjacent to the construction corridor. In addition, emissions from pipeline construction would be distributed along the entire 229-mile-long construction corridor, greatly reducing localized impacts.

Operation Air Quality Impacts

Emissions of criteria pollutants from operation of the compressor station and pipeline are shown in table 4.12.1.4-2. Most of the emissions result from fuel combustion in the compressor station turbines, boiler, and standby generator. Fugitive emissions result from the normal leakage of small amounts of methane, VOC, and HAP compounds from valves, flanges, and other components in the compressor station piping, as well as meter stations or valve sites along the pipeline. Venting emissions result from infrequent process upsets and planned maintenance activities.

TABLE 4.12.1.4-2

Criteria Pollutant Emissions from Operation of Klamath Compressor Station and Pacific Connector Pipeline (tons per year)

Source	CO	NO_x	SO_2	VOC	PM_{10}	$PM_{2.5}$	HAPs	GHGs (as CO_2e)
Compressor Station Turbines a/	146.4	144.6	8.7	9.9	17.1	17.1	2.88	379,251
Compressor Station Fugitive Emissions	0	0	0	7.3	0	0	0.27	10,307
Boiler a/	2.7	1.6	0.02	0.18	0.25	0.25	0.06	3,912
Generator	0.6	0.3	0.00	0.2	0.01	0.00	0.04	88
Pipeline Fugitive and Venting Emissions	0	0	0	1.01	0	0	--	162
Total	**149.7**	**146.5**	**8.72**	**18.59**	**17.36**	**17.35**	**3.25**	**393,720**

a/ Based on maximum potential emissions for all three turbines and boiler operating continuously at their rated capacities, with the exception that turbine operation at temperatures below 0 degrees Fahrenheit is excluded. This value corresponds to the potential-to-emit (PTE) for the Project based on the permitted number of turbines.

Routine Operation: The following compressor station and pipeline sources are expected to operate continuously during routine operation:

- three combustion turbines for the compressor drives;
- one boiler;
- compressor station fugitive emission sources (condensate tank, valves, flanges, and other equipment); and
- pipeline fugitive emission sources (valves, flanges, and other equipment at three meter and regulator stations).

Intermittent Operation: The following sources or activities would only operate intermittently, during startup or shutdown events, planned maintenance, process upsets, readiness testing, or emergency situations:

- one standby generator engine; and
- periodic venting and blowdown events, estimated at three major blowdown events per year.

The compressor station would remain below PSD major source thresholds for emissions of all criteria pollutants, HAP, and GHG, but would be a Title V major source for emissions of NO_x and CO. Pacific Connector submitted a standard ACDP initial application to ODEQ in May 2015 and submitted a modification to its standard ACDP application in September 2017.

Potential emissions of HAP from the turbines, boiler, and generator are estimated to be just 1.3 TPY. Potential emissions of four pollutants at the Klamath Compressor Station (NO_x, CO, PM_{10}, and $PM_{2.5}$) exceed the Significant Emission Rate threshold at OAR 340-200-0020 and require a dispersion modeling analysis. Potential emissions of SO_2 are below the Significant Emission Rate, but modeling of SO_2 was also performed as requested by the FERC. A screening model (AERSCREEN) was used for all pollutants and averaging periods with the exception of 1-hour NO_2 and 24-hour $PM_{2.5}$, which were modeled twice, first with AERSCREEN and then with AERMOD. AERMOD is a more refined model that allows the use of hourly meteorological data and produces a less conservative result than AERSCREEN. Modeling results are presented in table 4.12.1.4-3. Pacific Connector filed an ACDP air permit application with ODEQ in 2015, and the modeling was performed in accordance with the modeling protocol that was approved by ODEQ at that time. ODEQ may request updates to that modeling protocol as part of the state air permitting process.

Based on the results of the screening analysis using AERSCREEN, and the refined AERMOD analysis for 1-hour NO_2 and 24-hour $PM_{2.5}$, we conclude that the Project would not have a significant impact on regional air quality.

TABLE 4.12.1.4-3

Screening-Level CO and NO_2 Impacts from Compressor Station Turbines

Air Pollutant	Averaging Period	Model	Maximum Impact	Background a/	Maximum Impact + Background	AAQS
NO_2 (µg/m³)	1-Hour	AERMOD	96.4 b/	10.0	106.4	188
	Annual	AERSCREEN	29.6 b/	2.1	31.7	100
CO (µg/m³)	1-Hour	AERSCREEN	433	993	1,426	40,000
	8-Hour	AERSCREEN	390	748	1,138	10,000
PM_{10} (µg/m³)	24-Hour	AERSCREEN	32	32	64	150
$PM_{2.5}$ (µg/m³)	24-Hour	AERMOD	4.2	17	21.2	35
	Annual	AERSCREEN	5.3	5.3	10.6	12
SO_2 (µg/m³)	1-Hour	AERSCREEN	26.5	1.3	27.8	196

a/ Background concentrations based on design values for 2009-2011 estimated using NW AIRQUEST.
b/ Based on an assumed in-stack NO_2 to NO_X ratio of 0.19.

4.12.1.5 Environmental Consequences on Federal Lands

A quantitative analysis of air quality impacts from potential stationary emissions sources at the Jordan Cove LNG Project (but not the marine vessels or other major sources that obtained permits since the baseline dates) was conducted for Class I areas within 200 kilometers (km) of the Project site. First, AERMOD was used to evaluate impacts at receptors placed at a radius of 50 km from the Project site (the farthest distance for which AERMOD is recommended for use). If modeled impacts at all of the 50 km receptors were below the significant impact level (SIL) for a given pollutant and averaging period, then it was presumed that impacts would also be below the SIL at each Class I area (ranging in distance from 110 to 178 km from the Project site).

However, if modeled impacts at 50 km were above a SIL, then further analysis was conducted to simulate what impacts would be at the nearest boundary of each Class I area. This simulation was performed by selecting the receptor along the 50-km radius that had the highest modeled concentration (i.e., impact) when averaged over five years, and then comparing that impact at 50 km to the five-year average impact at a receptor located just 1 km from the Project site, in the direction of the maximum-impact 50 km receptor. The results at the 1-km and 50-km receptors were then extrapolated (using an exponential decay function) to evaluate impacts at the distance of each Class I area.

The results of this analysis are shown in table 4.12.1.5-1 and indicate that impacts from the Jordan Cove LNG Project at all Class I areas would be well below the SILs.

TABLE 4.12.1.5-1

Maximum Impacts of Jordan Cove LNG Project at Class I Areas

Air Pollutant	Averaging Period	Maximum Impact at 50 km	Maximum Impact at Class I Area Boundary	Class I SIL a/
SO_2 (µg/m^3)	3-Hour	1.33	0.24	1.0
	24-Hour	0.35	0.023	0.2
	Annual	0.012	N/A	0.1
NO_2 (µg/m^3)	Annual	0.032	N/A	0.1
PM_{10} (µg/m^3)	24-Hour	0.854	0.061	0.3
	Annual	0.026	N/A	0.2
$PM_{2.5}$ (µg/m^3)	24-Hour	0.854	0.061	0.07
	Annual	0.026	N/A	0.06

a/ SILs are based on the first highest concentration at any one location.
µg/m^3 = microgram per cubic meter

In addition to the modeling analysis described above, a screening test was also performed for Air Quality Related Values (AQRV) at Class I areas. This screening test is used by federal land managers to determine whether a source more than 50 km from a Class I area is likely to have any adverse impact on an AQRV, such as visibility impairment. If the ratio of emissions in tons per year (Q) divided by the distance to a Class I area in km (D) is less than 10, then a source is considered not to cause or contribute to a visibility impairment. This screening calculation showed that the Q/D ratio for combined annual emissions of NO_x, SO_2, and PM from stationary sources at the Jordan Cove LNG Project was less than or equal to 10, indicating that no further Class I AQRV impact analyses are required.

Air pollution regulations treat other (Class II) federal lands in the same manner as non-federal Class II lands. The nearest federal lands in the vicinity of the Jordan Cove LNG Project include the ODNRA immediately north, and COE and BLM land on the North Spit. The pipeline route would cross various parcels of Class II areas administered by the BLM, Forest Service, and Reclamation. Dispersion modeling of terminal operations illustrated that impacts at the locations nearest the terminal would be less than the maximum Class II impacts identified above in section 4.12.1.3.

The closest Class I area to the Klamath Compressor Station is Lava Beds National Monument in California. This Class I area is approximately 37 km (about 23 miles) to the southwest of the compressor station site. A Class I AQRV screening analysis for potential impacts from compressor station operational emissions on Lava Beds National Monument shows that the Q/D ratio is much less than 10, indicating that no further Class AQRV impact analyses are required.

The pipeline route would pass closest to the Mountain Lakes Wilderness Class I area. The shortest distance between the Mountain Lakes Wilderness boundary and the pipeline is 4.5 miles (7.3 km), located at about MP 172.5. Pipeline construction spread 5 would operate between MPs 169.5 and 228.8, a total distance of 59.3 miles (95.4 km). Thus, emission sources for construction spread 5 would vary in distance from Mountain Lakes as the spread moves along the right-of-way. The potential air quality impact on Mountain Lakes would decrease as the distance between construction spread activity and Mountain Lakes increases (as the spread moves away from the closest point to Mountain Lakes). Pipeline construction would generally occur at a steady pace; therefore, it is reasonable to expect that these construction emissions for spread 5 would be evenly distributed throughout the spread 5 construction corridor (except for in areas where terrain or other factors slow the rate of construction). For the pollutants of highest concern, emissions expected per kilometer of pipeline route would only be 0.21 ton/km of NO_x, 0.01 ton/km of SO_2, and 1.56 ton/km of PM_{10}. Applying the Class I AQRV screening analysis mentioned above to these emissions again results in impacts far below the screening criteria.

Pacific Connector would consult with the federal land managers of Class I areas during the air permit process. For the Class II federal lands areas that are crossed by the pipeline, construction sources would have only a temporary impact on air quality and there are no operational sources of emissions located in those areas (i.e., the terminal and compressor station are not located on or near federal lands).

Terminal sources are distant from federal lands. The nearest Class I area is more than 100 km (about 62.1 miles) away, and a quantitative air quality impact analysis, as summarized in table 4.12.1.5-1, shows that impacts from the Jordan Cove LNG Project would not be significant on federal lands. About 71 miles of pipeline route would cross federal lands. Emissions associated with pipeline construction activities are very low; and these activities would be temporary and transient as crews move in a linear fashion along the right-of-way. Therefore, based on the analysis presented above, Pacific Connector's commitment to consult with federal land managers of Class I areas, and the temporary nature of construction emissions on Class II areas, we conclude that the Project would not adversely affect air quality on federal lands.

4.12.1.6 Conclusion

Constructing and operating the Project would result in sort and long-term impacts on air quality. However, based on the implementation of the required BMPs, the Project would not significantly affect air quality.

4.12.2 Noise and Vibration

Noise would affect the local environment during both the construction and operation of the Project. At any location, both the magnitude and frequency of environmental noise may vary considerably over the course of the day and throughout the week. For construction activities, this variation in noise levels is caused primarily by changes in equipment operations and activity locations. For operational noise conditions, this variation is caused in part by variations in operational activities, changing weather conditions, and the effects of seasonal vegetative cover. In this section of the EIS, analysis of potential noise impacts on human receptors are discussed, while noise impacts on wildlife are addressed in sections 4.5 and 4.6.

Noise can be measured and quantified using many different metrics. Some of the most commonly used metrics used by federal agencies and presented in subsequent sections of this EIS are the equivalent sound level (L_{eq}), day-night sound level (L_{dn}), and the maximum sound level (L_{max}). Conventionally expressed in dBA, the L_{eq} is the energy-averaged, A-weighted sound level for the complete time period. It is defined as the steady, continuous sound level over a specified time, which has the same total sound energy as the actual varying sound levels over the specified period. The L_{dn} measures the 24-hour average noise level at a given location. It was adopted by the EPA for developing criteria for the evaluation of community noise exposure and also by the FERC when assessing noise. The L_{dn} is calculated by averaging the 24-hour hourly L_{eq} levels at a given location after adding 10 dB to the nighttime period (10:00 p.m. to 7:00 a.m.) to account for the increased sensitivity of people to noises that occur at night. The L_{max} sound level can be used to quantify the maximum instantaneous sound pressure level over a given measurement period or maximum sound generated by a source. The human ear's threshold of perception for noise change is considered to be 3 dBA; 6 dBA is clearly noticeable to the human ear, and 10 dBA is perceived as a doubling of noise (Bies and Hansen 1988).

4.12.2.1 Regulatory Requirements for Noise

Federal Noise and Vibration Criteria

In 1974, the EPA published *Information on Levels of Environmental Noise Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety* (EPA 1974). This publication evaluates the effects of environmental noise with respect to health and safety. The document provides information for state and local governments to use in developing their own ambient noise standards. The EPA has determined that in order to protect the public from activity interference and annoyance outdoors in residential areas, noise levels should not exceed an L_{dn} of 55 dBA. The FERC has adopted this criterion for new compression and associated pipeline facilities, and it is used here to evaluate noise emissions from operation of the Project. An L_{dn} of 55 dBA is equivalent to a continuous noise level of 48.6 dBA L_{eq} for facilities that operate at a constant level of noise. Therefore, a constant sound level of less than 48.6 dBA L_{eq} would ensure compliance with the FERC requirement limiting the L_{dn} at the nearest NSAs to less than or equal to 55 dBA.

The Commission has regulations in 18 CFR 380.12k(4)(v)(B) that state that any new or modified facility may not result in an increase in perceived vibration. In addition, the American National Standards Institute (ANSI) published ANSI S12.2-2008 that identifies criteria for sound pressure levels that should not be exceeded to avoid moderately perceptible vibration and rattle inside a room. These criteria are 65 dB and 70 dB in the 31.5 hertz (Hz) and 63 Hz octave bands, respectively, and are used to assess vibration levels.

State Noise and Vibration Standards

The State of Oregon has established statewide noise limits for industrial and commercial noise sources (OAR, Chapter 340, Division 35). No statewide vibration limits have been established. The specified noise limits apply to either the property line location closest to the noise source or to locations 25 feet toward the noise source from the noise-sensitive building, whichever distance from the noise source is greater. Noise-sensitive property includes residences and other facilities normally used for sleeping, schools, churches, hospitals, and public libraries. The primary noise limits set by the Oregon regulations are based on the statistical distribution of varying noise levels during daytime and nighttime hours. Noise limits are specified in terms of three percentile levels: L_{50}, the noise level exceeded 50 percent of the time; L_{10}, the noise level exceeded 10 percent of the time, and L_{01}, the noise level exceeded 1 percent of the time. In addition to noise limits for noise-sensitive properties, Oregon noise regulations establish additional noise limits for industrial and commercial noise sources in or near designated quiet areas. Quiet areas are defined as land or facilities where the qualities of serenity, tranquility, and quiet are of extraordinary importance and serve a public need. The State of Oregon has not designated any quiet areas, but some local noise ordinances have done so (Beyer 2007). Noise limits established by the Oregon noise control regulations are summarized in table 4.12.2.1-1.

TABLE 4.12.2.1-1

Oregon Noise Limits For Industrial and Commercial Noise Sources

Percentile Noise Level In Any One Hour	**Noise-Sensitive Properties Located Outside Designated Quiet Areas**		**Within Designated Quiet Areas at a Point 400 Feet or More from the Noise Source**	
	7 a.m. – 10 p.m.	**10 p.m. – 7 a.m.**	**7 a.m. – 10 p.m.**	**10 p.m. – 7 a.m.**
L_{50}	55 dBA	50 dBA	50 dBA	45 dBA
L_{10}	60 dBA	55 dBA	55 dBA	50 dBA
L_{01}	75 dBA	60 dBA	60 dBA	55 dBA

Notes: The noise limits in this table do not apply to noise from construction sites, agricultural or forestry operations, vehicle traffic, rail traffic, aircraft operations, and various other exempt sources.
Source: OAR 340-035-0035(1)(a), 340-035-0035(1)(b), and 340-035-0035(1)(c).

In addition to the overall dBA limits summarized in table 4.12.2.1-1, the Oregon noise regulations establish additional limits for discrete tones from industrial and commercial noise sources. These octave band noise limits are summarized in table 4.12.2.1-2.

TABLE 4.12.2.1-2

Octave Band Noise Limits For Industrial and Commercial Noise Sources

Center Frequency of Octave Band (Hertz)	**Median Sound Pressure Level Limit a/**	
	7 a.m. – 10 p.m.	**10 p.m. – 7 a.m.**
31.5 Hz	68 dB	65 dB
63 Hz	65 dB	62 dB
125 Hz	61 dB	56 dB
250 Hz	55 dB	50 dB
500Hz	52 dB	46 dB
1,000 Hz	49 dB	43 dB
2,000 Hz	46 dB	40 dB
4,000 Hz	43 dB	37 dB
8,000 Hz	40 dB	34 dB

a/ The noise limits in this table do not apply to noise from construction sites, agricultural or forestry operations, vehicle traffic, rail traffic, aircraft operations, and various other exempt sources.
The noise limits in this table apply to either the property line location closest to the noise source or to locations 25 feet toward the noise source from the noise-sensitive building, whichever distance from the noise source is greater.
If noise levels for any 1/3 octave band exceeds the encompassing octave band limit by more than 10 dB, additional limitations may apply.
Source: OAR 340-035-0035(1)(f).

Oregon noise regulations also establish a numerical noise level increase standard for new industrial or commercial noise sources located on a previously unused site. The regulations limit the increase in hourly L_{10} and L_{50} noise levels as measured at noise-sensitive properties to 10 dBA above the ambient background L_{10} and L_{50} noise levels (OAR 340-035-0035(1)(b)(B)(i)). The 10 dBA operational noise increment standard does not apply to noise from construction activities, agricultural or forestry operations, vehicle traffic, rail traffic, aircraft operations, or various other exempt sources.

Local Noise Standards

The City of North Bend has a noise ordinance that prohibits the making of "unnecessary noise," but the ordinance does not establish specific numerical noise limits (North Bend City Code, Section 9.04.030). Daytime construction activity between the hours of 7 a.m. and 6 p.m. is exempt from the City of North Bend noise ordinance. The counties of Coos, Douglas, and Jackson, Oregon, do not have local noise ordinances. Klamath County cites compliance to occur when federal and/or state noise regulations are met (Klamath County 2010, Policy 5).

Underwater Noise Criteria

Potential underwater noise impacts on marine mammals and fish were also evaluated as part of the Project assessment. Applicable criteria are prescribed by NMFS and are provided in section 4.5.2.

Noise Levels

Existing noise levels are variable depending on location relative to the Project. Therefore, the existing sound environment is broken down by the Project area near the Jordan Cove LNG Project and areas near the Pacific Connector pipeline.

4.12.2.2 Existing Conditions

Jordan Cove LNG Project

The major existing anthropogenic noise sources in the vicinity of the Jordan Cove LNG Project include vehicle traffic on the Trans-Pacific Parkway and U.S. Highway 101, RV use in the ODNRA, and boat traffic on Coos Bay. Aircraft operations at the Southwest Oregon Regional Airport in North Bend are an additional intermittent anthropogenic noise source. Wind, birds, and insects contribute to natural background noise levels. There are no noise sensitive areas (NSAs) within 1 mile of the LNG terminal site.

Jordan Cove has conducted several baseline sound surveys in the vicinity of the Project including one in 2005, 2013 and one most recently in 2017 which collected data for approximately 30 minutes per measurement. All NSAs and distances to the LNG terminal are shown in figure M-1 in appendix M and are described below. The purple shaded area identifies the overall Project area. However, the Project facilities and majority of construction activities would occur in the western portion of the Project area. Noise generated from the eastern portions of the Project area would be minimal. The overall facility site plan is shown in figures 2.1-1 and 2.1-3 located in chapter 2.

- NSA 1 consists of single-family residences in a subdivision consisting of approximately 180 single-family residences located about 1.3 miles south of the LNG terminal noise-producing equipment in the city of North Bend along the south side of the bay adjacent to the airport. The subdivision is bordered on the north by Colorado Avenue and on the west by Arthur Street.
- NSA 2 is a group of approximately 50 single-family residences, located approximately 2.2 miles east on Russell Point. Noise levels at this location are influenced by highway traffic located along the Oregon Coast Highway.
- NSA 3 is the Horsfall campground, the closest campground to the Jordan Cove LNG Project, located approximately 1.2 miles northeast of the LNG terminal noise producing equipment.
- REC 1 is the recreation area located to the west and northwest of the LNG terminal noise-producing equipment. The recreation area does not incorporate campground facilities.

Jordan Cove monitored the ambient noise levels at those NSAs over a period of greater than 24 hours; the results are presented in table 4.12.2.2-1.

TABLE 4.12.2.2-1

Ambient Noise Levels for the Jordan Cove LNG Terminal Measured at Nearby NSAs a/

Receptor	Distance from LNG Terminal to Receptor (miles)	Direction	Daytime L_{eq}, dBA	Nighttime L_{eq}, dBA	Ambient L_{dn}, dBA b/
NSA 1	1.3	South	52	44	53
NSA 2	2.2	East	63	58	65
NSA 3	1.3	Northeast	58	40	56
REC 1	0.7	West	51	48	55

a/ Data collected during the 2017 sound survey
b/ The L_{dn} is calculated by averaging the actual daytime noise levels with the nighttime levels plus 10 dBA.

Ambient underwater sound levels were also considered. Ambient underwater noise levels range from about 74 dB to 100 dB re 1 µPa in the open ocean with no ship traffic nearby, to about 115 dB to 135 dB re 1 µPa in large marine inlets with some recreational boat traffic (CaDOT 2009). Since Coos Bay is fairly active with existing shipping traffic, ambient underwater noise levels are expected to correspond to the latter range in the presence of shipping but may be lower at times corresponding to reduced boat traffic activity.

Pacific Connector Pipeline Project

For the Pacific Connector pipeline, ambient sound level data were collected in the vicinity of the proposed Klamath Compressor Station in 2012. Background sound levels obtained in the 2012 survey are appropriate for continued use in this analysis because there have been no changes to the surrounding land uses and no development that would increase background noise levels since the 2012 survey. The GTN and Ruby meter facilities, farm animals and equipment, traffic on local roads, and an occasional aircraft overhead are the existing noise sources that were captured in the background noise monitoring study. All NSAs and distances to the LNG terminal are shown on figure M-6 in appendix M and are described as follows:

- NSA 1: 34545 Malin Loop Road (Subsequent to the 2012 noise survey, PCGP purchased this property);
- NSA 2: 33909 Malin Loop Road (Subsequent to the 2012 noise survey, PCGP purchased this property);
- NSA 3: 20933 Morelock Road;
- NSA 4: 33535 Malin Loop Road;
- NSA 5: 33770 Malin Loop Road;
- NSA 6: 34631 Malin Loop Road; and
- NSA 7: possible new home 1,230 feet north of station location.

Pacific Connector monitored the ambient noise levels at those NSAs over a period of greater than 24 hours, and the results are presented in table 4.12.2.2-2.

TABLE 4.12.2.2-2

4.12.2.3 Jordan Cove LNG Project Impacts

Construction Noise Impacts

Construction of the Jordan Cove LNG Project would occur over a period of about four years. Major components would include berth facilities, buildings, LNG storage tanks, and mechanical/electrical equipment. Noise associated with construction activities would be intermittent because equipment is operated on an as-needed basis and mostly during daylight hours. During the site grading and filling operations, the equipment may be operated on two 10-hour shifts, 6 days per week, with the potential to increase to a 24/7 schedule if required. Construction would not result in generation of, or exposure of persons to, excessive noise or vibration levels. No blasting is anticipated to be required for construction as the entire site area consists of sand.

The most prevalent sound source during construction is anticipated to be the internal combustion engines used to provide mobility and operating power to construction equipment. The sound level at NSAs from construction operations would depend on the type of equipment used, the mode of operation of the equipment, the length of time the equipment is in use, the number of equipment used simultaneously, and the distance between the sound source and sensitive site. These factors would be constantly changing throughout the construction period, making it difficult to calculate an L_{dn} or L_{eq} sound level at any given location. However, construction noise was estimated using the Federal Highway Administration’s Roadway Construction Noise Model. Table M-1 in appendix M shows a schedule of the equipment expected to potentially be in simultaneous operation, along with the maximum sound level, L_{max}, at 50 feet, the usage percentage, and the expected L_{eq} at 50 feet considering the usage percentage. Noise levels from the construction equipment are expected to range from 71 dBA L_{eq} to 81 dBA L_{eq} at 50 feet.

Noise modeling was conducted with the commercially available computer-aided noise abatement (CadnaA) noise prediction model. The software is standards based, and the International Organization for Standardization (ISO) 9613 Part 2 standard was used for air absorption and other noise propagation calculations. Standard atmospheric conditions were selected and all receptor locations were modeled with all sound sources assumed to be in operation simultaneously. The ground absorption coefficient for all water surfaces was set to highly acoustically reflective with the remaining surfaces set to partially acoustically absorptive.

Table 4.12.2.3-1 presents the predicted daytime and nighttime sound levels at NSAs associated with general construction activities based on planned equipment usage for the currently planned equipment allocation for each year of construction. Figure M-2 in appendix M also visually displays the sound generated during general construction activities throughout the Project area in the form of color-coded sound contours.

TABLE 4.12.2.3-1

Predicted Construction Noise Levels at NSAs (dBA)

Receptor	Ambient L_{dn}	Construction Noise Level, Daytime, L_d	Construction Noise Level, Nighttime, L_n	Construction Noise Level, L_{dn}	Future Combined Level, L_{dn}	Increase over Ambient, L_{dn}
NSA 1	53	49	44	52	56	3
NSA 2	65	39	34	41	65	<1
NSA 3	56	42	37	45	57	<1
REC 1	55	49	44	52	57	2

The loudest construction activity would be installation of the LNG carrier berth sheet pile wall and installation of the piles associated with the marine slip docks. Up to 14 concurrent diesel impact pile hammers would be used during construction of the facility to drive approximately 3,600 pipe piles in the plant facility area. Up to six vibratory hammers would be in use to install the sheet piles. The pipe pile diameters would range from 24 to 72 inches, and the maximum sound pressure level data were analyzed. Vibratory pile drivers were modeled using an L_{max} level of 101 dBA at a distance of 50 feet having applied a usage factor of 20 percent.

Table 4.12.2.3-2 presents the predicted sound levels associated with pile driving activities at NSAs having accounted for equipment operating during daytime or nighttime periods and accounting for two daytime and nighttime hours during which there are no planned pile-driving activities due to the crew shift change. Additionally, table 4.12.2.3-2 provides the predicted L_{max} values of pile driving activities. The L_{dn} is a useful metric when evaluating continuous noise sources; however, for impulsive sound sources, L_{max} better represents the sound impacts of short and intense noise sources. Figure M-3 in appendix M also visually displays the sound generated during pile driving throughout the Project area in the form of color-coded sound contours.

TABLE 4.12.2.3-2

Predicted Pile Driving Noise Levels at NSAs (dBA)

Receptor	Ambient L_{dn}	Pile Driving Noise Level, Daytime, L_d	Pile Driving Noise Level, Nighttime, L_n	Pile Driving Noise Level, L_{dn}	Future Combined Level, L_{dn}	Increase over Ambient, L_{dn}	Predicted Maximum Level, L_{max}
NSA 1	53	54	53	60	61	8	65
NSA 2	65	39	38	45	65	<1	55
NSA 3	56	42	42	48	57	1	60
REC 1	55	51	51	57	59	4	69

Based on the noise levels provided in table 4.12.2.3-2, it is predicted that pile-driving operations could result in an increase greater than 3 dB L_{dn} on the ambient noise level at two NSAs. Additionally, using the L_{max} values, pile-driving activities would result in noise impacts at all NSAs at or greater than our noise criterion of 48.6 dBA L_{eq}[188]. Pile-driving operations are

[188] note that a L_{dn} of 55 dBA is equivalent to a continuous noise level of 48.6 dBA L_{eq} for facilities that operate at a constant level of noise

currently proposed to occur 20 hours a day for construction of the Jordan Cove LNG Project for 2 years. Based on the large number of residents who live across Coos Bay on the south and the east, the impulsive (short, intense) noise impacts associated with pile-driving activities, the predicted and perceptible noise impacts on nearby NSAs, the duration of pile-driving activities, as well as the lack of noise mitigation measures proposed by Jordan Cove, **we recommend that:**

- **<u>Following the start of pile-driving activities</u>, Jordan Cove should monitor daytime pile-driving and file <u>weekly</u> noise data reports with the Secretary that identify the noise impact on the nearest NSAs. If any measured daytime noise impacts (L_{max}) at the nearest NSAs are greater than 10 dBA over the L_{eq} ambient levels, Jordan Cove should:**

  a. cease pile-driving activities and implement noise mitigation measures; and

  b. file with the Secretary evidence of noise mitigation installation and request written notification from the Director of OEP that pile driving may resume.

Given the proximity of residences to construction and the predicted noise levels associated with pile driving, we conclude that pile-driving activities, without further noise mitigation, should be concluded within reasonable working hours. Therefore, **we recommend that**:

- **Jordan Cove should conduct all pile-driving activities only between the hours of 7 a.m. and 7 p.m. <u>throughout the duration of construction</u>.**

Dredging would also take place during the first three years of the Project. Dredging is anticipated to occur on a 24-hour basis during construction, and its sound level is estimated to be 59 dBA at a distance of 500 feet. Open water dredging activities would occur in five separate work areas, with four work areas along the Federal Navigation Channel and one in the slip area of the Project. Sound was conservatively modeled assuming dredging would take place concurrently at each of the five separate work areas, with all equipment operating simultaneously. Table 4.12.2.3-3 presents the predicted sound levels at NSAs associated with dredging activities. An additional NSA, labeled NSA D1, was included in the dredging evaluation because it is the closest residential area to the Federal Navigation Channel dredging area. Figure M-4 in appendix M visually displays the sound generated during dredging throughout the Project area in the form of color-coded sound contours.

TABLE 4.12.2.3-3

Predicted Dredging Noise Levels at NSAs (dBA)

Receptor	Ambient L_{dn}	Predicted Sound Level, L_{eq}	Predicted Sound Level, L_{dn}	Future Combined Level, L_{dn}	Increase over Ambient, L_{dn}
NSA 1	53	36	42	53	<1
NSA 2	65	25	31	65	<1
NSA 3	56	22	28	56	<1
REC 1	55	28	34	55	<1
NSA D1 a/	53	45	51	55	2

a/ Ambient sound levels at NSA D1 are assumed to be the same as at NSA 1, a residence in the same neighborhood, and the same distance from the bay and ocean as NSA D1

Noise from a cutter suction dredge varies with the capacity of the dredger and the type of material being dredged. A smaller dredge with an anticipated sound power level of 157 dB would be used for the Project; however, a larger dredger was also considered to assess worst-case noise impacts. Noise associated with dredging is largely related to ship traffic. It is not anticipated that dredging noise would cause more severe effects on marine mammals or fish than behavioral disturbance (see section 4.5). The noise from dredging and vessel movements would be similar to existing noise levels due to existing dredging and vessel activity in the Coos Bay channel.

Operational Noise Impacts

Operational noise associated with the Jordan Cove Project was modeled using noise prediction software (CadnaA version 2017) in accordance with ISO 9613. The following major noise-producing equipment would normally be in operation at the Jordan Cove LNG Project and were included in the acoustic modeling analysis:

- Five refrigerant compressors, combustion turbines, heat recovery steam generators, and associated piping;
- Refrigerant compressor interstage and discharge aerial coolers;
- Three steam turbines and their associated air-cooled condensers;
- Two BOG compressors with interstage and discharge aerial coolers; and
- Various other smaller condensers, coolers, pumps and valves.

The model simulates the outdoor propagation of sound from each noise source and accounted for sound wave divergence, atmospheric and ground absorption, sound directivity, and shielding due to interceding barriers and terrain. A database was developed that specified the location, octave-band sound levels, and sound directivity of each noise source. The model calculates the A-weighted sound pressure levels from the Project at the NSA locations. Noise modeling was based on normal operation, which excludes intermittent activities such as start-up, shut down, and any other abnormal or upset operating conditions.

To assess compliance relative to the OAR anti-degradation standard, the increase in sound level was assessed relative to the measured nighttime 1-hour L_{eq}, which is used by Jordan Cove as a surrogate to the L_{50}. The results of the analysis (table 4.12.2.3-4) indicate that the predicted NSA sound levels are below the 55 dBA L_{dn} FERC noise criterion. In addition, the Project demonstrates compliance with the OAR anti-degradation standard as there are no expected increases greater than 10 dBA relative to the measured nighttime 1-hour L_{eq}/L_{50} sound level.

TABLE 4.12.2.3-4

Predicted Project Noise Emissions at NSAs compared to Regulatory Limits for Jordan Cove LNG Project (dBA)

Receptor	Predicted Project Sound Level (L_{eq})	2017 Nighttime Measured 1-hour L_{eq}/L_{50}	Increase Over Existing Ambient	Predicted Project Sound Level (L_{dn})	Existing Ambient L_{dn}	Future Level (Project + Ambient)	Increase Over Existing Ambient
NSA 1	45	44	1	51	53	55	2
NSA 2	37	58	0	43	65	65	<1
NSA 3	43	40	3	49	56	57	1
REC 1	49	48	1	55	55	58	3

As currently designed, Jordan Cove would not install additional noise mitigation measures such as acoustical enclosures, acoustical barriers, or custom silencers beyond mitigation inherent to the specified equipment analyzed.

As far as ground-borne and low frequency air-borne vibration, facility equipment is designed and balanced to minimize extraneous vibration to preserve and extend the service life of the equipment. Ground-borne and low-frequency airborne vibration resulting from the Jordan Cove LNG Project equipment is not expected at the NSAs.

In terms of environmental noise, an increase to the ambient sound level of 3 dB is generally considered barely detectable by the human ear. The expected increases in L_{dn} noise levels at the nearest NSAs due to normal operation are less than 3 dB; however, to ensure that the noise from operation of the Jordan Cove LNG Project would not be significant, **we recommend that:**

- **Jordan Cove should file a full power load noise survey with the Secretary for the LNG terminal <u>no later than 60 days after</u> each liquefaction train is placed into service. If the noise attributable to operation of the equipment at the LNG terminal exceeds an L_{dn} of 55 dBA at the nearest NSA, <u>within 60 days</u> Jordan Cove should modify operation of the liquefaction facilities or install additional noise controls until a noise level below an L_{dn} of 55 dBA at the NSA is achieved. Jordan Cove should confirm compliance with the above requirement by filing a second noise survey with the Secretary <u>no later than 60 days</u> after it installs the additional noise controls.**

- **Jordan Cove should file a full power load noise survey with the Secretary <u>no later than 60 days after placing the entire LNG terminal into service</u>. If a full load noise survey is not possible, Jordan Cove should file an interim survey at the maximum possible horsepower load <u>within 60 days</u> of placing the LNG terminal into service and file the full operational surveys <u>within 6 months</u>. If the noise attributable to the operation of all the equipment of the LNG terminal exceeds 55 dBA L_{dn} at any nearby NSAs, under interim or full load conditions, Jordan Cove should file a report on what changes are needed and install additional noise controls to meet the level <u>within 1 year</u> of the in-service date. Jordan Cove should confirm compliance with this requirement by filing a second full power noise survey with the Secretary <u>no later than 60 days</u> after it installs the additional noise controls.**

Flaring would generate noise; however, since it would occur very infrequently, it is not considered part of typical operations. Cold process flaring is expected to occur five times a year and last for approximately 30 minutes, and warm process flaring is expected to take place once every three years and last for approximately two hours. The marine flare is expected to be used four times a year and could last approximately 14 hours per event.

Noise associated with flaring was modeled using measurement data from another similar flare and/or engineering references, as appropriate. Table 4.12.2.3-5 presents the predicted sound levels at NSAs associated with flaring. Since flaring lasts for fewer than 24 hours, the predictions were adjusted to reflect actual operation time. Compliance with the FERC noise criterion and State of Oregon noise requirements was successfully demonstrated for all flaring scenarios. Figure M-5 in appendix M also visually displays the sound generated during flaring throughout the Project area in the form of color-coded sound contours. Though process and marine flaring are not expected to take place simultaneously, they were also modeled together to be conservative. As shown in table 4.12.2.3-5, process flaring is substantially louder than marine flaring and therefore dominates the combined case, with process flaring as the only even with an increase over ambient levels being greater than 1 L_{dn}.

TABLE 4.12.2.3-5

REC 1	47	38	48	<1	44	55	53	1

During operation of the Jordan Cove LNG Project, the primary underwater sound sources would consist of LNG ships and tug boats. The Jordan Cove LNG Project would add about 110-120 LNG carriers on an annual basis to the existing 50 deep draft vessels per year operating in the area.

Noise from large vessels can range up to 188 dB re 1 µPa at 1 meter. Noise from vessels varies depending on size, power, propulsion system loading, and vessel speed. Typical transit speed for vessels within Coos Bay navigation channel is 7 knots. JASCO Research (2006) states that broadband noise from LNG carriers at half speed is expected to be around 175 re 1 µPa at 1 meter. Noise from tug boats is less speed dependent and, in fact, tugs under load can be noisier than larger vessels.

In accordance with the NMFS (2016) technical guidance, a cumulative assessment was conducted for vessel-related noise. The results showed that the noise from transiting vessels and tugs does not represent a potential risk of PTS to any of the identified marine mammal species. When tugs are operating semi-stationary under full power near the facility, individual harbor porpoises would need to remain within about 1 mile of the tug for 1 hour for there to be a potential for PTS. Killer whales would need to remain within about 100 feet of the tug for 1 hour for there to be potential for PTS.

4.12.2.4 Pacific Connector Pipeline Project Impacts

Construction Noise Impacts

Construction activities at the Klamath Compressor Station are expected to last between 12 and 18 months and would involve clearing and grading, placement of fill, excavation for foundations for the compressor unit packages, other equipment settings, ancillary equipment, associated unit housing, piping, and structures. Table M-2 in appendix M presents typical noise emission levels at various distances for the noise producing equipment that would be operating during the construction of the station.

Construction of the Klamath Compressor Station would cause temporary increases in ambient noise levels in the immediate vicinity of the construction site. Pacific Connector's standard construction operating hours are 7:00 a.m. to 7:00 p.m., Monday through Saturday. OAR 340-035-0035(5)(g) provides an exemption for construction noise from compliance with noise standards.

During construction of the Pacific Connector pipeline, construction noise would be audible to NSAs near the construction right-of-way. Some of the land crossed by the pipeline is categorized for residential, commercial, or industrial use. Over 100 structures are within 150 feet of the pipeline right-of-way or TEWAs, and several residences are within 50 feet of the pipeline construction right-of-way or TEWAs. See section 4.7 of this EIS for more information on land use. Due to the assembly-line nature of pipeline construction, activities in any area could occur intermittently over a period lasting from several weeks to a few months.

Construction equipment would be operated on an as-needed basis. Phase 6 includes rock blasting and represents the highest sound levels associated with pipeline construction. A blasting plan has been prepared within the POD that details mitigation measures for blasting activities. For this phase, sound levels at 50 feet are predicted to be 95 dBA L_{eq} and would attenuate to 87 dBA L_{eq} and 74 dBA L_{eq} at 100 feet and 300 feet, respectively. Noise would diminish rapidly as the distance from the noise source increases.

Access roads would be used by construction equipment to reach the right-of-way. There may be areas where access roads are limited in width, grade, or availability. Helicopters may be used during logging for right-of-way clearance. Helicopters that may be used for the Project are assumed to be at most 115 dBA at 50 feet (Michael Minor & Associates 2008), 112 dBA at 100 feet, and 98 dBA at 300 feet. The primary sources of wideband acoustic energy from helicopters are the main and tail rotor. Helicopters generally fly at low altitudes; therefore, potential temporary increases to ambient sound levels would occur in the area where helicopters are operating as well as along their flight path.

In addition to temporary disturbance near residences or other noise-sensitive land uses, construction noise would have localized but temporary effects on wildlife. In general, temporary noise from construction activities would result in some wildlife movements away from the pipeline corridor. See additional discussion of potential pipeline construction noise effects on wildlife in sections 4.5 and 4.6 of this EIS.

The majority of pipeline construction would occur during daytime hours only, with the exception of HDD operations. Other activities often conducted at night include operation of pumps at dry-ditch waterbody crossings; hydrostatic testing; and tie-ins. Pacific Connector may opt to perform these additional construction activities at night. The following mitigation measures would be implemented, as necessary, during construction of the pipeline and/or the Klamath Compressor Station:

- ensure that all equipment has sound control devices no less effective than those provided by the manufacturer;
- ensure that equipment would have muffled exhausts; and
- to the extent feasible, the construction site would be configured in a manner that keeps noisier equipment and activities as far as possible from noise sensitive locations.

If necessary, for greater noise reduction, moveable paneled noise shields, barriers, or enclosures adjacent to or around noisy equipment would be installed where required to meet applicable Project noise limits. If properly installed, temporary barriers can result in a noise reduction of up to 10 dBA at the receptor.

Horizontal Directional Drilling and Direct Pipe Crossings

Pacific Connector proposes to use HDD technology to cross under six waterbodies and a powerline/steep slope location at six sites. Some portions of HDD operations would occur as 12-hour work shifts, while other activities would normally occur as 24-hour-per-day operations. The overall duration of HDD operations is site-specific and would be determined by the drilling contractor. HDD operations are expected to last up to 4 weeks at each site.

The equipment would consist of an HDD drilling rig and auxiliary support equipment including electric mud pumps, a crane, mud mixing and cleaning equipment, and a shale shaker. Most significant noise sources would be at the entry and noise levels from the exit locations would be less than the entry noise levels. Table M-4 in appendix M provides sound power level data for the proposed HDD equipment by octave band.

Using a methodology consistent with ambient data collection for other portions of the Project, a measurement survey was conducted near each HDD crossing. The results of that survey are presented in table 4.12.2.4-1.

TABLE 4.12.2.4-1

Ambient Noise Levels for the Pacific Connector HDD Sites Measured at Nearby NSAs

Klamath River	NSA #1	62	46	61
	NSA #2	57	47	57
	NSA #3	53	43	53

Sound levels at the NSAs due to HDD construction were modeled assuming two scenarios: no noise mitigation and with noise mitigation, if necessary. The noise mitigation options considered were a barrier wall and two types of acoustic tents. The 20-foot-high barrier wall would wrap around the entire HDD site. The tents include a vinyl acoustic tent installed over the entire drilling site. The tent would be approximately 190 feet long by 90 feet wide by 35 feet high and would contain all equipment on the site and an additional special fabric acoustic tent installed over the entire drilling site. Table 4.12.2.4-2 shows the existing ambient sound level, expected drilling noise including mitigation (if necessary), future combined sound level and net increase in sound level above ambient, presented in terms of L_{eq} sound levels. In most cases, the HDD noise produced adheres to the FERC noise criterion of 55 dBA L_{dn} (or 48.6 dBA L_{eq}); however, there are a few instances where exceedances are predicted at the Coos Bay West and East crossings. At the Coos Bay West crossing, NSA#1 is expected to experience received sound levels above 48.6 dBA L_{eq}; however, during daytime hours, existing ambient sound levels are such that the increase in sound level due to HDD would be negligible. During nighttime hours, HDD activity would result in a net increase in sound level of approximately 7 dBA above nighttime ambient sound levels. At the Coos Bay East crossing, NSA #2 would experience an exceedance of the FERC noise criterion during nighttime hours and HDD activity would result in a net increase in sound level of approximately 7 dBA above nighttime ambient sound levels. We conclude that the noise from the HDD operations, especially during nighttime operations, should be mitigated. Therefore, **we recommend that:**

- **Prior to drilling activities at HDD sites, Pacific Connector should file a site-specific nighttime noise mitigation plan with the Secretary for review and written approval by the Director of OEP. During any drilling operations, Pacific Connector should implement the approved plan, monitor noise levels, and file in its biweekly reports documentation that the noise levels attributable to the drilling operations at NSAs does not exceed 55 L_{dn} dBA.**

Figures M-7 through M-13 in appendix M depict the HDD locations, predicted sound levels for HDD activity, and the location of the nearest NSAs.

TABLE 4.12.2.4-2

Summary of HDD Acoustic Modeling Results

Crossing	NSA	Distance (ft) / Direction from HDD a/	Ambient Sound Level L_{dn}, dBA	HDD Noise, L_{dn}, dBA	Future Combined Sound Level, L_{dn}, dBA	Net Increase, dBA

a/ Distances and direction were estimated from the figures in appendix M.
b/ NSA was not shown in the figures. It is assumed that these NSA's are at a greater distance from the HDD than the NSA shown on the figure.

Exhibit 27
Page 970 of 1120

The DP method is another trenchless construction methods that would be used to cross some waterbodies by Pacific Connector (see section 2), which is similar to HDD but is also combined with the process of microtunneling. Compared to HDD, a much larger cutterhead is used, eliminating the reaming process. Excavation and hole boring are performed with a microtunneling machine and cutterhead. Generally, completing a DP crossing takes less time than an HDD crossing and is considered less noisy since the majority of equipment is located at the crossing entry point, as opposed to both entry and exit points. Therefore, it is expected that the assessment of potential noise impacts using HDD technology is a conservative approach in comparison to use of the DP method.

Operational Noise Impacts

Compressor Station Operation

Operational noise associated with the Klamath Compressor Station was evaluated using manufacturers' noise emission data for the anticipated compressors, associated noise producing equipment, and typical noise control applications. The Klamath Compressor Station detailed design has not been completed; therefore, estimates of compressor station operational noise levels are based on best available information. Primary noise sources from equipment at the compressor station, along with corresponding estimated noise emission data and noise control equipment reduction values, were derived from measurements of similar equipment at other similar facilities (see table M-5 in appendix M).

Operational noise levels for the Klamath Compressor Station were estimated using CadnaA, as previously discussed, and noise prediction techniques consistent with ISO 9613 for sound propagation outdoor. These techniques take into account the noise generation of individual equipment items, shielding by buildings and barriers, spreading losses, ground and atmospheric effects, and reflections from surfaces. The modeling conservatively predicted the noise contribution during the operation of all three compressor units operating under full load conditions. The modeling included effects of the hillside excavated to form a partial noise barrier to the east.

During development of the detailed design, best practices applicable to noise reduction would be incorporated. Best design practices routinely incorporated in gas turbine stations are low noise air intakes; exhaust silencers; blow down silencers; gas cooler fans; and sound insulated buildings, housings, and piping. In rare cases, if necessary for compliance with noise limits, noise barriers may be installed. Insertion loss values of the noise mitigation measures incorporated into the acoustic modeling analysis are presented in table M-6 in appendix M.

The results of the operational acoustic modeling analysis are shown in table 4.12.2.4-3. FERC regulations require that during operation, compressor station noise increments not exceed an L_{dn} of 55 dBA (equivalent to a continuous noise level of 48.6 dBA L_{eq}) at the nearest NSA. Oregon noise regulations require that operational noise from new commercial or industrial facilities must not increase ambient L_{50} noise levels by more than 10 dBA. For a facility that operates continuously at a steady level, the L_{50} is often very similar to the L_{eq} level; therefore, predictions of compressor station sound levels are in L_{eq} but are comparable to L_{50} baseline sound levels. The results indicate that, having incorporated the indicated noise mitigation measures, the received sound levels at NSAs would be in compliance with the 55 dBA L_{dn} FERC noise criterion and the

Oregon noise regulations. In addition, figure M-14 in appendix M shows the sound contours associated with the operation of the Klamath Compressor Station.

TABLE 4.12.2.4-3

Predicted Operational Noise Levels of the Klamath Compressor Station

Receptor Location	Distance (feet) and Direction	Existing L_{50} (dBA)	Predicted L_{eq} (dBA)	Predicted Increase Over Existing L_{50} (dBA)	Existing L_{dn} (dBA)	Predicted L_{dn} (dBA)	Combined Existing plus Predicted L_{dn}, dBA	Predicted Increase Over Existing L_{dn} (dBA)
NSA 1				Property Purchased by Pacific Connector				
NSA 2				Property Purchased by Pacific Connector				
NSA 3	1,839/Northwest	32	40	9	39	46	47	8
NSA 4	2,820/Southwest	30	35	6	37	41	42	6
NSA 5	2,275/Southwest	36	37	4	52	43	43	1
NSA 6	1,500/Southeast	39	41	4	49	47	47	2
NSA 7	1,230/North	37	43	7	43	50	50	8

Pacific Connector has committed to implementing the following noise mitigation measures for the facility:

- The turbine intake and/or exhaust systems should be equipped with silencers having greater insertion losses than the standard Solar Titan 130 silencers in order to reduce the noise contribution at the nearest NSA (NSA 1) to a level below L_{dn} 55 dBA.
- The turbine exhaust duct located between the compressor building wall and the silencer should be acoustically insulated.
- The turbine lube oil coolers should have noise levels approximately equal to Solar's 85 dBA cooler. The cooler noise level at a horizontal distance of 50 feet from the center of each cooler would be about 54 dBA.
- The gas after-coolers should be designed so that the noise levels at a horizontal distance of 50 feet from the center of each cooler would be about 60 dBA.
- Outdoor aboveground gas piping should be inserted underground soon after exiting the compressor building.
- The compressor building should be acoustically insulated with 6 inches of 8 pounds/cubic feet density mineral wool insulation. The building shell should have 22-gauge metal outer sheeting in the walls and roof and a 26-gauge perforated metal liner.
- The compressor building roll-up door should have a minimum noise reduction rating of STC-28 through the door (this may require a double door).
- Personnel doors should be standard insulated doors with an STC-26 noise reduction rating.
- The compressor building ventilation system has not yet been designed. The building ventilation openings should be acoustically designed so that they are compatible with the silencing in the rest of the station.
- The compressor impeller wheels have not yet been selected and the unit piping noise levels could not be evaluated. It is expected that the unit piping would require acoustic insulation.

As shown in table 4.12.2.4-3, operation of the Klamath Compressor Station would result in clearly noticeable increases in noise levels at three of the five NSAs. However, the station's contribution would be less than the FERC requirement of L_{dn} 55 dBA. Although the Klamath Compressor Station is anticipated to operate in compliance with the applicable noise requirements to ensure that actual operational noise is at or below the FERC-recommended limits, and that there would be no significant effects on noise quality at the nearest NSAs, **we recommend that:**

- **Pacific Connector should file a noise survey with the Secretary <u>no later than 60 days after placing the Klamath Compressor Station in service</u>. If a full load condition noise survey is not possible, Pacific Connector should provide an interim survey at the maximum possible horsepower load and provide the full load survey <u>within six months</u>. If the noise attributable to the operation of all of the equipment at the Klamath Compressor Station under interim or full horsepower load conditions exceeds an L_{dn} of 55 dBA at any nearby NSAs, Pacific Connector should file a report on what changes are needed and should install the additional noise controls to meet the level <u>within one year</u> of the in-service date. Pacific Connector should confirm compliance with the above requirement by filing a second noise survey with the Secretary <u>no later than 60 days</u> after it installs the additional noise controls.**

<u>Venting/Blowdown Events</u>

These events are a venting of gas for safety purposes to relieve pressure in a pipeline component or at a compressor station prior to performing maintenance work (anticipated to occur on an annual basis). A venting or blowdown event at individual MLV locations is a rare and infrequent event. A blowdown vent with a silencer results in a sound power level of approximately 83 dBA. Noise levels at various distances based on that sound power level expected for routine blowdown events are given in table 4.12.2.4-4.

TABLE 4.12.2.4-4

Blowdown Valve Sound Pressure Level at Various Distances

	Distance (feet)/ Received Sound Level (dBA)			
Sound Source	**50**	**100**	**300**	**1,000**
Blowdown Valve with Silencer	48	42	33	22

Acoustic modeling was conducted to determine received sound levels associated with routine blowdowns at the closest NSAs to the block valve locations (table 4.12.2.4-5). Modeling results indicate compliance with applicable noise requirements prescribed by the FERC and the State of Oregon.

TABLE 4.12.2.4-5

Summary of Blowdown Acoustic Modeling Results

Receptor	County	Distance (Feet)	Sound Pressure Level, L_{eq} (dBA)	Sound Pressure Level, L_{dn} (dBA)
02 - AGF 15.69 (BVA #2)	Coos	72	25	31
05 - AGF 59.58 (BVA #5)	Douglas	1,224	21	27
06 - AGF 71.46 (BVA #6)	Douglas	1,096	21	27
08 - AGF 94.66 (BVA #8)	Douglas	20	36	42
10 - AGF 122.18 (BVA #10)	Jackson	89	23	29
15 - AGF 197.77 (BVA #15)	Klamath	1,092	21	27
16 - AGF 214.28 (BVA #16)	Klamath	60	27	33
17 - AGF 228.13 (Klamath Compressor Station, BVA #17)	Klamath	74	25	31

MLV blowdowns, if scheduled for maintenance activities during the life of the pipeline, would be communicated to the surrounding landowners in writing (e.g., letters and "door-hangers") in advance of the event. These events are conducted during daylight hours only. Such transient events are of very short duration and do not represent continuous or routine noise or disturbance to NSAs. Based on the infrequent and short duration of blowdowns, these events would not have significant adverse noise impacts on nearby NSAs.

Metering Station Noise

One meter station would be located very close to the Jordan Cove LNG terminal (at the gas gate), and two meter stations would be located within the Klamath Compressor Station fenceline. Noise may be generated by gas flow in the pipe used for measurement at the meter stations. However, noise generated by operation of the Jordan Cove LNG Project would dominate over the meter station near the terminal; similarly, noise generated by operation of the compressor station would dominate over the meter stations at the compressor station. Noise would not be expected to be audible beyond the edge of the meter station sites or pipeline right-of-way. Additionally, our recommendation that Pacific Connector and Jordan Cove complete noise surveys at both the compressor station and the LNG terminal would be inclusive of noise generated by the meter stations in and near these respective facilities; therefore, we do not believe that noise impacts due to operation of the meter stations would result in significant impacts on nearby NSAs.

4.12.2.5 Environmental Consequences on Federal Lands

The southern boundary of the ODNRA is less than 0.7 mile northwest of the Jordan Cove LNG Project. As shown on the noise contour maps in figure 4.12-3, estimated noise from general Jordan Cove LNG Project construction is expected to remain below an L_{dn} of 55 dBA (i.e., the noise level used by the EPA and FERC to protect the public from activity interference and annoyance outdoors in residential areas); however, during pile driving for installation of berth facilities at the Jordan Cove marine slip, predicted noise levels at the ODNRA are expected to exceed the FERC noise criterion (figure 4.12-4). In addition, predicted noise levels at the BLM boat ramp located about 1 mile southwest of the terminal site would exceed 55 dBA (figureM-4 in appendix M). Noise from pile driving would be noticeable to users of the ODNRA and BLM boat ramp during construction. This impact would be a temporary annoyance to users of the ODNRA and boat ramp. Due to the noise-generating activities associated with the ODNRA and BLM boat ramp, these locations are not considered to be an NSA.

During operation and flaring, predicted noise generated from the Jordan Cove LNG Project may also exceed the 55 dBA L_{dn} FERC noise criterion at the ODNRA and BLM boat ramp. During operation of the Jordan Cove LNG Project, BLM and COE lands near the Coos Bay navigation channel would receive limited noise impacts from LNG carriers arriving at and departing from the terminal. An estimated 110-120 ships per year would call on the Jordan Cove LNG Project. Noise levels during ship movements are estimated to be about 63 dBA at a distance of 300 feet during each passby event, which would be similar to noise generated from deep-draft cargo ships that currently traverse the Coos Bay navigation channel. Because the Coast Guard would impose a moving safety zone around LNG carriers, only one large vessel would be traversing any one location along the channel at any point in time. Current ship traffic at the Port is about 50 deep-draft commercial ship calls per year. The increase in the number of vessel calls at the Port resulting from operation of the Jordan Cove LNG Project would be less than one ship movement per day. Noise from LNG carriers would not be expected to create a noticeable change in overall noise levels at BLM and COE lands along the Coos Bay navigation channel.

During construction of the Pacific Connector pipeline, there would be temporary noise impacts on federal lands crossed by the pipeline or crossed by construction access roads. Construction noise could have localized and temporary effects on recreational users and wildlife on federal lands. Pipeline construction would proceed in a linear fashion along the right-of-way, and equipment would be operated on an as-needed basis; therefore, exact noise at a particular point cannot be determined. However, we can estimate noise levels as a function of the distance of the receptor from the equipment. Table M-3 in appendix M provides predicted construction noise levels at 50 feet, 100 feet, and 300 feet for pipeline construction. Noise would diminish rapidly as the distance from the noise source increases.

During operation of the pipeline, there would be no noise generated from the buried pipeline. Aboveground MLVs would be located within BLM lands. During operation, sound is sometimes detectable within several feet of MLVs; however, any noise impact during operation of the MLVs, with the exception of blowdown events discussed previously, would not be humanly perceptible beyond the operational right-of-way for the pipeline. The main source of noise from operation of the Pacific Connector would be from the Klamath Compressor Station, which would be located on private land, with no federal land adjacent or nearby. We conclude that construction and operation of the Pacific Connector Pipeline Project would not have significant adverse noise impacts on users of federal lands.

4.12.2.6 Conclusion

Constructing and operating the Project would result in noise-related impacts. However, based on the implementation of the proposed BMPs as well as inclusion of the recommendations made in this EIS, the Project would not cause significant noise-related impacts.

4.13 RELIABILITY AND SAFETY

4.13.1 Jordan Cove LNG Project

4.13.1.1 LNG Facility Reliability, Safety, and Security Regulatory Oversight

LNG facilities handle flammable and sometimes toxic materials that can pose a risk to the public if not properly managed. These risks are managed by the companies owning the facilities, through selecting the site location and plant layout as well as through suitable design, engineering, construction, and operation of the LNG facilities. Multiple federal agencies share regulatory authority over the LNG facilities and the operator's approach to risk management. The safety, security, and reliability of the Jordan Cove LNG Project would be regulated by the USDOT, the Coast Guard, and the FERC.

In February 2004, the USDOT, the Coast Guard, and the FERC entered into an Interagency Agreement to ensure greater coordination among these three agencies in addressing the full range of safety and security issues at LNG terminals and LNG marine vessel operations, and maximizing the exchange of information related to the safety and security aspects of LNG facilities and related marine operations. Under the Interagency Agreement, the FERC is the lead federal agency responsible for the preparation of the analysis required under NEPA for impacts associated with terminal construction and operation. The USDOT and the Coast Guard participate as cooperating agencies but remain responsible for enforcing their regulations covering LNG facility siting, design, construction, operation, and maintenance. All three agencies have some oversight and responsibility for the inspection and compliance during the LNG facility's operation.

The USDOT establishes and has the authority to enforce the federal safety standards for the location, design, installation, construction, inspection, testing, operation, and maintenance of onshore LNG facilities under the Natural Gas Pipeline Safety Act (49 U.S.C. 1671 et seq.). The USDOT's LNG safety regulations are codified in 49 CFR 193, which prescribes safety standards for LNG facilities used in the transportation of gas by pipeline that are subject to federal pipeline safety laws (49 U.S.C. 60101 et seq.), and 49 CFR 192. On August 31, 2018, USDOT and FERC signed a memorandum of understanding (MOU) regarding methods to improve coordination throughout the LNG permit application process for FERC jurisdictional LNG facilities. In the MOU, USDOT agreed to issue a Letter of Determination (LOD) stating whether a proposed LNG facility would be capable of complying with location criteria and design standards contained in Subpart B of Part 193. The Commission committed to rely upon the USDOT determination in conducting its review of whether the facilities would be consistent in the public interest. The issuance of the LOD does not abrogate USDOT's continuing authority and responsibility over a proposed project's compliance with Part 193 during construction and future operation of the facility. The USDOT's conclusion on the siting and hazard analysis required by Part 193 is based on preliminary design information which may be revised as the engineering design progresses to final design. USDOT regulations also contain requirements for the design, construction, installation, inspection, testing, operation, maintenance, qualifications and training of personnel, fire protection, and security for LNG facilities as defined in 49 CFR 193, which would be completed during later stages of the Project. If the Project is authorized and constructed, LNG facilities as defined in 49 CFR 193, would be subject to the USDOT's inspection and enforcement programs to ensure compliance with the requirements of 49 CFR 193.

The Coast Guard has authority over the safety of an LNG terminal's marine transfer area and LNG marine vessel traffic, as well as over security plans for the waterfront facilities handling LNG and LNG marine vessel traffic. The Coast Guard regulations for waterfront facilities handling LNG are codified in 33 CFR 105 and 33 CFR 127. As a cooperating agency, the Coast Guard assists the FERC staff in evaluating whether an applicant's proposed waterway would be suitable for LNG marine vessel traffic and whether the waterfront facilities handling LNG would be operated in accordance with 33 CFR 105 and 33 CFR 127. If the facilities are constructed and become operational, the facilities would be subject to the Coast Guard inspection program to ensure compliance with the requirements of 33 CFR 105 and 33 CFR 127.

The FERC authorizes the siting and construction of LNG terminals under the NGA and delegated authority from the DOE. The FERC requires standard information to be submitted to perform safety and reliability engineering reviews. FERC's filing regulations are codified in 18 CFR 380.12 (m) and (o), and requires each applicant to identify how its proposed design would comply with the USDOT's siting requirements of 49 CFR 193 Subpart B. The level of detail necessary for this submittal requires the applicant to perform substantial front-end engineering of the complete project. The design information is required to be site-specific and developed to the extent that further detailed design would not result in significant changes to the siting considerations, basis of design, operating conditions, major equipment selections, equipment design conditions, or safety system designs. As part of the review required for a FERC order, we use this information from the applicant to assess whether the proposed facilities would have a public safety impact and to suggest additional mitigation measures for the Commission to consider for incorporation as conditions in the order. If the facilities are approved and the suggested mitigation measures are incorporated into the order as conditions, FERC staff would review material filed to satisfy the conditions of the order and conduct periodic inspections throughout construction and operation.

In addition, the Energy Policy Act of 2005 requires FERC to coordinate and consult with the Department of Defense (DOD) on the siting, construction, expansion, and operation of LNG terminals that would affect the military. On November 21, 2007, the FERC and the DOD entered into a MOU formalizing this process.[189] On January 29, 2019, the FERC received a response letter from the DOD Siting Clearinghouse stating that Jordan Cove LNG Project would have a minimal impact on military training and operations conducted in the area.

4.13.1.2 USDOT Siting Requirements and 49 CFR Part 193 Subpart B Determination

Siting LNG facilities, as defined in 49 CFR 193, with regard to ensuring that the proposed site selection and location would not pose an unacceptable level or risk to public safety is required by USDOT's regulations in 49 CFR 193 Subpart B. The Commission's regulations under 18 CFR 380.12 (o) (14) require Jordan Cove to identify how the proposed design complies with the siting requirements in USDOT's regulations under 49 CFR 193 Subpart B. The scope of USDOT's siting authority under 49 CFR 193 applies to LNG facilities used in the transportation of gas by pipeline subject to the federal pipeline safety laws and 49 CFR 192.[190]

---

[189] http://www.ferc.gov/legal/mou/mou-dod.pdf

[190] 49 CFR 193.2001 (b) (3), Scope of part, excludes any matter other than siting provisions pertaining to marine cargo transfer systems between the LNG marine vessel and the last manifold (or in the absence of a manifold, the last valve) located immediately before a storage tank.

The requirements in 49 CFR 193 Subpart B, state that an operator or government agency must exercise legal control over the activities as long the facility is in operation that can occur within an "exclusion zone," defined as the area around an LNG facility that could be exposed to specified levels of thermal radiation or flammable vapor in the event of a release of LNG or ignition of LNG vapor. Approved mathematical models must be used to calculate the dimensions of these exclusion zones. The siting requirements specified in NFPA 59A (2001), an industry consensus standard for LNG facilities, are incorporated into 49 CFR 193 Subpart B by reference, with regulatory preemption in the event of conflict. The following sections of 49 CFR 193 Subpart B specifically address siting requirements:

- Section 193.2051, Scope, states that each LNG facility designed, replaced, relocated or significantly altered after March 31, 2000, must be provided with siting requirements in accordance with Subpart B and NFPA 59A (2001). In the event of a conflict with NFPA 59A (2001), the regulatory requirements in Part 193 prevail.
- Section 193.2057, Thermal radiation protection, requires that each LNG container and LNG transfer system have thermal exclusion zones in accordance with section 2.2.3.2 of NFPA 59A (2001).
- Section 193.2059, Flammable vapor-gas dispersion protection, requires that each LNG container and LNG transfer system have a dispersion exclusion zone in accordance with sections 2.2.3.3 and 2.2.3.4 of NFPA 59A (2001).
- Section 193.2067, Wind forces, requires that shop fabricated containers of LNG or other hazardous fluids less than 70,000 gallons must be designed to withstand wind forces based on the applicable wind load data in American Society of Civil Engineers (ASCE) 7 (2005). All other LNG facilities must be designed for a sustained wind velocity of not less than 150 mph unless the USDOT Administrator finds a lower wind speed is justified or the most critical combination of wind velocity and duration for a 10,000-year mean return interval.

As stated in 49 CFR 193.2051, LNG facilities must meet the siting requirements of NFPA 59A (2001), Chapter 2, and include but may not be limited to:

- NFPA 59A (2001) section 2.1.1 (c) requires consideration of protection against forces of nature.
- NFPA 59A (2001) section 2.1.1 (d) requires that other factors applicable to the specific site that have a bearing on the safety of plant personnel and surrounding public be considered, including an evaluation of potential incidents and safety measures incorporated in the design or operation of the facility.
- NFPA 59A (2001) section 2.2.3.2 requires provisions to minimize the damaging effects of fire from reaching beyond a property line, and requires provisions to prevent a radiant heat flux level of 1,600 British thermal units per square foot per hour (Btu/ft^2-hr) from reaching beyond a property line that can be built upon. The distance to this flux level is to be calculated with LNGFIRE3 or with models that have been validated by experimental test data appropriate for the hazard to be evaluated and that have been approved by USDOT.
- NFPA 59A (2001) section 2.2.3.4 requires provisions to minimize the possibility of any flammable mixture of vapors from a design spill from reaching a property line that can be built upon and that would result in a distinct hazard. Determination of the distance that the

flammable vapors extend is to be determined with DEGADIS or approved alternative models that take into account physical factors influencing LNG vapor dispersion.[191]

Taken together, 49 CFR 193 Subpart B, and NFPA 59A (2001) require that flammable LNG vapors from design spills do not extend beyond areas in which the operator or a government agency legally controls all activities. Furthermore, consideration of other hazards which may affect the public or plant personnel must be evaluated as prescribed in NFPA 59A (2001), section 2.1.1 (d).

Title 49 CFR 193 Subpart B, and NFPA 59A (2001) also specify three radiant heat flux levels which must be considered for LNG storage tank spills for as long as the facility is in operation:

- 1,600 Btu/ft^2-hr - This level can extend beyond the plant property line that can be built upon but cannot include areas that are used for outdoor assembly by groups of 50 or more persons;[192]
- 3,000 Btu/ft^2-hr - This level can extend beyond the plant property line that can be built upon but cannot include areas that contain assembly, educational, health care, detention or residential buildings or structures;[193] and
- 10,000 Btu/ft^2-hr - This level cannot extend beyond the plant property line that can be built upon.[194]

The requirements for design spills from process or transfer areas are more stringent. For LNG spills, the 1,600 Btu/ft^2-hr flux level cannot extend beyond the plant property line onto a property that can be built upon. In addition, section 2.1.1 of NFPA 59A (2001) requires that factors applicable to the specific site with a bearing on the safety of plant personnel and the surrounding public must be considered, including an evaluation of potential incidents and safety measures incorporated into the design or operation of the facility. USDOT has indicated that potential incidents, such as vapor cloud explosions and toxic releases should be considered to comply with Part 193 Subpart B.[195]

---

191 USDOT has approved two additional models for the determination of vapor dispersion exclusion zones in accordance with 49 CFR 193.2059: FLACS 9.1 Release 2 (Oct. 7, 2011) and PHAST-UDM Version 6.6 and 6.7 (Oct. 7, 2011).

192 The 1,600 Btu/ft^2-hr flux level is associated with producing pain in less than 15 seconds, first degree burns in 20 seconds, second degree burns in approximately 30 to 40 seconds, 1 percent mortality in approximately 120 seconds, and 100 percent mortality in approximately 400 seconds, assuming no shielding from the heat, and is typically the maximum allowable intensity for emergency operations with appropriate clothing based on average 10 minute exposure.

193 The 3,000 Btu/ft^2-hr flux level is associated with producing pain in less than 5 seconds, first degree burns in 5 seconds, second degree burns in approximately 10 to 15 seconds, 1 percent mortality in approximately 50 seconds, and 100 percent mortality in approximately 180 seconds, assuming no shielding from the heat, and is typically the critical heat flux for piloted ignition of common building materials (e.g., wood, PVC, fiberglass, etc.) with prolonged exposures.

194 The 10,000 Btu/ft^2-hr flux level is associated with producing pain in less than 1 seconds, first degree burns in 1 seconds, second degree burns in approximately 3 seconds, 1 percent mortality in approximately 10 seconds, and 100 percent mortality in approximately 35 seconds, assuming no shielding from the heat, and is typically the critical heat flux for unpiloted ignition of common building materials (e.g., wood, PVC, fiberglass) and degradation of unprotected process equipment after approximate 10 minute exposure and to reinforced concrete after prolonged exposure.

195 The USDOT PHMSA's "LNG Plant Requirements: Frequently Asked Questions" item H1, https://www.phmsa.dot.gov/pipeline/liquified-natural-gas/lng-plant-requirements-frequently-asked-questions, accessed Aug. 2018.

In accordance with the August 31, 2018 MOU, USDOT will issue a LOD to the Commission after USDOT completes its analysis of whether the proposed facilities would meet the USDOT siting standards. The LOD will evaluate the hazard modeling results and endpoints used to establish exclusion zones, as well as Jordan Cove's evaluation on potential incidents and safety measures incorporated in the design or operation of the facility specific to the site that have a bearing on the safety of plant personnel and surrounding public. The LOD will serve as one of the considerations for the Commission to deliberate in its decision to authorize or deny an application.

4.13.1.3 Coast Guard Safety Regulatory Requirements and Letter of Recommendation

LNG Marine Vessel Historical Record

Since 1959, marine vessels have transported LNG without a major release of cargo or a major accident involving an LNG marine vessel. There are more than 370 LNG marine vessels in operation routinely transporting LNG between more than 100 import/export terminals currently in operation worldwide. Since U.S. LNG terminals first began operating under FERC jurisdiction in the 1970s, there have been thousands of individual LNG marine vessel arrivals at terminals in the U.S. For more than 40 years, LNG shipping operations have been safely conducted in U.S. ports and waterways.

A review of the history of LNG maritime transportation indicates that there has not been a serious accident at sea or in a port which resulted in a spill due to rupturing of the cargo tanks. However, insurance records, industry sources, and public websites identify a number of incidents involving LNG marine vessels, including minor collisions with other marine vessels of all sizes, groundings, minor LNG releases during cargo unloading operations, and mechanical/equipment failures typical of large vessels. Some of the more significant occurrences, representing the range of incidents experienced by the worldwide LNG marine vessel fleet, are described below:

- **El Paso Paul Kayser** grounded on a rock in June 1979 in the Straits of Gibraltar during a loaded voyage from Algeria to the United States. Extensive bottom damage to the ballast tanks resulted; however, no cargo was released because no damage was done to the cargo tanks. The entire cargo of LNG was subsequently transferred to another LNG marine vessel and delivered to its U.S. destination.
- **Tellier** was blown by severe winds from its docking berth at Skikda, Algeria in February 1989 causing damage to the loading arms and the LNG marine vessel and shore piping. The cargo loading had been secured just before the wind struck, but the loading arms had not been drained. Consequently, the LNG remaining in the loading arms spilled onto the deck, causing fracture of some plating.
- **Mostefa Ben Boulaid** had an electrical fire in the engine control room during unloading at Everett, Massachusetts on February 5, 1996. The LNG marine vessel crew extinguished the fire and the ship completed unloading.
- **Khannur** had a cargo tank overfill into the LNG marine vessel's vapor handling system on September 10, 2001, during unloading at Everett, Massachusetts. Approximately 100 gallons of LNG were vented and sprayed onto the protective decking over the cargo tank dome, resulting in several cracks. After inspection by the Coast Guard, the Khannur was allowed to discharge its LNG cargo.

- **Mostefa Ben Boulaid** had LNG spill onto its deck during loading operations in Algeria in 2002. The spill, which is believed to have been caused by overflow rather than a mechanical failure, caused significant brittle fracturing of the steelwork. The LNG marine vessel was required to discharge its cargo, after which it proceeded to dock for repair.
- **Norman Lady** was struck by the USS Oklahoma City nuclear submarine while the submarine was rising to periscope depth near the Strait of Gibraltar in November 2002. The 87,000 m^3 LNG marine vessel, which had just unloaded its cargo at Barcelona, Spain, sustained only minor damage to the outer layer of its double hull but no damage to its cargo tanks.
- **Tenaga Lima** grounded on rocks while proceeding to open sea east of Mopko, South Korea due to strong current in November 2004. The shell plating was torn open and fractured over an approximate area of 20 by 80 feet, and internal breaches allowed water to enter the insulation space between the primary and secondary membranes. The LNG marine vessel was refloated, repaired, and returned to service.
- **Golar Freeze** moved away from its docking berth during unloading on March 14, 2006, in Savannah, Georgia. The powered emergency release couplings on the unloading arms activated as designed, and transfer operations were shut down.
- **Catalunya Spirit** lost propulsion and became adrift 35 miles east of Chatham, Massachusetts on February 11, 2008. Four tugs towed the LNG marine vessel to a safe anchorage for repairs. The Catalunya Spirit was repaired and taken to port to discharge its cargo.
- **Al Gharrafa** collided with a container ship, Hanjin Italy, in the Malacca Strait off Singapore on December 19, 2013. The bow of the Al Gharrafa and the middle of the starboard side of the Hanjin were damaged. Both ships were safely anchored after the incident. No loss of LNG was reported.
- **Al Oraiq** collided with a freight carrier, Flinterstar, near Zeebrugge, Belgium on October 6, 2015. The freight carrier sank, but the Al Oraiq was reported to have sustained only minor damage to its bow and no damage to the LNG cargo tanks. According to reports, the Al Oraiq took on a little water but was towed to the Zeebrugge LNG terminal where its cargo was unloaded using normal procedures. No loss of LNG was reported.
- **Al Khattiya** suffered damage after a collision with an oil tanker off the Port of Fujairah on February 23, 2017. Al Khattiya had discharged its cargo and was anchored at the time of the incident. A small amount of LNG was retained within the LNG marine vessel to keep the cargo tanks cool. The collision damaged the hull and two ballast tanks on the Al Khattiya, but did not cause any injury or water pollution. No loss of LNG was reported.

LNG Marine Vessel Safety Regulatory Oversight

The Coast Guard exercises regulatory authority over LNG marine vessels under 46 CFR 154, which contains the United States safety standards for self-propelled LNG marine vessels transporting bulk liquefied gases. The LNG marine vessels visiting the proposed facility would also be constructed and operated in accordance with the IMO *Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk and the International Convention for the Safety of Life at Sea*. All LNG marine vessels entering U.S. waters are required to possess a valid

IMO Certificate of Fitness and either a Coast Guard Certificate of Inspection (for U.S. flag vessels) or a Coast Guard Certificate of Compliance (for foreign flag vessels). These documents certify that the LNG marine vessel is designed and operating in accordance with both international standards and the U.S. regulations for bulk LNG marine vessels under 46 CFR 154.

The LNG marine vessels that would deliver or receive LNG to or from the proposed facility would also need to comply with various U.S. and international security requirements. The IMO adopted the *International Ship and Port Facility Security Code* in 2002. This code requires both ships and ports to conduct vulnerability assessments and to develop security plans. The purpose of the code is to prevent and suppress terrorism against ships; improve security aboard ships and ashore; and reduce the risk to passengers, crew, and port personnel on board ships and in port areas. All LNG marine vessels, as well as other cargo vessels (e.g., 500 gross tons and larger), and ports servicing those regulated vessels, must adhere to the IMO standards. Some of the IMO requirements for ships are as follows:

- marine vessels must develop security plans and have a Vessel Security Officer;
- marine vessels must have a ship security alert system to transmit ship-to-shore security alerts identifying the ship, its location, and indication that the security of the ship is under threat or has been compromised;
- marine vessels must have a comprehensive security plan for international port facilities, focusing on areas having direct contact with ships; and
- marine vessels may have equipment onboard to help maintain or enhance the physical security of the ship.

In 2002, the Maritime Transportation Security Act (MTSA) was enacted by the U.S. Congress and aligned domestic regulations with the maritime security standards of the *International Ship and Port Facility Security Code and the Code for the Construction and Equipment of Ships Carrying Liquefied Gases in Bulk and the International Convention for the Safety of Life at Sea*. The Coast Guard's regulations in 33 CFR 104 require marine vessels to conduct a vessel security assessment and develop a vessel security plan that addresses each vulnerability identified in the vessel security assessments. All LNG marine vessels servicing the facility would have to comply with the MTSA requirements and associated regulations while in U.S. waters.

The Coast Guard also exercises regulatory authority over LNG facilities that affect the safety and security of port areas and navigable waterways under EO 10173; the Magnuson Act (50 U.S.C. section 191); the Ports and Waterways Safety Act of 1972, as amended (33 U.S.C. section 1221, et seq.); and the MTSA of 2002 (46 U.S.C. section 701). The Coast Guard is responsible for matters related to navigation safety, LNG marine vessel engineering and safety standards, and all matters pertaining to the safety of facilities or equipment located in or adjacent to navigable waters up to the last valve immediately before the receiving tanks. The Coast Guard also has authority for LNG facility security plan review, approval, and compliance verification as provided in 33 CFR 105.

The Coast Guard regulations in 33 CFR 127 apply to the marine transfer area of waterfront facilities between the LNG marine vessel and the last manifold or valve immediately before the receiving tanks. Title 33 CFR 127 applies to the marine transfer area for LNG of each new waterfront facility handling LNG and to new construction in the marine transfer areas for LNG of each existing waterfront facility handling LNG. The scope of the regulations includes the design, construction, equipment, operations, inspections, maintenance, testing, personnel training, firefighting, and security of the marine transfer area of LNG waterfront facilities. The safety systems, including communications, emergency shutdown, gas detection, and fire protection, must comply with the regulations in 33 CFR 127. Under 33 CFR 127.019, Jordan Covewould be required to submit two copies of its Operations and Emergency Manuals to the Coast Guard Captain of the Port (COTP) for examination.

Both the Coast Guard regulations under 33 CFR 127 and FERC regulations under 18 CFR 157.21, require an applicant who intends to build an LNG terminal facility to submit a Letter of Intent (LOI) to the Coast Guard no later than the date that the owner/operator initiates pre-filing with FERC, but, in all cases, at least 1 year prior to the start of construction. In addition, the applicant must submit a Preliminary WSA to the COTP with the LOI.

The Preliminary WSA provides an initial explanation of the port community and the proposed facility and transit routes. It provides an overview of the expected impacts LNG operations may have on the port and the waterway. Generally, the Preliminary WSA does not contain detailed studies or conclusions. This document is used by the COTP to begin his or her evaluation of the suitability of the waterway for LNG marine traffic. The Preliminary WSA must provide an initial explanation of the following:

- port characterization;
- characterization of the LNG facility and the LNG marine vessel route;
- risk assessment for maritime safety and security;
- risk management strategies; and
- resource needs for maritime safety, security, and response.

A Follow-On WSA must be provided no later than the date the owner/operator files an application with FERC, but in all cases at least 180 days prior to transferring LNG. The Follow-on WSA must provide a detailed and accurate characterization of the waterfront facilities handling LNG, the LNG marine vessel route, and the port area. The Follow-on WSA provides a complete analysis of the topics outlined in the Preliminary WSA. It should identify credible security threats and navigational safety hazards for the LNG marine vessel traffic, along with appropriate risk management measures and the resources (i.e., federal, state, local, and private sector) needed to carry out those measures. Until a facility begins operation, applicants must also annually review their WSAs and submit a report to the COTP as to whether changes are required. This document is reviewed and validated by the Coast Guard and forms the basis for the agency’s Letter of Recommendation (LOR) to the FERC.

In order to provide the Coast Guard COTPs/Federal Maritime Security Coordinators, members of the LNG industry, and port stakeholders with guidance on assessing the suitability of a waterway for LNG marine traffic, the Coast Guard has published a Navigation and Vessel Inspection Circular – *Guidance on Assessing the Suitability of a Waterway for Liquefied Natural Gas (LNG) Marine Traffic* (NVIC 01-11).

NVIC 01-11 directs the use of the three concentric Zones of Concern, based on LNG marine vessels with a cargo carrying capacity up to 265,000 m^3, used to assess the maritime safety and security risks of LNG marine traffic. The Zones of Concern are:

- Zone 1 – impacts on structures and organisms are expected to be significant within 500 meters (1,640 feet). The outer perimeter of Zone 1 is approximately the distance to thermal hazards of 37.5 kilowatts per square meter (kW/m^2) (12,000 Btu/ft^2-hr) from a pool fire.
- Zone 2 – impacts would be significant but reduced, and damage from radiant heat levels are expected to transition from severe to minimal between 500 and 1,600 meters (1,640 and 5,250 feet). The outer perimeter of Zone 2 is approximately the distance to thermal hazards of 5 kW/m^2 (1,600 Btu/ft^2-hr) from a pool fire.
- Zone 3 – impacts on people and property from a pool fire or an un-ignited LNG spill are expected to be minimal between 1,600 meters (5,250 feet) and a conservative maximum distance of 3,500 meters (11,500 feet or 2.2 miles). The outer perimeter of Zone 3 should be considered the vapor cloud dispersion distance to the lower flammability limit from a worst case un-ignited release. Impacts to people and property could be significant if the vapor cloud reaches an ignition source and burns back to the source.

Once the applicant submits a complete Follow-On WSA, the Coast Guard reviews the document to determine if it presents a realistic and credible analysis of the public safety and security implications from LNG marine traffic both in the waterway and when in port. As required by its regulations (33 CFR 127.009), the Coast Guard is responsible for issuing a LOR to the FERC regarding the suitability of the waterway for LNG marine traffic with respect to the following items:

- physical location and description of the facility;
- the LNG marine vessel's characteristics and the frequency of LNG shipments to or from the facility;
- waterway channels and commercial, industrial, environmentally sensitive, and residential areas in and adjacent to the waterway used by LNG marine vessels en route to the facility, within 25 kilometers (15.5 miles) of the facility;
- density and character of marine traffic in the waterway;
- locks, bridges, or other manmade obstructions in the waterway;
- depth of water;
- tidal range;
- protection from high seas;
- natural hazards, including reefs, rocks, and sandbars;
- underwater pipes and cables; and
- distance of berthed LNG marine vessels from the channel and the width of the channel.

The Coast Guard may also prepare an LOR Analysis, which serves as a record of review of the LOR and contains detailed information along with the rationale used in assessing the suitability of the waterway for LNG marine traffic.

Jordan Cove LNG Project's Waterway Suitability Assessment

On January 9, 2017, Jordan Cove submitted a LOI and a Preliminary WSA to the COTP, Sector Colombia River, to notify the Coast Guard that it proposed to construct an LNG export terminal. The Preliminary WSA was based on a WSA dated April 10, 2006 that was previously submitted to the Coast Guard and was updated on December 29, 2012 for export operations. In addition, Jordan Cove has submitted annual WSA updates to the Coast Guard since the 2012 WSA update. On January 23, 2017, the Coast Guard accepted the Project's existing WSA as it relates to the new proposed project and stated that a new Follow-On WSA is not required.

LNG Marine Vessel Routes and Hazard Analysis

An LNG marine vessel's transit to the terminal would begin when it reaches the entrance of Coos Bay from the Pacific Ocean. Once inside the entrance, the marine vessel would turn north at the City of Charleston, Oregon and would transit to the Jordan Cove LNG Project marine berth. After reaching the turning basin near the Project site, the LNG marine vessel would turn to the right and back into the eastern side of the marine slip. The total inbound transit distance to the Jordan Cove LNG Project marine berth would be approximately 8.0 miles from the entrance of Coos Bay. The route would be reversed for outbound LNG marine vessel transits.

Pilotage is compulsory for foreign marine vessels and U.S. marine vessels under registry in foreign trade when in U.S. waters. All deep draft marine vessels currently entering the shared waterway would employ a U.S. pilot. The National Vessel Movement Center in the U.S. would require a 96-hour advance notice of arrival for deep draft marine vessels calling on U.S. ports. During transit, LNG marine vessels would be required to maintain voice contact with controllers and check in on designated frequencies at established way points.

NVIC 01-11 references the "Zones of Concern" for assisting in a risk assessment of the waterway. As LNG marine vessels proceed along the intended transit route, the estimated zones of concern would extend over resources such as residential and industrial areas, military installations, and also non-residential areas accessible to the public such as parks. Hazard Zone 1 would remain almost entirely over the water and would encompass coastal areas in Charleston and Coos Bay. Commercial vessels, recreational vessels, fishing vessels, Cape Arago Dock, I.C.I. Marine Industrical Park, North Bay Marine Industrial Park, and Roseburg Forest Products Facility would also fall within Zone 1. Zone 2 would cover a wider swath of coastal areas along Charleston, Coos Bay, Barview, and North Bend and would include multiple residential buildings, commercial buildings, industrial buildings, numerous Recreational Vehicle hook-up Parks, numerous recreational areas and boat launch ramps, Marine Research Center, Charleston Marina, South Slough Bridge, Coast Guard Sector Charleston, Charleston Fire District Stations 1 and 3, Madison Elementary School, Sunset Middle School, Coos Bay Fire Department Station 2, and the Southwestern Oregon Regional Airport. Zone 3 would span larger portions of Charleston, Coos Bay, Barview, and North Bend and would include Coast Guard Group North Bend, Railroad Bridge, Oregon Dunes Recreational Park, Southwestern Oregon Community College.

The areas impacted by the three different hazard zones are illustrated for accidental and intentional events in figures 4.13-1 and 4.13-2, respectively.

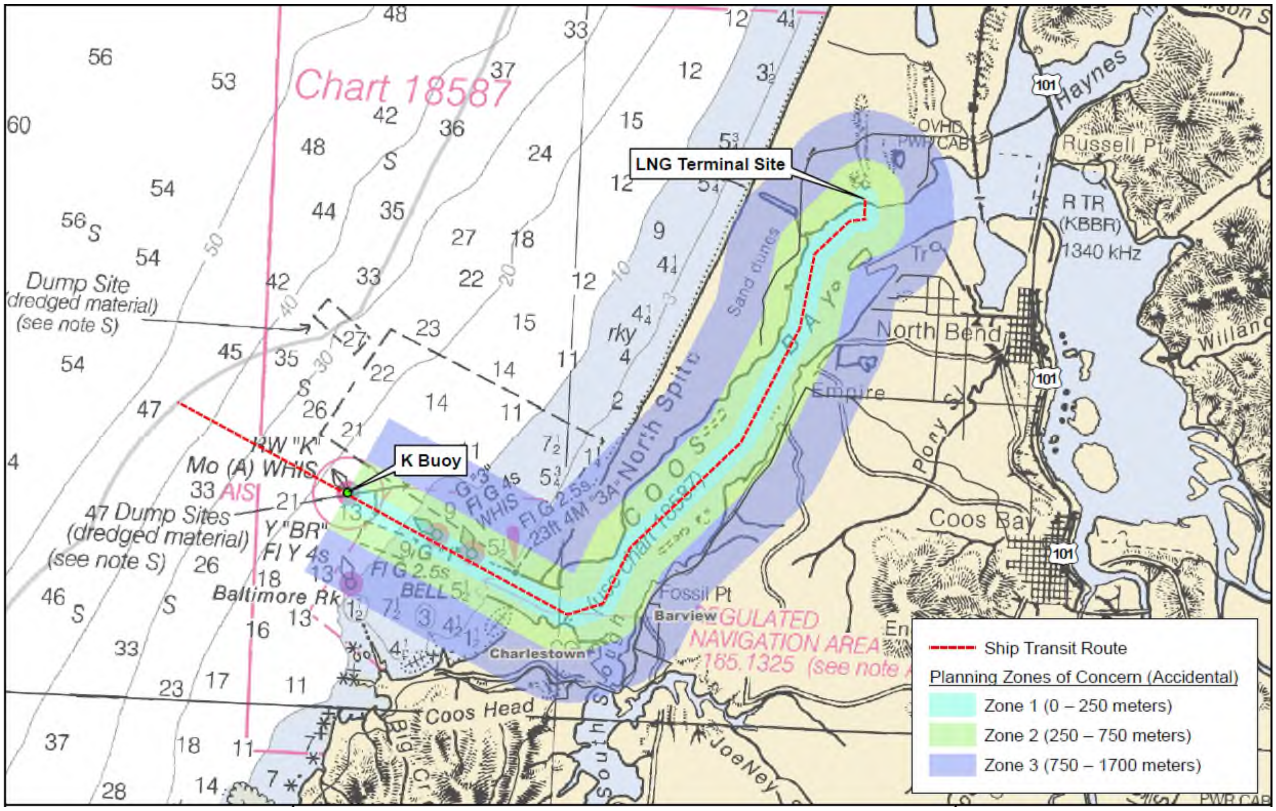

Figure 4.13-1 Accidental Hazard Zones along LNG Marine Vessel Route

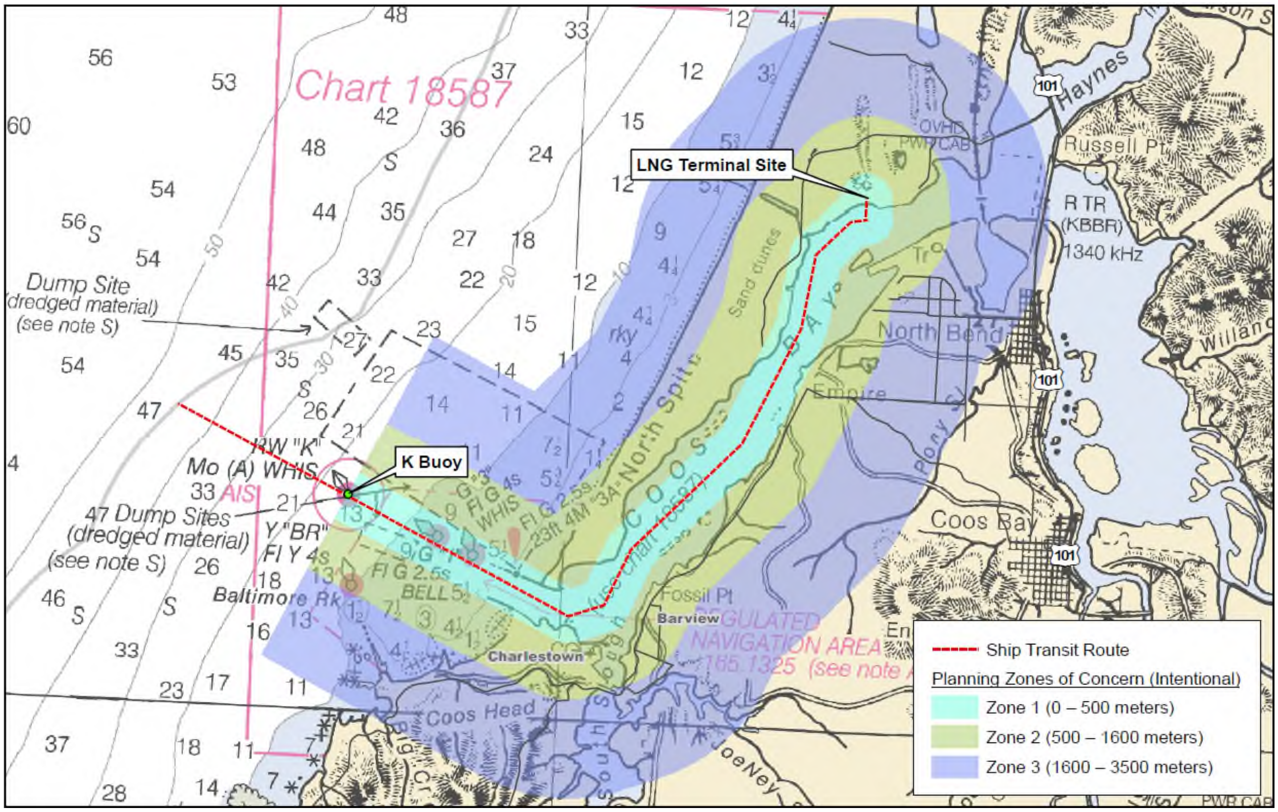

Figure 4.13-2. Intentional Hazard Zones along LNG Marine Vessel Route

U.S. Coast Guard Letter of Recommendation and Analysis

In a letter dated May 10, 2018, the Coast Guard issued an LOR and LOR Analysis to FERC stating that the Coos Bay Channel would be considered suitable for accommodating the type and frequency of LNG marine traffic associated with this Project. As part of its assessment of the safety and security aspects of this Project, the COTP Sector Columbia River consulted a variety of stakeholders including the Area Maritime Security Committees, Harbor Safety Committees, state representatives, pilot organizations, and local emergency responders. The LOR was based on full implementation of the strategies and risk management measures identified by the Coast Guard to Jordan Cove in its WSA.

Although Jordan Cove has suggested mitigation measures for responsibly managing the maritime safety and security risks associated with LNG marine traffic, the necessary vessel traffic and/or facility control measures may change depending on changes in conditions along the waterway. The Coast Guard regulations in 33 CFR 127 require that applicants annually review WSAs until a facility begins operation and submit a report to the Coast Guard identifying any changes in conditions, such as changes to the port environment, the LNG facility, or the LNG marine vessel route, that would affect the suitability of the waterway for LNG marine traffic.

The Coast Guard's LOR is a recommendation, regarding the current status of the waterway, to the FERC, the lead agency responsible for siting the on-shore LNG facility. Neither the Coast Guard nor the FERC has authority to require waterway resources of anyone other than the applicant under any statutory authority or under the Emergency Response Plan (ERP) or the Cost Sharing Plan.

As stated in the LOR, the Coast Guard would assess each transit on a case by case basis to identify what, if any, safety and security measures would be necessary to safeguard the public health and welfare, critical infrastructure and key resources, the port, the marine environment, and the LNG marine vessel.

Under the Ports and Waterways Safety Act, the Magnuson Act, the MTSA, and the Security and Accountability For Every (SAFE) Port Act, the COTP has the authority to prohibit LNG transfer or LNG marine vessel movements within his or her area of responsibility if he or she determines that such action is necessary to protect the waterway, port, or marine environment. If this Project is approved and if appropriate resources are not in place prior to LNG marine vessel movement along the waterway, then the COTP would consider at that time what, if any, vessel traffic and/or facility control measures would be appropriate to adequately address navigational safety and maritime security considerations.

4.13.1.4 LNG Facility Security Regulatory Requirements

The security requirements for the proposed project are governed by 33 CFR 105, 33 CFR 127, and 49 CFR 193 Subpart J - Security. Title 33 CFR 105, as authorized by the MTSA, requires all terminal owners and operators to submit a Facility Security Assessment (FSA) and a Facility Security Plan (FSP) to the Coast Guard for review and approval before commencement of operations of the proposed Project facilities. Jordan Cove would also be required to control and restrict access, patrol and monitor the plant, detect unauthorized access, and respond to security threats or breaches under 33 CFR 105. Some of the responsibilities of the applicant include, but are not limited to:

- designating a Facility Security Officer with a general knowledge of current security threats and patterns, security assessment methodology, vessel and facility operations, conditions, security measures, emergency preparedness, response, and contingency plans, who would be responsible for implementing the FSA and FSP and performing an annual audit for the life of the Project;
- conducting an FSA to identify site vulnerabilities, possible security threats and consequences of an attack, and facility protective measures; developing a FSP based on the FSA, with procedures for: responding to transportation security incidents; notification and coordination with federal, state, and local authorities; prevention of unauthorized access; measures to prevent or deter entrance with dangerous substances or devices; training; and evacuation;
- defining the security organizational structure with facility personnel with knowledge or training in current security threats and patterns; recognition and detection of dangerous substances and devices, recognition of characteristics and behavioral patterns of persons who are likely to threaten security; techniques to circumvent security measures; emergency procedures and contingency plans; operation, testing, calibration, and maintenance of security equipment; and inspection, control, monitoring, and screening techniques;
- implementing scalable security measures to provide increasing levels of security at increasing maritime security levels for facility access control, restricted areas, cargo handling, LNG marine vessel stores and bunkers, and monitoring; ensuring that the Transportation Worker Identification Credential (TWIC) program is properly implemented;

- ensuring coordination of shore leave for LNG marine vessel personnel or crew change out as well as access through the facility for visitors to the LNG marine vessel;
- conducting drills and exercises to test the proficiency of security and facility personnel on a quarterly and annual basis; and
- reporting all breaches of security and transportation security incidents to the National Response Center.

Title 33 CFR 127 has requirements for access controls, lighting, security systems, security personnel, protective enclosures, communications, and emergency power. In addition, an LNG facility regulated under 33 CFR 105 and 33 CFR 127 would be subject to the TWIC Reader Requirements Rule issued by the Coast Guard on August 23, 2016. This rule requires owners and operators of certain vessels and facilities regulated by the Coast Guard to conduct electronic inspections of TWICs (e.g., readers with biometric fingerprint authentication) as an access control measure. The final rule would also include recordkeeping requirements and security plan amendments that would incorporate these TWIC requirements. The implementation of the rule was first proposed to be in effect August 23, 2018. In a subsequent notice issued on June 22, 2018, the Coast Guard indicated delaying the effective date for certain facilities by three years, until August 23, 2021. On August 2, 2018, the President of the United States signed into law the Transportation Worker Identification Credential Accountability Act of 2018 (H.R. 5729). This law prohibits the Coast Guard from implementing the rule requiring electronic inspections of TWICs until after the Department of Homeland Security (DHS) has submitted a report to the Congress. Although the implementation of this rule has been postponed for certain facilities, the company should to consider the rule when developing access control and security plan provisions for the facility.

Title 49 CFR 193 Subpart J also specifies security requirements for the onshore components of LNG terminals, including requirements for conducting security inspections and patrols, liaison with local law enforcement officials, design and construction of protective enclosures, lighting, monitoring, alternative power sources, and warning signs. If the Project is authorized and constructed, compliance with the security requirements of 33 CFR 105, 33 CFR 127, and 49 CFR 193 Subpart J would be subject to the respective Coast Guard and USDOT inspection and enforcement programs.

Jordan Cove provided preliminary information as well as data request responses on these security features and indicated additional details would be completed in the final design. The Project site would install an impervious vapor barriers of heights ranging from 20 feet to 100 feet around portions of the property boundary. However, details of intrusion detection on the barriers would not be finalized until final design. We recommend in section 4.13.1.6 that Jordan Cove provide final design details on these security features for review and approval, including: lighting coverage drawings that illustrate photometric analyses demonstrating the lux levels at the interior of the terminal are in accordance with API 540, and other federal regulations for lighting along the perimeter fence line and along paths/roads of access and egress; camera coverage drawings that illustrate coverage areas of each camera such that the entire perimeter of the plant is covered with redundancy and the interior of plant is covered, including a camera be provided at the top of each LNG storage tank, within pretreatment areas, within liquefaction areas, within truck transfer areas, within marine transfer areas, and buildings; fencing drawings that demonstrate a fence would deter or mitigate entry along the perimeter of the entire facility and is set back from exterior structures and vegetation, and from interior hazardous piping and equipment by at least 10 feet; vehicle barrier and controlled access point drawings that demonstrate crash-rated barriers are provided to prevent uncontrolled access, inadvertent entry, and impacts to components containing hazardous fluids from vehicles. Furthermore, in accordance with the February 2004 Interagency Agreement among FERC, USDOT, and Coast Guard, FERC staff would collaborate with the Coast Guard and USDOT on the Project's security features.

4.13.1.5 FERC Engineering and Technical Review of the Preliminary Engineering Designs

LNG Facility Historical Record

The operating history of the U.S. LNG industry has been free of safety-related incidents resulting in adverse effects on the public or the environment with the exception of the October 20, 1944, failure at an LNG plant in Cleveland, Ohio. The 1944 incident in Cleveland led to a fire that killed 128 people and injured 200 to 400 more people.[196] The failure of the LNG storage tank was due to the use of materials not suited for cryogenic temperatures. LNG migrated through streets and into underground sewers due to inadequate spill impoundments at the site. Current regulatory requirements ensure that proper materials suited for cryogenic temperatures are used in the design and that spill impoundments are designed and constructed properly to contain a spill at the site. To ensure that this potential hazard would be addressed for proposed LNG facilities, we evaluate the preliminary and final specifications for suitable materials of construction and for the design of spill containment systems that would properly contain a spill at the site.

Another operational accident occurred in 1979 at the Cove Point LNG plant in Lusby, Maryland. A pump electrical seal located on a submerged electrical motor LNG pump leaked causing flammable gas vapors to enter an electrical conduit and settle in a confined space. When a worker switched off a circuit breaker, the flammable gas ignited, causing severe damage to the building and a worker fatality. With the participation of the FERC, lessons learned from the 1979 Cove Point accident led to changes in the national fire codes to better ensure that the situation would not occur again. To ensure that this potential hazard would be addressed for proposed facilities that have electrical seal interfaces, we evaluated the preliminary designs and recommend in section 4.13.1.6 that Jordan Cove provide, for review and approval, the final design details of the electrical seal design at the interface between flammable fluids and the electrical conduit or wiring system, details of the electrical seal leak detection system, and the details of a downstream physical break (i.e. air gap) in the electrical conduit to prevent the migration of flammable vapors.

On January 19, 2004, a blast occurred at Sonatrach's Skikda, Algeria, LNG liquefaction plant that killed 27 and injured 56 workers. No members of the public were injured. Findings of the accident investigation suggested that a cold hydrocarbon leak occurred at Liquefaction Train 40 and was introduced into a high-pressure steam boiler by the combustion air fan. An explosion developed inside the boiler firebox, which subsequently triggered a larger explosion of the hydrocarbon vapors in the immediate vicinity. The resulting fire damaged the adjacent liquefaction process and liquid petroleum gas separation equipment of Train 40, and spread to Trains 20 and 30. Although Trains 10, 20, and 30 had been modernized in 1998 and 1999, Train 40 had been operating with

---

[196] For a description of the incident and the findings of the investigation, see "U.S. Bureau of Mines, Report on the Investigation of the Fire at the Liquefaction, Storage, and Regasification Plant of the East Ohio Gas Co., Cleveland, Ohio, October 20, 1944," dated February 1946.

its original equipment since start-up in 1981. To ensure that this potential hazard would be addressed for proposed facilities, we evaluated the preliminary design for mitigation of flammable vapor dispersion and ignition in buildings and combustion equipment to ensure they would be adequately covered by hazard detection equipment that could isolate and deactivate any combustion equipment whose continued operation could add to or sustain an emergency. We also recommend in section 4.13.1.6 that Jordan Cove provide, for review and approval, the final design details of hazard detection equipment, including the location and elevation of all detection equipment, instrument tag numbers, type and location, alarm indication locations, and shutdown functions of the hazard detection equipment.

On March 31, 2014, a detonation occurred within a gas heater at Northwest Pipeline Corporation's LNG peak-shaving plant in Plymouth, Washington.[197] This internal detonation subsequently caused the failure of pressurized equipment, resulting in high velocity projectiles. The plant was immediately shut down, and emergency procedures were activated, which included notifying local authorities and evacuating all plant personnel. No members of the public were injured, but one worker was sent to the hospital for injuries. As a result of the incident, the liquefaction trains and a compressor station located onsite were rendered inoperable. Projectiles from the incident also damaged the control building that was located near pre-treatment facilities and penetrated the outer shell of one of the LNG storage tanks. All damaged facilities were ultimately taken out of service for repair. The accident investigation showed that an inadequate purge after maintenance activities resulted in a fuel-air mixture remaining in the system. The fuel-air mixture auto-ignited during startup after it passed through the gas heater at full operating pressure and temperature. To ensure that this potential hazard would be addressed for proposed facilities, we recommend in section 4.13.1.6 that Jordan Cove provide a plan for purging, for review and approval, which addresses the requirements of the American Gas Association Purging Principles and Practice and to provide justification if not using an inert or non-flammable gas for purging. In evaluating such plans, we would assess whether the purging could be done safely based on review of other plans and lessons learned from this and other past incidents. If a plan proposes the use of flammable mediums for cleaning, dry-out or other activities, we would evaluate the plans against other recommended and generally accepted good engineering practices, such as NFPA 56, Standard for Fire and Explosion Prevention during Cleaning and Purging of Flammable Gas Piping Systems.

We also recommend in section 4.13.1.6 that Jordan Cove provide, for review and approval, operating and maintenance plans, including safety procedures, prior to commissioning. In evaluating such plans, we would assess whether the plans cover all standard operations, including purging activities associated with startup and shutdown. Also, in order to prevent other sources of projectiles from affecting occupied buildings and storage tanks, we recommend in section 4.13.1.6 that Jordan Cove incorporate mitigation into their final design with supportive information, for review and approval, that demonstrates it would mitigate the risk of a pressure vessel burst or boiling liquid expanding vapor explosion (BLEVE) from occurring.

FERC Preliminary Engineering Review

FERC requires an applicant to provide safety, reliability, and engineering design information as part of its application, including hazard identification studies and front-end-engineering-design (FEED) information for its proposed Project. FERC staff evaluates this information with a focus

[197] For a description of the incident and the findings of the investigation, see Root Cause Failure Analysis, Plymouth LNG Plant Incident Investigation under CP14-515.

on potential hazards from within and nearby the site, including external events, which may have the potential to cause damage or failure to the Project facilities, and the engineering design and safety and reliability concepts of the various protection layers to mitigate the risks of potential hazards.

The primary concerns are those events that could lead to a hazardous release of sufficient magnitude to create an offsite hazard or interruption of service. Furthermore, the potential hazards are dictated by the site location and the engineering details. In general, FERC staff considers an acceptable design to include various layers of protection or safeguards to reduce the risk of a potentially hazardous scenario from developing into an event that could impact the offsite public. These layers of protection are generally independent of one another so that any one layer would perform its function regardless of the initiating event or failure of any other protection layer. Such design features and safeguards typically include:

- a facility design that prevents hazardous events, including the use of inherently safer designs; suitable materials of construction; adequate design margins from operating limits for process piping, process vessels, and storage tanks; adequate design for wind, flood, seismic, and other outside hazards;
- control systems, including monitoring systems and process alarms, remotely-operated control and isolation valves, and operating procedures to ensure that the facility stays within the established operating and design limits;
- safety instrumented prevention systems, such as safety control valves and emergency shutdown systems, to prevent a release if operating and design limits are exceeded;
- physical protection systems, such as appropriate electrical area classification, proper equipment and building spacing, pressure relief valves, spill containment, and cryogenic, overpressure, and fire structural protection, to prevent escalation to a more severe event;
- site security measures for controlling access to the plant, including security inspections and patrols, response procedures to any breach of security, and liaison with local law enforcement officials; and
- onsite and offsite emergency response, including hazard detection and control equipment, firewater systems, and coordination with local first responders, to mitigate the consequences of a release and prevent it from escalating to an event that could impact the public.

The inclusion of such protection systems or safeguards in a plant design can minimize the potential for an initiating event to develop into an incident that could impact the safety of the offsite public. The review of the engineering design for these layers of protection are initiated in the application process and carried through to the next phase of the proposed project in final design if authorization is granted by the Commission.

The reliability of these layers of protection is informed by occurrence and likelihood of root causes and the potential severity of consequences based on past incidents and validated hazard modeling. As a result of the continuous engineering review, we recommend mitigation measures and continuous oversight to the Commission for consideration to include as conditions in the order. If a facility is authorized and recommendations are adopted as conditions to the order, FERC staff would continue its engineering review through final design, construction, commissioning, and operation.

Process Design

In order to liquefy natural gas, most liquefaction technologies require that the feed gas stream be pre-treated to remove components that could freeze out and clog the liquefaction equipment or would otherwise be incompatible with the liquefaction process or equipment, including mercury, H_2S, CO_2, water, and heavy hydrocarbons. For example, mercury is typically limited to concentrations of less than 0.01 micrograms per normal cubic meter because it can induce embrittlement and corrosion resulting in a catastrophic failure of equipment.

The inlet gas would be conditioned to remove solids and water droplets prior to entering feed gas pretreatment processes. Once the inlet gas is conditioned, the feed gas would enter the mercury removal system to reduce the mercury concentration in the feed gas. After mercury removal, the feed gas would contact an amine-based solvent solution in the amine contactor column to remove the H_2S and CO_2 (i.e., acid gas) present in the feed gas. Once the acid gas components accumulate in the amine solution, the amine solution is routed to an amine regenerator column that utilizes a reboiler to create hot amine vapor. Contact with the hot amine vapor would regenerate the amine solution by using heat to release the acid gas. The regenerated amine solution would be recycled back to the amine contactor column and the removed acid gas would be sent through a sulfur removal unit to remove H_2S. The acid gas stream is then routed to a thermal oxidizer, where CO_2, trace amounts of H_2S not removed in the sulfur removal unit, and trace amounts of hydrocarbons would be incinerated. The feed gas exiting the amine contactor column enters a knock out drum where bulk water would be recovered and recycled back to the amine contactor column. After the knock out drum, any remaining water in the feed gas would be removed using regenerative molecular sieve beds. Water collected during the molecular sieve regeneration process would be routed back to the amine contactor column. After water removal, the treated dry gas would flow to the liquefaction unit.

Heavy hydrocarbon removal would be integrated into the liquefaction process. The first pass through the refrigeration process would be used to remove heavy hydrocarbons at intermediate temperatures. The feed gas would flow into deethanizer to remove the liquids. The vapor portion would reenter the refrigeration process and would be sub-cooled into LNG. The liquid portion from the deethanizer would flow into the deethanizer reboiler stabilizer to further separate the heavier hydrocarbons from the lighter hydrocarbons. The heavier hydrocarbons exiting the deethanizer reboiler would be sent to the fuel gas system and the lighter hydrocarbons would be returned to the deethanizer for further processing. The LNG exiting the refrigeration process would flow to an LNG expander to reduce pressure, then into an LNG flash vessel before being pumped to two full containment LNG storage tanks.

In order to achieve the cryogenic temperatures needed to liquefy the natural gas stream in the above process, the gas would be cooled by a thermal exchange process driven by a closed loop refrigeration system using mixed refrigerants comprised of a mixture of nitrogen, methane, ethylene, propane, and isopentane. Methane would be provided from the treated dry feed gas stream entering the refrigeration process and the other refrigerants required for the liquefaction process would be delivered by truck and stored onsite for initial filling and use, as needed, for make-up. Truck unloading facilities would be provided to unload make-up refrigerants.

During export operations, LNG stored within the LNG storage tanks would be sent out through multiple in-tank pumps (the pump discharge piping would penetrate through the roof and is an inherently safer design when compared to penetrating the side of an LNG storage tank) and would be routed through a marine transfer line and multiple liquid marine transfer arms connected to an LNG marine vessel. In order to keep the marine transfer line cold between LNG export cargoes, an LNG recirculation line would keep the marine transfer line cold and avoid cool down prior to every LNG marine vessel loading operation. The LNG transferred to the LNG marine vessel would displace vapors from the marine vessel, which would be sent back through a vapor marine transfer arm, a vapor return line, and into the boil-off gas (BOG) header. Once loaded, the LNG marine vessel would be disconnected and leave for export. Low pressure BOG generated from stored LNG (LNG is continuously boiling), vapors returned during LNG marine vessel filling operations, and flash gas from the LNG flash vessel would be compressed and would be routed to the fuel gas system. The closed BOG system would prevent the release of BOG to the atmosphere and would be in accordance with NFPA 59A. This would be an inherently safer design when compared to allowing the BOG to vent to the atmosphere.

The Project would include many utilities and associated auxiliary equipment. The major auxiliary systems required for the operation of the liquefaction facility include BOG, fuel gas, flares, instrument and utility air supply, water supply, demineralized water, steam, aqueous ammonia, nitrogen, diesel, and backup power. Three flare systems would be designed to handle and control the vent gases from the process areas. The warm and cold flare would be routed to a common ground flare and the marine flare would be routed to a dedicated enclosed cylindrical ground flare. High pressure steam created using refrigerant compressor driver exhaust gas waste heat would generate electricity for the facility via the Steam Turbine Generators and would also supply heat to the Regeneration Gas Heater. Low pressure steam would provide heat to the Feed Inlet Heater, Amine Reboiler, Sulfur Scavenger Inlet Heater, Fuel Gas Superheater, and the Defrost Heater. An auxiliary steam boiler would be provided to generate steam when the refrigerant compressors are not in operation. A diesel storage tank would be provided to supply two standby diesel generators that would support the black start and power backup capability. The diesel storage tank would also supply three diesel firewater pumps. Trucks would fill a liquid nitrogen storage tank and vaporizers would supply gaseous nitrogen for refrigerant make-up. Site generated nitrogen would be used for compressor seals, purging activities, and utility stations as well as for pre-commissioning and start-up activities. In addition, aqueous ammonia would be used for pH adjustment in the steam system and to reduce nitrogen oxide emissions from the refrigerant compressor drivers.

The failure of process equipment could pose potential harm if not properly safeguarded through the use of appropriate engineering controls and operation. Jordan Cove would install process control valves and instrumentation to safely operate and monitor the facilities. Alarms would have visual and audible notification in the control room to warn operators that process conditions may be approaching design limits. Jordan Cove would design their control systems and human machine interfaces to the International Society for Automation (ISA) Standards 5.3, 5.5, 60.1, 60.3, 60.4, and 60.6, and other standards and recommended practices. Jordan Cove indicates that an alarm management program in accordance with ISA Standard 18.2 would be in place to ensure the effectiveness of the alarms. We recommend in section 4.13.1.6 that Jordan Cove develop and implement the alarm management program prior to introduction of hazardous fluids.

Operators would have the capability to take action from the control room to mitigate an upset. Jordan Cove would develop facility operation procedures after completion of the final design; this timing is fully consistent with accepted industry practice. We recommend in section 4.13.1.6 that Jordan Cove provide more information, for review and approval, on the operating and maintenance procedures, including safety procedures, hot work procedures and permits, abnormal operating conditions procedures, and personnel training prior to commissioning. We would evaluate these procedures to ensure that an operator can operate and maintain all systems safely, based on benchmarking against other operating and maintenance plans and comparing against recommended and generally accepted good engineering practices, such as American Institute of Chemical Engineers (AIChE) Center for Chemical Process Safety (CCPS), *Guidelines for Writing Effective Operating and Maintenance Procedures*, AIChE CCPS, *Guidelines for Management of Change for Process Safety*, AIChE CCPS, *Guidelines for Effective Pre-Startup Safety Reviews, AGA, Purging Principles and Practices*, and NFPA 51B, *Standards for Fire Prevention During Welding, Cutting, and Other Hot Work*. In addition, we recommend in section 4.13.1.6 that Jordan Cove tag and label instrumentation and valves, piping, and equipment and provide car-seals/locks to address human factor considerations and improve facility safety and prevent incidents.

In the event of a process deviation, emergency shutdown (ESD) valves and instrumentation would be installed to monitor, alarm, shutdown, and isolate equipment and piping during process upsets or emergency conditions. The Project would also have a plant-wide emergency shutdown system to initiate closure of valves and shutdown of the process during emergency situations as well as the ability to shutdown specific areas to address local emergency conditions. Safety-instrumented systems would comply with ISA Standard 84.00.01 and other recommended and generally accepted good engineering practices. We also recommend in section 4.13.1.6 that Jordan Cove file information, for review and approval, on the final design, installation, and commissioning of instrumentation and emergency shutdown equipment to ensure appropriate cause-and-effect alarm or shutdown logic and enhanced representation of the emergency shutdown system in the plant control room and throughout the plant.

In developing the FEED, Jordan Cove conducted a Hazard Identification (HAZID) review project's preliminary design based on the proposed process flow diagrams and the plot plans. In addition, the Jordan Cove performed two Hazard and Operability and Layer of Protection Analysis (HAZOP and LOPA) Studies. Each HAZOP was used to identify and analyze the potential hazards within the design that might pose an unacceptable risk to people, the environment, and assets and was based on the piping and instrumentation diagrams. Each LOPA was used to analyze selected scenarios of high risk to personnel, the environment, or assets, as identified in the HAZOP, to assure the appropriate risk level reduction, based on risk reduction factors for the hazard.

A more detailed hazard and operability review (HAZOP) analysis would be performed by Jordan Cove during the final design to identify the major process hazards that may occur during the operation of the facilities. The HAZOP study would be intended to address hazards of the process, engineering, and administrative controls and would provide a qualitative evaluation of a range of possible safety, health, and environmental consequences that may result from the process hazard, and identify whether there are adequate safeguards (e.g., engineering and administrative controls) to prevent or mitigate the risk from such events. Where insufficient engineering or administrative controls were identified, recommendations to prevent or minimize these hazards would be generated from the results of the HAZOP review. We recommend in section 4.13.1.6 that Jordan Cove file the HAZOP study on the completed final design for review and approval. We would evaluate the HAZOP to ensure all systems and process deviations are addressed appropriately based on likelihood, severity, and risk values with commensurate layers of protection in accordance with recommended and generally accepted good engineering practices, such as American Institute of Chemical Engineers, Guidelines for Hazard Evaluation Procedures. We also recommend in section 4.13.1.6 that Jordan Cove file the resolutions of the recommendations generated by the HAZOP review be provided for review and approval by FERC staff. Once the design has been subjected to a HAZOP review, the design development team would track, manage, and keep records of changes in the facility design, construction, operations, documentation, and personnel. Jordan Cove would evaluate these changes to ensure that the safety, health, and environmental risks arising from these changes are addressed and controlled based on its management of change procedures. If our recommendations are adopted into the order, resolutions of the recommendations generated by the HAZOP review would be monitored by FERC staff. We also recommend in section 4.13.1.6 that Jordan Cove file all changes to their FEED for review and approval by FERC staff. However, major modifications could require an amendment or new proceeding.

If the Project is authorized and constructed, Jordan Cove would install equipment in accordance with its design. We recommend in section 4.13.1.6 that Project facilities be subject to construction inspections and that Jordan Cove provide, for review and approval, commissioning plans, procedures and commissioning demonstration tests that would verify the performance of equipment. In addition, we recommend in section 4.13.1.6 that Jordan Cove provide semi-annual reports that include abnormal operating conditions and planned facility modifications. Furthermore, we recommend in section 4.13.1.6 that the Project facilities be subject to regular inspections throughout the life of the facilities to verify that equipment is being properly maintained and to verify basis of design conditions, such as feed gas and sendout conditions, do not exceed the original basis of design.

Mechanical Design

Jordan Cove provided codes and standards for the design, fabrication, construction, and installation of piping and equipment and specifications for the facility. The design specifies materials of construction and ratings suited to the pressure and temperature conditions of the process design. Piping would be designed, fabricated, assembled, erected, inspected, examined, and tested in accordance with the American Society of Mechanical Engineers (ASME) Standards B31.3, B36.10, and B36.19. Valves and fittings would be designed to standards and recommended practices such as API Standards 594, 598, 600, 602, 603, 607, 608, 609, and 623; ASME Standards B16.5, B16.9, B16.10, B16.20, B16.21, B16.25, B16.34, B16.36 and B16.47; and ISA Standards 75.01.01, 75.05.01, 75.08.01, and 75.08.05. Portions of the facility regulated under 33 CFR 127 for the marine transfer system, including piping, hoses, and loading arms should also be tested in accordance with 33 CFR 127.407.

Pressure vessels must be designed, fabricated, inspected, examined, and tested in accordance with ASME Boiler and Pressure Vessel Code (BPVC) Section VIII and per 49 CFR 193 Subparts C, D, and E and NFPA 59A (2001). LNG storage tanks must be designed, fabricated, tested, and inspected in accordance with 49 CFR 193 Subpart D, NFPA 59A (2001 and 2006), and API Standard 620. In addition, Jordan Cove would design, fabricate, test, and inspect the LNG storage tanks in accordance with API Standard 625 and American Concrete Institute (ACI) 376. Other low-pressure storage tanks such as the amine storage tank would be designed, inspected, and maintained in accordance with the API Standards 650 and 653. All LNG storage tanks would also include boil-off gas compression to prevent the release of boil-off to the atmosphere in accordance with NFPA 59A (2001) for an inherently safer design. The Heat exchangers would be designed to ASME BPVC Section VIII standards; API Standards 660 and 661; the Tubular Exchanger Manufacturers Association (TEMA) standards; and Aluminum Plate-Fin Heat Exchanger Manufacturer's Association (ALPEMA) guidelines. Rotating equipment would be designed to standards and recommended practices, such as API Standards 610, 613, 614, 617, 618, 619, 670, 672, 674, 675, 676, and 682; and ASME Standards B73.1 and B73.2. Fired heaters would be specified and designed to standards and recommended practices, such as API Standards 530, 556 and 560, and NFPA 85.

Pressure and vacuum safety relief valves, a vent stack, and flares would be installed to protect the storage containers, pressure vessels, process equipment, and piping from an unexpected or uncontrolled pressure excursion. The safety relief valves would be designed to handle process upsets and thermal expansion within piping, per NFPA 59A (2001) and ASME Section VIII; and would be designed in accordance with API Standards 520, 521, 526, 527, 537, and 2000; ASME Standards B31.3; and other recommended and generally accepted good engineering practices. In addition, the operator should verify the set pressure of the pressure relief valves meet the requirements in 33 CFR 127.407. We recommend in section 4.13.1.6 Jordan Cove provide final design information on pressure and vacuum relief devices, vent stack, and flares, for review and approval, to ensure that the final sizing, design, and installation of these components are adequate and in accordance with the standards reference and other recommended and generally accepted good engineering practices.

Although many of the codes and standards were listed as ones the project would meet, Jordan Cove did not make reference to all codes and standards required by regulations or are recommended and generally accepted good engineering practices. Therefore, we recommend in section 4.13.1.6 that Jordan Cove provide the final specifications for all equipment and a summarized list of all referenced codes and standards for review and approval. If the Project is authorized and constructed, Jordan Cove would install equipment in accordance with its specifications and design, and FERC staff would verify equipment nameplates to ensure equipment is being installed based on approved design. In addition, FERC staff would conduct construction inspections including reviewing quality assurance and quality control plans to ensure construction work is being performed according to proposed Project specifications, procedures, codes, and standards. We recommend in section 4.13.1.6 Jordan Cove provide semi-annual reports that include equipment malfunctions and abnormal maintenance activities. In addition, we recommend in section 4.13.1.6 that the Project facilities be subject to inspections to verify that the equipment is being properly maintained during the life of the facility.

Hazard Mitigation Design

If operational control of the facilities were lost and operational controls and emergency shutdown systems failed to maintain the Project within the design limits of the piping, containers, and safety relief valves, a release could potentially occur. FERC regulations under 18 CFR 380.12 (o) (1) through (4) require applicants to provide information on spill containment, spacing and plant layout, hazard detection, hazard control, and firewater systems. In addition, 18 CFR 380.12 (o) (7) require applicants to provide engineering studies on the design approach and 18 CFR 380.12 (o) (14) requires applicants to demonstrate how they comply with 49 CFR 193 and NFPA 59A.

As required by 49 CFR 193 Subpart I and by incorporation section 9.1.2 of NFPA 59A (2001), fire protection must be provided for all USDOT regulated LNG facilities based on an evaluation of sound fire protection engineering principles, analysis of local conditions, hazards within the facility, and exposure to or from other property. NFPA 59A (2001) also requires the evaluation on the type, quantity, and location of hazard detection and hazard control, passive fire protection, emergency shutdown and depressurizing systems, and emergency response equipment, training, and qualifications. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 Subpart I and would be subject to USDOT's inspection and enforcement programs. However, NFPA 59A (2001) also indicates the wide range in size, design, and location of LNG facilities precludes the inclusion of detailed fire protection provisions that apply to all facilities comprehensively and includes subjective performance-based language on where ESD systems and hazard control are required and does not provide any additional guidance on placement or selection of hazard detection equipment and provides minimal requirements on firewater. Also, the project marine facilities would be subject to 33 CFR 127, which incorporates sections of NFPA 59A (1994), which have similar performance-based guidance. Therefore, FERC staff evaluated the proposed spill containment and spacing, hazard detection, emergency shutdown and depressurization systems, hazard control, firewater coverage, structural protection, and onsite and offsite emergency response to ensure they would provide adequate protection of the LNG facilities as described below.

Jordan Cove performed a preliminary fire protection evaluation to ensure that adequate mitigation would be in place, including spill containment and spacing, hazard detection, emergency shutdown and depressurization systems, hazard control, firewater coverage, structural protection, and onsite and offsite emergency response. We recommend in section 4.13.1.6 that Jordan Cove provide a final fire protection evaluation that evaluates the type, quantity, and location of hazard detection and hazard control, passive fire protection, emergency shutdown and depressurizing systems, and emergency response equipment, training, and qualifications in accordance with NFPA 59A (2001), and to provide more information on the final design, installation, and commissioning of spill containment, hazard detection, hazard control, firewater systems, structural fire protection, and onsite and offsite emergency response procedures for review and approval.

Spill Containment

In the event of a release, sloped areas at the base of storage and process facilities would direct a spill away from equipment and into the impoundment system. This arrangement would minimize the dispersion of flammable vapors into confined, occupied, or public areas and minimize the potential for heat from a fire to impact adjacent equipment, occupied buildings, or public areas if ignition were to occur.

Title 49 CFR 193.2181 Subpart C specifies that each impounding system serving an LNG storage tank must have a minimum volumetric liquid capacity of 110 percent of the LNG tank's maximum design liquid capacity for an impoundment serving a single tank, unless surge is accounted for in the impoundment design. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 Subpart C and would be subject to USDOT's inspection and enforcement programs. For full containment LNG tanks, we also consider it prudent to provide a barrier to prevent liquid from flowing to an unintended area (i.e., outside the plant property). The purpose of the barrier is to prevent liquid from flowing off the plant property and does not define containment or an impounding area for thermal radiation or flammable vapor exclusion zone calculations or other code requirements already met by sumps and impoundments throughout the site. Jordan Cove proposes two full-containment LNG storage tanks for which the outer tank wall would serve as the impoundment system. FERC staff verified that the LNG storage tank's outer concrete wall would have a liquid capacity of at least 110 percent of the inner LNG tank's maximum liquid capacity. In addition, Jordan Cove would also install a berm around the LNG storage tank area to prevent liquid in the storage tank area from flowing off-site in the event of an outer tank impoundment failure.

Jordan Cove proposes to install curbing, paving, and trenches to direct potential LNG, refrigerant, and heavy hydrocarbon liquid releases to the Process/Tank Impoundment Basin. LNG releases from ship loading piping would be directed to either the Process/Tank Impoundment Basin or the Marine Impoundment Basin. Releases in the refrigerant storage area or from refrigerant delivery trucks would be collected in curbed areas and directed via a trench to the Refrigerant Storage Impoundment Basin. This basin would be sized to be greater than the largest refrigerant storage tank. Jordan Cove would also include local containment walls around the Amine Make-up Storage Tank, Liquid Nitrogen Storage Tank, Ammonia Storage Tank, and Diesel Storage Tank which would have a volumetric capacity of greater than 110 percent of the maximum liquid volume in each storage tank. The design would also include curbed areas in the acid gas removal area to contain amine releases. However, Jordan Cove did not propose a spill containment system to collect liquid releases from the Warm Flare Knockout Drum. Therefore we recommend in section 4.13.1.6 that Jordan Cove specify a spill containment system around the Warm Flare Knockout Drum.

Under NFPA 59A (2001), section 2.2.2.2, the capacity of impounding areas for vaporization, process, or LNG transfer areas must equal the greatest volume that can be discharged from any single accidental leakage source during a 10-minute period or during a shorter time period based upon demonstrable surveillance and shutdown provisions acceptable to the USDOT. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 Subpart C and would be subject to USDOT's inspection and enforcement programs. The impoundment system design for the marine facilities would be subject to the Coast Guard's 33 CFR 127, which does not specify a spill or duration for impoundment sizing. However, we evaluate whether all hazardous liquids are provided with spill containment based on the largest flow capacity from a single pipe for 10 minutes accounting for de-inventory or the liquid capacity of the largest vessel (or total of impounded vessels) served, whichever is greater and whether providing spill containment reduces consequences from a release. We recommend in section 4.13.1.6 that Jordan Cove provide additional information on the final design of the impoundment systems for review and approval.

Jordan Cove indicated that all piping, hoses, and equipment that could produce a hazardous liquid spill would be provided with spill collection and/or spill conveyance systems. Furthermore, Jordan Cove indicates that the stormwater pumps would be automatically operated by level control and interlocked using redundant low temperature detectors to prevent pumps from operating if LNG is present within the LNG spill basins. Although stormwater removal pumps would be proposed for the large impoundment basins, Jordan Cove proposes to install normally-closed valves on local curbed areas and within bund walls to allow analysis of stormwater prior to routing it to the drainage channels. Jordan Cove is consulting with USDOT on the use of normally-closed valves instead of stormwater removal pumps required in 49 CFR 193 Subpart C. Therefore we recommend in section 4.13.1.6 that Jordan Cove provide correspondence from USDOT on the use of normally closed valves to remove stormwater from curbed areas. In addition, low temperature detectors would not stop the stormwater removal pumps from operating in the event a relatively warm heavy hydrocarbon release reaches the impoundment basins. Therefore, Jordan Cove indicated that gas detectors would be provided to prevent the stormwater removal pumps from operating if warm refrigerant or heavy hydrocarbon releases could reach an impoundment basin. If the facilities are approved and constructed, final compliance with the requirements of 49 CFR 193 Subpart C, would be subject to USDOT's inspection and enforcement programs.

If a project is authorized and constructed, Jordan Cove would install spill impoundments in accordance with its design and FERC staff would verify during construction inspections that the spill containment system including dimensions, and slopes of curbing and trenches, and volumetric capacity matches final design information. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility to verify that impoundments are being properly maintained.

Spacing and Plant Layout

The spacing of vessels and equipment between each other, from ignition sources, and to the property line must meet the requirements of 49 CFR 193 Subparts C, D, and E, which incorporate NFPA 59A (2001). NFPA 59A (2001) includes spacing and plant layout requirements and further references NFPA 30, NFPA 58, and NFPA 59 for additional spacing and plant layout requirements. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 and would be subject to USDOT's inspection and enforcement programs.

In addition, FERC staff evaluated the spacing to determine if there could be cascading damage and to inform what fire protection measures may be necessary to reduce the risk of cascading damage. If spacing to mitigate the potential for cascading damage was not practical, we evaluated whether other mitigation measures were in place and evaluated those systems in further detail as discussed in subsequent sections in section 4.13.5.5. We evaluated the spacing of buildings in line with AIChE CCPS *Guidelines for Evaluating Process Plant Buildings for External Explosions and Fires* and API 752, which provide guidance on identifying and evaluating explosion and fire impacts to plant buildings and occupants resulting from events external to the buildings. Jordan Cove submitted a building siting analysis based on API 752 and also indicated it would meet ASCE 59 to determine explosion impacts to plant buildings. In addition, FERC staff evaluated other hazards associated with releases and whether any damage would likely occur at buildings or would result in cascading damage.

To minimize the risk of cryogenic spills causing structural supports and equipment from cooling below their minimum design metal temperature, Jordan Cove would generally locate cryogenic equipment away from process areas and would have spill containment systems for cryogenic spills that would direct them to a remote impoundment. In addition, Jordan Cove would protect equipment and structural steel against cold shocks through selection of suitable materials of construction or by the application of cold spill protection. We recommend in section 4.13.1.6 that Jordan Cove file drawings and specifications for structural passive protection systems to protect equipment and supports that could be exposed to cryogenic releases.

To minimize risk for flammable or toxic vapor ingress into buildings and from reaching areas that could result in cascading damage from explosions, Jordan Cove would generally locate buildings away from process areas and would locate fired equipment and ignition sources away from process areas. In addition, the LNG storage tanks are generally located away from process equipment and process facilities are relatively unconfined and uncongested. Therefore, we recommend in section 4.13.1.6 that Jordan Cove conduct a technical review of facility, for review and approval, identifying all combustion/ventilation air intake equipment and the distances to any possible flammable gas or toxic release; and verify that these areas would be adequately covered by hazard detection devices that would isolate or shut down any combustion or heating ventilation and air conditioning equipment whose continued operation could add to or sustain an emergency. In addition, we recommend in section 4.13.1.6 that Jordan Cove demonstrate adequate ventilation and detection in the battery rooms to mitigate hydrogen build up from battery off-gas. We also recommend in section 4.13.1.6 that Project facilities be subject to periodic inspections during construction to verify flammable/toxic gas detection equipment is installed in heating, ventilation, and air condition intakes of buildings at appropriate locations. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facilities to continue to verify that flammable/toxic gas detection equipment installed in building air intakes function as designed and are being maintained and calibrated.

To minimize overpressures from vapor cloud explosions, we evaluated how flammable vapors would be prevented from accumulating within confined areas. Jordan Cove would design for overpressures in accordance with API 753, ASCE 41088, and other recommended and generally accepted good engineering practices. In addition, explosions in process areas were evaluated and demonstrated to produce less than 1 psi side on overpressure at the LNG storage tanks. However, vapor dispersion could disperse underneath the LNG storage tanks. Therefore, we recommend in section 4.13.1.6 that Jordan Cove file an analysis for review and approval that demonstrates the flammable vapor dispersion from design spills would be prevented from dispersing underneath the elevated LNG storage tanks or detail how the LNG storage tanks would be able to withstand an overpressure due to ignition of the flammable vapors that disperse underneath the elevated LNG storage tanks.

To minimize the risk of pool fires from causing cascading damage, Jordan Cove located the spill impoundments such that the radiant heats would have a minimal impact on most areas of the plant. Fires within the process impoundments would be spaced such that there would not be high radiant heats on any equipment. A fire from the LNG storage tank outer containment walls would result in radiant heats over 10,000 Btu/ft^2-hr at the adjacent LNG storage tank. Therefore, we recommend in section 4.13.1.6 that Jordan Cove file an analysis for review and approval demonstrating the tanks can withstand the radiant heat from adjacent LNG storage tank fires. In addition, a fire from the tank outer walls would result in less than 4,000 Btu/ft^2-hr in most other areas of the plant with the exception of the LNG Flash Drum and the Auxiliary Boiler. Jordan Cove would install fixed water spray systems that would cover the LNG Flash Drum and Auxiliary Boiler. In addition, the LNG Flash Drum would be insulated for cryogenic service which would shield the equipment from the radiant heat.

To minimize the risk of jet fires from causing cascading damage that could exacerbate the initial hazard, Jordan Cove would shroud the LNG transfer piping and LNG product header and would locate flammable and combustible containing piping and equipment away from buildings and process areas that do not handle flammable and combustible materials. Jordan Cove would also install emergency shutdown systems that would limit the duration of a jet fire event, depressurization systems that would reduce the pressure in equipment, and would install firewater systems to cool equipment and structures as described in subsequent sections in section 4.13.5.5. In addition, we recommend in section 4.13.1.6 that Jordan Cove file drawings of the passive structural fire protection for review and approval for structural supports and equipment.

In addition, FERC staff evaluated the spacing to determine if there could be cascading damage and to inform what fire protection measures may be necessary to reduce the risk of cascading damage. Thermal radiation levels from an LNG tank roof top fire and other impoundments could potentially impact process equipment, process vessels, and piperacks located within the pretreatment area, liquefaction trains, BOG compressor area, the utility area, and at the Marine Flare. To mitigate against a LNG tank roof top fire, impoundment fires, and jet fires within the plant, Jordan Cove proposes thermal radiation mitigation measures to prevent cascading events in the design, including thermal protection insulation, fire-retardant insulation materials, emergency depressurization, flame, combustible gas and low temperature detectors, fire proofing of structural steel columns supporting critical equipment, fixed automatic firewater spray system, high expansion foam system, and firewater monitors and hydrants. However, details of these systems would be done in final design. Therefore, we recommend in section 4.13.1.6 that Jordan Cove provide the final design of these thermal mitigation measures, for review and approval, to demonstrate cascading events would be mitigated.

If the project is authorized, Jordan Cove would finalize the plot plan, and we recommend in section 4.13.1.6 that Jordan Cove provide any changes for review and approval to ensure capacities and setbacks are maintained. If the facilities are constructed, Jordan Cove would install equipment in accordance with the spacing indicated on the plot plans. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to periodic inspections during construction to verify equipment is installed in appropriate locations and the spacing is met in the field. We also recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facilities to continue to verify that equipment setbacks from other equipment and ignition sources are being maintained during operations.

Ignition Controls

Jordan Cove LNG Project's plant areas would be designated with a hazardous electrical classification and process seals commensurate with the risk of the hazardous fluids being handled in accordance with NFPA 59A (2001), 70, 497, and API RP 500. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 and would be subject to USDOT's inspection and enforcement programs, which require compliance, by incorporation by reference, with NFPA 59A (2001) and NFPA 70 (1999). The marine facilities must comply with similar electrical area classification requirements of NFPA 59A (1994) and NFPA 70 (1993), which are incorporated by reference into the Coast Guard regulations in 33 CFR 127. Depending on the risk level, these areas would either be unclassified or classified as Class 1 Division 1, or Class 1 Division 2. Electrical equipment located in these areas would be designed such that in the event a flammable vapor is present, the equipment would have a minimal risk of igniting the vapor. We evaluated Jordan Cove's electrical area classification drawings to determine whether Jordan Cove would meet these electrical area classification requirements and good engineering practices in NFPA 59A, 70, 497, and API RP 500. We recognize that Jordan Cove appears to meet NFPA 59A (1994 and 2001), NFPA 70 (1993 and 1999), and most of NFPA 497 and API 500, and recommend in section 4.13.1.6 that Jordan Cove provide final electrical area classification drawings for review and approval.

If the project is authorized, Jordan Cove would finalize the electrical area classification drawings and would describe changes made from the FEED design. We recommend in section 4.13.1.6 that Jordan Cove file the final design of the electrical area classification drawings for review and approval. If facilities are constructed, Jordan Cove would install appropriately classed electrical equipment, and we recommend in section 4.13.1.6 that Project facilities be subject to periodic inspections during construction for FERC staff to spot check electrical equipment and verify equipment is installed per classification and are properly bonded or grounded in accordance with NFPA 70. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility to ensure electrical equipment is maintained (e.g., bolts on explosion proof equipment properly installed and maintained, panels provided with purge, etc.), and electrical equipment are appropriately de-energized and locked out and tagged out when being serviced.

In addition, submerged pumps and instrumentation must be equipped with electrical process seals, and instrumentation in accordance with NFPA 59A (2001) and NFPA 70. We recommend in section 4.13.1.6 that Jordan Cove provide, for review and approval, final design drawings showing process seals installed at the interface between a flammable fluid system and an electrical conduit or wiring system that meet the requirements of NFPA 59A (2001) and NFPA 70. In addition, we recommend in section 4.13.1.6 that Jordan Cove file, for review and approval, details of an air gap or vent equipped with a leak detection device that should continuously monitor for the presence of a flammable fluid, alarm the hazardous condition, and shut down the appropriate systems. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility to ensure electrical process seals for submerged pumps continue to conform to NFPA 59A and NFPA 70 and that air gaps are being properly maintained.

Hazard Detection, Emergency Shutdown, and Depressurization Systems

Jordan Cove would also install hazard detection systems to detect cryogenic spills, flammable and toxic vapors, and fires. The hazard detection systems would alarm and notify personnel in the area and control room to initiate an emergency shutdown, depressurization, or initiate appropriate procedures, and would meet NFPA 72, ISA Standard 12.13, and other recommended and generally accepted good engineering practices. In addition, we recommend in section 4.13.1.6 that Jordan Cove provide specifications, for review and approval, for the final design of fire safety specifications, including hazard detection, hazard control, and firewater systems.

FERC staff also evaluated the adequacy of the general hazard detection type, location, and layout to ensure adequate coverage to detect cryogenic spills, flammable and toxic vapors, and fires near potential release sources (i.e., pumps, compressors, sumps, trenches, flanges, and instrument and valve connections). We recommend in section 4.13.1.6 that Jordan Cove file a hazard detection study to evaluate the effectiveness of their flammable and combustible gas detection and flame and heat detection systems in accordance with ISA 84.00.07 or equivalent methodologies. This evaluation would need to demonstrate that 90 percent or more of releases (unignited and ignited) that could result in an off-site or cascading impact would be detected by two or more detectors and result in isolation and de-inventory within 10 minutes. The analysis should take into account the set points, voting logic, wind speeds, and wind directions. FERC staff also reviewed the fire and gas cause and effect matrices to evaluate the detectors that would initiate an alarm, shutdown, depressurization, or other action based on the FEED. Jordan Cove did not provide the fire and gas system cause and effect matrices that indicate how each detector would initiate an alarm, shutdown, depressurization, or conduct other action. Therefore, we recommend in section 4.13.1.6 that Jordan Cove provide, for review and approval, the cause and effect matrices for process instrumentation, fire and gas detection system, and emergency shutdown system.

In addition, Jordan Cove specified low oxygen detectors at the liquid nitrogen storage tanks, but did not denote the location of the low oxygen detectors in the Project drawings. Therefore, we recommend in section 4.13.1.6 that Jordan Cove provide additional information, for review and approval, on the final design of all hazard detection systems (e.g., manufacturer and model, elevations, etc.) and hazard detection layout drawings. If the project is authorized and constructed, Jordan Cove would install hazard detectors according to its final specifications and drawings, and we recommend in section 4.13.1.6 that Project facilities be subject to periodic inspections during construction to verify hazard detectors and ESD pushbuttons are appropriately installed per approved design and functional based on cause and effect matrixes prior to introduction of hazardous fluids. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility to verify hazard detector coverage and functionality is being maintained and are not being bypassed without appropriate precautions.

Hazard Control

If ignition of flammable vapors occurred, hazard control devices would be installed to extinguish or control incipient fires and releases, and would meet NFPA 59A; NFPA 10, 12, 17, and 2001; API Standard 2510A; and other recommended and generally accepted good engineering practices. We evaluated the adequacy of the number and availability of handheld, wheeled, and fixed fire extinguishing devices throughout the site based on the FEED. FERC staff also evaluated whether the spacing of the fire extinguishers would meet NFPA 10 and agent type and capacities meet NFPA 59A (2009 and later editions). The hazard control plans appeared to meet NFPA 10 travel distances to most components containing flammable or combustible fluids (Class B) for handheld fire extinguishers (30 to 50 feet) and wheeled extinguishers (100 feet) and NFPA 10 travel distance to most other components that could pose an ordinary combustible hazard (Class A) or associated electrical (Class C) hazard for handheld extinguishers (75 feet). Buildings also appear to be provided with handheld extinguishers that appear to satisfy NFPA 10 requirements, including placement at each entry/exit. The agent type (potassium bicarbonate) and agent storage capacities for wheeled (minimum 125 pounds [lb]) and for handheld extinguishers (minimum 20 lb) also appear to meet NFPA 59A requirements. In addition, travel distances, installation heights, visibility, flow rate capacities, and other requirements should be confirmed in final design and in the field where design details, such as manufacturer, obstructions, and elevations, would be better known. Therefore, we recommend in section 4.13.1.6 that Jordan Cove files the final design of these systems, for review and approval, where details are yet to be determined (e.g., manufacturer and model, elevations, flowrate, capacities, etc.) and where the final design could change as a result of these details or other changes in the final design of the Project.

In addition, we evaluated whether clean agent systems would be installed in all instrumentation buildings in accordance with NFPA 2001. Jordan Cove would install clean agent fire suppression systems in accordance with NFPA 2001 in buildings that house electrical and control equipment such as the Control Room, power distribution equipment rooms, and power generation houses. Jordan Cove also indicated that CO2 extinguishers as well as dry chemical extinguishers would be provided in the electrical powerhouses. In addition, Jordan Cove would provide a carbon dioxide extinguishing system for the refrigerant compressors turbines in accordance with NFPA 12.

If the Project is authorized and constructed, Jordan Cove would install hazard control equipment, and we recommend in section 4.13.1.6 that Project facilities be subject to periodic inspections during construction to verify hazard control equipment is installed in the field and functional prior to introduction of hazardous fluids. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility to verify in the field that hazard control coverage and is being properly maintained and inspected.

Passive Cryogenic and Fire Protection

If cryogenic releases or fires could not be mitigated from impacting facility components to insignificant levels, passive protection (e.g., fireproofing structural steel, cryogenic protection, etc.) should be provided to prevent failure of structural supports of equipment and pipe racks. The structural fire protection would comply with NFPA 59A (2001) and other recommended and generally accepted good engineering practices. NFPA 59A (2001) section 6.4.1 requires pipe supports, including any insulation systems used to support pipe whose stability is essential to plant safety, to be resistant to or protected against fire exposure, escaping cold liquid, or both, if they are subject to such exposure. However, NFPA 59A (2001) does not provide the criteria for determining if they are subject to such exposure or the level of protection needed to protect the pipe supports against such exposures. In addition, NFPA 59A does not address cryogenic or structural protection of pressure vessels or other equipment.

Therefore, FERC staff evaluated whether passive cryogenic and fire protection would be applied to pressure vessels and structural supports to facilities that could be exposed to cryogenic liquids or radiant heats of 4,000 Btu/ft^2-hr or greater from fires with durations that could result in failures[198] and that they are specified in accordance with recommended and generally accepted good engineering practices with a fire protection rating commensurate to the exposure. The structural fire protection would comply with NFPA 59A (2001); API RP 2218; Association of the Wall and Ceiling Industry Technical Paper 12-A; International Organization for Standardization (ISO) 12944 and 22899; Underwriters Laboratories (UL) 1709; and other recommended and generally accepted good engineering practices.

To minimize the risk of cryogenic spills causing structural supports and equipment from cooling below their minimum design metal temperature, Jordan Cove would protect equipment and structural steel against cold shocks through selection of suitable materials of construction or by the application of coldproofing. In addition, Jordan Cove would have spill containment systems surrounding cryogenic equipment and would generally locate cryogenic equipment away from process areas that do not handle cryogenic materials. Cryogenic protection would comply with NFPA 59A (2001), ISO 20088, and other recommended and generally accepted good engineering practices. In addition, Jordan Cove would install a firewall between the refrigerant storage tanks and the Refrigerant Storage Impoundment Basin to prevent cascading damage from radiant heats in excess of 4,000 Btu/ft^2-hr. We recommend in section 4.13.1.6 that Jordan Cove file drawings and specifications of the final design, for review and approval, for the structural passive protection systems to protect equipment and supports from cryogenic releases.

---

198 Pool fires from impoundments are generally mitigated through use of emergency shutdowns, depressurization systems, structural fire protection, and firewater, while jet fires are primarily mitigated through the use of emergency shutdowns, depressurization systems, and firewater with or without structural fire protection.

To minimize the risk of a pool or jet fire from causing cascading damage, Jordan Cove would generally locate flammable and combustible containing piping, equipment, and impoundments away from buildings and other process areas that do not handle flammable and combustible materials. Jordan Cove demonstrated that the radiant heats from pool fires from the LNG storage tank outer containment walls and impoundments would have a minimal impact on most areas of the plant. A pool fire from the outer tank wall would result in less than 4,000 Btu/ft^2-hr in most other areas of the plant with the exception of the LNG Flash Drum and Auxiliary Boiler. Fires within the other impoundments would be spaced such that there would be less than 4,000 Btu/ft^2-hr on any equipment.

In addition, we recommend in section 4.13.1.6 that Jordan Cove demonstrate that passive protection is provided in areas where jet fires may result in failure of structural supports. Jordan Cove would need to file drawings of the passive structural fire protection for review and approval for structural supports and equipment that could result in a failure when exposed to a jet fire. In addition, we recommend in section 4.13.1.6 that Jordan Cove provide additional information on final design of these systems, for review and approval, where details are yet to be determined (e.g., calculation of structural fire protection materials, thicknesses, etc.) and where the final design could change as a result of these details or other changes in the final design of the Project.

We also note that it was unclear whether Jordan Cove would install fire walls in transformer areas, which would be required for certain transformers. Therefore, we recommend in section 4.13.1.6 that Jordan Cove separate or provide fire walls for transformer in accordance with NFPA 850 or equivalent that would prevent cascading damage.

If the Project is authorized and constructed, Jordan Cove would install structural cryogenic and fire protection according to its design, and we recommend in section 4.13.1.6 that Project facilities be subject to periodic inspections during construction to verify structural cryogenic and fire protection is properly installed in the field as designed prior to introduction of hazardous fluids. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility to continue to verify that passive protection is being properly maintained.

Firewater Systems

Jordan Cove would also provide firewater systems, including remotely operated firewater monitors, sprinkler systems, fixed water spray systems, and firewater hydrants and hoses for use during an emergency to cool the surface of storage vessels, piping, and equipment exposed to heat from a fire. These firewater systems would be designed, tested, and maintained to meet NFPA 59A (2001), 13, 14, 15, 20, 22, 24, and 25 requirements. Jordan Cove would also provide high expansion foam for each LNG spill impoundment basin to reduce vaporization rates from LNG pools and would meet NFPA 59A (2001) and NFPA 11. FERC staff evaluated the adequacy of the general firewater or foam system coverage and verified the appropriateness of the associated firewater demands of those systems and worst-case fire scenarios to size the firewater and foam systems. Jordan Cove provided firewater coverage drawings for the firewater monitors and fire hydrants, however, where coverage circles intersect pipe racks, large vessels or process equipment, the firewater coverage could be blocked, and the coverage circles should be modified to account for obstructions during the final design. Additionally, not all areas of the gas pretreatment are adequately covered. We recommended in section 4.13.1.6 that Jordan Cove provide adequate firewater coverage for all of the pretreatment equipment. We recommend in section 4.13.1.6 that Jordan Cove file additional information on the final design of these systems, for review and approval, where details are yet to be determined (e.g., manufacturer and model, nozzle types, etc.) and where the final design could change as a result of these details or other changes in the final design of the Project.

FERC staff also assessed whether the reliability of the firewater pumps, firewater source, and onsite storage volume would be appropriate. Jordan Cove would provide a primary and backup firewater pump with different drivers per NFPA 20. Jordan Cove also states that the firewater tanks would meet NFPA 22 and API Standard 650. However, the firewater tank data sheet denotes that the firewater tanks would be designed to API Standard 650 and does not make reference to NFPA 22. Therefore, we recommend in section 4.13.1.6 that Jordan Cove design the firewater tanks in accordance with NFPA 22 or justify how API Standard 650 provides an equivant or better level of safety. Furthermore, Jordan Cove would provide a fully staffed fire department adjacent to the firewater tanks that would meet NFPA 600.

We also recommend in section 4.13.1.6 that Jordan Cove should specify that the firewater flow test meter is equipped with a transmitter and that a pressure transmitter is installed upstream of the flow transmitter, which should both be connected to the DCS and recorded to keep a history of flow test data. In addition, we recommend in section 4.13.1.6 that the largest firewater pump or component be able to be removed for maintenance from the firewater pump shelter. If the Project is authorized and constructed, Jordan Cove would install the firewater and foam systems as designed, and we recommend in section 4.13.1.6 that Project facilities be subject to periodic inspections during construction and that companies provide results of commissioning tests to verify the firewater and foam systems are installed and functional as designed prior to introduction of hazardous fluids. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility to ensure firewater and foam systems are being properly maintained and tested.

Geotechnical and Structural Design

Jordan Cove provided geotechnical and structural design information for its facilities to demonstrate the site preparation and foundation designs would be appropriate for the underlying soil characteristics and to ensure the structural design of the Project facilities would be in accordance with federal regulations, standards, and recommended and generally accepted good engineering practices. The application focuses on the resilience of the Project facilities against natural hazards, including extreme geological, meteorological, and hydrological events, such as earthquakes, tsunamis, seiche, hurricanes, tornadoes, floods, rain, ice, snow, regional subsidence, sea level rise, landslides, wildfires, volcanic activity, and geomagnetism.

Geotechnical Evaluation

FERC regulations under 18 CFR 380.12 (h) (3) require geotechnical investigations to be provided. In addition, FERC regulations under 18 CFR 380.12 (o) (14) require an applicant demonstrate compliance with regulations under 49 CFR 193 and NFPA 59A. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 and would be subject to USDOT's inspection and enforcement programs. USDOT regulations incorporate by reference NFPA 59A (2001). NFPA 59A (2001) section 2.1.4 requires soil and general investigations of the site to determine the design basis for the facility. However, no additional requirements are set out in 49 CFR 193 or NFPA 59A on minimum requirements for evaluating existing soil site conditions or evaluating the adequacy of the foundations, therefore FERC staff evaluated the existing site conditions, geotechnical report, and proposed foundations to ensure they are adequate for the LNG facilities as described below.

The Project would be located within the Pacific Border Physiographic province at the western edge of the coastal headlands of the Central Coast Mountain Range, on the North Spit of Coos Bay. The North Spit of Coos Bay marks the southern edge of the Holocene Epoch Coos Bay dune sheet (Peterson et al. 2006). The Project would be located near the eastern edge of the Cascadia Subduction Zone (CSZ), where the North American Plate is overriding the Explorer, Juan de Fuca, and Gorda tectonic plates (Wells et al. 2016). The converging tectonic plates have resulted in the accumulation of marine deltaic sediments and volcanic seamounts, referred to as the Siletzia Terrance, along the western edge of the North American tectonic plate (Heller and Ryberg 1983). The plates have also created a deformation zone along the western edge of the accumulation wedge complex, strike-slip and thrust/reverse faulting in the North American tectonic place, and a zone of bedrock folding extending from the coast eastward. The major tectonic elements associated with the subduction zone include the accumulation wedge complex, a deformed forearc basin consisting of the Coast Range and Willamette Valley, a volcanic arc complex consisting of the Cascade Mountain Range, and a backarc in eastern Oregon and Washington. The Project would be located at the junction of the accumulation wedge complex and the forearc basin. Local bedrock structures reflect east-west compressional deformation resulting from ongoing oblique subduction of the CSZ that has occurred since the late-middle Miocene Epoch (Wells and Peck 1961), and includes the megathrust itself, north-south trending folds, north-south trending reverse and thrust faults, and west-northwest trending oblique strike-slip faults (Black and Madin 1995; Madin et al. 1995; Goldfinger et al. 1992). The location and extent of local fold and fault structures have been inferred from stratigraphic, geomorphic, and geophysical evidence. Geologic structures south of the site include the South Slough Syncline, the Westport Arc (anticline), and the eastern and the western forks on the Westport Arc (Allen and Baldwin 1944).

Jordan Cove contracted KBJ (a joint venture consisting of Kiewit, Black & Veath, and JGC) and its subconsultants to conduct geotechnical investigations and report to evaluate existing soil site conditions and proposed foundation design for the Project. During the investigation, the facility was subdivided into three primary areas: Ingram Yard area, Access and Utility Corridor area and South Dunes area. The LNG liquefaction trains, LNG storage tanks, and marine facilities would be located in the Ingram Yard area. The average elevation of the existing grade in Ingram Yard area ranged from +20 to +125 feet North American Vertical Datum 1988 (NAVD 88), the Access and Utility Corridor area ranged from +20 to +135 feet NAVD 88, and the South Dune area was less variable and was approximately +15 feet NAVD 88. KBJ indicated that the geologic profile consists primarily of sand overlying sand and silt, and then overlies clayey silt. Below elevation −30 feet NAVD 88, the subsurface material is relatively consistent and generally dense. Above elevation −30 feet, the material is more variable, with organics, clay, and fill present in the upper near surface profile in portions of the Project site. The Project site would be demolished, cleared, relocated, grubbed, and prepared using standard earthmoving and compaction equipment. Site preparation would result in a final grade elevation from +46 to +70 feet NAVD 88 with varying amounts of fill/cut that cross the site. Exceptions include the LNG storage tanks and water-dependent facilities such as the marine terminal and the Material Offloading Facility (MOF). The LNG storage tank basins would have an elevation of approximately +27 feet NAVD 88 that would be surrounded by a tertiary protective berm with a crest elevation of no less than +46 feet NAVD

88. Jordan Cove indicated that the parts of the marine facilities that would be normally occupied or operational would typically be at an elevation of +34.5 feet or greater, whereas normally unoccupied/non-operational parts of the marine facilities may be at a lower elevation.

KBJ conducted subsurface investigations work including mud-rotary borings with standard penetration tests (SPTs), cone penetration test (CPT) soundings, test pits, electrical resistivity testing, measurement of shear and compression wave velocities, pressuremeter testing, infiltrometer testing, pump testing, geophysical surveys, and laboratory testing. The borings and shear wave velocity logging on the Project site were completed to depths of approximately 300 feet. Geotechnical laboratory testing was completed on representative samples of the soil obtained from the explorations for the purpose of determining its physical characteristics and engineering properties. Approximately 132 borings to depths ranging from 14 to 300 feet below existing grade, approximately 90 cone penetration tests (CPTs) to depths ranging from 16 to 80 feet (or to refusal) below existing grade, 21 temporary piezometers to measure groundwater levels, and over 5 different tests on recovered soil samples, including classification tests (water content, Atterberg liquid and plastic limits, sieve tests), compression tests, corrosion potential tests (pH, sulfate, chloride, electrical resistivity) in general accordance with pertinent American Society for Testing and Materials (ASTM) standards. Based on the results of analytical laboratory testing, the exposure of concrete and steel to the soil would not require special considerations. The results for sulfate in the groundwater tested indicate that no special considerations would be required to protect the concrete for the existing groundwater conditions. The electrical resistivity test results indicate a corrosion specialist should be consulted. In addition, Coos Bay is a salt water environment; therefore, materials in contact with the surface water in Coos Bay or in the immediate vicinity of Coos Bay should be protected from exposure to salt water. Currently the groundwater below the site is fresh water; however, if the marine slip is authorized and dredged, it is unclear how much water from Coos Bay would infiltrate into the dredged sands and increase the chloride content. Therefore, it is standard practice that the chloride content of the dredged sand be tested as dredging is performed. If the chloride contents are oberserved to increase during dredging, then any necessary corrosion protection should be implemented.

Based on the test borings conducted, a number of design profiles were developed for the Project site. At Ingram Yard area: the subsurface conditions are relatively consistent below EL −30 feet. The existing sands above EL −30 feet consists of either existing sand fill or native dune or estuary sand deposits. In the area of the dune on the eastern portion of the Ingram Yard area, the sands are native starting at the ground surface. Below EL −30 feet, the native sands is predominantly fine-grained, with occasional shells and silt zones. A sand-silt unit is present beneath the native sand at elevations ranging from −110 feet to −140 feet. Investigation borings completed near the south LNG storage tank in the Ingram Yard area encountered hard clayey silt that was classified as poorly indurated silty shale at a depth of approximately −252 feet. Another boring drilled about 480 feet north, did not encounter the poorly indurated silty shale when terminated at a depth of about −280 feet. At the Access and Utility Corridor area, the subsurface conditions are generally similar to Ingram Yard. Below EL −30 feet, the conditions are similar to the Ingram Yard area. Above EL −30 feet, the soil consists primarily of sand with both fill and native sand encountered. Organics and peat were encountered only in the western end of the Access and Utility Corridor between EL −11 feet and EL −10.5 feet. At the South Dune area, as at Ingram Yard and along the Access Utility Corridor, the subsurface conditions at the South Dunes area are relatively constant below EL −30 feet. The conditions above EL −30 feet vary mainly because of variation in the sands and the presence or absence of peat/organics. Peat/organics were encountered in several areas of the South Dunes area at elevations ranging from 4 to 9 feet. The existing sand above EL −30 feet consists of fill, and native dune and estuary sand deposits. In the northeast quadrant of the South Dunes a layer of clay was encountered from EL 6 to 3.5 feet. The clay thickness varies from 0.3 foot to 2.5 feet and the material is very soft to soft with high plasticity. In the east central portion of the South Dunes, the driftwood was estimated to extend not more than 10 feet below ground surface. Below elevation −30 feet, the South Dunes subsurface conditions are fairly consistent. The native sand is predominantly fine grained, with occasional shells and silt zones. A deep boring at the South Dunes indicates that the native sand extends to elevation −151 feet. Below EL −151 feet, dark gray, very stiff to very hard, moist, and high plasticity clayey silt with sand and cementation was encountered that extended to an elevation of at least −223 feet.

The subsurface data from geotechnical soil borings and CPT soundings indicate that the subsurface conditions are relatively consistent across the site. Generally, the profile consists of existing sand fill from the ground surface near EL 20 feet to EL 9.5 feet. Near approximately EL 9.5 feet, an up to 2 feet thick layer of peat is present in many locations across the site. Beneath the peat layer is medium dense, native sand that extends to EL −30 feet. The medium dense, native sand would be improved by vibro-compaction to mitigate potentially liquefiable soils prior to construction of the LNG storage tanks. The peat layer would be removed and replaced prior to the ground improvement for soil liquefaction mitigation. Below EL −30 feet is dense to very dense, native sand that extends to about EL −135 feet. From EL −135 feet to below EL −260 feet. A clayey silt material identified as poorly indurated silty shale was found below about EL −235 feet.

FERC staff evaluated the geotechnical investigation to ensure the adequacy in the number, coverage, and types of the geotechnical borings, CPTs, SCPTs, and other tests, and found them to adequately cover major facilities, including the marine facilities, liquefaction areas, pretreatment areas, flare system, buildings, power generation, storage tanks, and berms at the site. Jordan Cove states that additional investigation would be performed to support final final design, including borings, CPTs, PMTs, and geophysical testing. FERC staff will continue its review of the results of the geotechnical investigation to ensure foundation designs are appropriate prior to construction of final design and throughout the life of the facilities.

Measured groundwater elevations have varied from a high of approximately 18 feet to 1 foot NAVD 88 below grade. Groundwater elevations increase with distance to the north away from Coos Bay. Considering the subsurface conditions for the LNG facility, Jordan Cove is proposing to support the LNG storage tanks and most of the facility structures on shallow isolated foundations, raft foundations, or deep foundations placed on improved ground. The recommended deep foundations to support large loads proposed would be either drilled piers or open-ended steel pipe piles. KBJ indicated the estimated depth of frost penetration for the site is approximately 1 foot below ground surface, therefore, the bottom of the foundations should be located at minimum depth of 1 foot below finished grade. The subsurface conditions at the site require soil improvement before any structures can be built for the LNG facilities. These conditions include peat, clay, buried driftwood, and liquefiable soil. KBJ provided considerations for ground improvement techniques including vibro-compaction; sand compaction; dry excavation and removal; wet excavation and removal and soil mixing. In areas where ground improvement would be utilized, Jordan Cove proposes to utilize vibro-compaction and deep soil mixing ranging in depth from the groundwater table to a maximum of approximately EL −30 feet NAVD 88, depending on the foundation loading and soil suitability for ground improvement, to bring foundations capacities and settlements within acceptable limits. Deep soil mixing would consist of installing overlapping (secant) soil mixed columns to create shear walls that reinforce the liquefiable soil mass. The deep soil mixed shear walls would be installed. KBJ performed settlement analysis for the Project site. At Ingram Yard, the potential total settlement was estimated to be none to approximately 11.5 inches. Along the Access and Utility Corridor, the potential total settlement was estimated to be approximately 0.8 to 9.5 inches. At the South Dunes, the potential total settlement was estimated to be approximately 0.5 inch up to 7 inches. KBJ stated that the ground improvement, vibro compaction method was proposed to reduce the settlement to 3 inch or less. KBJ stated that the preliminary estimates of LNG storage tank settlement based on the available ground investigation data and proposed ground improvement indicate that differential settlements would be in line with the requirements of ACI 376. The influence of soil structure interaction on local settlement gradients near the LNG storage tank edge would be evaluated with more detailed analysis and models in the detailed design phase, together with the limits that can be absorbed by the tank components. Due to the wide range of settlement values, we recommend in section 4.13.1.6 that Jordan Cove file an upper limit for total settlement for large flexible foundations and the maximum total edge settlement for equipment and structures consistent with applicable codes, including but not limited to API 620, API 625, API 653, and ACI 376.

Dredging would be required for the LNG marine vessels to traverse to the terminal as well as for the construction of the marine facilities. The existing shoreline would be excavated, dredged, and sloped during construction. To prevent slumping of the dredged slope, maintain the berthing line position, and provide structural integrity support to the landside facilities, the excavated shoreline would be protected from scour and erosion using stone or cement based rip-rap armoring. The Project basin shoreline would be protected from scour and erosion using stone or a cement based rip rap. The North Slope would be protected against scour from the toe to above the water line. Above the waterline, alternative scour (and wind/rain erosion) protection systems for less frequent events would be provided using any number of potential techniques including; concrete cellular mattresses, grout-injected geotextile fabric mattresses (fabriform) and/or geotextile reinforced vegetative planting. The proposed rip-rap armoring would minimize the potential for erosion where the shoreline would be excavated.

The results of Jordan Cove's geotechnical investigation at the Project site indicate that subsurface conditions are suitable for the proposed facilities, if proposed site preparation, foundation design, and construction methods are implemented in addition to the satisfaction of proposed recommendations.

Structural and Natural Hazard Evaluation

FERC regulations under 18 CFR 380.12 (m) requires applicants address the potential hazard to the public from failure of facility components resulting from accidents or natural catastrophes, evaluate how these events would affect reliability, and describe what design features and procedures that would be used to reduce potential hazards. In addition, 18 CFR 380.12 (o) (14) require an applicant to demonstrate how they would comply with 49 CFR 193 and NFPA 59A. USDOT regulations under 49 CFR 193 have some specific requirements on designs to withstand certain loads from natural hazards and also incorporates by reference NFPA 59A (2001 and 2006) and ASCE 7-05 and ASCE 7-93 via NFPA 59A (2001). NFPA 59A (2001) section 2.1.1 (c) also requires that Jordan Cove consider the plant site location in the design of the Project, with respect to the proposed facilities being protected, within the limits of practicality, against natural hazards, such as from the effects of flooding, storm surge, and seismic activities. This would be covered in USDOT's LOD on 49 CFR 193 Subpart B. However, the LOD would not cover whether the facility is designed appropriately against these hazards, which would be part of 49 CFR 193 Subpart C. Unlike other natural hazards, wind loads are covered in 49 CFR 193 Subpart B and would be covered in the LOD. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 and would be subject to USDOT's inspection and enforcement programs. The marine facilities would be subject to 33 CFR 127, which requires if the waterfront facility handling LNG is in a region subject to earthquakes the piers and wharves must be designed to resist earthquake forces. In addition, Coast Guard regulations under 33 CFR 127 incorporates by reference certain portions of NFPA 59A (1994) and ASCE 7-88 via NFPA 59A (1994). However, Coast Guard regulations do not provide criteria for a region subject to earthquakes or the earthquake forces the piers and wharves are to withstand and NFPA 59A (1994) section referenced in 33 CFR 127 is for seismic design only and is applicable to stationary LNG containers, which would not be under 33 CFR 127. Therefore, we evaluated the basis of design for all facilities for all natural hazards under FERC jurisdiction, including those under USDOT and Coast Guard jurisdiction.

Jordan Cove states that FERC and NEPA 59A requirements to design in accordance with ASCE 7-05 conflict with local building code requirements in the Oregon Structural Specialty Code (OSSC) of 2014. Specifically, OSSC 2014 is based on ASCE 7-10. To alleviate this conflict, Jordan Cove indicated that they would follow the requirements of ASCE 7-05 and ASCE 7-10 in parallel, with the final design made equal to or greater than the requirements of ASCE 7-05 and ASCE 7-10. Jordan Cove also indicated that in case of conflict, the more stringent requirement would govern. Thus, the final design would be intended to satisfy the FERC, NEPA 59A, ASCE 7-05, and ASCE 7-10 requirements. Jordan Cove states the facilities would also be constructed to the requirements in the 2006 International Building Code (IBC) and the 2014 Oregon State Specialty Code. These standards require various structural loads to be applied to the design of the facilities, including live (i.e., dynamic) loads, dead (i.e., static) loads, and environmental loads. FERC staff also evaluated potential engineering design to withstand impacts from natural hazards, such as earthquakes, tsunamis, seiche, hurricanes, tornadoes, floods, rain, ice, snow, regional subsidence, sea level rise, landslides, wildfires, volcanic activity, and geomagnetism. We recommend in section 4.13.1.6 that Jordan Cove file final design information (e.g., Civil/Structural drawings, specifications, and calculations) and associated quality assurance and control procedures with the documents reviewed, approved, and stamped and sealed by the professional engineer of record in Oregon.

If a project is authorized and constructed, the company would install equipment in accordance with its final design. In addition, we recommend in section 4.13.1.6 that Jordan Cove file, for review and approval, settlement results during hydrostatic tests of the LNG storage containers and periodically thereafter to verify settlement is as expected and does not exceed the applicable criteria in API Standards 620, 625, 653, and ACI 376.

Earthquakes, Tsunamis, and Seiche

FERC regulations under 18 CFR 380.12 (h) (5) requires evaluation of earthquake hazards based on whether there is potential seismicity, surface faulting, or liquefaction. Earthquakes and tsunamis have the potential to cause damage from shaking ground motion and fault ruptures. Earthquakes and tsunamis often result from sudden slips along fractures in the earth's crust (i.e., faults) and the resultant ground motions caused by those movements, but can also be a result of volcanic activity or other causes of vibration in the earth's crust. The damage that could occur as a result of ground motions is affected by the type/direction and severity of the fault activity and the distance and type of soils the seismic waves must travel from the hypocenter (or point below the epicenter where seismic activity occurs). To assess the potential impact from earthquakes and tsunamis, Jordan Cove evaluated historic earthquakes along fault locations and their resultant ground motions.

The USGS maintains a database containing information on surface and subsurface faults and folds in the United States that are believed to be sources of earthquakes of greater than 6.0 magnitude occurring during the past 1.6 million years (Quaternary Period).[199] KBJ performed a site-specific fault and seismic analysis for the Project, involving field investigations and subsequent data evaluation. The project site is covered by more than 100 feet of unconsolidated sand that prevents direct inspection of the bedrock, faults within 5 miles of the Project site have been identified from existing geologic maps. A total of 12 active and potentially active faults were identified within 100 miles of the Project site, but only the Barview fault is within 5 miles of the site. The Barview fault is a south dipping thrust fault that has offset the Miocene Epoch (23 to 5.3 million years ago) Empire Formation and Pleistocene Epoch (2.6 million to 11.7 thousand years ago) marine terrace platforms by about 3 feet. The mapped length of the Barview fault is less than 2 miles and extends from Coos Bay to the east-southeast north of Barview, Oregon (Madin et al., 1995). Based on the distance of the Barview fault from the Project site and its west-northwest strike, the Barview fault would not create a potential for fault offset at or near the ground surface at or near the Project site. KBJ indicated that neither fault is identified to potentially fault material younger than the Eocene Epoch and the location and extent of both faults is uncertain, they are considered unlikely to potentially create fault offset at or near the ground surface at the Project site. The Barview fault is included with South Slough thrust and reverse faults in the USGS Quaternary Fault and Fold database. Ground motions that Barview fault could potentially generate at the site would be evaluated in the Deterministic Seismic Hazard Analysis (DSHA). The Barview Fault and the South Slough thrust and reverse faults are both incorporate into the Probabilisitc Seismic Hazard Analysis (PSHA) as part of the gridded seismic sources and are not explicitly modeled as individual faults. Additionally, Jordan Cove states that there is no historically reported earthquakes have been associated with faults within 5 miles of the site; and the subsurface investigations at the site have not identified fault ruptures and there is no potential for affection faulting on the site.

The Jordan Cove LNG Project is in a region that has exhibited moderate to low seismic activity during the historic record, within the last 170 years. The region has been subject to numerous earthquakes of moment magnitude (MW) 4 or greater; however, the regional rate of seismicity is lower than in California and Washington. Earthquake records dating back to 1900 indicate there is only one record or an earthquake with a magnitude greater than 3 within a 50 km radius of the site. Near-fault effects such as rupture directivity and velocity or displacement pulses are typical for faults within 15 to 30 km of the site (National Earthquake Hazards Reduction [NEHRP], 2009; 2015). Directivity pulses are reasonably likely at 10 to 20 km from a site and polarization of seismic waves in the fault-normal and fault-parallel directions typically extends about 3 to 5 km from the fault (NEHRP 2015). The rupture directivity and pulses are considered for the Project

[199] USGS, Earthquake Hazards Program, Quaternary Fault and Fold Database of the United States, https://earthquake.usgs.gov/hazards/qfaults/, accessed Aug 2018.

site while fault-normal and fault-parallel directions of grounds motion are not considered. KBJ stated the Project site would not be located up-dip from the fault plane and significant directivity or pulses are unlikely. While large magnitude earthquakes have not occurred in the Pacific Northwest during the Historical record, based on the geological record, large magnitude earthquakes with moment magnitudes of 9 have occurred on the CSZ during the past 11,000 years with the last occurring in the year 1700. The CSZ is the dominate earthquake ground motion hazard source for the site. Onshore directivity is not expected for the CSZ because of the anticipated rupture geometry (Baker et al. 2012). Jordan Cove stated that the subsurface investigations at the Project site have not identified fault ruptures, and identified active faults in the region do not have a potential for affecting faulting, and growth faults are not present. While the presence of major tectonic faults and growth faults can require special consideration, the presence or lack of major tectonic faults identified near the site does not define whether earthquake ground motions can impact the site because ground motions can be felt large distances away from an earthquake hypocenter depending on number of factors. Jordan Cove stated that ground motions at the facility would be monitored by three sets of seismometers. An open-field seismometer located in a clear area away from other equipment would provide a baseline ground movement reference for any event. Two seismometers located on the top and bottom of each LNG storage tank. If any of the three seismometers exceeds safe limits, an alarm would sound in the control room where operators could shut down operations.

To address the potential ground motions at the site, USDOT regulations in 49 CFR 193.2101 Subpart C require that field-fabricated LNG tanks must comply with section 7.2.2 of NFPA 59A (2006) for seismic design. NFPA 59A (2006) requires LNG storage tanks be designed to continue safely operating with earthquake ground motions at the ground surface at the site that have a 10 percent probability of being exceeded in 50 years (475 year mean return interval), termed the operating basis earthquake (OBE). In addition, USDOT regulations in 49 CFR 193.2101 Subpart C require that LNG tanks be designed to have the ability to safely shutdown when subjected to earthquake ground motions which have a 2 percent probability of being exceeded in 50 years (2,475 year mean return interval), termed the safe shutdown earthquake (SSE). USDOT regulations in 49 CFR 193.2101 Subpart C also incorporate by reference NFPA 59A (2001) Chapter 6, which require piping systems conveying flammable liquids and flammable gases with service temperatures below −20°F, be designed as required for seismic ground motions. If authorized and constructed, LNG facilities as defined in 49 CFR 193, would be subject to the USDOT's inspection and enforcement programs.

In addition, FERC staff recognizes Jordan Cove would also need to address hazardous fluid piping with service temperatures at −20 degrees Fahrenheit and higher and equipment other than piping, and LNG storage (shop built and field fabricated) containers. We also recognize the current FERC regulations under 18 CFR 380.12 (h) (5) continue to incorporate National Bureau of Standards Information Report (NBSIR) 84-2833. NBSIR 84-2833 provides guidance on classifying stationary storage containers and related safety equipment as Category I and classifying the remainder of the LNG project structures, systems, and components as either Category II or Category III, but does not provide specific guidance for the seismic design requirements for them. Absent any other regulatory requirements, this guidance recommends that other LNG project structures classified as Seismic Category II or Category III be seismically designed to satisfy the Design Earthquake (DE) and seismic requirements of the ASCE 7-05 in order to demonstrate there is not a significant impact on the safety of the public. ASCE 7-05 is recommended as it is a complete American National Standards Institute (ANSI) consensus design standard, its seismic requirements are based directly on the National Earthquake Hazards Reduction Program (NEHRP) Recommended Provisions, and it is referenced directly by the IBC. Having a link directly to the IBC and ASCE 7 is important to accommodate seals by the engineer of record because the IBC is directly linked to state professional licensing laws while the NEHRP Recommended Provisions are not.

The geotechnical investigations of the existing site performed by KBJ indicate the site class was determined in accordance with ASCE 7-05, ASCE 7-10, and the 2014 edition of the OSSC (Oregon Structural Special Specialty Code) in the Geotechnical Report (KBJ, 2017) using the shear wave velocity measurements form the downhole P-S suspension logging and cross hole seismic logging. The average shearwave velocity in the upper 100 feet (30 meters), VS30 of 697.5 to 783 feet per second, at two of the three locations at the LNG storage tanks. The shear wave velocity measurement at the one location indicated Seismic Site Class E (VS30 of 480.9 feet per second); however, all the locations would be Seismic Site Class D after ground improvement to mitigate liquefiable soils. Seismic Site Class D is valid once liquefiable soils at the site have been mitigated to eliminate Seismic Site Class F conditions (KBJ, 2017). This is in accordance with ASCE 7-05, which is incorporated directly into 49 CFR 193 for shop fabricated containers less than 70,000 gallons and via NFPA 59A (2006) for field fabricated containers.[200] This is also in accordance with IBC (2006). Sites with soil conditions of this type would experience significant amplifications of surface earthquake ground motions at longer periods. Due to the presence of the CSZ (dips under the site) the seismic risk to the site is considered high.

KBJ performed a site-specific seismic hazard study for the site. The study concluded that the site would have a Horizontal Operating Basis Earthquake (OBE) peak spectral ground acceleration at 0.2 s-period of 0.857 g, and a Horizontal Safe Shutdown Earthquake (SSE) peak spectral ground acceleration at 0.2 s-period of 1.537 g based on improved site conditions. The OBE has a 10% probability of being exceed in 50 years (475 year mean return interval) while the SSE has a 2% chance of being exceeded in 50 years (2,475 year mean return interval). The study also provided the site-specific Design Earthquake (DE) values SDS and SD1 of 1.025 g and 1.002 g, respectively. KBJ also developed the Vertical response spectra using the horizontal response spectra and vertical-to-horizontal (V/H) ratios and indicated the V/H ratios are not less than ½ for the Project. Based on the design ground motions for the site and the importance of the facilities, the facility seismic design is assigned Seismic Design Category D in accordance with the IBC (2006) and ASCE 7-05. FERC staff independently evaluated the OBE PGA, SSE PGA, 0.2-second design spectral acceleration, and 1.0-second design spectral accelerations for the site using the Applied Technology Council (ATC) and USGS Earthquake Hazards Program Seismic Design Maps[201] and Unified Hazard[202] tools for all occupancy categories (I through IV). Based on the ATC and USGS tools, FERC found the OBE and SSE peak spectral accelerations at 0.2 s-period for the site based on Site Class D to equal 0.722 g and 1.694 g, respectively. The OBE and SSE that Jordan Cove

---

[200] There are six different site classes in ASCE 7-05, A through F, that are representative of different soil conditions that impact the ground motions and potential hazard ranging from Hard Rock (Site Class A), Rock (Site Class B), Very dense soil and soft rock (Site Class C), Stiff Soil (Site Class D), Soft Clay Soil (Site Class E), to soils vulnerable to potential failure or collapse, such as liquefiable soils, quick and highly sensitive clays, and collapsible weakly cemented soils (Site Class F).

[202] USGS, Unified Hazards Tool , https://earthquake.usgs.gov/hazards/interactive/, accessed Dec 2018

provided are about 80 percent of the values from the ATC/USGS websites which would be acceptable for site specific values.

In addition to the review of the peak ground accelerations, FERC staff reviewed the correlation between the peak ground accelerations, the Modified Mercalli Intensity scale,[203] and Richter scale. FERC staff found that there is no direct correlation between an earthquake's magnitude and the peak ground accelerations experience at a site. The peak ground accelerations at a site are determined by multiple factors such as site classification, soil types, the distance from an earthquake's epicenter, and would vary from location to location; while an earthquake's magnitude is determined by the amplitude of the seismic wave and energy dispersed. Although there is no direct correlation between a site's peak ground acceleration and a magnitude on the Richter scale, there is an empirical correlation, by the USGS, between the peak ground acceleration and the Modified Mercalli Intensity scale, as well as between the Modified Mercalli Intensity scale and the Richter scale.[204] The Modified Mercalli Intensity scale measures the perceived intensity of an earthquake and the potential damage that could occur to structures based on ground acceleration and velocity. Given the OBE and SSE values provided in the study, the site would experience an Intensity rating of 9, which corresponds to perceived violent shaking and a potential for heavy damage to structures. Taking the Modified Mercalli Intensity rating of 9 and comparing that to the Richter scale, FERC staff found that the OBE and SSE would correspond to a magnitude 6 or greater earthquake from the closest fault. However, FERC staff also acknowledges that this is not a direct comparison and relies on multiple empirical correlations between the accelerations and scales.

ASCE 7-05 also requires determination of the Seismic Design Category based on the Occupancy Category (or Risk Category in ASCE 7-10 and 7-16) and severity of the earthquake design motion. The Occupancy Category (or Risk Category) is based on the importance of the facility and the risk it poses to the public.[205] FERC staff has identified the Project as a Seismic Design Category D based on the ground motions for the site and an Occupancy Category (or Risk Category) of II or III or IV, this seismic design categorization would appear to be consistent with the IBC (2006) and ASCE 7-05 (and ASCE 7-10).

Seismic events can also result in soil liquefaction in which saturated, non-cohesive soils temporarily lose their strength/cohesion and liquefy (i.e., behave like viscous liquid) as a result of

---

204 USGS, Magnitude/Intensity Comparison, https://earthquake.usgs.gov/learn/topics/mag_vs_int.php, accessed March 2019

205 ASCE 7-05 defines Occupancy Categories I, II, III, and IV. Occupancy Category I represents facilities with a low hazard to human life in even of failure, such as agricultural facilities; Occupancy Category III represents facilities with a substantial hazard to human life in the event of failure or with a substantial economic impact or disruption of day to day civilian life in the event of failure, such as buildings where more than 300 people aggregate, daycare facilities with facilities greater than 150, schools with capacities greater than 250 for elementary and secondary and greater than 500 for colleges, health care facilities with 50 or more patients, jails and detention facilities, power generating stations, water treatment facilities, telecommunication centers, hazardous facilities that could impact public; Occupancy Category IV represents essential facilities, such as hospitals, fire, rescue, and police stations, emergency shelters, power generating stations and utilities needed in an emergency, aviation control towers, water storage and pump structures for fire suppression, national defense facilities, and hazardous facilities that could substantially impact public; and Occupancy Category II represents all other facilities. ASCE 7-10 changed the term to Risk Categories I, II, III, and IV with some modification.

increased pore pressure and reduced effective stress when subjected to dynamic forces such as intense and prolonged ground shaking. Areas susceptible to liquefaction may include saturated soils that are generally sandy or silty. Typically, these soils are located along rivers, streams, lakes, and shorelines or in areas with shallow groundwater. The site-specific seismic study indicates liquefiable soils are present throughout the Project site, and their depths vary with the location. The liquefiable soils at Ingram Yards area and the Access and Utility Corridor have a maximum of approximately EL −30 feet NAVD 88. At the LNG terminal and the Access and Utility Corridor, the liquefiable layers are predicted to extend below the dunes present on the site. At the South Dunes Area, liquefaction is estimated in a soil zone that starts at the groundwater table and extends to variable depths from EL 0 feet to approximately EL −25 feet NAVD 88. Jordan Cove indicated that a detailed review of the potential methods of soil improvement has been undertaken, and a number of these proven methods could be employed for the Project, depending on the results of the final site investigations planned. Those methods are: vibro-compaction; sand compaction; dry excavation and removal; wet excavation and removal and soil mixing. Jordan Cove has indicated that the LNG facilities at the site would be constructed on either a site improved with deep soil mixing or in some cases deep foundations, which would mitigate any potential impacts of soil liquefaction to minimize or eliminate any effects soil liquefaction. Also to counteract associated lateral spreading effects at the marine facilities, Jordan Cove has elected to install a permanent sheet pile wall in combination with improved soils for the LNG marine vessel berth.

Seismic events in waterbodies can also cause tsunamis or seiches by sudden displacement of the sea floors in the ocean or standing water. Tsunamis and seiche may also be generated from volcanic eruptions or landslides. Tsunami wave action can cause extensive damage to coastal regions and facilities. The west coast of the United States has historically been subject to minor inundation from tsunamis generated by distant earthquakes in South America, Alaska, and Japan. Kelsey et al. (2005) note that tsunamis generated from these distant subduction zone earthquakes have minor inundation effects because of the long diagonal approach of tsunami waves to the west coast form these sources. In addition, northern California, Oregon, and Washington have been subjected to large tsunamis from CSZ megathrust earthquakes, with the last one occurring approximately in the year 1700. Jordan Cove conducted hydrodynamic and tsunami modeling studies for the Project site and indicated a tsunami generated by a megathrust earthquake on the CSZ would present the greatest tsunami inundation risk at the project site and the maximum design tsunami run-up elevation for the project site is no greater than 34.5 feet NAVD 88 including co-seismic subsidence and sea level rise effects. The co-seismic subsidence information indicates that the largest coastal subsidence, of 3 to 6 feet, occurred in northern Oregon and southern Washington, with subsidence ranging from 0 to 3 feet elsewhere. Leonard et al. (2004) estimated an average of 2 feet of co-seismic subsidence occurred in the Coos Bay area during the 1700 earthquake. For the Project site and in accordance with more recent tsunami modeling completed for the Southern Oregon Coast (Witter et al. 2011), the estimated subsidence would be on the order of 7.6 feet. Jordan Cove indicated that the Project would be designed to mitigate inundation due to the design tsunami and the design tsunami run-up elevations are established including an allowance for subsidence. In addition, Jordan Cove indicated the design tsunami run-up elevations have been determined in conjuction with a mean high water tide. Jordan Cove also indicated that furthermore tsunami protection berms, safety critical elements of the facility, point of support elevations, invert levels and underside of essential equipment, would be at least 1 foot above the estimated maximum run-up elevation and most will be far above that elevation. The criteria used to evaluate tsunami wave heights it based on new requirements provided in ASCE 7-16 which indicates that Maximum Considered Tsunami (MCT) events should use the same maximum earthquake criteria as used to determine Maximum Consider Ground Motions (and SSE ground motions). FERC staff worked with NOAA who helped developed Tsunami maps for ASCE 7-16 and NOAA determined that inundation elevations from the MCT event for the Jordan Cove LNG Project site were consistent with those determined by Jordan Cove. Therefore, FERC staff agrees that the tsunami elevations that Jordan Cove provided are suitable for the Project site.

Hurricanes, Tornadoes, and other Meteorological Events

Hurricanes, tornadoes, and other meteorological events have the potential to cause damage or failure of facilities due to high winds and floods, including failures from flying or floating debris. To assess the potential impact from hurricanes, tornadoes, and other meteorological events, Jordan Cove evaluated such events historically. The severity of these events are often determined on the probability that they occur and are sometimes referred to as the average number years that the event is expected to re-occur, or in terms of its mean return/recurrence interval.

Because of its location, the Project site would not likely be subject to hurricane force winds during the life of the Project, however, strong extratropical cyclones (baroclinic, cold core systems are common in the region. These storms are capable of producing winds of hurricane force, and as such, Jordan Cove has indicated that the project site would be designed to withstand strong wind events. However, because wind speeds at the Project location are considerably less than those that occur in the Gulf Coast east region and the east cose of the US, Jordan Cove stated that the wind load combinations specified in Chapter 2 of ASCE 7-10 should be used. Jordan Cove stated that the design wind speed using ASCE 7-10 Load and Resistance Factor Design (LRFD) and Allowable Stress Design (ASD) for LNG facilities and hazardous structures, which would be categorized as Risk Category III and IV (Occupancy Category in ASCE 7-05).

Jordan Cove hired Cermak Peterka Peterson (CPP) to perform a site specific wind speed assessment for this Project. CPP determined 127 mph 3-second gust as the Design Wind Speed (3-second gust, 33 feet, Exposure category C). The 127 mph 3-second gust was determined based on the criteria specified in 49 CFR 193.2067 and ASCE 7 based on a 10,000 year mean return interval, or a 0.5 percent probability of occurrence within a 50-year period for the site. CPP stated that the 127 mph wind speed is a strength level speed corresponding directly to the mean recurrence interval (MRI) criteria. The 127 mph 3-second gust converts to a sustained wind speed of approximately 102 mph. When using this wind speed with ASCE 7-05 load combinations, the value should be reduced by a factor of square root of 1.6 or the design wind pressure reduced by a factor of 1.6 in order to achieve the desired 10,000-year MRI. When using the 127 mph wind speed with ASCE 7-10 load combinations, no additional factors are required. In both cases, the wind importance factor is not applicable due to the wind speed directly corresponding with the required return period. The 127 mph 3-second gust equates to a strong Category 2 Hurricane using the Saffir-Simpson scale (96 to 110 mph sustained winds, 117 to 140 mph 3-second gusts). FERC staff found that when reviewing Figure 6-1A of ASCE 7-05, the Project location would be closest to the 90 mph 3-second gust isocontour in the special wind region area. Because the Project site is located within a special wind region, FERC staff did not utilize the ATC hazard tool, but instead utilized the ASCE 7 hazard tool, which provides the 3-second gust at a height of 33 feet above ground level and Exposure Category C. For the Project site, the ASCE 7-10 3-second gust is observed to be 115 mph. Jordan Cove indicated that non-hazardous buildings and structures would be designed to satisfy the design win speed requirements of the OSSC, rather than the requiremnts of USDOT regulations. Moreover, Jordan Cove confirmed that all facilities, including those containing LNG or other hazardous fluids (and associated safety systems), would be designed for wind loads in accordance with Chapters 26 through 31 of ASCE 7-10 using the site specific wind speed in accordance with 49 CFR 193.2067 and code-based wind directionality factor, velocity pressure exposure coefficient and topographic factor as specified in ASCE 7-10 based on Exposure Category D and structure type, accordingly. For simplicity and consistency, Jordan Cove intends to use a single conservative Exposure Category D for all wind design regardless of physical location within the facility. Jordan Cove's final wind speed design 127 mph 3-second gust, 33 feet, Exposure Category D is more conservative than CPP suggested 127 mph 3-second gust, 33 feet, Exosure Category C. However it is unclear whether some of the non-hazardous buildings and structures would qualify as LNG facilities under USDOT regulations, and, if so, whether a 10,000 year return period (123 mph 3-second gust, Exposure Category D) would meet USDOT requirements. Therefore, we recommend in section 4.13.1.6 that Jordan Cove consult with USDOT staff as to whether the design wind speed for other non-hazardous buildings and structures would be subject to USDOT requirements prior to the end of the comment period of the draft EIS.

Jordan Cove must meet 49 CFR 193.2067 Subpart B for wind load requirements. In accordance with the MOU, the USDOT will evaluate in its LOD whether an applicant's proposed Project meets the USDOT requirements under Subpart B. If the Project is authorized and constructed, the facilities would be subject to the USDOT's inspection and enforcement programs. Final determination of whether the facilities are in compliance with the requirements of 49 CFR 193 Subpart B would be made by the USDOT staff.

In addition, as noted in the limitation of ASCE 7-05 section 6.5.4.3 and ASCE 7-10 section 26.5.4, tornadoes were not considered in developing basic wind speed distributions. This leaves a potential gap in potential impacts from tornadoes. Therefore, FERC staff evaluated the potential for tornadoes. Appendix C of ASCE 7-05 makes reference to American Nuclear Society 2.3 (1983 edition), *Standard for Estimating Tornado and Extreme Wind Characteristics at Nuclear Power Sites*. This document has since been revised in 2011 and reaffirmed in 2016 and is consistent with NUREG/CR-4461, *Tornado Climatology of the Contiguous U.S.*, Rev. 2 (NUREG 2007). These documents provide maps of a 100,000 mean year return period for tornadoes using 2 degree latitude and longitude boxes in the region to estimate a tornado impacting a structure with a 200 foot characteristic length. Figures 5-8 and 8-1 from NUREG/CR-4461 indicate a 100,000 year maximum tornado wind speeds would be less than 65 mph 3-second gusts for the Project site location. Later editions of ASCE 7 (ASCE 7-10 and ASCE 7-16) make reference to International Code Council (ICC) 500, *Standard for Design and Construction of Storm Shelters*, for 10,000 year tornadoes. However, the ICC 500 maps were conservatively developed based on tornadoes striking regions and indicate a 130 mph 3-second gust for a 10,000 year event, which is higher than the 65 mph 3-second gust in American Nuclear Society 2.3 and NUREG/CR-4461. As a result, we conclude the use of an equivalent 127 mph 3-second gust, 33 feet, Exposure Category D, is adequate for the LNG storage tanks and conservative from a risk standpoint for the other LNG and hazardous facilities. USDOT will provide a LOD on the Project's compliance with 49 CFR 193 Subpart B in regard to wind speed. This determination will be provided to the Commission as further consideration to the Commission on its decision to authorize or deny the Project.

The USDOT regulations in 49 CFR 193.2067 Subpart B would require the impounding system for the LNG storage tanks to withstand impact forces from wind borne missiles. ASCE 7 also recognizes the facility would be in a wind borne debris region. Wind borne debris has the potential to perforate equipment and the LNG storage tanks if not properly designed to withstand such impacts. The potential impact is dependent on the equivalent projectile wind speed, characteristics of projectile, and methodology or model used to determine whether penetration or perforation would occur. However, no criteria are provided in 49 CFR 193 or ASCE 7 for these specific parameters. NFPA 59A (2016) recommends Comite Euro-International du Beton (CEB) 187 be used to determine projectile perforation depths. In order to address the potential impact, we recommend in section 4.13.1.6 that Jordan Cove provide a projectile analysis for review and approval to demonstrate that the outer concrete impoundment wall of a full-containment LNG tank could withstand wind borne projectiles prior to construction of the final design. The analysis should detail the projectile speeds and characteristics and method used to determine penetration or perforation depths. FERC staff would compare the analysis and specified projectiles and speeds using established methods, such as CEB 187, and DOE and Nuclear Regulatory Commission (NRC) guidance.

In addition, FERC staff evaluated historical tropical storm, hurricane, and tornado tracks in the vicinity of the project facilities using data from the Department of Homeland Security (DHS) Homeland Infrastructure Foundation Level Data (HILFD) and NOAA Historical Hurricane Tracker.[206,207] Since 1900, there is no historical storm or hurricane that has been reported within 65 nautical miles of the LNG terminal site. Hurricanes do not occur near the LNG terminal site as the environment does not support these barotropic, warm core systems. Since 1950, there is no historical tornado event that has been reported within 10 nautical miles of the LNG terminal site. Although tropical cyclones do not occur at the Project site, extreme storms offshore sometimes cause the water level along the coastline to raise significantly beyond the normal tide levels. This phenomenon is referred to as storm surge. Jordan Cove discussed storm surge expected at the site based on the NAVD 88 using a Federal Emergency Management Agency (FEMA) conversion factor, indicating a storm surge elevation of 24.62 feet at the Project site. Jordan Cove indicated that the storm surge is not considered additive to the tsunami inundation height as both storm surge and tsunami are low frequency events. FERC staff agrees that storm surge and tsunami would not need to be considered simultaneously.

Potential flood levels may also be informed from the FEMA Flood Insurance Rate Maps, which identify Special Flood Hazard Areas (base flood) that have a 1 percent probability of exceedance in 1 year to flood (or a 100 year mean return interval) and moderate flood hazard areas that have a 0.2 percent probability of exceedance in 1 year to flood (or a 500 year mean return interval). According to the FEMA National Flood Hazard Layer, portions of the Project would be located in the 100-year floodplain. In addition, according to FEMA flood hazard maps (2018), the 100-year flood elevation at the site is +12.4 feet NAVD 88 and the 500-year flood elevation is +13 feet NAVD 88. We recognize that a 500 year flood event has been recommended as the basis of design for critical infrastructure in publications, including ASCE 24, Flood Resistant Design and Construction. Therefore, it is our opinion that it is good practice to design critical energy infrastructure to withstand 500 year event from a safety and reliability standpoint for the still water elevation (SWEL) and wave crests. Furthermore, we determined the use of intermediate values

[206] DHS, Homeland Infrastructure Foundation Level Data, https://hifld-geoplatform.opendata.arcgis.com/, August 2018.
[207] NOAA, Historical Hurricane Tracker, https://coast.noaa.gov/hurricanes/, August 2018.

from NOAA for sea level rise and subsidence is more appropriate for design and higher projections are more appropriate for planning in accordance with NOAA (2017)[208] which recommends defining a central estimate or mid-range scenario as baseline for shorter-term planning, such as setting initial adaptation plans for the next two decades and defining upper bound scenarios as a guide for long-term adaptation strategies and a general planning envelope. Jordan Cove has indicated that the facility would be designed to handle a 100-year storm surge without any wave overtopping, and would be designed to accommodate the wave overtopping that would occur from a 500-year storm surge. Jordan Cove stated the storm surge expected at the site based on the NAVD 88 using a FEMA conversion factor, indicating a coastal flooding (storm surge) elevation of 24.62 feet at the Project site. The Project site elevations of pipeline and all above ground facilities are higher than the maximum coastal flooding elevations estimated.

Jordan Cove proposes to construct most structures above the elevation +46 feet NAVD 88 which would minimize impacts associated with potential storm surges. Exceptions include the LNG storage tanks and water-dependent facilities such as the marine terminal and Material Offloading Facility (MOF). The LNG storage tank base would have an elevation of approximately +27 feet NAVD 88 would be surrounded by a tertiary protective berm with a crest elevation of no less than +46 feet NAVD 88. Jordan Cove indicated that the parts of the marine facilities that are normally occupied or operational would typically be at an elevation of +34.5 feet or greater, whereas normally unoccupied/non-operational parts of the marine facilities may be at a lower elevation.

We generally evaluate the design against a 500-year SWEL with a 500-year wave crest and relative sea level rise and subsidence. According to FEMA Flood Insurance Study (FIS) for Coos County, Oregon, the average wave height offshore from Coos County is 8.5 feet, while the average peak spectral wave period is 11.1 seconds, although a period of 20 to 25 seconds is not uncommon. Also we would expect an intermediate projected sea level rise of 1.02 feet between 2020 and 2050 as provided by NOAA (2017). Adding the 500-year storm surge, wave crest elevations, relative sea level rise and subsidence results in a total elevation of 42 feet. FERC staff evaluated Jordan Cove's proposed 500-year flood against the 2014 FEMA Flood Insurance Study (FIS) for Coos County, Oregon, which provides various transection lines and associated 10-, 50-, 100-, and 500-year SWELs, 500-year wave envelopes, and 500-year wave effects along the length of the transection lines. We believe the use of intermediate values from NOAA for relative sea level rise and subsidence is more appropriate for design and higher projections are more appropriate for planning envelope. Also, the Project area is outside of the VE (velocity wave) zone that corresponds to the 100-year (1 percent annual chance) coastal floodplains that have additional hazards associated with storm waves. The Project area is also outside the 500-year (0.2 percent annual chance) flood area. As a result, we conclude that the facility would be able to withstand storm surge without damage during a 500-year storm event.

Shoreline erosion could occur at the Project site and along the opposite shoreline as a result of waves, currents, and vessel wakes. Jordan Cove stated that the Project basin shoreline would be protected from scour and erosion using stone or a cement based rip rap. Even though shoreline erosion is a concern at the site, the proposed mitigation measures would minimize erosion and scour impacts.

[208] Global And Regional Sea Level Rise Scenarios for the United States, U.S. Department Of Commerce, National Ocean and Atmospheric Administration, National Ocean Service Center for Operational Oceanographic Products and Services, January 2017.

FERC staff evaluated the basis of design for the Project relating to withstanding rain, ice, and snow events. To handle the rain the area receives, Jordan Cove stated that the roofs of permanent structures to be located onsite would be designed to preclude instability resulting from ponding effects by ensuring adequate primary and secondary drainage systems, slope, and member stiffness. Jordan Cove discussed the ice load design for the Project and stated the ice load is not applicable for the Project site and design ice thickness is 0 inches in accordance with ASCE 7-10 and climatological studies. The coastal location of this Project also impacts the amount of snow the area receives. Jordan Cove states that the snow design for this Project was based on ASCE 7-10 design maps and the 2014 OSSC. Jordan Cove indicated the snow load design bases for this Project are 5 pounds per square foot (psf) for ground snow load and 20 psf for the roof snow load.

Landslides and other Natural Hazards

Landslides in the United States occur in all 50 states. The primary regions of landslide occurrence and potential are the coastal and mountainous areas of California, Oregon, and Washington, the states comprising the intermountain west, and the mountainous and hilly regions of the eastern United States. Jordan Cove evaluated the type and occurrence of landslides in the vicinity of the Project site and indicated that no landslide deposits were identified within the Project area. There is a moderate to high landslide susceptibility hazard on the dune ridges at the Project site; however, the active landslides have not been identified on the sand dunes. The high susceptibility at the Project site is primarily based on the steep slopes of the dune deposits. Jordan Cove states that they would regrade the steep dunes thereby eliminating potential landslide hazards related to dune sand stability. The potential for tsunamis associated with submarine landslides is more likely a source in the CSZ. Jordan Cove evaluated the type and occurrence of landslides for the Project area and indicated that no landslides deposits were identified with the Project site. A moderate to high landslide susceptibility hazard is mapped on the dune ridges at the Project site; however, active landslides have not been identified on the sand dunes. The high susceptibility indicated at the Project site is primarily based on the steep slopes of the dune deposits. Jordan Cove would regrade the steep dunes thereby eliminating potential landslide hazards related to dune sand stability.

Volcanic activity is primarily a concern along plate boundaries on the West Coast and Alaska and also Hawaii. Based on FERC staff review of maps from USGS[209] and DHS[210] and Jordan Cove report: the Cascade Mountain Range is the volcanic arc complex of the CSZ and is located approximately 100 miles east of the Project site. Volcanoes of the Cascade Mountains are found from northern California to British Columbia. The nearest Cascade Volcano is the Crater Lake caldera that was formed during the eruption and collapse of Mount Mazama approximately 7,700 years ago. The Project site would not be directly affected by the various types of volcanic eruption hazards due to the distance of the hazards, the upwind location of the Project site from the volcanic hazard, and the low likelihood of volcanic eruption during the lifetime of the Project.

The west coast is often associated with the potential of wildfires. According to the Oregon Department of Forestry (ODF), have been a number of fires that have occurred within 100 miles of the Jordan Cove site, however, none of these fires occurred in the immediate proximity of Coos

[209] United States Geological Survey, U.S. Volcanoes and Current Activity Alerts, https://volcanoes.usgs.gov/index.html, accessed Aug 2018.

[210] Department of Homeland Security, Homeland Infrastructure, Foundation-Level data (HIFLD), Natural Hazards, hifld-geoplatform.opendata.arcgis.com, accessed Aug 2018

Bay. In addition, Jordan Cove site is surrounded by water on the southern and eastern side, separating the site from the more forested areas to the east of the site. As such, it is unlikely that a wildfire would occur at the Project site. Additionally, Jordan Cove indicated that the plans for how to handle fires are provided in the Emergency Response Plan that has been developed for the site.

Geomagnetic disturbances (GMDs) may occur due to solar flares or other natural events with varying frequencies that can cause geomagnetically induced currents, which can disrupt the operation of transformers and other electrical equipment. USGS provides a map of GMD intensities with an estimated 100 year mean return interval.[211] The map indicates the Jordan Cove site could experience GMD intensities of 400 nano-Tesla (nT) with a 100 year mean return interval. However, Jordan Cove would be designed such that if a loss of power were to occur the valves would move into a fail-safe position. In addition, Jordan Cove is an export facility that does not serve any U.S. customers.

External Impact Review

To assess the potential impact from external events, FERC staff conducted a series of reviews to evaluate transportation routes, land use, and activities within the facility and surrounding the the LNG terminal site, and the safeguards in place to mitigate the risk from events, where warranted. FERC staff coordinated the results of the reviews with other federal agencies to assess potential impacts from vehicles and rail; aircraft impacts to and from nearby airports and heliports; pipeline impacts from nearby pipelines; impacts to and from adjacent facilities that handle hazardous materials under the EPA's Risk Management Plan (RMP) regulations and power plants, including nuclear facilities under the Nuclear Regulatory Commission's regulations. Specific mitigation of impacts from use of external roadways, rail, helipads, airstrips, or pipelines are also considered as part of the engineering review done in conjunction with the NEPA review.

FERC staff uses a risk-based approach to assess the potential impact of the external events and the adequacy of the mitigation measures. The risk-based approach uses data based on the frequency of events that could lead to an impact and the potential severity of consequences posed to the LNG terminal site and the resulting consequences to the public beyond the initiating events. The frequency data is based on past incidents and the consequences are based on past incidents and/or hazard modeling of potential failures.

Road

FERC staff reviewed whether any truck operations would be associated with the project and whether any existing roads would be located near the site. FERC staff uses this information to evaluate whether the project and any associated truck operations could increase the risk along the roadways and subsequently to the public and whether any pre-existing unassociated vehicular traffic could adversely increase the risk to a project site and subsequently increase the risk to the public. In addition, if authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 and would be subject to the USDOT's inspection and enforcement programs. USDOT regulations under 49 CFR 193.2155 (a) (5) (ii) Subpart C require that structural members of an impoundment system must be designed and constructed to

[211] United States Geological Survey, Magnetic Anomaly Maps and Data for North America, https://mrdata.usgs.gov/magnetic/map-us.html#home, accessed Aug 2018.

prevent impairment of the system's performance reliability and structural integrity as a result of a collision by or explosion of a tank truck that could reasonably be expected to cause the most severe loading if the liquefaction facility adjoins the right-of-way of any highway. Similarly, NFPA 59A (2001), section 8.5.4, requires transfer piping, pumps, and compressors to be located or protected by barriers so that they are safe from damage by rail or vehicle movements. However, the USDOT regulations and NFPA 59A (2001) requirements do not indicate what collision(s) or explosion(s) could reasonably be expected to cause the most severe loading. FERC staff evaluated consequence and frequency data from these events to evaluate these potential impacts.

FERC staff evaluated the risk of the truck operations based on the consequences from a release, incident data from the USDOT's Federal Highway Administration (FHWA), National Highway Traffic Safety Administration (NHTSA), and Pipeline and Hazardous Materials Safety Administration (PHMSA), EPA, NOAA, and other reports[212,213,214,215,216,217,218], and frequency of trucks and proposed mitigation to prevent or reduce the impacts of a vehicular incident.

Incident data from DOT FHWA, DOT NHTSA, and DOT PHMSA indicate hazardous material incidents are very infrequent (4e-3 incidents per lane mile per year) and nearly 75 to 80 percent of hazardous material vehicular incidents occur during unloading and loading operations while the other 20 to 25 percent occur while in transit or in transit storage. In addition, approximately 99 percent of releases are 1,000 gallons or less and catastrophic events that would spill 10,000 gallons or more make up less than 0.1 percent of releases. In addition, less than 1 percent of all reportable hazardous material incidents with spillage result in injuries and less than 0.1 percent of all reportable hazardous material incidents with spillage result in fatalities.

The EPA and NOAA report that 80 percent of fires that lead to container ruptures results in projectiles and that 80 percent of projectiles from liquefied petroleum gas (LPG) incidents, which constitute the largest product involved in BLEVEs, travel less than 660 feet. The EPA also reports that on average container ruptures would result in less than four projectiles for cylindrical containers and 8.3 for spherical vessels. FERC staff evaluated other reports that affirmed the EPA estimates based on data for approximately 150 experimental and accidental pressure vessel bursts (PVBs) and BLEVEs with approximately 683 total projectiles (4.6 average fragments per incident) that showed approximately 80 percent of fragments traveled 490 to 820 feet and within 6.25 times the estimated or observed fireball radius. The data also showed projectiles have traveled up to 3,900 feet for large LPG vessels and 1,200 feet for LPG rail cars. In all the documented cases, the

projectiles traveled less than 15 times the fireball diameter, but one of the reports indicated up to 30 times the fireball diameter is possible albeit very rare.

Unmitigated consequences under average ambient conditions from releases of 1,000 gallons through a 1-inch hole would result in distances ranging from 25 to 200 feet for flammable vapor dispersion, and 75 to 175 feet for jet fires. Unmitigated consequences under worst case weather conditions from catastrophic failures of trucks proposed at the site generally can range from 200 to 2,000 feet for flammable vapor dispersion, 275 to 350 feet for radiant heat of 5 kW/m^2 from jet fires, 800 to 1,050 feet to a 1 psi overpressure from a BLEVE, 850 to 1,500 feet for a heat dose equivalent to a radiant heat of 5 kW/m^2 over 40 seconds from 250 to 325 feet radii fireballs burning for 5 to 15 seconds from a BLEVE, and projectiles from BLEVEs possibly extending farther. Based on distribution function of the projectile distances, FERC staff estimate approximately 90 percent of all projectiles for a 10,000-gallon tanker truck would be within 0.5 mile and there is approximately a 1 percent probability they would extend beyond 1 mile and less than 0.1 percent probability they would extend 30 times the fireball diameter. These values are also close to the distances provided by the USDOT FHWA for designating hazardous material trucking routes (0.5 mile for flammable gases for potential impact distance) and USDOT PHMSA for emergency response (0.5 to 1 mile for initial evacuation and 1 mile for potential BLEVEs for flammable gases).

During startup and operation of the project, Jordan Cove estimates 22 refrigerant make-up trucks, 8 amine trucks, 4 nitrogen trucks, 160 aqueous ammonia trucks, and 28 diesel trucks would be needed at the site annually. The most frequent truck deliveries would occur during commissioning and startup activity at the site and would deliver refrigerants to load the liquefaction trains. Between 15 and 20 trucks are expected over an approximately 2 week timefame to load each liquefaction train. The refrigerant deliveries would be repeated for the startup of each subsequent liquefaction train. Jordan Cove does not plan to utilize any trucks to deliver LNG. The Transpacific Parkway, which connects to State Highway (SH) 101 is located directly to the north of the facility property and would be used to access the Jordan Cove Project site. The Transpacific Parkway is a two lane bi-directional route with a 45 mph speed limit. Jordan Cove provided a Road Safety and Reliability Impact Study (RSRIS). The RSRIS addresses potential safety and reliability impacts of proposed tanker trucks loaded or unloaded at the LNG terminal, and from commercial and recreational roadway traffic along the Transpacific Parkway. The separation distance between the Transpacific Parkway and the Project facilities that would contain hazardous fluids would be greater than 300 feet which would exceed the distances estimated for flammable vapor dispersion and radiant heat from an LNG truck 1-inch hole release. In addition, the Project would install an 80-feet tall impervious barrier that would separate the Transpacific Parkway and the process equipment located in the Ingram Yards area. FERC staff did not identify any other major highways or roads within close proximity to piping or equipment containing hazardous materials at the site that would not be protected by this separation distance and 80-feet tall barrier to raise concerns of direct impacts from a vehicle impacting the site.

Therefore, we conclude that the Project would not pose a significant risk or significant increase in risk to the public due to vehicle impacts as a result of the potential consequences, incident data, frequency of trucks, proposed mitigation by Jordan Cove, and additional mitigation measures proposed by FERC staff.

Rail

FERC staff reviewed whether any rail operations would be associated with the Project and whether any existing rail lines would be located near the site. FERC staff uses this information to evaluate whether the Project and any associated rail operations could increase the risk along the rail line and subsequently to the public and whether any pre-existing unassociated rail operations could adversely increase the risk to the Jordan Cove site and subsequently increase the risk to the public. In addition, if authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 and would be subject to the USDOT's inspection and enforcement programs. USDOT regulations under 49 CFR 193.2155 (a) (5) (ii) Subpart C state that if the LNG facility adjoins the right-of-way of any railroad, the structural members of an impoundment system must be designed and constructed to prevent impairment of the system's performance reliability and structural integrity as a result of a collision by or explosion of a train or tank car that could reasonably be expected to cause the most severe loading.

Section 8.5.4 of NFPA 59A (2001), incorporated by reference in 49 CFR 193, requires transfer piping, pumps, and compressors to be located or protected by barriers so that they are safe from damage by rail or vehicle movements. However, the USDOT regulations and NFPA 59A (2001) requirements do not indicate what collision(s) or explosion(s) could reasonably be expected to cause the most severe loading. Therefore, FERC staff evaluated consequence and frequency data from these events to evaluate these potential impacts. FERC staff evaluated the risk of the rail operations based on the consequences from a release, incident data from the Federal Rail Administration (FRA) and PHMSA, and frequency of rail operations nearby Jordan Cove.

FERC staff evaluated the risk of the rail operations based on the consequences from a release, incident data from the DOT Federal Railroad Administration (FRA) and DOT PHMSA, and frequency of rail operations near the LNG Terminal site. Incident data from DOT FRA and DOT PHMSA indicates hazardous material incidents are very infrequent (6e-3 incidents per rail mile per year). In addition, approximately 95 percent of releases are 1,000 gallons or less, and catastrophic events that would spill 30,000 gallons or more make up less than 1 percent of releases. In addition, less than 1 percent of hazardous material incidents result in injuries and less than 0.1 percent of hazardous material incidents result in fatalities.

As previously discussed, the EPA and NOAA report that 80 percent of fires that lead to container ruptures results in projectiles and that 80 percent of projectiles from LPG incidents, which constitute the largest product involved in BLEVEs, travel less than 660 feet. The EPA also reports that on average container ruptures would result in less than four projectiles for cylindrical containers and 8.3 for spherical vessels. FERC staff evaluated other reports that affirmed the EPA estimates based on data for approximately 150 experimental and accidental PVBs and BLEVEs with approximately 683 total projectiles (4.6 average fragments per incident) that showed approximately 80 percent of fragments traveled 490 to 820 feet and within 6.25 times the estimated or observed fireball radius. The data also showed projectiles have traveled up to 3,900 feet for large LPG vessels and 1,200 feet for LPG rail cars. In all the documented cases, the projectiles traveled less than 15 times the fireball diameter, but one of the reports indicated up to 30 times the fireball diameter is possible albeit very rare.

Unmitigated consequences under average ambient conditions from releases of 1,000 gallons through a 1-inch hole would result in distances ranging from 25 to 200 feet for flammable vapor dispersion, and 75 to 175 feet for jet fires. Unmitigated consequences under worst-case weather conditions from catastrophic failures of rail cars containing various flammable products generally can range from 300 to 3,000 feet for flammable vapor dispersion, 450 to 575 feet for radiant heat of 5 kW/m^2 from jet fires, 1,225 to 1,500 feet to a 1 psi overpressure from a BLEVE, 1,250 to 2,100 feet for a heat dose equivalent to a radiant heat of 5 kW/m^2 over 40 seconds from 350 to 450 feet radii fireballs burning for 7 to 20 seconds from a BLEVE, and projectiles from BLEVEs possibly extending farther. Based on distribution function of the projectile distances, FERC staff estimate approximately 80 percent of all projectiles for a 30,000 gallon rail car would be within 0.5 mile and there is approximately a 5 percent probability they would extend beyond 1 mile and less than 0.1 percent probability they would extend 30 times the fireball diameter. These values are also close to the distances provided by USDOT PHMSA for emergency response (0.5 to 1 mile for initial evacuation and 1 mile for potential BLEVEs for flammable gases).

The closest rail line would be the Coos Bay Rail Line (CBRL) located directly to the north of the Project site. The CBRL is a single line railroad that provides delivery of forestry products (e.g., wood products, fertilizer, organic dairy feed) to the nearby Roseburg Forest Products Plant. The Project would install an 80-feet tall impervious barrier that would separate the CBRL and the process equipment. BakerRisk, Inc. performed a rail risk safety analysis and security risk assessment for Jordan Cove that evaluated the potential safety, security, and reliability impacts from the CBRL.

The closest Project facilities would be the ground flare approximately 60 feet from the rail line separated by a retaining wall, the closest auxiliary power generators and pretreatment facilities approximately 400 to 450 feet from the rail line, the closest LNG storage tank approximately 1,150 feet from the rail line, and the closest liquefaction train approximately 1,200 feet from the rail line. However the rail line would not transport pressurized or flammable hazard fluids. Therefore the rail road would not pose a vapor dispersion, fireball, jet fire, pool fire, BLEVE, or projectile hazard to the Project. In addition, Jordan Cove would coordinate with local emergency responders with regard to potential rail incidents. Due to the extremely low likelihood and mitigating actions, we conclude the Project would not pose a significant increase in risk to the public as a result of the proximity of the Project to the rail lines

In addition Jordan Cove would install a railroad construction spur within the plant boundaries that would be located approximately 750 feet east of the process equipment and anticipates to utilize the construction spur approximately 2 times every 3 years for maintenance. The Project would install a 100-feet tall impervious barrier that would separate the construction spur and the process equipment. If the Project is authorized, Jordan Cove would keep the construction spur in place to provide delivery of maintenance equipment, spare parts, and other oversized equipment that would be suited for rail transport. Based on the potential consequences, incident data, distance, and location of the CBRL as well as the anticipated frequency of railroad delivery via the construction spur, we conclude that the Project would not pose a significant increase in risk to the public as a result of the proximity of the Project to the rail lines.

Air

FERC staff reviewed whether any aircraft operations would be associated with the Project and whether any existing aircraft operations would be located near the site. FERC staff uses this information to evaluate whether the Project and any associated aircraft operations could increase the risk to the public and whether any pre-existing unassociated aircraft operations could adversely increase the risk to the Project site and subsequently increase the risk to the public. In addition, if authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 193 and would be subject to the USDOT's inspection and enforcement programs. USDOT regulations under 49 CFR 193.2155 (b), Subpart C, require a LNG storage tank must not be located within a horizontal distance of one mile from the ends, or 0.25 miles from the nearest point of a runway, whichever is longer and that the height of LNG structures in the vicinity of an airport must comply with USDOT FAA requirements. In addition, FERC staff evaluated the risk of an aircraft impact from nearby airports.

Two mixed use aviation airports, Southwest Oregon Regional Airport and Lakeside Municipal Airport, would be located 0.6 mile southeast and 10.9 miles northeast of the LNG terminal site, respectively. The one general aviation airport is the Sunnyhill- North Bend Airport located 4.7 miles northeast of the LNG terminal site. These are all farther than the 0.25-mile distance referenced in USDOT regulations.

FAA regulations in 14 CFR 77 require Jordan Cove to provide a notice to the FAA of its proposed construction. This notification should identify all equipment that are more than 200 feet above ground level or lesser heights if the facilities are within 20,000 feet of an airport (at 100:1 ratio or 50:1 ratio depending on length of runway) or within 5,000 feet of a helipad (at 100:1 ratio). In addition, mobile objects, including the LNG marine vessel that would be above the height of the highest mobile object that would normally traverse it would require notification to FAA.

The Project would include permanent structures that would be taller than 200 feet. Therefore, in accordance with the regulations in 14 CFR 77, Jordan Cove submitted notice to the FAA for an aeronautical obstruction study for the tallest structures at its property. However, Jordan Cove did not submit a notice for temporary construction equipment, such as cranes, derricks, etc., which may be taller than permanent structures and would be used during construction of the Project. Therefore we recommend in section 4.13.1.6 that Jordan Cove file notice to the FAA for temporary structures that would require an Aeronautical Study.

On May 7, 2018, the FAA issued its findings for the LNG marine vessel (at multiple locations during transit), LNG storage tanks, Amine regenerator column, and the thermal oxidizer stack and stated that each of the structures would exceed obstruction standards and would be a presumed hazard to air navigation. However, it should also be noted that the FAA's Notice of Presumed Hazard is not a final determination and each notice states that if the maximum heights of the structures that exceed obstruction standards were reduced to 167 feet above mean seal level (AMSL), it would not create a substantial adverse effect and a favorable determination could subsequently be issued. Jordan Cove has indicated that it would continue to meet with FAA to investigate potential options for eliminating or mitigating the presumed hazards. While Jordan Cove did not provide any additional correspondence with FAA or Southwest Oregon Regional Airport, these potential hazards were previously discussed in the Jordan Cove Energy Project FEIS under Docket Number CP13-483-000 and would be applicable here as similar tall structures reported in the previous application also received a Notice of Presumed Hazard.

As discussed in the Jordan Cove Energy Project FEIS under Docket Number CP13-483-000, two options were identified for mitigating the presumed hazards. One option would maintain the existing flight pattern and require additional lighting and markings on the LNG storage tanks and amine columns. Raising the altitude of planes would provide another level of safety. The other option would "flip" the flight patterns for Runway 04 from their current alignment as a left-handed pattern to the north of the airport that would fly over the Project site, to a right-handed pattern south of the airport that would avoid the terminal. However, the Southwest Oregon Regional Airport did not support the concept of flipping the flight patterns at Runway 04 because that would place aircraft over a populated area. Instead, the Southwest Oregon Regional Airport preferred marking the tanks and towers and concluded that the Jordan Cove LNG terminal would not represent a substantial hazard to aircraft because:

- the existing floor of the airport's traffic pattern is 1,000 feet AMSL and no aircraft flying in the pattern would have to change course or altitude to avoid any of the proposed structures;
- the amine towers are lower than surrounding structures, terrain, and surveyed trees. The LNG storage tanks are taller than the trees, but still lower than the McCullough bridge located within the flight pattern area at 268 feet AMSL; and
- marked obstacles (including both structures and trees) are higher than the airport's elevation and require aircraft to operate at altitudes more than 500 feet above the amine towers and the LNG tanks and no current visual flight rules would have to change course or altitude to avoid the proposed structures.

However, since the FAA has not issued the final determination, there is a potential significant impact to the safe air operations of the Southwest Oregon Regional Airport if a resolution cannot be settled. Therefore, we recommend in section 4.13.1.6 that Jordan Cove should file the final determinations from the FAA prior to initial site preparation that indicate there will be no hazard to aircraft using the Southwest Oregon Regional Airport, and copies of all studies related to the Project's potential impact on the airport. If a determination of no hazard cannot be reached then a notice to proceed with the project would not be granted and a modification, variance, or amendment may be needed.

In addition, FERC staff used DOE Standard 3014, Accident Analysis for Aircraft Crash into Hazardous Facilities, which utilizes a 22-mile threshold radius around the hazardous facility for consideration of hazards posed by airport and heliport operations to the Project facilities. There are two mixed use airports (commercial, military, and general aviation), and one general aviation airport within the 22-mile radius. Per the DOE standard 3014, heliports need only be considered if there are local overflights associated with facility operations and/or area operations. The Project site does have a facility associated heliport in the South Dunes area that would be located approximately 1.2 miles east of processing areas. The heliport would support the Southwest Oregon Regional Safety Center and would generally be used for emergency response and annual exercises. In addition, the Project would install a 100-feet tall impervious barrier that would located between the process equipment and the heliport. Based on the potential separation distance between the process equipment and the heliport as well as the anticipated limited use of the heliport, we conclude the impact risk due to heliport operations would not be significant.

Comments from the public and feedback from FAA indicated potential impacts to and from the Project and the nearby Southwest Oregon Regional Airport. FERC staff conducted internal analyses, and requested information from the applicant on the likelihood and consequences from a potential aircraft impacting the Project and determined that the potential impact to the facility would be above the initial 3e-5 per year screening threshold identified for the process areas and the LNG storage tanks. The potential consequences of such an incident at the tank roof or in the process areas would likely result in a release and fire that would be within the existing hazard footprints already evaluated for a complete tank roof fire and full impoundment fire that is sized for the largest spill in the process area. However depending on the location of impact and extent of damage, the potential fire hazard could extend beyond those evaluated from the LNG storage tank roof fire and the impoundment basin fires. Therefore, FERC staff evaluated whether the full containment walls would withstand aircraft impacts using established methods, such as CEB 187 and other publications. Based on this analysis, FERC staff determined that the full containment LNG storage tanks could withstand general aviation impacts without perforation of the outer tank wall from aircraft impacts that exceed frequencies of 3e-5 per year. However, FERC staff also determined that the LNG storage tanks may not withstand commercial aviation impacts without perforation of the outer tank wall from aircraft impacts that exceed frequencies of 3e-5 per year. As discussed above, potential fire hazard distances from aircraft impacts to the LNG storage tank could extend beyond the property lines, however, these fire hazards would not impact the public. Therefore, we conclude that with the implementation of our recommendations, the Project would not pose a significant risk or increase risk to the public from aircraft impacts to either the LNG storage tanks or the process areas due to the potential consequences, incident data, and the distance and position of aircraft operations relative to the populated areas in the North Bend community.

Pipelines

FERC staff reviewed whether any pipeline operations would be associated with the Project and whether any existing pipelines would be located near the site. FERC staff uses this information to evaluate whether the Project and any associated pipeline operations could increase the risk to the pipeline facilities and subsequently to the public and whether any pre-existing unassociated pipeline operations could adversely increase the risk to the Project site and subsequently increase the risk to the public. In addition, pipelines associated with this Project must meet USDOT regulations under 49 CFR 192 and are discussed in section 4.13.3. If authorized and constructed, LNG facilities as defined in 49 CFR 193, must comply with the requirements of 49 CFR 192 and 49 CFR 193 and would be subject to the USDOT's inspection and enforcement programs. FERC staff evaluated the risk of a pipeline incident impacting the Project and the potential of cascading damage increasing the risk to the public based on the consequences from a release, incident data from the USDOT PHMSA, and proposed mitigation to prevent or reduce the impacts of a pipeline incident from Jordan Cove.

For existing pipelines, FERC staff identified an existing natural gas pipeline located approximately 1.75 miles southwest of the site. FERC staff evaluated the potential risk from an incident from the pipeline and its potential impacts by considering the design and operating conditions and location of the pipeline. This pipeline would be located too far to impact the Project site in the event of an incident.

In addition, based on the potential likelihood of pipeline incidents and potential consequences from a pipeline incident, we conclude that the Project would not significantly increase the risk to the public beyond existing risk levels that would be present from a pipeline leak or pipeline rupture worst-case event near the Project site.

Hazardous Material Facilities and Power Plants

FERC staff reviewed whether any EPA RMP regulated facilities handling hazardous materials and power plants were located near the site to evaluate whether the facilities could adversely increase the risk to the Project site and whether the Project site could increase the risk to the EPA RMP facilities and power plants and subsequently increase the risk to the public.

There were no facilities handling hazardous materials or power plants identified adjacent to the site. The closest EPA RMP regulated facilities handling hazardous materials would be the City of North Bend Wastewater Treatment Plant located approximately 1.03 miles away, and the Pony Creek Water Treatment Plant located approximately 3.50 miles away. The EPA RMP regulations require certain hazard distances to be calculated and a risk management plan to be developed commensurate with those consequences. In addition, the closet power plant identified would be the Douglas County Forest Products Biomass Plant approximately 46 miles away and the closest nuclear plant would be the Columbia Generating Station located over 300 miles away.

Given the distances, locations, and risk management plan requirements of the facilities relative to the populated areas of the North Bend communities, we conclude that the Project would not pose a significant increase in risk to the public or that the hazardous material facilities and power plants would not pose a significant risk to the Project and subsequently to the public.

Onsite and Offsite Emergency Response Plans

As part of its application, Jordan Cove indicated that the Project would develop a comprehensive ERP with local, state, and federal agencies and emergency response officials to discuss the Facilities. Jordan Cove would continue these collaborative efforts during the development, design, and construction of the Project. The emergency procedures would provide for the protection of personnel and the public as well as the prevention of property damage that may occur as a result of incidents at the Project facilities. The facility would also provide appropriate personnel protective equipment to enable operations personnel and first responder access to the area.

As required by 49 CFR 193.2509 Subpart F, Jordan Cove would need to prepare emergency procedures manuals that provide for: a) responding to controllable emergencies and recognizing an uncontrollable emergency; b) taking action to minimize harm to the public including the possible need to evacuate the public; and c) coordination and cooperation with appropriate local officials. Specifically, 49 CFR 193.2509 (b) (3) requires "Coordinating with appropriate local officials in preparation of an emergency evacuation plan…," which sets forth the steps required to protect the public in the event of an emergency, including catastrophic failure of an LNG storage tank. USDOT regulations under 49 CFR 193.2905 Subpart J also require at least two access points in each protective enclosure to be located to minimize the escape distance in the event of emergency.

Title 33 CFR 127.307 also requires the development of emergency manual that incorporates additional material, including LNG release response and emergency shutdown procedures, a description of fire equipment, emergency lighting, and power systems, telephone contacts, shelters, and first aid procedures. In addition, 33 CFR 127.207 establishes requirements for warning alarm systems. Specifically, 33 CFR 127.207 (a) requires that the LNG marine transfer area to be equipped with a rotating or flashing amber light with a minimum effective flash intensity, in the horizontal plane, of 5000 candelas with at least 50 percent of the required effective flash intensity in all directions from 1.0 degree above to 1.0 degree below the horizontal plane. Furthermore, 33 CFR 127.207 (b) requires the marine transfer area for LNG to have a siren with a minimum 1⁄3- octave band sound pressure level at l meter of 125 decibels referenced to 0.0002 microbars. The siren must be located so that the sound signal produced is audible over 360 degrees in a horizontal plane. Lastly, 33 CFR 127.207 (c) requires that each light and siren must be located so that the warning alarm is not obstructed for a distance of 1.6 km (1 mile) in all directions. The warning alarms would be required to be tested in order to meet 33 CFR 127. Jordan Cove would be required to meet the warning alarms requirements specified in 33 CFR 127.207.

In accordance with the EPAct 2005, FERC must also approve an ERP covering the terminal and ship transit prior to construction. Section 3A (e) of the NGA, added by section 311 of the EPAct 2005, stipulates that in any order authorizing an LNG terminal, the Commission must require the LNG terminal operator to develop an ERP in consultation with the Coast Guard and state and local agencies. The final ERP would need to be evaluated by appropriate emergency response personnel and officials. Section 3A (e) of the NGA (as amended by EPAct 2005) specifies that the ERP must include a Cost-Sharing Plan that contains a description of any direct cost reimbursements the applicant agrees to provide to any state and local agencies with responsibility for security and safety at the LNG terminal and in proximity to LNG marine vessels that serve the facility. The Cost-Sharing Plan must specify what the LNG terminal operator would provide to cover the cost of the state and local resources required to manage the security of the LNG terminal and LNG marine vessel, and the state and local resources required for safety and emergency management, including:

- direct reimbursement for any per-transit security and/or emergency management costs (for example, overtime for police or fire department personnel);
- capital costs associated with security/emergency management equipment and personnel base (for example, patrol boats, firefighting equipment); and
- annual costs for providing specialized training for local fire departments, mutual aid departments, and emergency response personnel; and for conducting exercises.

The cost-sharing plan must include the LNG terminal operator's letter of commitment with agency acknowledgement for each state and local agency designated to receive resources.

Jordan Cove submitted a draft ERP to address emergency events and potential release scenarios in the Application. The ERP would include public notification, protection, and evacuation. As part of the FEED review, FERC staff evaluated the initial draft of the emergency response procedures to assure that it covers the hazards associated with the Project. In addition, we recommend in section 4.13.1.6 that Jordan Cove provide additional information, for review and approval, on development of updated emergency response plans prior to initial site preparation. We also recommend in section 4.13.1.6 that Jordan Cove file three dimensional drawings, for review and approval, that demonstrate there is a sufficient number of access and egress locations. If this Project is authorized and constructed, Jordan Cove would coordinate with local, state, and federal agencies on the development of an emergency response plan and cost sharing plan. We recommend in section 4.13.1.6 that Jordan Cove provide periodic updates on the development of these plans for review and approval, and ensure they are in place prior to introduction of hazardous fluids. In addition, we recommend in section 4.13.1.6 that Project facilities be subject to regular inspections throughout the life of the facility and would continue to require companies to file updates to the ERP.

4.13.1.6 Recommendations from FERC Preliminary Engineering and Technical Review

Based on our preliminary engineering and technical review of the reliability and safety of the Jordan Cove LNG Project, we recommend the following mitigation measures as conditions to any order authorizing the Project. These recommendations would be implemented prior to the end of the DEIS comment period, prior to initial site preparation, prior to construction of final design, prior to commissioning, prior to introduction of hazardous fluids, prior to commencement of service, and throughout the life of the facility to enhance the reliability and safety of the facility and to mitigate the risk of impact on the public.

- **Prior to end of the draft EIS comment period, Jordan Cove should file with the Secretary documentation of consultation with USDOT PHMSA staff as to whether the design wind speed for other non-hazardous buildings and structures would be subject to USDOT requirements.**

- **Prior to the end draft EIS comment period, Jordan Cove should file with the Secretary an analysis that demonstrates the flammable vapor dispersion from design spills would be prevented from dispersing underneath the elevated LNG storage tanks, or the LNG storage tanks would be able to withstand an overpressure due to ignition of the flammable vapor dispersion cloud that disperses underneath the elevated LNG storage tanks.**

- **Prior to initial site preparation, Jordan Cove should file with the Secretary documentation demonstrating it has received a determination of no hazard (with or without conditions) by USDOT FAA for all permanent structures, temporary construction equipment, and mobile objects that exceed the height requirements in 14 CFR 77.9.**

- **Prior to construction of final design, Jordan Cove should file with the Secretary the following information, stamped and sealed by the professional engineer-of-record, registered in Oregon:**

  a. site preparation drawings and specifications;

  b. LNG terminal structures, LNG storage tank, and foundation design drawings and calculations (including prefabricated and field constructed structures);

  c. seismic specifications for procured Seismic Category I equipment prior to the issuing of request for quotations;

  d. quality control procedures to be used for civil/structural design and construction; and

  e. a determination of whether soil improvement is necessary to counteract soil liquefaction.

  In addition, Jordan Cove should file, in its Implementation Plan, the schedule for producing this information.

- **<u>Prior to construction of final design,</u> Jordan Cove should file with the Secretary consultation with USDOT PHMSA staff as to whether the use of normally closed valves to remove stormwater from curbed areas would meet USDOT PHMSA requirements.**

- **<u>Prior to commencement of service</u>, Jordan Cove should file with the Secretary a monitoring and maintenance plan, stamped and sealed by the professional engineer-of-record registered in Oregon, which ensures the facilities are protected for the life of the LNG terminal considering settlement, subsidence, and sea level rise.**

Information pertaining to the following specific recommendations should be filed with the Secretary for review and written approval by the Director of OEP, or the Director's designee, within the timeframe indicated by each recommendation. Specific engineering, vulnerability, or detailed design information meeting the criteria specified in Order No. 833 (Docket No. RM16-15-000), including security information, should be submitted as critical energy infrastructure information pursuant to 18 CFR 388.113. See Critical Electric Infrastructure Security and Amending Critical Energy Infrastructure Information, Order No. 833, 81 Fed. Reg. 93,732 (December 21, 2016), FERC Stats. & Regs. 31,389 (2016). Information pertaining to items such as offsite emergency response, procedures for public notification and evacuation, and construction and operating reporting requirements would be subject to public disclosure. All information should be filed **<u>a minimum of 30 days</u>** before approval to proceed is requested.

- **<u>Prior to initial site preparation</u>, Jordan Cove should file an overall Project schedule, which includes the proposed stages of the commissioning plan.**

- **<u>Prior to initial site preparation</u>, Jordan Cove should file procedures for controlling access during construction.**

- **<u>Prior to initial site preparation</u>, Jordan Cove should file quality assurance and quality control procedures for construction activities for both the Engineering Procurement Contractor and Jordan Cove to monitor construction activities.**

- **<u>Prior to initial site preparation</u>, Jordan Cove should specify a spill containment system around the Warm Flare Knockout Drum.**

- **<u>Prior to initial site preparation</u>, Jordan Cove should develop an ERP (including evacuation) and coordinate procedures with the Coast Guard; state, county, and local emergency planning groups; fire departments; state and local law enforcement; and appropriate federal agencies. This plan should include at a minimum:**

  a. designated contacts with state and local emergency response agencies;

  b. scalable procedures for the prompt notification of appropriate local officials and emergency response agencies based on the level and severity of potential incidents;

  c. procedures for notifying residents and recreational users within areas of potential hazard;

  d. evacuation routes/methods for residents and public use areas that are within any transient hazard areas along the route of the LNG marine transit;

e. **locations of permanent sirens and other warning devices; and**

f. **an "emergency coordinator" on each LNG marine vessel to activate sirens and other warning devices.**

Jordan Cove should notify the FERC staff of all planning meetings in advance and should report progress on the development of its ERP <u>at 3‑month intervals</u>.

- **<u>Prior to initial site preparation</u>, Jordan Cove should file a Cost-Sharing Plan identifying the mechanisms for funding all Project-specific security/emergency management costs that would be imposed on state and local agencies. This comprehensive plan should include funding mechanisms for the capital costs associated with any necessary security/emergency management equipment and personnel base. Jordan Cove should notify FERC staff of all planning meetings in advance and should report progress on the development of its Cost Sharing Plan at <u>3-month intervals</u>.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file change logs that list and explain any changes made from the FEED provided in Jordan Cove LNG Project's application and filings. A list of all changes with an explanation for the design alteration should be provided and all changes should be clearly indicated on all diagrams and drawings.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file information/revisions pertaining to Jordan Cove's response numbers 8c, 13, 15, 21, 22, 23, 24, 26, 27, 28, and 31 of its December 20, 2018 filing and 6, 9, 10, 11, 17, 19, 32, 34, and 36 of its February 6, 2019 filing which indicated features to be included or considered in the final design.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file drawings and specifications for crash rated vehicle barriers at each facility entrance for access control.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file drawings of the security fence. The fencing drawings should provide details of fencing that demonstrates it would restrict and deter access around the entire facility and has a setback from exterior features (e.g., power lines, trees, etc.) and from interior features (e.g., piping, equipment, buildings, etc.) that does not allow the fence to be overcome.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file drawings of internal road vehicle protections, such as guard rails, barriers, and bollards to protect transfer piping, pumps, compressors, hydrants, monitors, etc. to ensure that they are located away from roadway or protected from inadvertent damage from vehicles.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file security camera and intrusion detection drawings. The security camera drawings should show the locations, areas covered, and features of each camera (e.g., fixed, tilt/pan/zoom, motion detection alerts, low light, mounting height, etc.) to verify camera coverage of the entire perimeter with redundancies for cameras interior to the facility to enable rapid monitoring of the facility, including a camera at the top of each LNG storage tank,**

and coverage within pretreatment areas, within liquefaction areas, within truck transfer areas, within marine transfer areas, and buildings. The drawings should show or note the location of the intrusion detection to verify it covers the entire perimeter of the facility.

- **<u>Prior to construction of final design</u>, Jordan Cove should file lighting drawings. The lighting drawings should show the location, elevation, type of light fixture, and lux levels of the lighting system and should be in accordance with API 540 and provide illumination along the perimeter of the facility, process equipment, mooring points, and along paths/roads of access and egress to facilitate security monitoring and emergency response operations.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a plot plan of the final design showing all major equipment, structures, buildings, and impoundment systems. This lighting plan should also be in compliance with the lighting recommendation in section 4.5.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file three-dimensional plant drawings to confirm plant layout for maintenance, access, egress, and congestion.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file up-to-date process flow diagrams (PFDs) and piping and instrument diagrams (P&IDs) including vendor P&IDs. The PFDs should include heat and material balances. The P&IDs should include the following information:**

  a. **equipment tag number, name, size, duty, capacity, and design conditions;**
  b. **equipment insulation type and thickness;**
  c. **storage tank pipe penetration size and nozzle schedule;**
  d. **valve high pressure side and internal and external vent locations;**
  e. **piping with line number, piping class specification, size, and insulation type and thickness;**
  f. **piping specification breaks and insulation limits;**
  g. **all control and manual valves numbered;**
  h. **relief valves with size and set points; and**
  i. **drawing revision number and date.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file P&IDs, specifications, and procedures that clearly show and specify the tie-in details required to safely connect subsequently constructed facilities with the operational facilities.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a car seal philosophy and a list of all car-sealed and locked valves consistent with the P&IDs.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file information to demonstrate the EPC contractor has verified that all FEED HAZOP and LOPA recommendations have been addressed.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a hazard and operability review prior to issuing the P&IDs for construction. A copy of the review, a list of the recommendations, and actions taken on the recommendations should be filed.**

- **Prior to construction of final design<u>, Jordan Cove should provide a check valve upstream of the amine contractor column to prevent backflow or provide a a dynamic simulation that shows that upon plant shutdown, the swan neck would be sufficient for this purpose.</u>**

- **<u>Prior to construction of final design</u>, Jordan Cove should specify how Mole Sieve Gas Dehydrator support and sieve material would be prevented from migrating to the piping system.**

- **<u>Prior to construction of final design</u>, Jordan Cove should specify how the regeneration gas heater tube design temperature would be consistent with the higher shell side steam temperatures.**

- **<u>Prior to construction of final design</u>, Jordan Cove should specify a cold gas bypass around the defrost gas heater to prevent defrost gas heater high temperature shutdown during low flow and startup conditions.**

- **<u>Prior to construction of final design</u>, Jordan Cove shall demonstrate that the differential pressure (dp) level transmitters on the LNG flash drum would not result in an excess number of false high-high-high level shutdowns.**

- **<u>Prior to construction of final design</u>, Jordan Cove should specify a means to stop LNG flows to the BOG suction drum when the BOG compressor is shutdown to prevent filling the BOG suction drum with LNG.**

- **<u>Prior to construction of final design</u>, Jordan Cove should specify a low instrument air pressure shutdown to prevent loss of control to air operated valve.**

- **<u>Prior to construction of final design</u>, Jordan Cove should evaluate and, if applicable, address the potential for cryogenic feed gas back flow in the event relief valve 30-PSV-01002A/B is open.**

- **<u>Prior to construction of final design</u>, Jordan Cove should include LNG tank fill flow measurement with high flow alarm.**

- **<u>Prior to construction of final design</u>, Jordan Cove should specify a discretionary vent valve on each LNG storage tank that is operable through the Distributed Control System (DCS). In addition, a car sealed open manual block valve should be provided upstream of the discretionary vent valve.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file the safe operating limits (upper and lower), alarm and shutdown set points for all instrumentation (e.g., temperature, pressures, flows, and compositions).**

- **<u>Prior to construction of final design</u>, Jordan Cove should file cause-and-effect matrices for the process instrumentation, fire and gas detection system, and emergency shutdown system. The cause-and-effect matrices should include alarms and shutdown functions, details of the voting and shutdown logic, and set points.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file an up-to-date equipment list, process and mechanical data sheets, and specifications. The specifications should include:**

  a. **building specifications (e.g., control buildings, electrical buildings, compressor buildings, storage buildings, pressurized buildings, ventilated buildings, blast resistant buildings);**

  b. **mechanical specifications (e.g., piping, valve, insulation, rotating equipment, heat exchanger, storage tank and vessel, other specialized equipment);**

  c. **electrical and instrumentation specifications (e.g., power system, control system, safety instrument system [SIS], cable, other electrical and instrumentation); and**

  d. **security and fire safety specifications (e.g., security, passive protection, hazard detection, hazard control, firewater).**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a list of all codes and standards and the final specification document number where they are referenced.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a complete specifications and drawings of the proposed LNG tank design and installation.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file an evaluation of emergency shutdown valve closure times. The evaluation should account for the time to detect an upset or hazardous condition, notify plant personnel, and close the emergency shutdown valve(s).**

- **<u>Prior to construction of final design</u>, Jordan Cove should file an evaluation of dynamic pressure surge effects from valve opening and closure times and pump startup and shutdown operations.**

- **<u>Prior to construction of final design</u>, Jordan Cove should demonstrate that, for hazardous fluids, piping and piping nipples 2 inches or less in diameter are designed to withstand external loads, including vibrational loads in the vicinity of rotating equipment and operator live loads in areas accessible by operators.**

- **<u>Prior to construction of final design</u>, Jordan Cove should clearly specify the responsibilities of the LNG tank contractor and the EPC contractor for the piping associated with the LNG storage tank.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file the sizing basis and capacity for the final design of the flares and/or vent stacks as well as the pressure and vacuum relief valves for major process equipment, vessels, and storage tanks.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file an updated fire protection evaluation of the proposed facilities. A copy of the evaluation, a list of recommendations and supporting justifications, and actions taken on the recommendations should be filed. The evaluation should justify the type, quantity, and location of hazard detection and hazard control, passive fire protection, emergency shutdown and depressurizing systems, firewater, and emergency response equipment, training, and qualifications in accordance with NFPA 59A (2001). The justification for the flammable and combustible gas detection and flame and heat detection systems should be in accordance with ISA 84.00.07 or equivalent methodologies and would need to demonstrate 90 percent or more of releases (unignited and ignited) that could result in an off-site or cascading impact would be detected by two or more detectors and result in isolation and de inventory within 10 minutes. The analysis should take into account the set points, voting logic, wind speeds, and wind directions. The justification for firewater should provide calculations for all firewater demands based on design densities, surface area, and throw distance as well as specifications for the corresponding hydrant and monitors needed to reach and cool equipment.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file spill containment system drawings with dimensions and slopes of curbing, trenches, impoundments, and capacity calculations considering any foundations and equipment within impoundments, as well as the sizing and design of the down-comers. The spill containment drawings should show containment for all hazardous fluids including all liquids handled above their flashpoint, from the largest flow from a single line for 10 minutes, including de-inventory, or the maximum liquid from the largest vessel (or total of impounded vessels) or otherwise demonstrate that providing spill containment would not significantly reduce the flammable vapor dispersion or radiant heat consequences of a spill.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file electrical area classification drawings.**

- **<u>Prior to construction of final design</u>, Jordan Cove should provide documentation demonstrating adequate ventilation, detection, and electrical area classification based on the final selection of the batteries, and associated hydrogen off-gassing rates.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file drawings and details of how process seals or isolations installed at the interface between a flammable fluid system and an electrical conduit or wiring system meet the requirements of NFPA 59A (2001).**

- **<u>Prior to construction of final design</u>, Jordan Cove should file details of an air gap or vent installed downstream of process seals or isolations installed at the interface between a flammable fluid system and an electrical conduit or wiring system. Each**

air gap should vent to a safe location and be equipped with a leak detection device that should continuously monitor for the presence of a flammable fluid, alarm the hazardous condition, and shut down the appropriate systems.

- **<u>Prior to construction of final design</u>, Jordan Cove should file complete drawings and a list of the hazard detection equipment. The drawings should clearly show the location and elevation of all detection equipment. The list should include the instrument tag number, type and location, alarm indication locations, and shutdown functions of the hazard detection equipment.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a technical review of facility design that:**

  a. identifies all combustion/ventilation air intake equipment and the distances to any possible flammable gas or toxic release; and

  b. demonstrates that these areas are adequately covered by hazard detection devices and indicates how these devices would isolate or shutdown any combustion or heating ventilation and air conditioning equipment whose continued operation could add to or sustain an emergency.

- **<u>Prior to construction of final design</u>, Jordan Cove should file a design that includes hazard detection suitable to detect high temperatures and smoldering combustion products in electrical buildings and control room buildings.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file an evaluation of the voting logic and voting degradation for hazard detectors.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a list of alarm and shutdown set points for all hazard detectors that account for the calibration gas of the hazard detectors when determining the lower flammable limit set points for methane, ethylene, propane, isopentane, and condensate.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a list of alarm and shutdown set points for all hazard detectors that account for the calibration gas of hazard detectors when determining the set points for toxic components such as condensate and hydrogen sulfide.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a drawing showing the location of the emergency shutdown buttons. Emergency shutdown buttons should be easily accessible, conspicuously labeled, and located in an area which would be accessible during an emergency.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file facility plan drawings and a list of the fixed and wheeled dry-chemical, hand-held fire extinguishers, and other hazard control equipment. Plan drawings should clearly show the location by tag number of all fixed, wheeled, and hand-held extinguishers and should demonstrate the spacing of extinguishers meet prescribed NFPA 10 travel distances. The list should include the equipment tag number, type, capacity, equipment covered, discharge rate,**

and automatic and manual remote signals initiating discharge of the units and should demonstrate they meet NFPA 59A.

- **<u>Prior to construction of final design</u>, Jordan Cove should file drawings and specifications for the structural passive protection systems to protect equipment and supports from cryogenic releases.**
- **<u>Prior to construction of final design</u>, Jordan Cove should file calculations or test results for the structural passive protection systems to protect equipment and supports from cryogenic releases.**
- **<u>Prior to construction of final design</u>, Jordan Cove should file drawings and calculations that demonstrate passive protection is provided in areas where jet fires may result in failure of structural supports.**
- **<u>Prior to construction of final design</u>, Jordan Cove should file a detailed quantitative analysis to demonstrate that adequate thermal mitigation would be provided for each significant component within the 4,000 Btu/ft^2-hr zone from an impoundment, or provide an analysis that assesses the consequence of pressure vessel bursts and boiling liquid expanding vapor explosions. Trucks at the truck transfer station should be included in the analysis. A combination of passive and active protection should be provided and demonstrate the effectiveness and reliability. Effectiveness of passive mitigation should be supported by calculations for the thickness limiting temperature rise and effectiveness of active mitigation should be justified with calculations demonstrating flow rates and durations of any cooling water would mitigate the heat absorbed by the vessel.**
- **<u>Prior to construction of final design</u>, Jordan Cove should file an evaluation and associated specifications and drawings of how they would prevent cascading damage of transformers (e.g., fire walls or spacing) in accordance with NFPA 850 or equivalent.**
- **<u>Prior to construction of final design</u>, Jordan Cove should file facility plan drawings showing the proposed location of the firewater and any foam systems. Plan drawings should clearly show the location of firewater and foam piping, post indicator valves, and the location and area covered by, each monitor, hydrant, hose, water curtain, deluge system, foam system, water-mist system, and sprinkler. All areas of the pretreatment area should have adequate coverage. The drawings should also include piping and instrumentation diagrams of the firewater and foam systems.**
- **<u>Prior to construction of final design</u>, Jordan Cove should specify that the firewater pump shelter is designed to remove the largest firewater pump or other component for maintenance with an overhead or external crane.**
- **<u>Prior to construction of final design</u>, Jordan Cove should demonstrate that the firewater storage tanks are in compliance with NFPA 22 or demonstrate how API Standard 650 provides an equivalent or better level of safety.**

- **<u>Prior to construction of final design</u>, Jordan Cove should specify that the firewater flow test meter is equipped with a transmitter and that a pressure transmitter is installed upstream of the flow transmitter. The flow transmitter and pressure transmitter should be connected to the DCS and recorded.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file the settlement results during hydrostatic tests of the LNG storage containers and periodically thereafter to verify settlement is as expected and does not exceed the applicable criteria in API 620, API 625, API 653, and ACI 376.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file drawings of the storage tank piping support structure and support of horizontal piping at grade including pump columns, relief valves, pipe penetrations, instrumentation, and appurtenances.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file the structural analysis of the LNG storage tank and outer containment demonstrating they are designed to withstand all loads and combinations.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file an analysis of the structural integrity of the outer containment of the full containment LNG storage tank demonstrating it can withstand the radiant heat from a roof tank top fire or adjacent tank roof fire.**

- **<u>Prior to construction of final design</u>, Jordan Cove should file a projectile analysis to demonstrate that the outer concrete impoundment wall of a full-containment LNG storage tank could withstand projectiles from explosions and high winds. The analysis should detail the projectile speeds and characteristics and method used to determine penetration or perforation depths.**

- **<u>Prior to commissioning</u>, Jordan Cove should file a detailed schedule for commissioning through equipment startup. The schedule should include milestones for all procedures and tests to be completed: prior to introduction of hazardous fluids and during commissioning and startup. Jordan Cove should file documentation certifying that each of these milestones has been completed before authorization to commence the next phase of commissioning and startup will be issued.**

- **<u>Prior to commissioning</u>, Jordan Cove should file detailed plans and procedures for: testing the integrity of onsite mechanical installation; functional tests; introduction of hazardous fluids; operational tests; and placing the equipment into service.**

- **<u>Prior to commissioning</u>, Jordan Cove should file settlement results from the hydrostatic tests of the LNG storage containers and should file a plan to periodically verify settlement is as expected and does not exceed the applicable criteria set forth in API 620, API 625, API 653, and ACI 376. The program should specify what actions would be taken after various levels of seismic events.**

- **<u>Prior to commissioning</u>, Jordan Cove should file the operation and maintenance procedures and manuals, as well as safety procedures, hot work procedures and**

permits, abnormal operating conditions reporting procedures, simultaneous operations procedures, and management of change procedures and forms.

- **<u>Prior to commissioning</u>, Jordan Cove should file a plan for clean-out, dry-out, purging, and tightness testing. This plan should address the requirements of the American Gas Association's Purging Principles and Practice, and should provide justification if not using an inert or non-flammable gas for clean-out, dry-out, purging, and tightness testing.**

- **<u>Prior to commissioning</u>, Jordan Cove should tag all equipment, instrumentation, and valves in the field, including drain valves, vent valves, main valves, and car-sealed or locked valves.**

- **<u>Prior to commissioning</u>, Jordan Cove should file a plan to maintain a detailed training log to demonstrate that operating, maintenance, and emergency response staff have completed the required training.**

- **<u>Prior to commissioning</u>, Jordan Cove should file the procedures for pressure/leak tests which address the requirements of ASME VIII and ASME B31.3. The procedures should include a line list of pneumatic and hydrostatic test pressures.**

- **<u>Prior to introduction of hazardous fluids</u>, Jordan Cove should complete and document a pre-startup safety review to ensure that installed equipment meets the design and operating intent of the facility. The pre-startup safety review should include any changes since the last hazard review, operating procedures, and operator training. A copy of the review with a list of recommendations, and actions taken on each recommendation, should be filed.**

- **<u>Prior to introduction of hazardous fluids</u>, Jordan Cove should complete and document all pertinent tests (Factory Acceptance Tests, Site Acceptance Tests, Site Integration Tests) associated with the DCS and SIS that demonstrates full functionality and operability of the system.**

- **<u>Prior to introduction of hazardous fluids</u>, Jordan Cove should develop and implement an alarm management program to reduce alarm complacency and maximize the effectiveness of operator response to alarms.**

- **<u>Prior to introduction of hazardous fluids</u>, Jordan Cove should complete and document a clean agent acceptance tests.**

- **<u>Prior to introduction of hazardous fluids</u>, Jordan Cove should complete and document a firewater pump acceptance test and firewater monitor and hydrant coverage test. The actual coverage area from each monitor and hydrant should be shown on facility plot plan(s).**

- **<u>Prior to introduction of hazardous fluids</u>, Jordan Cove should complete and document foam system and sprinkler system acceptance tests.**

- **Jordan Cove should file a request for written authorization from the Director of OEP <u>prior to unloading or loading the first LNG commissioning cargo</u>. After production of first LNG, Jordan Cove should file weekly reports on the commissioning of the proposed systems that detail the progress toward demonstrating the facilities can safely and reliably operate at or near the design production rate. The reports should include a summary of activities, problems encountered, and remedial actions taken. The weekly reports should also include the latest commissioning schedule, including projected and actual LNG production by each liquefaction train, LNG storage inventories in each storage tank, and the number of anticipated and actual LNG commissioning cargoes, along with the associated volumes loaded or unloaded. Further, the weekly reports should include a status and list of all planned and completed safety and reliability tests, work authorizations, and punch list items. Problems of significant magnitude should be reported to the FERC within 24 hours.**

- **<u>Prior to commencement of service</u>, Jordan Cove should file a request for written authorization from the Director of OEP. Such authorization would only be granted following a determination by the Coast Guard, under its authorities under the Ports and Waterways Safety Act, the Magnuson Act, the MTSA of 2002, and the Security and Accountability For Every Port Act, that appropriate measures to ensure the safety and security of the facility and the waterway have been put into place by Jordan Cove or other appropriate parties.**

- **<u>Prior to commencement of service</u>, Jordan Cove should notify the FERC staff of any proposed revisions to the security plan and physical security of the plant.**

- **<u>Prior to commencement of service</u>, Jordan Cove should label piping with fluid service and direction of flow in the field, in addition to the pipe labeling requirements of NFPA 59A (2001).**

- **<u>Prior to commencement of service</u>, Jordan Cove should provide plans for any preventative and predictive maintenance program that performs periodic or continuous equipment condition monitoring.**

- **<u>Prior to commencement of service</u>, Jordan Cove should develop procedures for offsite contractors' responsibilities, restrictions, and limitations and for supervision of these contractors by Jordan Cove staff.**

In addition, we recommend that the following measures should apply <u>throughout the life of the Jordan Cove LNG Project</u>.

- **The facility should be subject to regular FERC staff technical reviews and site inspections on at least an <u>annual</u> basis or more frequently as circumstances indicate. Prior to each FERC staff technical review and site inspection, Jordan Cove should respond to a specific data request including information relating to possible design and operating conditions that may have been imposed by other agencies or organizations. Up-to-date detailed P&IDs reflecting facility modifications and provision of other pertinent information not included in the semi-annual reports described below, including facility events that have taken place since the previously submitted semi-annual report, should be submitted.**

- **<u>Semi-annual</u> operational reports should be filed with the Secretary to identify changes in facility design and operating conditions; abnormal operating experiences; activities (e.g., ship arrivals, quantity and composition of imported and exported LNG, liquefied and vaporized quantities, boil off/flash gas); and plant modifications, including future plans and progress thereof. Abnormalities should include, but not be limited to, unloading/loading/shipping problems, potential hazardous conditions from offsite vessels, storage tank stratification or rollover, geysering, storage tank pressure excursions, cold spots on the storage tank, storage tank vibrations and/or vibrations in associated cryogenic piping, storage tank settlement, significant equipment or instrumentation malfunctions or failures, non-scheduled maintenance or repair (and reasons therefore), relative movement of storage tank inner vessels, hazardous fluids releases, fires involving hazardous fluids and/or from other sources, negative pressure (vacuum) within a storage tank, and higher than predicted boil off rates. Adverse weather conditions and the effect on the facility also should be reported. Reports should be submitted <u>within 45 days after each period ending June 30 and December 31</u>. In addition to the above items, a section entitled "Significant Plant Modifications Proposed for the Next 12 Months (dates)" should be included in the semi-annual operational reports. Such information would provide the FERC staff with early notice of anticipated future construction/maintenance at the LNG facilities.**

- **In the event the temperature of any region of the LNG storage container, including any secondary containment and imbedded pipe supports, becomes less than the minimum specified operating temperature for the material, the Commission should be notified <u>within 24 hours</u> and procedures for corrective action should be specified.**

- **Significant non-scheduled events, including safety-related incidents (e.g., LNG, condensate, refrigerant, or natural gas releases; fires; explosions; mechanical failures; unusual over pressurization; and major injuries) and security-related incidents (e.g., attempts to enter site, suspicious activities) should be reported to the FERC staff. In the event that an abnormality is of significant magnitude to threaten public or employee safety, cause significant property damage, or interrupt service, notification should be made <u>immediately</u>, without unduly interfering with any necessary or appropriate emergency repair, alarm, or other emergency procedure. In all instances, notification should be made to the FERC staff <u>within 24 hours</u>. This notification practice should be incorporated into the liquefaction facility's emergency plan. Examples of reportable hazardous fluids-related incidents include:**

  a. **fire;**

  b. **explosion;**

  c. **estimated property damage of $50,000 or more;**

  d. **death or personal injury necessitating in-patient hospitalization;**

  e. **release of hazardous fluids for 5 minutes or more;**

  f. **unintended movement or abnormal loading by environmental causes, such as an earthquake, landslide, or flood, that impairs the serviceability, structural**

integrity, or reliability of an LNG facility that contains, controls, or processes hazardous fluids;

g. **any crack or other material defect that impairs the structural integrity or reliability of an LNG facility that contains, controls, or processes hazardous fluids;**

h. **any malfunction or operating error that causes the pressure of a pipeline or LNG facility that contains or processes hazardous fluids to rise above its maximum allowable operating pressure (or working pressure for LNG facilities) plus the build-up allowed for operation of pressure-limiting or control devices;**

i. **a leak in an LNG facility that contains or processes hazardous fluids that constitutes an emergency;**

j. **inner tank leakage, ineffective insulation, or frost heave that impairs the structural integrity of an LNG storage tank;**

k. **any safety-related condition that could lead to an imminent hazard and cause (either directly or indirectly by remedial action of the operator), for purposes other than abandonment, a 20 percent reduction in operating pressure or shutdown of operation of a pipeline or an LNG facility that contains or processes hazardous fluids;**

l. **safety-related incidents from hazardous fluids transportation occurring at or en route to and from the LNG facility; or**

m. **an event that is significant in the judgment of the operator and/or management even though it did not meet the above criteria or the guidelines set forth in an LNG facility's incident management plan.**

In the event of an incident, the Director of OEP has delegated authority to take whatever steps are necessary to ensure operational reliability and to protect human life, health, property, or the environment, including authority to direct the LNG facility to cease operations. Following the initial company notification, the FERC staff would determine the need for a separate follow-up report or follow up in the upcoming semi-annual operational report. All company follow-up reports should include investigation results and recommendations to minimize a reoccurrence of the incident.

4.13.2 Pacific Connector Pipeline Project

The transportation of natural gas by pipeline involves some incremental risk to the public due to the potential for accidental release of natural gas. The greatest hazard is a fire or explosion following a major pipeline rupture.

Methane, the primary component of natural gas, is colorless, odorless, and tasteless. It is not toxic, but is classified as a simple asphyxiant, possessing a slight inhalation hazard. If breathed in high concentration, oxygen deficiency can result in serious injury or death. Methane has an auto-ignition temperature of 1,000°F and is flammable at concentrations between 5.0 percent and 15.0

Exhibit 27
Page 1046 of 1120

percent in air. An unconfined mixture of methane and air is not explosive; however, it may ignite and burn if there is an ignition source.

4.13.2.1 Safety Standards

The USDOT is mandated to provide pipeline safety under 49 U.S.C. § 601. The PHMSA Office of Pipeline Safety (OPS) administers the national regulatory program to ensure the safe transportation of natural gas and other hazardous materials by pipeline. It develops safety regulations and other approaches to risk management that ensure safety in the design, construction, testing, operation, maintenance, and emergency response of pipeline facilities. Many of the regulations are written as performance standards which set the level of safety to be attained and allow the pipeline operator to use various technologies to achieve safety. The PHMSA ensures that people and the environment are protected from the risk of pipeline incidents. This work is shared with state agency partners and others at the federal, state, and local level. Section 5(a) of the Natural Gas Pipeline Safety Act provides for a state agency to assume all aspects of the safety program for intrastate facilities by adopting and enforcing the federal standards, while section 5(b) permits a state agency that does not qualify under section 5(a) to perform certain inspection and monitoring functions. A state may also act as the USDOT's agent to inspect interstate facilities within its boundaries; however, the USDOT is responsible for enforcement action. Most of the states have either 5(a) certifications or 5(b) agreements, while nine states act as interstate agents.

Under an MOU on natural gas transportation facilities dated January 15, 1993 between the USDOT and the FERC, the USDOT has the exclusive authority to promulgate federal safety standards used in the transportation of natural gas. The USDOT pipeline standards are published in 49 CFR Parts 190-199; Part 192 of 49 CFR specifically addresses natural gas pipeline safety issues. Section 157.14(a)(9)(vi) of the FERC's regulations require that an applicant certify that it will design, install, inspect, test, construct, operate, replace, and maintain the facility for which a certificate is requested in accordance with federal safety standards and plans for maintenance and inspection, or shall certify that it has been granted a waiver of the requirements of the safety standards by the USDOT in accordance with section 3(e) of the Natural Gas Pipeline Safety Act. The FERC accepts this certification and does not impose additional safety standards other than the USDOT standards. If the Commission becomes aware of an existing or potential safety problem, there is a provision in the MOU to promptly alert the USDOT. The MOU also provides for referring complaints and inquiries made by state and local governments as well as the general public involving safety matters related to pipelines under the Commission's jurisdiction.

The FERC also participates as a member of the USDOT's Technical Pipeline Safety Standards Committee, which determines if proposed safety regulations are reasonable, feasible, and practicable.

The Pacific Connector pipeline and aboveground facilities must be designed, constructed, operated, and maintained in accordance with the USDOT Minimum Federal Safety Standards in 49 CFR Part 192. The regulations are intended to ensure adequate protection for the public and to prevent natural gas facility accidents and failures. The USDOT specifies material selection and qualification; minimum design requirements; and protection from internal, external, and atmospheric corrosion.

The USDOT also defines area classifications, based on population density in the vicinity of the pipeline, and specifies more rigorous safety requirements for populated areas. The class location unit is an area that extends 220 yards on either side of the centerline of any continuous 1-mile length of pipeline. The four area classifications are defined below:

- Class 1 – Location with 10 or fewer buildings intended for human occupancy;
- Class 2 – Location with more than 10 but less than 46 buildings intended for human occupancy;
- Class 3 – Location with 46 or more buildings intended for human occupancy or where the pipeline lies within 100 yards of any building, or small well-defined outside area occupied by 20 or more people on at least 5 days per week for 10 weeks in any 12-month period; and
- Class 4 – Location where buildings with four or more stories aboveground are prevalent.

Class locations representing more populated areas require higher safety factors in pipeline design, testing, and operation. Pipelines constructed on land in Class 1 locations must be installed with a minimum depth of cover of 30 inches in normal soil and 18 inches in consolidated (solid) rock. Class 2, 3, and 4 locations, as well as drainage ditches of public roads and railroad crossings, require a minimum cover of 36 inches in normal soil and 24 inches in consolidated rock.

Class locations also specify the maximum distance to a sectionalizing block valve (e.g., 10.0 miles in Class 1, 7.5 miles in Class 2, 4.0 miles in Class 3, and 2.5 miles in Class 4). Pipe wall thickness and pipeline design pressures, hydrostatic test pressures, MAOP, inspection and testing of welds, and frequency of pipeline patrols and leak surveys must also conform to higher standards in more populated areas. Class locations by MP are listed in table 4.13.2-1.

TABLE 4.13.2.1-1

USDOT Class Locations for the Proposed Pacific Connector Pipeline

Beginning MP	Ending MP	Class Location
0	1.24	1
1.24	1.33	3
1.33	2.34	1
2.34	3.11	2
3.11	3.38	1
3.38	6.47	2
6.47	21.12	1
21.12	21.25	3
21.25	22.39	1
22.39	22.74	2
22.74	22.89	1
22.89	23.26	2
23.26	50.66	1
50.66	51.14	2
51.14	51.39	1
51.39	51.59	2
51.6	55.54	1
55.54	57.76	2
57.76	94.67	1
94.68	94.89	2
94.89	121.88	1

TABLE 4.13.2.1-1 (continued)

USDOT Class Locations for the Proposed Pacific Connector Pipeline

Beginning MP	Ending MP	Class Location
121,88	122.15	2
122.15	122.18	1
122.18	122.43	2
122.43	122.45	1
122.45	123.23	2
123.23	132.46	1
132.47	169.50	1
169.51	197.65	1
197.65	198.08	3
198.08	198.17	1
198.17	198.57	2
198.57	198.61	1
198.61	198.74	3
198.74	198.96	1
198.96	199.09	3
199.09	203.79	1
199.09	203.79	1
203.79	204.13	2
204.13	204.58	2
204.58	204.90	2
204.9	228.81	1

If a subsequent increase in population density adjacent to the right-of-way indicates a change in class location for the pipeline, Pacific Connector would be required to reduce the MAOP or replace the segment with pipe of sufficient grade and wall thickness, if applicable, to comply with the USDOT code of regulations for the new class location.

We received comments requesting that unified safety standards be applied across the entire pipeline route; however, as discussed previously, the FERC does not have the jurisdiction to require safety standards beyond those outlined by Part 192 of 49 CFR (which are required and enforced by the USDOT).

The USDOT Pipeline Safety Regulations require operators to develop and follow a written integrity management program that contain all the elements described in 49 CFR 192.911 and address the risks on each transmission pipeline segment. The rule establishes an integrity management program which applies to all high consequence areas (HCA).

The USDOT has published rules that define HCAs where a gas pipeline accident could do considerable harm to people and their property and requires an integrity management program to minimize the potential for an accident. This definition satisfies, in part, the Congressional mandate for USDOT to prescribe standards that establish criteria for identifying each gas pipeline facility in a high-density population area.

The HCAs may be defined in one of three ways. In the first method, an HCA includes:

- current Class 3 and 4 locations, or

- any area in Class 1 or 2 where the potential impact radius[223] is greater than 660 feet and there are 20 or more buildings intended for human occupancy within the potential impact circle,[224] or
- any area in Class 1 or 2 where the potential impact circle includes an identified site.[225]

In the second method, an HCA includes any area within a potential impact circle which contains:

- 20 or more buildings intended for human occupancy, or
- an identified site.

Once a pipeline operator has determined the HCAs on its pipeline, it must apply the elements of its integrity management program to those segments of the pipeline within HCAs. The USDOT regulations specify the requirements for the integrity management plan at section 192.911. Table 4.13.2.1-2 identifies the HCAs that are crossed by or adjacent to the proposed pipeline route. The pipeline integrity management rule for HCAs requires inspection of the entire pipeline in HCAs every 7 years.

TABLE 4.13.2.1-2

USDOT Class 3 Locations and High Consequence Areas Crossed by and Adjacent to the Proposed Pacific Connector Pipeline

Beginning MP	Ending MP	Criteria
1.24	1.33	Vicinity to ball park and commercial buildings with potential occupancy of over 20 people
21.12	21.25	Vicinity to cell tower with associated commercial buildings with potential occupancy of over 20 people
197.65	198.08	Vicinity to sawmill with potential occupancy of over 20 people
198.61	198.74	Vicinity to commercial buildings with potential occupancy of over 20 people
198.96	199.09	Vicinity to commercial buildings with potential occupancy of over 20 people

Part 192 prescribes the minimum standards for operating and maintaining pipeline facilities, including the requirement to establish a written plan governing these activities. Under section 192.615, each pipeline operator must also establish an emergency response plan (ERP) that includes procedures to minimize the hazards in a natural gas pipeline emergency. Pacific Connector would establish written procedures, in accordance with 49 CFR 192.615, that provide the following:

- establishing and maintaining adequate means of communication with appropriate fire, police, and other public officials;
- notifying appropriate fire, police, medical and other public, local, and state official of gas pipeline emergencies and coordinating with them both planned responses and actual responses during an emergency;
- receiving, identifying, and classifying notices of events that require immediate response by the operator;

[223] The potential impact radius is calculated as the product of 0.69 and the square root of the MAOP of the pipeline in psi multiplied by the pipeline diameter in inches.
[224] The potential impact circle is a circle of radius equal to the potential impact radius.
[225] An identified site is an outside area or open structure that is occupied by 20 or more persons on at least 50 days in any 12-month period; a building that is occupied by 20 or more persons on at least 5 days per week for any 10 weeks in any 12-month period; or a facility that is occupied by persons who are confined, are of impaired mobility, or would be difficult to evacuate.

- prompt and effective response to a notice of each type of emergency (gas detection, fire, explosion, natural disaster); prescribe actions directed toward protecting people first and then property; emergency shutdown and pressure reduction in any section of the pipeline necessary to minimize hazards to life or property;
- actions required to be taken by control room personnel during an emergency in accordance with 49 CFR section 192.631;
- ensuring the availability of service subcontractors, personnel, equipment, tools, and materials, as needed at the scene of any emergency;
- making safe any actual or potential hazard to life or property;
- safely restoring any service outage; and
- beginning incident investigation process as soon after the end of the emergency as possible.

Part 192 requires that each operator must establish and maintain liaison with appropriate fire, police, and public officials to learn the resources and responsibilities of each organization that may respond to a natural gas pipeline emergency, and to coordinate mutual assistance. The operator must also establish a continuing education program to enable customers, the public, government officials, and those engaged in excavation activities to recognize a gas pipeline emergency and report it to appropriate public officials. Operations personnel will attend training for emergency response procedures and plans prior to commencing pipeline operation. No additional specialized local fire protection equipment would be required to handle pipeline emergencies.

Pipeline system emergencies can include gas leaks, fire or explosion, and/or damage to the pipeline and aboveground facilities. Pacific Connector would maintain 24-hour emergency response capabilities, including an emergency-only phone number, which accepts collect charges. The number would be included in informational mail-outs, posted on all pipeline markers (installed at public road crossings), and provided to local emergency agencies in the vicinity of the pipeline and compressor station.

As part of Pacific Connector's ERP, operations personnel would attend training for emergency response procedures and plans prior to commencing pipeline operations. Pacific Connector would meet with local emergency responder groups (fire departments, police departments, land-managing agencies including the BLM, Forest Service, and Reclamation, and other public officials) to review plans and would work with these groups to communicate the specifics about the pipeline facilities in the area and the need for emergency response. Pacific Connector would also meet periodically with the groups to review the plans and revise them when necessary. If requested by local public emergency response personnel, Pacific Connector would participate in any operator-simulated emergency exercises and post-exercise critiques. Pacific Connector would use adequate local or contract resources to support the pipeline and facilities if an emergency occurs.

All of the information that Pacific Connector gathers about its system would be used to tailor its safety and integrity management activities, so that parts of the system in the greatest need of attention receive greater scrutiny, such as residential areas or areas subject to growth and development. For example, Pacific Connector would decide where and when to internally inspect the pipeline based on this information. Risk assessment of the pipeline system determines what inspection criteria are required. This may include many different types of assessment tools that provide specific types of information about the condition of the pipeline.

The Klamath Compressor Station would also be equipped with automatic emergency detection and shut down systems. For example, the station would have hazardous gas and fire detection systems, and an emergency shutdown system. These safety and emergency systems would be tested routinely to ensure they are operating properly. The emergency shutdown system would be designed to shut down and isolate elements of the compressor station in the event of a fire, before the development of a flammable mixture of gas could occur. The system would include sensors for detecting natural gas concentrations as well as ultraviolet sensors for detecting flames. Additionally, the compressor station equipment would be designed to shut down automatically if a mechanical failure poses risk to the equipment or otherwise constitutes a hazard. The compressor station would be equipped with relief valves to protect the piping from over pressurization and would be equipped with a blowdown system that can safely and rapidly depressurize part or all of the compressor station to a safe location.

Personnel would be able to respond to a compressor station emergency in 60 minutes or less during non-scheduled work hours and within a few minutes if they are at the compressor station. Personnel would be on call at all times, 24 hours a day, 365 days a year to respond to emergencies. Emergencies while the compressor station is unattended would be monitored remotely via Pacific Connector's gas control facility. Personnel living within a 30-minute travel time of the compressor station would be dispatched by the gas control facility in the event of an emergency at the compressor station.

Personnel would be Operator Qualified per USDOT PHMSA requirements for operational and emergency situations at the station. Fire protection, first aid, and safety equipment would be maintained at the compressor station, and personnel would be trained in first aid and proper equipment use.

The Pacific Connector pipeline would cross areas subject to ongoing and future land management activities on federal lands managed by BLM, Forest Service, and Reclamation. Pacific Connector would be required to prepare a POD for activities on these federal lands that also addresses other safety and reliability measures requested by the BLM, Forest Service, and Reclamation. The BLM, Forest Service, and Reclamation would review and approve draft plans to ensure all safety concerns associated with construction and operation of the proposed Pacific Connector pipeline on federally managed lands are addressed.

Pipeline Standards to Minimize Fire Risk to Forest Lands

The Pacific Connector pipeline would be in areas where forest fires could occur. Pacific Connector proposes to meet or exceed USDOT pipeline burial depth requirements (found in 49 CFR Part 192) and would install the Pacific Connector pipeline with at least 36 inches of cover in Class I locations with normal soils and at least 24 inches of cover in consolidated rock areas.

Pursuant to 49 CFR 192.615, each pipeline operator must also develop an ERP that includes procedures to minimize the hazards in the event of a natural gas pipeline emergency. The key elements of the required plan include establishing and maintaining communications with local fire officials and coordinating emergency response, emergency shutdown of the system and safe restoration of service, making personnel, equipment, tools, and materials available at the scene of an emergency, and protecting people and property from hazards. Part 192 specifically requires that each pipeline operator establish and maintain liaison with appropriate fire officials to learn the resources and responsibilities of each organization that may respond to a natural gas pipeline emergency, and must coordinate mutual assistance. The previous discussion in section 4.13.9.1 describes the specific emergency response capabilities of the Project, including maintenance by Pacific Connector of 24-hour emergency response capabilities.

In addition, in compliance with the federal requirements discussed above, Pacific Connector must develop an ERP for the entire system. A draft ERP was included as Appendix H to the POD.[226] The ERP requires operations personnel to attend training for emergency response procedures and requires the pipeline operators to meet with local emergency responder groups, including fire departments, to review plans and educate the responder groups on the specifics of the pipeline facilities within the relevant service area. After the initial coordination with local responders, Pacific Connector would also meet periodically with the groups to review plans and revise them when necessary. Finally, if requested by local response personnel, Pacific Connector would participate in any simulated emergency exercises and post-exercise critiques. Through these coordination activities, the fire response personnel would become familiar with the location and specific safety and fire issues associated with the pipeline. This information would significantly reduce risks to the fire response personnel responding to a fire either caused by or in the vicinity of the pipeline alignment. The majority of the training costs would be borne by Pacific Connector; therefore, the coordination requirements would not significantly increase fire suppression costs.

In the event a fire was to occur on the surface in the vicinity of the pipeline, the presence of the pipeline would not increase fire hazards. Fires on the surface are not a direct threat to underground natural gas pipelines because of the insulating effects of soil cover over the pipeline. Soil is a poor conductor of heat with thermal conductivity values ranging from 0.44 to 1.44 Btu/ft-hr-°F. The heat capacity of most soils is 0.20 to 0.25 Btu/lb-°F. Based on the proposed burial depth of 24 to 36 inches, and the insulating effects of soil cover over the pipeline, we do not believe that forest fires would affect pipeline integrity. In addition, we do not believe that additional burial depth beyond what is proposed by Pacific Connector would be necessary to protect against damage by forest fires.

When forest fires arise in the area, Pacific Connector would closely monitor and protect the pipeline from wildfires. Pacific Connector would also have facilities built along the pipeline to aid in protecting the pipeline from wildfires. Along with Pacific Connector's pipeline control there are MLV sites on the pipeline to aid in isolating which portions of the pipeline have product in them. Pacific Connector would be in communications with emergency management office and monitoring the wildfires. Pacific Connector can determine what actions need to be taken to protect the pipeline and facilities in the area of the wildfires. If a wildfire was near Pacific Connector's facility locations or an MLV site, Pacific Connector would consider shutting down and isolating those facilities until the fire risk was mitigated. After all threats to safety for the area were assessed those facilities would be inspected to ensure there was no damage from the fire before restarting. In past situations, local operation personnel have protected above ground mainline valves by burying the valves with sand and earth material. Pacific Connector remains in close

[226] Pacific Connector's POD was filed with the FERC on January 23, 2018.

communication with its operations staff at each of their locations to ensure the circumstance of the fire is tended to accordingly.

Pacific Connector has also developed a *Fire Prevention and Suppression Plan.*[227] This plan is consistent with Forest Service and BLM policies and current practices. Although designed for federal lands, it would be applicable to the entire pipeline route; regardless of landownership. The intent of the plan is to identify measures to minimize the chances of a fire starting and spreading from project facilities and to reduce the risk of wildland and structural fire.

4.13.2.2 Pipeline Accident Data

The USDOT requires all operators of natural gas transmission pipelines to notify the USDOT of any significant incident and to submit a report within 20 days. Significant incidents are defined as any leaks that:

- caused a death or personal injury requiring hospitalization; or
- involve property damage of more than $50,000 (1984 dollars[228]).

During the 20-year period from 1996 through 2015, a total of 1,310 significant incidents were reported on the more than 300,000 total miles of natural gas transmission pipelines nationwide.

Additional insight into the nature of service incidents may be found by examining the primary factors that caused the failures. Table 4.13.2.2-1 provides a distribution of the causal factors as well as the number of each incident by cause.

TABLE 4.13.2-3

Natural Gas Transmission Pipeline Significant Incidents by Cause (1996–2015) a/

Cause	No. of Incidents	Percentage
Corrosion	311	23.7
Excavation b/	210	16.0
Pipeline material, weld or equipment failure	354	27.0
Natural force damage c/	146	11.1
Outside force c/	84	6.4
Incorrect operation	40	3.1
All other causes d/	165	12.6
Total	**1,310**	**100**

a/ All data gathered from PHMSA Significant Transmission Pipeline Incident files. https://hip.phmsa.dot.gov/analyticsSOAP/saw.dll?Go
b/ Includes third-party damage.
c/ Fire, explosion, vehicle damage, previous damage, intentional damage
d/ Miscellaneous causes or unknown causes

The dominant causes of pipeline incidents are corrosion and pipeline material, weld or equipment failure constituting 50.7 percent of all significant incidents. The pipelines included in the data set in table 4.13.2.2-1 vary widely in age, diameter, and level of corrosion control. Each variable influences the incident frequency that may be expected for a specific segment of pipeline.

[227] Included as Appendix K to Pacific Connector's 2018 POD.
[228] $50,000 in 1984 dollars is approximately $122,000 based on the March 2018 Consumer Price Index.

The frequency of significant incidents is strongly dependent on pipeline age. Older pipelines have a higher frequency of corrosion incidents, since corrosion is a time-dependent process. The use of both an external protective coating and a cathodic protection system[229], required on all pipelines installed after July 1971, significantly reduces the corrosion rate compared to unprotected or partially protected pipe.

Outside forces are the cause in 33.5 percent of significant pipeline incidents. These result from the encroachment of mechanical equipment such as bulldozers and backhoes; earth movements due to soil settlement, washouts, or geologic hazards; weather effects such as winds, storms, and thermal strains; and willful damage.

Older pipelines have a higher frequency of outside forces incidents partly because their location may be less well known and less well marked than newer lines. In addition, the older pipelines contain a disproportionate number of smaller-diameter pipelines; which have a greater rate of outside forces incidents. Small-diameter pipelines are more easily crushed or broken by mechanical equipment or earth movement. Table 4.13.2.2-2 shows the various causes of outside force incidents.

TABLE 4.13.2.2-2

Outside Forces Significant Incidents by Cause (1996-2015) a/

Cause	No. of Incidents	Percent of all Incidents b/, c/
Third-party excavation damage	172	13.6
Operator excavation damage	25	1.9
Unspecified excavation damage/previous damage	13	1.0
Heavy rain/floods	74	5.7
Earth movement	32	2.4
Lightning/temperature/high winds	27	2.1
Natural force (unspecified and other)	13	1.0
Vehicle (not engaged with excavation)	49	3.7
Fire/explosion	9	0.7
Previous mechanical damage	6	0.5
Fishing or maritime activity	9	0.7
Intentional damage	1	0.1
Electrical arcing from other equipment/facility	1	0.1
Other outside force	9	0.7
Total	**440**	**33.5**

a/ All data gathered from PHMSA Significant Transmission Pipeline Incident files. https://hip.phmsa.dot.gov/analyticsSOAP/saw.dll?Go
b/ Percentage of all incidents was calculated as a percentage of the total number of natural gas transmission pipeline significant incidents (i.e., all causes) presented in table 4.13.9.2-1.
c/ Due to rounding, column does not sum to 33.5 percent.

Since 1982, operators have been required to participate in "One Call" public utility programs in populated areas to minimize unauthorized excavation activities in the vicinity of pipelines. The "One Call" program is a service used by public utilities and some private sector companies (e.g., oil pipelines and cable television) to provide preconstruction information to contractors or other maintenance workers on the underground location of pipes, cables, and culverts.

[229] Cathodic protection is a technique to reduce corrosion (rust) of the natural gas pipeline through the use of an induced current or a sacrificial anode (like zinc) that corrodes at faster rate to reduce corrosion.

4.13.2.3 Impact on Public Safety

Pipeline Construction

Active pipeline construction can increase safety risks to the public generally in two ways, from an increase of traffic on roadways in the vicinity of the pipeline, and from potential exposure to construction activity itself within the construction right-of-way.

During periods of active construction, roadways in the vicinity of the pipeline project would experience an increase in small vehicle traffic from the construction work force, as well as large vehicle traffic transporting construction equipment and materials. Where the pipeline would cross roadways, access to and from the right-of-way by construction vehicles and construction activity itself at the roadway crossing could disrupt traffic and create potential safety hazards to the public. Pacific Connector has developed Transportation Plans for both private and federal lands that describe measures that it would implement to minimize public access and safety concerns as a result of construction vehicle traffic and construction activity at roadway crossings (see additional discussion in section 4.10). In addition, Pacific Connector would obtain all necessary permits for public roadway crossings and roadway use, and would comply with traffic control and public safety mitigation measures that are conditions of these permits.

During pipeline construction, the general public could be exposed to safety hazards within the pipeline construction right-of-way itself. Hazards would be typical of a construction site involving clearing, grading, and excavation, and could include timber felling, heavy equipment operation including on steep slopes, open trench, falling or rolling rock on steep slopes, and fly rock from blasting. During active construction the contractor and company personnel present on the job would limit access to the public to potentially hazardous situations such as operation of heavy equipment, or blasting for trench excavation. During construction off hours, the public could be exposed to hazards such open trench or loose rock. Locating the pipeline in non-populated areas helps to minimize the chance for unauthorized public access to the right-of-way.

Where the pipeline would be placed within residential areas, Pacific Connector would minimize impacts and potential safety hazards by ensuring that the construction proceeds quickly through such areas. Where the construction work area would be within 50 feet of a residence, Pacific Connector would install safety fence along the edge of the work area for a distance of 100 feet on either side of the residence. Fencing would be maintained, at a minimum, throughout the open trench phases of pipeline installation. Where feasible, Pacific Connector has reduced the width of the construction right-of-way near residences and placed TEWAs as far as practicable from the residences. In residential areas Pacific Connector would also limit the period of time the trench remains open prior to backfilling to 10 days. For the residences within 50 feet of the proposed right-of-way, Pacific Connector has developed site-specific plans showing the temporary and permanent rights-of-way and noting special construction techniques and mitigation measures.

The BLM, Forest Service, and Reclamation can require Pacific Connector to incorporate additional specific public safety measures into the POD as a condition of a Right-of-Way Grant for use of federal lands.

Pipeline Operation

During pipeline operation Pacific Connector would comply with the USDOT pipeline safety standards as well as regular monitoring and testing of the pipeline. While pipeline failures are rare, the potential for pipeline systems to rupture and the risk to nearby residents is discussed below.

The serious incidents data summarized in table 4.13.2.3-1 include pipeline failures of all magnitudes with widely varying consequences. Table 4.13.2.3-1 presents the average annual injuries and fatalities that occurred on natural gas transmission lines in the 5-year period between 2013 and 2017.

TABLE 4.13.2.3-1

Injuries and Fatalities – Natural Gas Transmission Pipelines

Year	Injuries	Fatalities
2013	2	0
2014	1	1
2015	16	6
2016	3	3
2017	3	3

The majority of fatalities from pipelines are due to local distribution pipelines not regulated by the FERC. These are natural gas pipelines that distribute natural gas to homes and businesses after transportation through interstate natural gas transmission pipelines. In general, these distribution lines are smaller diameter pipes and/or plastic pipes which are more susceptible to damage. Local distribution systems do not have large rights-of-way and pipeline markers common to the FERC-regulated natural gas transmission pipelines.

The nationwide totals of accidental fatalities from various anthropogenic and natural hazards are listed in table 4.13.2.3-2 to provide a relative measure of the industry-wide safety of natural gas transmission pipelines. Direct comparisons between accident categories should be made cautiously, however, because individual exposures to hazards are not uniform among all categories. The data nonetheless indicate a low risk of death due to incidents involving natural gas transmission pipelines compared to the other categories. Furthermore, the fatality rate is much lower than the fatalities from natural hazards such as lightning, tornados, or floods.

TABLE 4.13.2.3-2

Accidental Deaths by Cause

Type of Accident	Number of Fatalities a/
All injuries (unintentional)	146,571
Motor vehicle accident	37,757
Poisoning (unintentional)	47,478
Falls (unintentional)	33,381
Suffocation (unintentional)	6,917
Drowning (unintentional)	3,602
Fire/flame (unintentional)	2,646
Floods b/	84
Lightning b/	47
Natural gas distribution lines c/	11
Natural gas transmission pipelines c/	3

a/ All data, unless otherwise noted, reflect 2015 statistics from the National Vital Statistics Reports https://www.cdc.gov/nchs/data/nvsr/nvsr66/nvsr66_06.pdf
b/ NOAA National Weather Service, Office of Climate, Water and Weather Services, 30-year average (1987-2016) http://www.weather.gov/om/hazstats.shtml.
c/ PHMSA significant incident files, March 16, 2018. https://hip.phmsa.dot.gov/analyticsSOAP/saw.dll, 20-year average.

The available data show that natural gas transmission pipelines continue to be a safe, reliable means of energy transportation. From 1998 to 2017, there were an average of 68 significant incidents, 9 injuries, and 3 fatalities per year. The number of significant incidents over the more than 2.21 million miles of natural gas transmission lines in service indicates that the risk is low for an incident at any given location. The operation of the Pacific Connector pipeline would represent a slight increase in risk to the nearby public.

4.13.3 Conclusions

As part of the NEPA review and NGA determinations, Commission staff assesses the potential impact to the human environment in terms of safety and whether the proposed facilities would operate safely, reliably, and securely.

As a cooperating agency, the USDOT assists the FERC by determining whether Jordan Cove LNG Project's proposed design would meet the USDOT's 49 CFR 193 Subpart B siting requirements. USDOT will provide a Letter of Determination on the Project's compliance with 49 CFR 193 Subpart B. This determination will be provided to the Commission as further consideration to the Commission on its decision to authorize or deny the Project. If the Project is authorized and constructed, the facility would be subject to the USDOT's inspection and enforcement program and final determination of whether a facility is in compliance with the requirements of 49 CFR 193 would be made by the USDOT staff.

As a cooperating agency, the Coast Guard also assisted the FERC staff by reviewing the proposed LNG terminal and the associated LNG marine vessel traffic. The Coast Guard reviewed a WSA submitted by Jordan Cove that focused on the navigation safety and maritime security aspects of LNG marine vessel transits along the affected waterway. On May 10, 2018, the Coast Guard issued an LOR that recommended the Coos Bay Channel be considered suitable for accommodating the type and frequency of LNG marine traffic associated with this Project based on the WSA and in accordance with the guidance in the Coast Guard's NVIC 01-11. If the Project is authorized and constructed, the facilities would be subject to the Coast Guard's inspection and enforcement program to ensure compliance with the requirements of 33 CFR 105 and 33 CFR 127.

FERC staff conducted a preliminary engineering and technical review of the Jordan Cove LNG Project design, including potential external impacts based on the site location. Based on this review, we recommend a number of mitigation measures, which would ensure continuous oversight prior to initial site preparation, prior to construction of final design, prior to commissioning, prior to introduction of hazardous fluids, prior to commencement of service, and throughout life of the facility to enhance the reliability and safety of the facility to mitigate the risk of impact on the public. With the incorporation of these mitigation measures and oversight, FERC staff concluded that the Jordan Cove LNG Project design would include acceptable layers of protection or safeguards that would reduce the risk of a potentially hazardous scenario from developing into an event that could impact the offsite public.

The pipeline would be constructed in compliance with the USDOT pipeline standards (as published in 49 CFR Parts 190-199; Part 192 of 49 CFR). Based on the implementation of the required BMPs and adherence to USDOT standards, the Project would not significantly affect public safety.

4.14 CUMULATIVE IMPACTS

Coastal and southern Oregon have been affected by human activity for thousands of years and the existing environmental conditions in the Project area reflect extensive changes to natural resources brought about by past human activities. In 1850, there were about 432,808 acres of farmland in Oregon. By 1954, farmland increased to 21 million acres. In 2007, 16.4 million acres in Oregon were used for agriculture (Ballard 1959; Sorte et al. 2011). Farming activities have modified the environment through land clearing and planting of non-native species.

Oregon has lost an estimated 38 percent of its original wetlands (Morlan 2000). Most Oregon estuaries have been significantly altered through the diking and draining of marshes in the early to mid-1900s for agricultural use, and urban development. Between 1870 and 1970, tidal wetlands within the Coos Bay estuary decreased an estimated 66 percent (Oregon Progress Board 2009).

Cutting of forests in the region began with Euro-American settlement. Initially, forests in the valley floors were cleared to make way for agriculture. Lowland areas close to population centers were logged first, followed by less accessible areas in more mountainous terrain.

Shortly after World War II, improvements in the gas-powered chain saw and transportation led to increased logging in the Pacific Northwest, with a shift to timber sales on federal lands. There was a boom in demand for wood products during the 1950s and 1960s, with a post-war need for framing lumber and plywood for new housing. More than 70 plywood plants opened in Oregon between 1940 and 1960, including plants in North Bend, Coos Bay, and Coquille. As timber inventories on private lands were depleted, pressure to harvest timber on federal lands increased. In 1952, western Oregon's peak year for timber production, about one-third of the 10.4 billion board feet harvested came from federal lands. By 1963, more timber was harvested on federal lands than private lands.

As a result of over a century of logging and fire control, the portions of forests of the Pacific Northwest consist of a mosaic of recent clearcuts, thinned stands, and young plantations interspersed with unmanaged stands. The remaining unmanaged stands range from 1,000-year-old or older forests with large trees to relatively young, even-aged stands that have regenerated following wildfires. Because wildfires and windstorms often killed only some of the trees in a stand, natural stands are frequently characterized by a mixture of trees that survived a catastrophic event and younger trees that filled in the understory after the event. Where many large old trees remain in the overstory, these stands have been referred to as "old growth," "late successional," or "ancient" forests (FEMAT 1993). Where only scattered individuals or patches of large old trees remain and the majority of the stand consists of young or mature trees, stands are referred to as "mixed age" or even "young." Mixed-age stands are particularly common in some areas, such as the Oregon Coast Range, where extensive fires occurred in the 1800s. Species associated with or dependent on these late-successional and old-growth forests, such as the NSO and MAMU, have been negatively affected by habitat loss (see section 4.6 of this EIS).

Today, Oregon's environment reflects a mixture of natural processes and human influences across a range of conditions, from areas defined by relatively natural structures and functions to areas completely dominated by human activities (Oregon Progress Board 2000). In the past decade, large, stand-replacing wildfires have affected public lands in southwest Oregon. Since the inception of the NWFP in 1994, the majority of the NSO habitat loss in the region has been the result of stand-replacing wildfire.

Concerning these past activities, the CEQ issued an interpretive memorandum on June 24, 2005, regarding analysis of past actions, which stated: "agencies can conduct an adequate cumulative effects analysis by focusing on the current aggregate effects of past actions without delving into the historical details of individual past actions." These activities are included herein to provide historical context. To understand the contribution of past actions to the cumulative effects of the proposed action, this analysis relies on current environmental conditions as a proxy for the effects of past actions. Existing conditions reflect the aggregate effects of all prior human actions and natural events that have affected the environment and might contribute to cumulative effects. In this analysis, we generally consider the effects of past projects as part of the affected environment (environmental baseline) which was described previously. However, this analysis does consider, as applicable, the present effects of past actions.

This analysis is also consistent with Forest Service implementing NEPA Regulations (36 CFR 220.4(f)) (July 1, 2012), which state, in part:

> *CEQ regulations do not require the consideration of the individual effects of all past actions to determine the present effects of past actions. Once the agency has identified those present effects of past actions that warrant consideration, the agency assesses the extent that the effects of the proposal for agency action or its alternatives will add to, modify, or mitigate those effects. The final analysis documents an agency assessment of the cumulative effects of the actions considered (including past, present, and reasonable foreseeable future actions) on the affected environment. With respect to past actions, during the scoping process and subsequent preparation of the analysis, the agency must determine what information regarding past actions is useful and relevant to the required analysis of cumulative effects. Cataloging past actions and specific information about the direct and indirect effects of their design and implementation could in some contexts be useful to predict the cumulative effects of the proposal. The CEQ regulations, however, do not require agencies to catalogue or exhaustively list and analyze all individual past actions. Simply because information about past actions may be available or obtained with reasonable effort does not mean that it is relevant and necessary to inform decision making. (40 CFR 1508.7)*

In accordance with NEPA, we identified other actions near the Project facilities and evaluated the potential for a cumulative effect on the environment. As defined by the CEQ, a cumulative effect is the impact on the environment resulting from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, regardless of which agency or person undertakes such other actions. "Past" actions were addressed in the preceding discussion. "Present" actions are those currently ongoing, either being constructed or are in operation and affecting the environment in such a manner that could contribute to a cumulative impact. "Reasonably foreseeable actions" are proposed projects or developments that have applied for a permit from local, state, or federal authorities or planned projects which have been publicly announced.

Consistent with CEQ guidance, and cooperating agencies' regulations and recommendations, we identified and considered present and reasonably foreseeable actions within an appropriate "geographic scope". The geographic scopes considered in this analysis vary depending on the environmental resource and are identified in table 4.14-1. Actions located outside the geographic scopes are not evaluated because their potential to contribute to a cumulative impact diminishes with increasing distance from the Project.

A nearby project must affect the same resource as the Project to have a cumulative impact on that resource. As previously stated, the effects of more distant actions/projects (outside the HUC 10 or HUC 8 watersheds) are not assessed because their impacts are not expected to overlap with the Project; and therefore, would not contribute to a cumulative impact. Two examples representing opposite ends of the spectrum with regard to geographic scope are cultural resources and air quality. With some exceptions, Project effects on cultural resource sites are localized in nature. For example, a direct impact on an archaeological site would typically not affect other sites; therefore, the geographic scope for archaeological sites is limited to the area within which sites could be directly or indirectly affected by an action. In contrast, the impact of air emissions could be felt over a relatively large distance; therefore, the geographic scope for air quality is larger than for other resources. When determining the significance of a cumulative impact, we consider the duration of the impact; the geographic, biological, and/or social context in which the impact would occur; and the magnitude and intensity of the impact. The duration, context, and magnitude of impacts vary by resource and therefore significance varies accordingly.

As identified in table 4.14-1, we are generally considering HUC 10 (fifth-field) watersheds crossed as the geographic scope for potential cumulative impacts. The Project facilities would be located within 19 HUC 10 watersheds (figures 4.14-1a and 4.14-1b). Additionally, the COE currently considers HUC 8 (fourth-field) watershed to assess cumulative effects, therefore, we are including impacts and compensatory mitigation information provided by the COE within the larger HUC 8 watershed area for analysis of cumulative impacts on wetlands and surface waters. Project facilities would be located within six HUC 8 watersheds. Within these watersheds we have identified six general actions/project types that could contribute to a cumulative impact. These actions are: COE permits and mitigation projects, minor federal agency projects (including road/utility improvements, water flow control, weed treatments, and miscellaneous mitigation), residential and commercial development, timber harvest and forest management activities, livestock grazing, and solar power panel fields.

Of these six project types, some additional context is necessary for livestock grazing and timber harvest and forest management. Livestock grazing occupies far and away the largest footprint of any of the project types considered (approximately 292,000 acres or about 83 percent of the projects considered in our analysis). It also displays a complex temporal niche in that grazing, having occurred for hundreds of years in Oregon, is both a present and reasonably foreseeable activity and a large component of the affected environment. That is, the continuation of grazing is now essentially just the maintenance of the existing environment. The exception, of course, is for the addition of lands not previously open to grazing. These additions include an episodic and conversional set of impacts that would be cumulative with the resources also affected by the Project if they occurred during construction and restoration of the pipeline.

The continued use of grazed lands does not contribute episodic impacts, but rather ongoing perturbation that may have a set of related resource impacts, such as suppression of arboreal and natural vegetative communities that would otherwise develop. In addition, livestock grazing disrupts soil profiles, breaks down stream banks, and contributes to water quality degradation of streams. Accordingly, we characterize livestock grazing impacts as ongoing, landscape-level impacts with relatively small incremental impacts distributed over the present and future timeframe that is also affected by the Project. Consequently, livestock grazing impacts during any discrete period of time, such as the limited period that pipeline construction would occur within a given HUC-10 watershed, contributes only minor impacts on the resources also affected by the Project. For this reason, we identify ongoing livestock grazing projects in our list of projects within the geographic scope of our cumulative impacts analysis, but unless otherwise noted, we do not include them in our analysis of potential cumulative impacts on each resource.

Timber harvesting and forest management activities make up the second largest footprint of the project types considered (50,950 acres or about 14 percent of the projects considered in our analysis). Timber harvesting and forest management impacts are episodic and conversional. Timber harvesting dramatically alters multiple interlaced resources including vegetative and wildlife communities, soils, water resources, and visual aesthetics. In addition to the larger scale of the impacts, there is a longer-term temporal impact. While revegetation of affected communities may be allowed to occur after harvesting, complete restoration (i.e., the point in which the affected area no longer contributes to cumulative impacts) is most often measured in decades.

Additionally, non-jurisdictional utilities at the terminal site, the use of LNG carriers, ongoing maintenance dredging, the Port's Channel Modification Project, Project impact mitigation projects, and the removal of PacifiCorp dams on the Klamath River could also contribute to a cumulative impact(s). Table 4.14-2 identifies these actions by watershed, and table N-1 in appendix N lists the resources each project could affect and summarizes the area of known impacts. We generally do not include in our analysis projects such as small commercial developments and small road projects located within towns and other developed areas, because these actions have a small footprint, are consistent with surrounding land uses, and contribute only minutely to cumulative impacts on the resources evaluated in this EIS.

In addition to the geographic relationship between the Project and other projects, we also consider the temporal relationship. For the purposes of this analysis, the temporal extent of other projects would start generally in the past[230] and extend out for the expected duration of the impacts caused by the Project.

Not all future projects that may occur are well defined with regard to scope, location, timing, and resource footprint. Without specific information, inclusion of these projects may not be meaningful. For example, between 2010 and 2017, the counties crossed by the Project have grown by an average of about 4 percent; and along with that growth, numerous residential subdivisions, commercial developments, roads and utilities, and maintenance and upgrading of existing infrastructure have been constructed (or were proposed). If growth continues, similar future actions may occur, affecting a range of natural resources, including soils, waterbodies and wetlands, vegetation, and wildlife. There is also the potential that over time federal and state agencies and private conservation organizations may implement projects and actions that improve habitat, water quality, and air quality throughout the Project area. It is not possible to quantify or assess the potential cumulative impacts or benefits that may accrue from these undefined future projects. In addition, we anticipate that at a future date the Forest Service may address the

[230] We consider only those past projects that contribute ongoing effects on resources. Generally, more recent projects contribute a greater impact.

cumulative effects of currently undefined Project-related mitigation actions that these agencies may require on Forest Service and BLM-managed lands.

Additional discussion of cumulative effects on federally listed and proposed wildlife, fish, and plant species will be provided in our pending BA. The ESA defines cumulative effects as the "effects of future state or private activities, not involving Federal activities (Federal activities are subject to project-specific, individual ESA reviews), that are reasonably certain to occur within the action area of the Federal action subject to consultation." The determinations of effect in the BA will consider cumulative effects. Additionally, the Services are required to consider cumulative effects in formulating their biological opinions (50 CFR §402.14(g)(3) and (4)).

TABLE 4.14-1

Geographic Scope, by Resource, for Cumulative Effects Analysis

Resource	Geographic Scope	Rationale for Potential Cumulative Impact Analysis Area
Soils	HUC-10 watersheds	Projects within the HUC-10 watershed could contribute to cumulative impacts on soils within the watershed; therefore, the Project would result in additional incremental impacts on soils within the HUC-10 watersheds.
Water Resources and Wetlands	HUC-10 watersheds HUC-8 watersheds for COE wetland mitigation projects	Projects within the HUC-10 watershed could contribute to cumulative impacts on water resources and wetlands within the watershed.
Vegetation	HUC-10 watersheds	Projects within the HUC-10 watershed could contribute to cumulative impacts on vegetation within the watershed
Wildlife and Aquatic Resources	HUC-10 watersheds marine waters outside of Coos Bay	Projects within the HUC-10 watershed could contribute to cumulative impacts on wildlife and aquatic resources within the watershed; and projects from the mouth of Coos Bay to the outer continental shelf could contribute to impacts on listed marine species
Land Use	HUC-10 watersheds	Projects within the HUC-10 watershed could contribute to cumulative impacts on land use within the watershed
Recreation and Visual Resources	HUC-10 watersheds Viewshed from which Project construction or permanent facilities can be seen	Projects within the HUC-10 watershed could contribute to cumulative impacts on recreation; and projects within the viewshed of the Project could contribute to cumulative impacts on visual resources
Socioeconomics	Coos, Douglas, Jackson, and Klamath counties	Projects within the four counties with proposed Project facilities could contribute to cumulative impacts on socioeconomics
Environmental Justice	The census tracts directly affected by the Project	Projects within the census tracts directly affected by the proposed Project facilities could contribute to cumulative impacts on Environmental Justice communities
Transportation	Coos, Douglas, Jackson, and Klamath counties and the Coos Bay Federal Navigation Channel	Projects within the four counties with proposed Project facilities, as well as those along the Coos Bay Federal Navigation Channel could contribute to cumulative impacts on transportation
Cultural Resources	Direct and indirect Area of Potential Effect (APE)	Projects within the disturbance footprint (direct APE) or adjacent areas that could potentially experience visual, atmospheric, or audible cumulative impacts from Project construction or operation (indirect APE) could contribute to cumulative impacts on cultural resources
Air Quality	Within 0.25 mile of construction, and 50 km of LNG terminal and Klamath Compressor Station during operation	Projects within these geographic scopes could contribute to cumulative impacts on air quality during construction and operation
Noise	Within 0.25 mile (daytime) and 0.5 mile (nighttime) of construction, and 1 mile of LNG terminal and Klamath Compressor Station during operation	Projects within these geographic scopes could contribute to cumulative impacts on daytime and nighttime noise during construction and operation

a/ Details on most future activities on private lands, such as commercial harvests, are not publicly available. These activities are expected to continue at current rates. See appendix N for acreage, status, approximate location relative to nearest Project facilities, and resources potentially affected by each project listed in this table.

b/ The Port's project is made up of several proposed actions to improve navigation efficiency, reduce shipping transportation costs, and facilitate the shipping industry's transition to larger, more efficient vessels. The Port is currently in the engineering and design phase and is coordinating with the COE since they play several roles in the area, including new long-term maintenance of the channel. The project will also require authorization from the COE and other agencies before conducting the dredging activities. The COE is preparing an EIS to analyze the potential impacts associated with the project.

The Ruby and GTN pipeline system are present in this watershed; however, as stated previously, we consider the effects of past projects as part of the affected environment

4.14.1 Cumulative Effects

Based on available information, the actions listed in table 4.14-2 would affect soils, water resources, vegetation, wildlife, fisheries and aquatic resources, socioeconomics, land use, recreation and visual resources, transportation, cultural resources, air quality, and noise; and as such, we are assessing the potential for cumulative impacts on these resources. Project impacts on geology were assessed in this EIS; however, because impacts on geology (with exceptions) are generally limited, we are not assessing cumulative impacts on geology unless specifically noted.

The acres affected by the projects listed in table 4.14-2 are summarized in table 4.14.1-1 by HUC-10 watershed, including the percentage of each watershed. The values presented for project-related mitigation on federal lands are approximate and may be subject to change within or between watersheds as a result of changing conditions and agency management priorities. In some of these watersheds, the cumulative effects from the other projects included in this analysis represent a relatively large percentage of the total watershed area. In these cases, the significance of the cumulative impact may be only minimally altered by the contribution of the Project. For example, the Elk Creek HUC-10 watershed covers about 54,356 acres. The Project's impacts (as described in the preceding analyses) within this watershed are inconsequential (40 acres) when compared to the total watershed area, and contribute impacts on only 0.07 percent of the watershed. However, the other projects considered have/would impact about 12,248 acres, or 22.6 percent of the watershed. In this example, whether the Project is constructed or not has no discernible effect on the cumulative impact exerted on the resources and approval and implementation of the other projects determines the significance of the cumulative impact.

TABLE 4.14.1-1

Area Affected by Projects Included in Cumulative Effects Analysis, by Watershed

HUC-10 Watershed	Total Area Within HUC-10 Watershed (Acres)	Proposed Project Impact Area (Acres) a/	Other Project Impact Area (Acres) b/	Combined Area of HUC-10 Watershed (%)
Coos Bay-Frontal Pacific	151,611	370	713	0.7

a/ Only includes watersheds with at least 1 acre of Project disturbance.
b/ Includes projects listed in table 4.14-2 and table N-1 with exception of ongoing grazing on existing allotments.

4.14.1.1 Soils and Sediments

The other projects occurring in Coos Bay including the Port's Channel Modification Project and the COE's North Jetty Maintenance Project would temporarily and periodically impact Coos Bay sediments. Disturbing Coos Bay sediments would affect channel dynamics, water quality, adjacent sediments, fisheries and other aquatic organisms, and aquatic vegetation (see sections 4.1, 4.2, 4.3, 4.4, and 4.5). The impacts of these projects when combined with the impacts of the Project could result in a cumulative impact. However, the magnitude of any cumulative impact would depend on the location and timing of the other projects relative to the Project. The Port's Channel Modification Project would occur in part, adjacent to the LNG terminal site and associated marine facilities, but would likely occur after construction of the marine facilities is complete. It is possible that dredging activities associated with both the Project and the Port's Channel Modification Project could overlap. The North Jetty Maintenance Project would occur at the mouth of Coos Bay; however, a final construction schedule is still being developed. The North Jetty Maintenance Project would occur approximately seven river miles downstream from the LNG terminal site, but would be located less than two river miles from the nearest portion of the Project's proposed modifications to the marine waterway.

Sediments present in Coos Bay are naturally disturbed, flushed, and replenished by water inflows into the system. Dredging sediments disrupts the naturally occurring sediment flow process resulting in sediment reductions and accumulations. The other projects could impact the Coos Bay shoreline. Specifically, the use of marine vessels to construct and maintain the other projects would increase wave action within Coos Bay, and when combined with the wave actions resulting from Project-related vessels (tugs, barges, and LNG carriers) could result in a cumulative impact. Based on the location of the Project (including the Project's proposed modifications to the marine waterway), the locations of the other projects relative to the Project, and the expected timing of the other projects impacts (initial construction and maintenance), which we assume will not be concurrent (however, at some point in the future channel maintenance and Project maintenance may occur simultaneously), we conclude that the cumulative impact on sediments and the Coos Bay shoreline would not be significant.

At least six timber sale projects affecting a total of over 5,000 acres of land have or would cross/overlap about six miles of pipeline construction right-of-way and workspace. It is also likely that an undeterminable amount of other timber-related activities; maintenance, commercial thinning, and management have or would cross/overlap pipeline construction right-of-way and workspace. The Project would affect about 4,500 acres of land. Cumulative impacts on soils may result from the additive loss of soil (erosion), rutting and compaction, or disturbance of the profile that may affect the revegetation potential. In general, the use of heavy equipment, and the harvesting and maintenance of timber related to timber sales and other timber-related activities would impact underlying soils in a manner similar to that described for construction of the pipeline. However, these combined impacts would not be significant because the cumulative impact on soils would be limited to the relatively narrow width of the pipeline construction right-of-way (and associated construction workspace) and because of the minimization and protection measures included in the erosion control plans for the projects. The approximately 9,500 acres of land cumulatively affected by the six timber sale projects and the proposed Project that could potentially overlap represents about 0.02 percent of the total amount of land within the watersheds crossed by the Project.

By implementing the measures discussed in section 4.1, the Project would minimize incremental impacts on soils. With the exception of the timber sale projects discussed above, other projects identified in table 4.14-2 would not overlap with the pipeline construction workspace, and therefore, we conclude that the cumulative impact on soils would not be significant.

4.14.1.2 Water Resources and Wetlands

All of the projects identified in table 4.14-2 could affect underlying groundwater. Ground disturbing activities including aboveground facility and pipeline construction; and the use of equipment in support of those activities can affect groundwater recharge (surface water infiltration), subsurface lateral water flow, and groundwater quantity and quality. Together, the Project and the other projects would affect about 65,000 acres of land which represents about 2.5 percent of the total amount of land within the watersheds crossed by the Project. With the exception of three watersheds, cumulative impacts on lands within an individual watershed vary between less than 0.1 percent and 5.3 percent of total land amounts. The three remaining watersheds experience a greater cumulative impact due to the presence of large timber sales, and other timber-related activities (4,470 – 12,248 acres of impact in each watershed). Withdrawal requirements from underlying groundwater associated with these projects, if any, are unknown.

As described previously, we conclude that the impacts of the Project on groundwater would not be significant. These impacts would also be temporary, relatively minor, and localized. Additionally, the ground-disturbance and subsequent effects on groundwater resulting from timber-related activities are common in the region have not been found to be individually or cumulatively significant in other federal actions. Therefore, based on the cumulative amount of land affected and that area's proportion of the overall amount of land within the affected watersheds, we conclude that the cumulative impact on groundwater would not be significant.

The COE permits and mitigation projects, including stream restoration and enhancement projects affecting a total of about 71.0 river/stream miles, would occur in the watersheds affected by the Project. Additionally, the use of the Coos Bay Navigation Channel by LNG carriers travelling to and from the terminal facilities, the proposed modification of this channel, the regular maintenance of the channel, and the removal of dams along the Klamath River would also contribute to a cumulative impact on waterbodies affected by the Project. Other projects that could contribute to a cumulative impact on waterbodies crossed by the Project include minor federal agency projects (instream and aquatic restoration projects), and timber-related activities.

Numerous concerns about cumulative impacts on water quality in Coos Bay have been expressed by the public, the CTLUSI, the CIT, and the COE. The Port's Channel Modification Project would likely have the largest incremental contribution to cumulative impacts on Coos Bay. The Port's Channel Modification Project's impacts will be disclosed through the COE's review process; however, detailed information on this project is limited at this time. Additional information about the Port's Channel Modification Project, would be incorporated into the assessment presented in our final EIS. The CTCLUSI's Hollering Place which includes the installation of sheet piling along the shoreline of Coos Bay is currently under construction and would not significantly contribute to a cumulative impact on water quality. As described previously, other projects in Coos Bay would affect water quality and channel dynamics including channel geometry and flow. Changes to water quality would also affect fisheries and other aquatic organisms, and aquatic vegetation. These impacts when combined with the impacts of the Project could result in a cumulative impact on water resources, but this impact would also depend on the location and timing of the other projects. Based on available information, it is expected that dredging in Coos Bay would be temporary and periodic, generally occurring over several months. Impacts on water quality due to increased turbidity and sedimentation would be localized and temporary, returning to pre-construction conditions in a relatively short amount of time due to the dynamic and natural hydraulic regime of Coos Bay. The navigational channel improvements and the other projects, primarily the Port's Channel Modification Project would contribute to a cumulative impact on channel dynamics (e.g., channel geometry and flow). This change to channel geometry and flow would be permanent; however, the Project's contribution to this change would be significantly less than the Port's Channel Modification Project's contributions, which would have the largest incremental contribution to this permanent effect. Regular channel maintenance activities would not likely occur at the same time as the initial construction dredging activities associated with the Project and the Port's Channel Modification Project; therefore, a cumulative impact during construction is not anticipated, although a cumulative impact during operation is possible. Should channel and Project marine facility maintenance occur at or near the same time, a cumulative impact would occur; however, again, this impact would be temporary. Therefore, we conclude that the cumulative impact on Coos Bay would not be significant.

The impacts of LNG carriers and tug vessels traversing Coos Bay are different in nature than those of dredging projects, but would still affect water quality in the bay. LNG carrier water withdrawals and discharges related to ballast and engine cooling operations would affect small portions of Coos Bay (via potential introduction of invasive species and modifying water temperatures) primarily at and near the LNG marine facilities (see section 4.3 and 4.5). However, given the size of Coos Bay, the frequency of LNG carries in the bay, and the current use of the bay by other marine vessels, we conclude that any cumulative would not be significant.

Along the pipeline route, in-water work and ground disturbing activities near waterbodies can affect water quality. The locations, scopes of work, and timing of the other projects are not all known, so we cannot quantify the specific impacts of these projects or determine if these impacts would overlap with the impacts of the Project. However, based on available information (see table 4.14.-2) and the temporary and localized impacts of the Project on surface waters as described in the preceding environmental analyses, Pacific Connector's use of HDDs to cross major waterbodies, and its implementation of erosion and sediment control measures as well as other impact minimization measures, we conclude that these impacts and the potential impacts of the other projects would result in a cumulative impact; but, this impact would not be significant.

Additionally, the Klamath, Yurok, and Karuk Tribes expressed concern that an adverse cumulative impact on the Klamath River in Klamath County and downstream into California would occur resulting from the Project and the removal of dams along the Klamath River. The tribes expressed concern about impacts on water quality and fish, especially salmon. Pacific Connector would cross the Klamath River using an HDD. Furthermore, Pacific Connector has prepared a site-specific crossing plan for the Klamath River that indicates all workspaces and measures that would be implemented to avoid and minimize impacts on the Klamath River. As described previously, the use of an HDD significantly reduces the potential for impacts on a waterbody. Should an inadvertent release of drilling fluid(s) occur into the Klamath River, water quality would be temporarily affected. The river would experience increased turbidity and sedimentation. However, these increases would subside quickly, and the resulting turbidity would also settle out quickly. The removal of dams along the Klamath River would result in a significant impact on downstream water quality; however, these significant impacts would not occur in areas where the Project's impacts would occur. Furthermore, because the Project would use an HDD to cross the river and would likely be completed before the dams are removed, the Project's incremental contributions to a cumulative impact would not be significant.

COE permits and mitigation projects would affect a total of about 50 acres of wetlands in the watersheds crossed by the Project. The extent of impacts on wetlands from the other projects identified in table 4.14.-2 (beyond the COE permits and mitigation projects in Coos Bay) are unknown, but we assume wetlands could be affected. As described previously, the Project would impact about 200 acres of wetlands, with about 45 percent of the wetlands affected by the Project associated with the LNG terminal facilities. Of the remaining 55 percent, about 110 acres of wetlands would experience temporary to short-term impacts, and about 3 acres of forested wetland would experience long-term impacts. Cumulatively, at least 250 acres of wetlands would be affected. However, this cumulative impact would not be significant given the sizes of the watersheds crossed, relative to the extent and duration of the impacts.

4.14.1.3 Vegetation

Timber sales, commercial thinning, forest management, timber-related activities, and other projects would affect over 40,000 acres of vegetation within the watersheds crossed by the Project. These projects would primarily impact forest and herbaceous vegetation. Impacts include permanent clearing and loss, and long- and short-term disturbance (clearing and thinning). Many of these projects are BLM or Forest Service projects and as such have undergone an environmental review.

As described previously, the Project would affect about 4,500 acres of vegetation. Cumulatively, the Project along with the projects identified in table 4.14-2 would impact over 65,000 acres. If all 65,000 acres were vegetated, this impact would account for about 2.5 percent of the total amount of vegetation within the watersheds crossed by the Project. Considering forest vegetation, if the entire area affected by the projects considered in this analysis were forested it would account for about 4.6 percent of the total amount of forested area within the watersheds based on USGS National Land Cover Database which estimates about 1.4 million acres of forest within the watersheds. Additionally, the Project would impact 773 acres of LSOG forest. Pacific Connector would fund various projects on federal lands that would mitigate for the impacts on LSOG on federal lands to the extent required by BLM and Forest Service LRMPs. Implementation of new LRMPs and RMPs on both BLM and NFS lands in the 1990s resulted in a substantial reduction in lands available for timber harvest due to the establishment of LSRs and Riparian Reserves. Regrowth in previously harvested areas would, over time, result in more area supporting LSOG in the watersheds crossed by the Project. The clearing of LSOG by the Project would represent a loss of 0.01 percent of the remaining LSOG forest in the four physiographic provinces crossed by the Project.

Any of the projects identified in table 4.14-2 could result in the introduction or spread of invasive or noxious weeds as a result of ground disturbance and/or movement of equipment from one site to another. To avoid introducing or spreading invasive species, Jordan Cove would follow recommendations from several state and federal plans and programs including ODA, OISC, and BLM, as well as Project-specific measures (see section 4.4.1.6). It would be expected that the other projects on federal lands, or that would be subject of a federal permit review, would also implement some measures to minimize or control the spread of invasive or noxious weeds. Therefore, based on the analysis provided above, we conclude that the cumulative impact on vegetation would not be significant.

4.14.1.4 Wildlife and Aquatic Resources

All of the projects identified in table 4.14-2 could affect wildlife, including threatened and endangered species, and other species of concern. Ground-disturbing activities; and the use of equipment in support of those activities can increase the rates of stress, injury, and mortality experienced by wildlife. Additionally, these activities can result in the temporary and permanent loss or conversion of wildlife habitats. Threatened and endangered species may be particularly vulnerable to these ground-disturbing activities and associated habitat loss. The timber harvest projects and a number of the other timber-related projects could result in the long-term loss of forested habitat which supports a variety of wildlife, including MAMU and NSO. Timber sales projects could also result in the loss of forested habitat and affect wildlife. For the purposes of this analysis, we consider timber harvest and timber sales collectively as potential impacts on mature wildlife habitat; however, we recognize that some of these projects could be beneficial for forest health and wildlife. Furthermore, some timber management activities would affect mature wildlife habitat, but would generally result in temporary impacts with a goal of promoting the long-term enhancement of mature habitat. As discussed previously, wildlife would generally avoid or be displaced by disturbance. As a result, wildlife would experience increased rates of stress, injury, and mortality. Additionally, when wildlife is displaced or behaviors change in response to disturbance and habitat loss, competition and predation pressures from other wildlife that move to occupy abandoned habitats or are occupying habitats that displaced wildlife is trying to use can increase which can result in a decrease in overall fitness (including reduced rates of reproduction) for some species.

Impacts on wildlife (and threatened and endangered species) would vary depending on the amount and quality of habitat, and the duration of impacts, the fitness of an individual(s), and the concentration of individuals within affected habitats. As stated previously, the Project and the other projects would affect about 65,000 acres of land (and associated wildlife habitats) which represents about 2.5 percent of the total amount of land within the watersheds crossed by the Project. However, some habitat types may be more sensitive to disturbance that others, such as those defined as “irreplaceable, essential, or limited” by the ODFW (see section 4.5); information on the extent of impacts that would occur to these sensitive habitat types as a result of the reasonable foreseeable projects is not available or quantifiable at this time. Therefore, we conclude that the resulting cumulative impact of the Project and the other projects would not be significant because of the total amount of land and habitat affected relative to the amounts available within the watersheds crossed and wildlife’s general ability to avoid construction activities and adapt to disturbance.

In Section 4.06, we address the Project’s extensive impacts on federally listed threatened and endangered species. In the forthcoming biological assessment, we address cumulative effects on federally listed threatened and endangered species. However, acknowledging that many federally-protected species in the Project area depend on LSOG habitat for one or more life stages and due to their particular sensitivity, we discuss further cumulative impacts on two of those species MAMU and NSO. The projects identified in table 4.14-12 include timber sales and forest management projects involving timber harvest on about 694 acres within watersheds where MAMU occur and about 10,439 acres within watersheds where NSO occur. The majority of these harvests are of regenerating stands rather than LSOG, so they are more likely to prevent forested habitat from becoming LSOG (and thus suitable for LSOG-associated species) than remove existing LSOG that is currently suitable for MAMU and NSO. As a result, the Project-related habitat loss described in section 4.6 would contribute to a cumulative impact on MAMU and NSO habitat. Furthermore, of the projects considered in this analysis, this Project would have the largest incremental impact to these species.

COE permits and mitigation projects, minor federal agency projects (instream and aquatic restoration projects), timber-related activities, and livestock grazing would occur in the watersheds affected by the Project and would impact aquatic resources, including threatened and endangered species and other species of concern. Additionally, LNG carriers, the Port's Channel Modification Project, the regular maintenance of the channel, other projects in Coos Bay, and the removal of dams along the Klamath River would also impact aquatic resources including fish, marine mammals, and other aquatic organisms. In-water work and ground-disturbing activities associated with these projects would affect aquatic habitats, fish, marine mammals, and other aquatic organisms in a manner similar to that described for the Project (see sections 4.5 and 4.6). Aquatic habitats would be both temporarily and permanently affected; and fish and water-dependent wildlife would experience increased rates of stress, injury, and mortality.

Concerns about the importance of fish to communities affected by the Project and the potential for cumulative impacts on fish were expressed in numerous comments to the Commission. Comments provided by several tribes specifically identified Coos Bay and the Klamath River as fisheries that could be subject to adverse cumulative impacts. With the exception of the Port's Channel Modification Project, the COE's North Jetty Maintenance Project, LNG carriers, and channel maintenance activities, the other projects affecting Coos Bay are temporary in nature resulting in temporary impacts on aquatic habitats, fish, marine mammals and other aquatic organisms primarily from dredging activities that result in the loss of habitat and increase rates of turbidity and sedimentation. LNG carriers and other marine vessel traffic in Coos Bay would occur regularly; however, the disturbance caused by ships (increased wave action, underwater noise, and water withdrawal/discharge) in Coos Bay is not expected to adversely impact fish and other aquatic resources including crabbing. Channel maintenance activities would occur periodically, but the impacts of these activities on fisheries and aquatic resources would be temporary. The impacts of these projects when combined with the impacts of the Project would not result in a significant cumulative impact on fish, marine mammals, and other aquatic organisms in Coos Bay.

Along the pipeline route, in-water work, ground-disturbing activities, and vegetation clearing related to other projects can affect aquatic habitats, fish, and water-dependent wildlife. Aquatic habitat disturbance would affect fish behavior, migration, feeding, and reproduction, and would increase rates of stress, injury, and mortality experienced by fish and other wildlife. Threatened, endangered, and other special status fish species may be particularly vulnerable to these ground-disturbing activities and the associated aquatic habitat disturbance. As described previously, the details of the other projects are not well known, so we cannot quantify the specific impacts of these projects or determine if these impacts would overlap with the impacts of the Project. Turbidity generated by the various projects is generally not additive because the generation of plumes is uncommonly synchronized and spatially overlapping. Sedimentation, however, would be additive at common settling points. Settling points within each stream are largely determined by flow dynamics within short stream segments. Consequently, the common deposition points are likely to be past and ongoing points where sediments accumulate. Additional sediment accumulation at these points is clearly an impact, but likely not a conversion of habitat type. Based on the Project's impacts on aquatic resources and the impacts of the other projects which are expected to be similar to those of the Project, we conclude that the resulting cumulative impact would not be significant.

Pacific Connector would cross the Klamath River using an HDD. As described previously, the use of an HDD significantly reduces the potential for impacts on a waterbody and any aquatic resources within or dependent on that waterbody. Should an inadvertent release of drilling fluid occur into the Klamath River, aquatic habitat and fish would be temporarily affected. The removal of the four dams along the Klamath River would temporarily and permanently significantly affect fish and other aquatic resources in the river. Short-term impacts on aquatic resources would result from increases in turbidity and long-term beneficial impacts would result from the permanent modification of (and access to) stream reaches due to changes in flow. The closest dam removal planned to the Project's crossing of the Klamath River would occur about 20 miles downstream. Because the dam is 20 miles downstream, the impacts of its removal would not be additive with the impacts of the Project; therefore, we conclude that the Project would not significantly contribute to an adverse cumulative impact.

4.14.1.5 Land Use

There are no other projects in Coos Bay whose impacts when combined with those of the LNG terminal would result in a significant cumulative impact on land use. As described previously, the Project and the other projects identified in table 4.14-2 would cumulatively affect about 65,000 acres of land (about 2.5 percent of the total amount of land within the watersheds crossed by the Project). Affected lands support a number of uses including natural forest, silviculture, residential, grazing, commercial, agricultural, and industrial activities. Timber and forest management are commonplace in the region and are not, with the exception of growth of trees and installation of permanent aboveground facilities over the pipeline, prohibited or restricted by the Project. Clearing of forested areas for construction of the Pacific Connector pipeline would amount to less than nine percent of the acreage of timberlands affected by the BLM and Forest Service vegetation management projects listed in table 4.14-2. The acreage of forested land affected by the pipeline that would not be reforested (i.e., the permanent operational right-of-way and aboveground facilities) would constitute less than two percent of the timberlands affected by the BLM and Forest Service vegetation management projects listed in table 4.14-2. Overall, the impacts of the Project when combined with the impacts of the other projects would not result in a significant cumulative impact on land use.

4.14.1.6 Visual Resources and Recreation

The only projects listed in table 4.14-2 that involve new permanent aboveground facilities within the viewshed of the LNG terminal is the City of North Bend's Department of Human Services Building and the CTCLUSI Hollering Place. The non-jurisdictional SORSC would be located within the footprint of the LNG terminal site and is considered from a visual perspective as part of the LNG terminal site. Also, although not a permanent aboveground facility, the regular use of the Federal Navigational Channel by LNG carriers and associated project-related marine vessel traffic would also constitute an impact on the visual character of Coos Bay. The Department of Human Services Building is located less than a mile from the LNG terminal and may be visible from the same vantage points (viewpoints 6-10 as shown on figure 4.8-2); however, it is located on the developed Southwest Oregon Regional Airport property and is visually consistent with the existing industrial/commercial visual character. When complete, the CTCLUSI's Hollering Place would be located just over 2 miles southwest of the LNG terminal site along the community of Empire's shoreline. The LNG carries would occur frequently in Coos Bay and would be distinguishable from other marine traffic where the navigation channel is visible from vantage points in Charleston, Barview, Empire, and North Bend. As described in section 4.8.2, we conclude that the LNG terminal would have a significant impact on a limited number of viewers and locations around Coos Bay. Therefore, because the Project's impact on Coos Bay's visual character would be significant, a significant cumulative impact would result; however, we conclude that the impacts of the Human Services building, CTCLUSI's Hollering Place, and the increased marine traffic would not contribute to a greater impact on the visual character of Coos Bay.

As described previously, at least six timber sale projects affecting a total of over 5,000 acres of land have or would cross/overlap about six miles of pipeline construction right-of-way and workspace. It is also likely that an undeterminable amount of other timber-related activities; maintenance, commercial thinning, and timber management have or would cross/overlap pipeline construction right-of-way and workspace. A cumulative impact on visual resources would occur if visible impacts of these projects and the Project are observable from one or more shared vantage points. Numerous commenters including the Klamath Indian Tribe have expressed concern about an adverse cumulative impact on the visual character of the Project area. Commenters cited the spiritual and intrinsic value of potentially affected viewsheds. Timber-related activities, sales, and forest management are common practices in Oregon and their visual impacts can be observed across the landscape. The impact of the pipeline operational easement would resemble other utilities and forest access roads, and would not generally be out of character for the region. There would, however, be locations where the pipeline route would be in less developed and managed areas and its visual impact would be less common; but because of the remote siting, the number of possible viewpoints and receptors would be small. According to the Forest Service, the majority of the timber-related activities involve thinning younger stands to speed the development of late successional old-growth habitat in LSRs and on the Matrix lands. These thinning prescriptions would generally not result in large new openings in the forest canopy. Additionally, where the pipeline would cross remote and steep topography, locations where the permanently cleared operational easement would be visible would be limited. Therefore, we conclude that a cumulative impact would occur, but that this impact would not be significant.

Two projects - the Turkey Hill Solar Project and the transmission line associated with the Swan Lake Hydroelectric Pumped Storage Project - are located in the vicinity of the proposed Klamath Compressor Station. The compressor station would be painted with a color that blends with the hues of the surrounding landscape and the grounds would be landscaped to reduce visual impacts on area residents. Given the distance to the Turkey Hill Solar Project and Swan Lake Hydroelectric Pumped Storage Project transmission line (2.2 miles and 1.9 miles, respectively), and existing topography, we conclude that the impacts of these projects would not contribute to a significant cumulative impact on visual resources.

As described in comments to the Commission about the Project, Coos Bay provides numerous recreational opportunities including boating, fishing, crabbing, hiking, bird watching, and scenic viewing. The cumulative impacts of the Project and the other projects in Coos Bay on water quality, aquatic resources, and transportation, all of which affect recreational use of the bay would not be significant, so the cumulative impact on recreation in Coos Bay would not be significant. Recreational users of Coos Bay may be inconvenienced by delays associated with the increased use of the channel by LNG carriers and other Project-related marine traffic; however, no other additional long-term marine traffic has been identified as occurring in the bay. Dredging activities associated with the other projects in Coos Bay would temporarily increase traffic in the channel, but any cumulative impact would not be significant as the dredging activities would be temporary and periodic. These inconveniences when added to existing marine traffic would contribute to a cumulative impact; but this impact would not significantly impair a user's ability to participate in recreation activities in the bay.

Southern and West-central Oregon provide the public a large number of diverse recreational opportunities including camping, hiking, off-road vehicle trails, hunting, fishing, boating, and wildlife watching. Cumulative impacts along the pipeline route could occur if the Project and one or more other projects affect the same recreational resource (trail, natural area, etc.). However, none of the other projects identified along the pipeline route are expected to significantly reduce overall recreational opportunities for the public. As described previously, the Project would not significantly affect recreation. Based on the impacts of the Project and other projects, we conclude that there would not be a significant cumulative impact on recreation occurring along the pipeline route.

4.14.1.7 Socioeconomics

Constructing the Project would temporarily impact the socioeconomic character of the region as described in section 4.9. The socioeconomic impacts of the Project would occur because of the introduction of a new construction workforce, which would affect total population, available housing, and tax revenue during the period of construction; and would draw on existing public services such as police, fire, and healthcare. We do not anticipate that the other projects occurring in the watersheds affected by the Project would require a significant influx of non-local labor because these projects are common to the region. Therefore, we conclude that the other projects would not meaningfully contribute to a cumulative impact on the socioeconomic character of the region. However, as described in section 4.9, the Project would result in a significant impact on housing in Coos County during construction; therefore, a significant cumulative impact would result.

4.14.1.8 Transportation

The proposed modification of the Coos Bay Federal Navigational Channel as well as other projects in Coos Bay would require the use of marine vessels. As described in section 4.10.1, constructing and operating the Project would increase the number of vessels in Coos Bay as a result of the addition of approximately 70 water deliveries via a mix of ocean-going vessels and barges during the two-year construction period and 120 LNG carriers per year transiting to and from the Jordan Cove LNG terminal during its operation. This increase in marine traffic combined with current deep-draft vessel traffic would be less than historic ship traffic through the channel. In addition, in a Letter of Recommendation for the Project the Coast Guard considers that the Coos Bay channel to be suitable for the proposed type and frequency of LNG carriers traffic (see appendix B). Therefore, we conclude that while some marine traffic might be temporarily inconvenienced, the passage of construction-related and LNG carriers through the channel would not have significant or long-term impacts on other boats in Coos Bay. Numerous commenters have expressed concern that a modified navigational channel would induce additional marine vessel traffic. To our knowledge, additional marine vessel traffic utilizing the modified channel has not been proposed; therefore, we cannot speculate on unknown future impacts. However, the Coast Guard and other authorities would continue to regulate any future marine traffic within the channel.

Of the projects identified in table 4.14-2, timber-related activities may result in use of large, heavy equipment and log trucks on local and regional roadways. Other projects planned for the area are road improvements or other relatively small-scale projects not requiring a significant workforce. As described in section 4.10, the Project would contribute vehicle trips to Project-area roads during construction, and would affect these roads and their users. Together, the Project and other projects would result in a cumulative impact on area roads and traffic; however, the degree of impact would depend on the extent of overlap in time and space during active construction of the projects.

4.14.1.9 Cultural Resources

Cumulative impacts on cultural resources would only occur if other projects were to share (and impact) the same APE as the Project. Several forest- and timber-management projects listed in table 4.14-2 would share the same APE as the Project and could contribute to a cumulative impact on cultural resources. The federal agencies managing these projects would be required to follow the regulatory requirements of 36 CFR Part 800 and/or other implementing regulations. Under these regulations, the lead federal agency, in consultation with the SHPO, would identify historic properties in the project APE, assess potential effects, and resolve adverse effects through an agreement document that outlines a treatment plan.

We received numerous and detailed comments from Indian tribes, particularly the CTCLUSI, expressing and reiterating concern about the Project's contribution to a cumulative impact on cultural resources. In their comments, the CTCLUSI state that the extensive geotechnical work (e.g., drilling and core sampling) that has occurred at the LNG terminal site over the three iterations of this Project has adversely affected cultural resources. We acknowledge that a considerable amount of geotechnical work has occurred at the LNG terminal site, but we are not aware of any documented impacts on cultural resources resulting from geotechnical work at this site. Ingram Yard and the South Dunes areas were surveyed by archeologists and no historic properties were identified. As described previously, we consider the impacts of past projects as part of the environmental baseline, but are addressing these comments because of the sensitive nature of cultural resources and the significance attributed to them by the CTCLUSI. Once construction of the LNG terminal is complete, the site would be permanently transformed into an industrial facility and would not be subject to impacts from other projects; therefore, a cumulative impact on cultural resources would not occur.

As described previously, the Project would have adverse impacts on historic properties. Further, surveys of both the LNG terminal facilities and pipeline are incomplete and may result in the identification of additional historic properties. Also, an ethnographic study of the Project and the identification of traditional cultural resources is incomplete. One known TCP is present in Coos Bay and overlies the Project facilities. Once evaluations are complete, adverse effects on historic properties would be resolved by implementing the procedures outlined in a Project-specific MOA following completion of the Section 106 process pursuant to the NHPA. The MOA would also include provisions for inventorying areas not yet surveyed to identify historic properties that may be affected by the Project. Although the required review processes are not complete, we conclude, given state and federal laws and regulations protecting cultural resources and the other projects affecting the Project's APE, that any cumulative impact on cultural resources would not be significant.

4.14.1.10 Air Quality, Climate Change, and Noise

Air Quality

Constructing the Project, as well as the other projects listed in table 4.14.2, would temporarily affect air quality due to emissions from the combustion engines used to power construction equipment, vehicle emissions traveling to and from the project sites, deliveries of construction materials, and from fugitive dust emissions resulting from earth-disturbing activities and equipment movement on dirt roads. The potential for cumulative construction emissions impacts would be greatest during site preparation when fugitive dust production would likely be at its peak. Emissions from equipment engines and vehicles operating concurrently would also result in cumulative air quality impacts in the local area. Most of the reasonably foreseeable projects are located outside of the geographic scope for cumulative construction emissions. The only projects that would potentially overlap with the geographic scope for cumulative construction emissions are associated with the non-jurisdictional Project facilities, COE Coos Bay Federal Navigation Channel Maintenance Dredging, the Port's Channel Modification Project, Southwest Oregon Regional Airport Expansion, and various BLM and Forest Service vegetation maintenance projects.

The primary projects in the construction air emissions geographic scope of the Jordan Cove LNG Project with the potential to be constructed in a similar timeframe are the COE Coos Bay Navigation Channel Maintenance Dredging Project and the Southwest Oregon Regional Airport Extension. The COE Maintenance Dredging Project would result in the short-term release of criteria pollutants from the operation of dredges. Estimated emissions of criteria pollutants would not result in exceedances of the NAAQS in the Project area. Furthermore, the cumulative impact analysis conducted as part of the 2015 COE EA (which included the Southwest Oregon Regional Airport Extension and the originally proposed Jordan Cove Project) found that no substantial cumulative effects would occur. Based on this information, and the implementation of mitigation measures discussed above, cumulative air quality impacts during construction of the Jordan Cove LNG Project would not be significant.

The majority of the pipeline would be located in an attainment area for the NAAQS. However, a small portion of the pipeline would be located in a PM10 maintenance area and a PM2.5 nonattainment area. Due to the de minimis construction emissions that would not exceed General Conformity thresholds, and the limited scope of Project construction in the nonattainment area, the Project is not expected to contribute discernable cumulative impacts on the nearby nonattainment areas or maintenance areas. To minimize impacts due to construction emissions during pipeline construction, Pacific Connector would implement mitigation measures to minimize construction impacts on air quality, including implementing a fugitive dust control plan, compliance with applicable EPA mobile source emission performance standards, and use of equipment manufactured to meet air quality standards.

The projects identified within the construction geographic scope of the pipeline include various BLM and Forest Service vegetation maintenance projects and the Klamath Dam Removal. While these projects would likely cause minor short-term air quality impacts, it is unlikely that they would cause significant cumulative impacts when combined with the pipeline.

Operation of the LNG facilities would have long-term effects on air quality due to operational emissions associated with the facilities. Jordan Cove would be required to obtain a Title V Operating Permit for Project operation, and would be required to comply with any operating conditions of this permit, including measures to reduce emissions.

A cumulative ambient air quality analysis was conducted that showed that operation of the LNG facilities, when considered along with existing sources and background air quality, would not result in an exceedance of the NAAQSs. The only project identified within the 50 km geographic scope for cumulative operational air quality impacts is the non-jurisdictional LNG carriers. Emissions and exhaust parameters from the LNG carriers were included in the cumulative modeling analysis starting from the process of transit, berthing, to hoteling and LNG loading, and finally to connecting the towlines and de-berthing. Based on our air quality analysis, operational cumulative impacts associated with the Jordan Cove LNG Project are expected to be minor.

Operation of the Pacific Connector Pipeline Project would have long-term effects on air quality due to emissions from the Klamath Compressor Station. The compressor station would be located in an attainment area for the NAAQS. The compressor station emissions would be below the General Conformity *de minimis* thresholds; therefore, the compressor station would not significantly impact nonattainment or maintenance areas.

Pacific Connector would require an Air Contaminant Discharge Permit from the ODEQ to construct the Klamath Compressor Station and a Title V Operating Permit to operate the compressor station. The permits for this facility would include mitigation measures and operational requirements to ensure that air emissions do not exceed the permit requirements and that the facilities would be operated in compliance with applicable air quality regulations.

Pacific Connector completed air quality modeling for the operational emissions of the Klamath Compressor Station. The results of the air quality modeling are summarized in section 4.12 and provide the estimated facility air quality impacts combined with background air quality concentrations for NO_2, CO_2, PM_{10}, $PM_{2.5}$, and SO_2, and include existing operating air emission sources. Based on this analysis, the operation of Klamath Compressor Station would not result in an exceedance of any of the NAAQS. No projects were identified within the geographic scope of the Klamath Compressor Station that would result in operational air quality impacts. Therefore, the Project would not result in cumulative impacts on air quality from the operation of the Pacific Connector Pipeline Project.

Climate Change and Greenhouse Gas Emissions

Climate change is the variation in climate (including temperature, precipitation, humidity, wind, and other meteorological variables) over time, whether due to natural variability, human activities, or a combination of both, and cannot be characterized by an individual event or anomalous weather pattern. For example, a severe drought or abnormally hot summer in a particular region is not a certain indication of climate change. However, a series of severe droughts or hot summers that statistically alter the trend in average precipitation or temperature over decades may indicate climate change. Recent research has begun to attribute certain extreme weather events to climate change (USGCRP 2018).

The leading U.S. scientific body on climate change is the U.S. Global Change Research Program (USGCRP), composed of representatives from thirteen federal departments and agencies.[231] The Global Change Research Act of 1990 requires the USGCRP to submit a report to the President and Congress no less than every four years that "1) integrates, evaluates, and interprets the findings of the Program; 2) analyzes the effects of global change on the natural environment, agriculture, energy production and use, land and water resources, transportation, human health and welfare, human social systems, and biological diversity; and 3) analyzes current trends in global change, both human induced and natural, and projects major trends for the subsequent 25 to 100 years." These reports describe the state of the science relating to climate change and the effects of climate change on different regions of the U.S. and on various societal and environmental sectors, such as water resources, agriculture, energy use, and human health.

In 2017 and 2018, the USGCRP issued its *Climate Science Special Report: Fourth National Climate Assessment*, Volumes I and II (Fourth Assessment Report) (USGCRP, 2017; and USGCRP, 2018, respectively). The Fourth Assessment Report states that climate change has resulted in a wide range of impacts across every region of the country. Those impacts extend beyond atmospheric climate change alone and include changes to water resources, transportation, agriculture, ecosystems, and human health. The U.S. and the world are warming; global sea level is rising and acidifying; and certain weather events are becoming more frequent and more severe. These changes are driven by accumulation of GHG in the atmosphere through combustion of fossil fuels (coal, petroleum, and natural gas), combined with agriculture, clearing of forests, and other natural sources. These impacts have accelerated throughout the end 20th and into the 21st century (USGCRP 2018).

Climate change is a global phenomenon; however, for this analysis, we will focus on the existing and potential cumulative climate change impacts in the Project area. The USGCRP's Fourth Assessment Report notes the following observations of environmental impacts are attributed to climate change in the Northwest region (USGCRP, 2017; USGCRP, 2018):

- the region has warmed nearly 2°F since 1900;
- warmer winters have led to reductions in mountain snowpack, resulting in drought, water scarcity, and large wildfires;
- declines in dissolved oxygen in streams and lakes have caused fish kills and loss of aquatic species diversity; and
- moderate to severe spring and summer drought areas have increased 12 percent to 14 percent.

[231] The USGCRP member agencies are: Department of Agriculture, Department of Commerce, Department of Defense, Department of Energy, Department of Health and Human Services, Department of the Interior, Department of State, Department of Transportation, Environmental Protection Agency, National Aeronautics and Space Administration, National Science Foundation, Smithsonian Institution, and U.S. Agency for International Development.

The USGCRP's Fourth Assessment Report notes the following projections of climate change impacts in the Project region with a high or very high level of confidence[232] (USGCRP, 2018):

- increases in stream temperature indicate a 22 percent reduction in salmon habitat by the late 20th century;
- more frequent severe winter storms, which may contribute to storm surge, large waves, coastal erosion, and flooding in low-lying coastal areas;
- the warming trend is projected to be accentuated in certain mountain areas in the Northwest in late winter and spring, further exacerbating snowpack loss and increasing the risk for insect infestations and wildfires;
- longer periods of time between rainfall events may lead to declines in recharge of groundwater and decreased water availability, and responses to decreased water availability, such as increased groundwater pumping, may lead to stress or depletion of aquifers and strain on surface water sources; and
- increases in evaporation and plant water loss rates may alter the balance of runoff and groundwater recharge, which would likely to lead to saltwater intrusion into shallow aquifers.

It should be noted that while the impacts described above taken individually may be manageable for certain communities, the impacts of compound extreme events (such as simultaneous heat and drought, wildfires associated with hot and dry conditions, or flooding associated with high precipitation on top of saturated soils) can be greater than the sum of the parts (USGCRP 2018).

The GHG emissions associated with construction and operation of the Project are identified in section 4.12.1.1 for the Jordan Cove LNG Project and section 4.12.1.2 for the Pacific Connector Klamath Compressor Station and pipeline. Both the Jordan Cove LNG Project and the Pacific Connector Klamath Compressor Station and pipeline would remain below PSD major source thresholds and are therefore not required to conduct a Best Available Control Technology analysis for mitigating GHG emissions. The construction and operation of the Project would increase the atmospheric concentration of GHGs, in combination with past, current, and future emissions from all other sources globally and contribute incrementally to future climate change impacts. Project emissions would contribute incrementally to future climate change impacts.

Currently, there is no universally accepted methodology to attribute discrete, quantifiable, physical effects on the environment to the Project's incremental contribution to GHGs. We have looked at atmospheric modeling used by the EPA, National Aeronautics and Space Administration, the Intergovernmental Panel on Climate Change, and others and we found that these models are not reasonable for project-level analysis for a number of reasons. For example, these global models are not suited to determine the incremental impact of individual projects, due to both scale and

[232] The report authors assessed current scientific understanding of climate change based on available scientific literature. Each "Key Finding" listed in the report is accompanied by a confidence statement indicating the consistency of evidence or the consistency of model projections. A high level of confidence results from "moderate evidence (several sources, some consistency, methods vary and/or documentation limited, etc.), medium consensus." A *very* high level of confidence results from "strong evidence (established theory, multiple sources, consistent results, well documented and accepted methods, etc.), high consensus." https://science2017.globalchange.gov/chapter/front-matter-guide/

overwhelming complexity. We also reviewed simpler models and mathematical techniques to determine global physical effects caused by GHG emissions, such as increases in global atmospheric CO_2 concentrations, atmospheric forcing, or ocean CO_2 absorption. We could not identify a reliable, less complex model for this task and we are not aware of a tool to meaningfully attribute specific increases in global CO_2 concentrations, heat forcing, or similar global impacts to project-specific GHG emissions. Similarly, it is not currently possible to determine localized or regional impacts from GHG emissions from the Project. Absent such a method for relating GHG emissions to specific resource impacts, we are not able to assess potential GHG-related impacts attributable to this project. Without the ability to determine discrete resource impacts, we are unable to determine the significance of the Project's contribution to climate change.

We have not been able to find any GHG emission reduction goals established at the federal level.[233] The State of Oregon has set GHG reduction goals with a state-wide target of 51 million metric tons of CO_2e by 2020 (a 10 percent reduction from 1990 levels), and 14 million metric tons of CO_2e by 2050 (a 75 percent reduction from 1990 levels) (Oregon Global Warming Commission 2017). The Oregon Global Warming Commission projects that Oregon will fall short of these goals without additional legislative action. Direct emissions from the Jordan Cove LNG and Pacific Connector Pipeline Projects would result in annual CO_2e emissions of about 2.14 million metric tons of CO_2e, which would represent 4.2 percent and 15.3 percent of Oregon's 2020 and 2050 GHG goals, respectively.

Noise

the Project would involve various types of equipment and activities, including pile driving, dredging, and drilling. These activities would temporarily increase noise in the surrounding areas. Projects listed in table 4.14-2 that are located within the geographic scope that could contribute to a cumulative noise impact include non-jurisdictional Project facilities, COE Coos Bay Federal Navigation Channel Maintenance Dredging, the Port's Channel Modification Project, Southwest Oregon Regional Airport Expansion, various BLM and Forest Service vegetation maintenance projects, and the Klamath Dam Removal. Based on the schedule and proximity of the other projects, there may be some cumulative construction noise impacts. The exact level of noise impacts that would occur from the projects identified in table 4.14-2 is not known; however, most construction is expected to take place during daytime hours and would be intermittent rather than continuous. Construction noise would primarily last for short periods and would vary as the equipment moves along the construction spread.

To minimize the Project's contribution to a cumulative impact, Jordan Cove would implement mitigation measures including selecting low-noise alternative equipment, restricting time of day for construction, installing temporary noise barriers, enclosing equipment, and preparing site-specific noise management plans. The HDD or DP crossing method would be used to cross under six waterbodies and a powerline/steep slope location along the BPA Powerline Corridor. Per our recommendation in section 4.12.2, Pacific Connector would be required to ensure that noise attributable to drilling operations does not exceed an 55 L_{dn} dBA. Because construction noise is temporary and would dissipate with distance, and the applicants would implement BMPs and noise

[233] The national emissions reduction targets expressed in the EPA's Clean Power Plan and the Paris climate accord are pending repeal and withdrawal, respectively.

mitigation as well as adhere to our recommendations, we conclude cumulative impacts on noise levels would not be significant.

Operation of the Jordan Cove LNG Project and Pacific Connector's Klamath Compressor Station would result in long-term increases in noise levels in the vicinity of these aboveground facilities. Noise at the Jordan Cove LNG Project would be associated with refrigerant gas turbines/compressors, boil-off gas compressors/motors, various pumps/motors, steam turbine generators, air-cooled condensers, and blow-down events. Operational noise was modeled at four NSAs near the Jordan Cove LNG terminal as discussed in section 4.12. This modeling indicated noise attributable to the LNG terminal at the NSAs would be within the FERC's limit of L_{dn} 55 dBA. Overall predicted noise increases at one of the NSAs would be noticeable but are not likely to be significant. Noise increases at the remaining three NSAs are unlikely to be perceptible. None of the other projects located within 1 mile of the Jordan Cove LNG Project are expected to have any operational noise impacts; therefore, operation of the Project would not contribute to broader cumulative noise impacts.

Underwater noise levels from large commercial ships are fairly consistent, ranging from about 177 to 188 dB re 1 µPA at 1 meter. Considering peak noise levels and cumulative sound exposure, vessel noise is not expected to exceed the NMFS guideline thresholds for the onset of permanent threshold shift for cetaceans and pinnipeds. Total underwater noise from maintenance dredging, LNG carriers, tugs, and other marine vessels would increase during operation of the Project; however this cumulative impact would not be significantly greater than existing underwater noise levels in Coos Bay.

Noise at the Klamath Compressor Station would be associated with gas turbines, compressors, pumps, cooling fans, and blowdown events. Operational noise was modeled at five NSAs near the Klamath Compressor Station. This modeling indicated noise attributable to the compressor station at the NSAs would be within FERC's limit of L_{dn} 55 dBA. Pacific Connector would adopt the acoustic design recommendations for the Klamath Compressor Station outlined in the noise study report. Overall predicted noise increases at NSAs #5 and #6 are unlikely to be perceptible based upon the existing background noise. The predicted noise increases at the remaining NSAs would be noticeable but are not likely to be significant. None of the known existing or future projects located within 1 mile of the Klamath Compressor Station are expected to have any operational noise impacts; therefore, operation of the Pacific Connector Pipeline Project would not contribute to broader cumulative noise impacts.

4.14.2 Cumulative Impact Conclusions

The impacts of the Project when added to those of the other projects would result in cumulative impacts on the environment. For the federal projects, existing laws and regulations protect waterbodies and wetlands, threatened and endangered species, and historic properties, and limit impacts on air and noise. In addition, Federal land-managing agencies, such as the BLM and Forest Service, have requirements in their LRMPs and RMPs to protect resources on their lands. Given the BMPs and impact avoidance, minimization, and mitigation measures that would be implemented; and federal and state laws and regulations protecting the environment; we conclude that with the exception of significant impacts on visual resources and available housing in the Coos Bay area, cumulative impacts on the environment would not be significant.

5.0 CONCLUSIONS AND RECOMMENDATIONS

5.1 CONCLUSIONS OF THE ENVIRONMENTAL ANALYSIS

The conclusions and recommendations presented below are those of the FERC environmental staff. They were prepared in cooperation with the BLM, Forest Service, Reclamation, DOE, COE, EPA, FWS, NOAA, Coast Guard, USDOT, and Coquille Tribe. However, these agencies may present their own conclusions and recommendations in their respective and applicable records of decision. The cooperating agencies can adopt this final EIS consistent with 40 CFR 1501.3 if, after an independent review of the document, they conclude that their requirements have been satisfied. Otherwise, they may elect to conduct their own supplemental environmental analyses.

Based on our review as described in the preceding sections, we conclude that constructing and operating the Project would result in temporary, long-term, and permanent impacts on the environment and a number of significant environmental impacts; however, a majority of impacts would be less than significant due to the implementation of proposed and recommended impact avoidance, minimization, and mitigation measures. As part of our review we developed measures that would appropriately and reasonably further avoid, minimize, or mitigate environmental impacts resulting from construction and operation of the proposed Project. Therefore, we recommend that these measures be attached as conditions to any authorizations issued by the Commission.

5.1.1 Geology

The LNG terminal would be located in Coos Bay within the seismically active CSZ. Numerous comments were received by the Commission about the potential affects to the LNG terminal from a tsunami. Recognizing the concern, and as described in the LNG safety and reliability section, Jordan Cove designed the terminal facilities consistent with maximum tsunami run-up elevations and considered tsunami wave heights and inundation elevations; therefore, FERC staff agrees that the equipment elevations that Jordan Cove provided are suitable for the proposed LNG terminal site. We also conclude that the LNG terminal would be able to withstand without damage a storm surge during a 500-year storm event. Although much of the pipeline would be located in the CSZ, we conclude, based on a review of potential impacts, historical data, seismic hazard mapping, peak horizontal ground acceleration values, pipeline tolerances, and Pacific Connector's proposed impact avoidance and minimization measures, that construction and operation the Project would not be significantly affected by potential geological hazards including ground shaking, surface ruptures, soil liquefaction and lateral spreading, landslides, and slope failures. Additionally, about 90 miles of pipeline would cross the Cascade and Klamath mountain ranges, which increases concerns for erosion, landslides, and slope failures. However, we conclude, based on our evaluation of the Project and Pacific Connector's proposed construction methods including its implementation of erosion control devices and other impact avoidance and minimization measures, that construction and operation of the pipeline would not be significantly affected. To ensure landslides in six moderate risk areas are further minimized, we are recommending that Pacific Connector file final monitoring protocols and mitigation measures. Furthermore, due to the absence of mining and other mineral extraction activities along the pipeline route, we conclude that these activities would also not be affected.

5.1.2 Soils and Sediments

Constructing and operating the LNG terminal would permanently impact underlying soils, including sands, fine sands, silt loams, and dune lands. Erosions control measures compliant with our Plan and Procedures would be implemented to control and minimize erosion and sedimentation. The pipeline would be located across numerous soil types including soils prone to erosion and compaction. The pipeline would also be located across about 149 miles of soils that have been rated as having reclamation sensitivity or poor revegetation potential. Impacts on soils would be reduced by Pacific Connector's implementation of erosion control measures and its use of best management practices including spill prevention and response procedures. Furthermore, Pacific Connector would install permanent erosion control measures and, if necessary, decompact soils (ripping) and implement other soil remediation measures.

To address contaminated soils at the terminal site, Jordan Cove would develop a disposal plan consistent with state requirements. An assessment of these soils concluded that residual contaminants did not exceed ODEQ screening levels for worker exposure. To ensure potential contamination is fully addressed, we are also recommending that Jordan Cove consult with the ODEQ regarding existing soil and groundwater contamination at affected sites.

The marine loading facilities and LNG carrier berth would permanently modify the Coos Bay shoreline and access to the navigational channel. A study of vessel wakes concludes that operating the LNG terminal (and LNG carriers) would not increase shoreline impacts. The marine berth would be constructed to account for concerns about LNG carrier propeller wash affecting the operational ability of the terminal.

Based on our review, we conclude that constructing and operating the Project would temporarily and permanently impact soils; however, based on the proposed construction and operations procedures and methods and the impact avoidance, minimization, and mitigation measures that would be implemented, these impacts would not be significant.

5.1.3 Water Resources and Wetlands

5.1.3.1 Groundwater

Based on the characteristics of groundwater underlying the LNG terminal site, our determination that the Project would not affect nearby (about 3,500 feet north of the terminal) CBNBWB water withdrawal wells, and Jordan Cove's implementation of BMPs and impact avoidance, minimization, and mitigation measures to address potential inadvertent releases of equipment related fluids, we conclude that impacts on groundwater resources at the LNG terminal site may occur, but would be minimized to the extent practicable, and would not be significant. Constructing and operating the pipeline could temporarily and/or permanently affect springs, seeps, and wells. These resources could experience changes in quantity (flow and volume) and quality (contamination due to the inadvertent release of equipment related fluids). To minimize impacts on these resources, Pacific Connector would implement measures described in its *Groundwater Supply Monitoring and Mitigation, SPCC Plan,* and *Contaminated Substances Discovery Plans.* Therefore, we conclude that constructing and operating the Project would not significantly affect groundwater resources.

5.1.3.2 Surface Water

Creating the LNG marine berth and access channel, as well as modifying the navigation channel would temporarily increase turbidity and sedimentation in Coos Bay, affecting overall water quality. The increased turbidity and sedimentation would occur as a result of initial dredging activities over varying distances depending on hydrological conditions and then again periodically in association with maintenance dredging. LNG carriers traversing the navigational channel and operating in the marine berth would not have a measurable effect on water quality other than a minor increase in turbidity along the bottom of the berth due to propeller wash. LNG carrier water withdrawals and discharges associated with ballast and normal engine operations during LNG loading would recirculate over 3 million gallons of water per hour. LNG carrier operations are not expected to significantly affect water quality (e.g., temperature, salinity, or dissolved oxygen levels) in Coos Bay.

The pipeline would be constructed across or in close proximity to 352 waterbodies; 270 intermittent streams and ditches, 69 perennial waterbodies, and several ponds and other surface water features. Pacific Connector developed a *Stream Crossing Risk Analysis* that, in conjunction with following their *Procedures*, would avoid and minimize impacts on waterbodies. Waterbodies would be crossed during low-flow periods whenever possible and within ODFW recommended in-water construction windows.

Pacific Connector would cross five major waterbodies (defined as those over 100 feet wide) including two crossings of Coos Bay and one at the Coos River using HDD methods and two locations on the South Umpqua River using DP and diverted open-cut methods. The Rogue River and Klamath River would also be crossed via HDD methods. Pacific Connector prepared an *HDD Contingency Plan and Failure Procedures* that describes measures to deal with HDD failure and contain an inadvertent release of drilling mud during the HDD process.

Other than the limited number of HDD, DP, bores, and one diverted open cut, all other crossings would use dry open-cut methods (including dam-and-pump and fluming). These methods would reduce the potential for turbidity from flowing water disturbance during active flow construction. Impacts from dry crossings would be temporary and localized, with most construction occurring at a single crossing within a 48-hour period.

The pipeline would cross three rivers listed on the Nationwide Rivers Inventory: the North Fork of the Coquille River, the East Fork of the Coquille River, and the South Umpqua River. The pipeline would cross the North Fork of the Coquille River (at about MP 23) and the East Fork of the Coquille River (at about MP 30) using a dry open-cut method. Pacific Connector proposes to use a DP and diverted open cut, respectively, at the two crossings of the South Umpqua River (at about MPs 71 and 95).

During construction, Pacific Connector would use a total of about 75,000 gallons per day of water for dust control. All required permits would be obtained prior to water use from both private and public water sources, which would stipulate allowable flow rates of withdrawal and discharge. Based on Jordan Cove's proposed dredging and vessel operation methods, Pacific Connector's proposed waterbody crossing and restoration methods, as well as the required impact avoidance and minimization measures (including implementation of erosion controls, water management plans, hazardous substance management procedure, and construction timing), we conclude that the Project would not result in significant impacts on surface water resources.

5.1.3.3 Wetlands

Constructing and operating the LNG terminal would affect about 86.1 acres of wetlands and result in the loss of about 22.3 acres of wetlands. Constructing and operating the pipeline would temporarily affect about 112.2 acres of wetlands and result in long-term impacts on about 5.8 acres of wetlands.

Jordan Cove and Pacific Connector developed a *Compensatory Wetland Mitigation Plan* to address unavoidable impacts on wetlands. Impacts on freshwater wetland resources would be mitigated via the Kentuck project site, and impacts on estuarine wetland resources would be mitigated via the Eelgrass Mitigation site and Kentuck project site (see Jordan Cove and Pacific Connector's *Compensatory Wetland Mitigation Plan*). These mitigation plans are still being reviewed by the COE, ODSL, and applicable federal and state agencies. Approval of these mitigation plans by these agencies would be required prior to the issuance of federal and state wetland permits.

Based on our review of the Project and Jordan Cove and Pacific Connector's implementation of measures to reduce impacts on wetlands, we conclude that constructing and operating the Project would not significantly affect wetlands.

5.1.4 Vegetation

Constructing and operating the Project would affect over 4,000 acres of vegetation. Over 2,000 acres of forested vegetation including about 773 acres of LSOG forest would be cleared and experience long-term and permanent impacts. However, most of the vegetation types affected by the Project are common and widespread in the region. The temporary and permanent clearing of vegetation would affect soils, wildlife, and water resources; would result in the creation of forest "edges"; and could increase the introduction and spread of exotic and invasive species. To reduce the impacts of clearing vegetation along the pipeline route, Pacific Connector would implement erosion control devices and numerous other measures as described in its *ECRP*, *Fire Prevention and Suppression Plan*, and its *Integrated Pest Management Plan.* Based on the types and amounts of vegetation that would be affected by the Project, the measures that would be implemented to avoid, minimize, and mitigate the resulting impacts, our recommendation for Pacific Connector to develop a final *Integrated Pest Management Plan*, and the abundance of similar vegetation in the affected watersheds, we conclude that constructing and operating the Project would have permanent but not significant impacts on vegetation.

5.1.5 Wildlife and Aquatic Resources

Over 600 species of terrestrial and aquatic wildlife including amphibians, reptiles, birds, fish, and mammals occur in the Project area. Constructing and operating the Project would temporarily and permanently affect these species. Wildlife would avoid and be displaced by construction activities and changes to habitat caused by the Project. Avoidance, displacement, and impacts on other behaviors as well as the loss of habitat would increase the rates of stress, injury, and mortality experienced by wildlife. Additionally, we concluded that operational noise from the LNG terminal may affect terrestrial and aquatic wildlife depending on their proximity to the terminal and each species' tolerance for increased noise. We also conclude that the LNG terminal would not significantly affect mammals currently occupying the North Spit. To further minimize impacts on wildlife and aquatic resources from terminal lighting, we are recommending that Jordan Cove document consultations with appropriate resource agencies and develop a final lighting plan, as well as develop a final *Fish Salvage Plan* and a *Hydrostatic Test Plan* that requires that any water withdrawal from a flowing stream does not exceed an instantaneous flow reduction of more than 10 percent of stream flow. Regarding potential impacts on wildlife and aquatic species due to increased marine traffic (and potential fuel and/or equipment fluid releases), we conclude that impacts on migratory birds and aquatic species would be low and not significant. We also conclude that entrainment and impingement from LNG carrier water intakes at the terminal would not have substantial adverse effects on any marine phase of aquatic resources (e.g., the juvenile stage of salmonids) or their food sources. With the exception of forested habitats and associated wildlife, impacts on wildlife and aquatic resources would generally be temporary. To minimize impacts on wildlife and aquatic resources, the applicants would implement numerous best management practices and impact avoidance and minimization measures. Therefore, based on the implementation of these measures, the characteristics of wildlife and aquatic species in the Project area, and the applicant's proposed construction and operation procedures and methods, we conclude that the Project would not significantly impact wildlife and aquatic resources.

5.1.6 Threatened, Endangered, and Other Special Status Species

The Project would be located across lands with habitats supporting 34 federally-listed and proposed threatened and endangered species. Based on surveys conducted by the applicants, our assessment of these species and impacts on them resulting from construction and operation of the Project, and in consultation with the FWS and NMFS, we have determined that the Project is not likely to adversely affect 21 of the 34 identified threatened and endangered species; and is likely to adversely affect 13 of the 34 identified threatened and endangered species. The threatened species MAMU, NSO, green sturgeon (Southern DPS), Pacific eulachon (Southern DPS), coho salmon (SONCC), coho salmon (Oregon Coast ESU), vernal pool fairy shrimp, and Kincaid's lupine are likely to be adversely affected. The endangered species Lost River sucker, shortnose sucker, Applegate's milk-vetch, and Gentner's fritillary are also likely to be adversely affected. The proposed threatened Pacific fisher (West Coast DPS) is also likely to be adversely affected. At this time, the applicants have not proposed measures to mitigate these impacts.

To ensure impacts on federally listed threatened and endangered species are sufficiently minimized, we are making several recommendations concerning noise, construction methods, and workspace. Whales may be affected by construction-related noise; therefore, we are recommending that Jordan Cove prepare a Marine Mammal Monitoring Plan that identifies the measures that would be implemented to reduce noise impacts and to ensure compliance with NMFS underwater noise criteria pertaining to listed whales. We are also recommending that Pacific Connector adhere to FWS-recommended timing restrictions concerning MAMU stands and NSO activity centers. Lastly, we are recommending that Pacific Connector prepare a Klamath Basin suckers fish salvage plan, and that workspace be eliminated to avoid impacts on Gentner's fritillary.

In compliance with Section 7 of the ESA, we are preparing a BA. This BA will be submitted to the FWS and the NMFS prior to the issuance of the final EIS. Along with the BA, we will request the initiation of formal consultation with the FWS and NMFS. The BA will be appended to the final EIS. The BA will request formal consultation with the FWS and NMFS. In response to our BA, the FWS and NMFS would then issue biological opinions where they will determine if the Project would likely jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. To ensure compliance with the ESA, we are recommending that construction not occur until consultation is complete. Concerning state-listed species and other species of concern, we conclude that constructing and operating the Project would not significantly affect these species.

5.1.7 Land Use

The Project would temporarily and permanently affect numerous land uses including managed and unmanaged forest, industrial/commercial (including utility), unmanaged (open), residential, agricultural (pasture, row crop, and other), recreational, timber, transportation (roads and highways), and range. The Project would also cross lands managed by the COE, Forest Service, BLM, and Reclamation. The LNG terminal site comprises primarily privately controlled land consisting of a combination of brownfield decommissioned industrial facilities, an existing landfill requiring closure, and open land. With the exception of a COE easement and BLM land crossed by the industrial wastewater pipeline (within an existing utility corridor), no federal lands would be affected at the LNG terminal site. The nearest residence to the LNG terminal is about 1.1 miles away. The pipeline would cross a mix of private and public lands, with privately owned lands making up about two-thirds and federal lands accounting for about one-third, with some state lands also crossed. The pipeline and/or associated workspaces would be located within 50 feet of seven residences. Impacts on residences would be minimized by the implementation of residential best management practices. Following construction, lands temporarily affected would be able to resume previous land uses. Some permanently affected lands would also be able to resume previous land uses (agriculture, unmanaged, and range), and other lands would be permanently converted to industrial/commercial use, precluding the resumption of previous land uses. Based on the impacts on land uses, we conclude that constructing and operating the Project would not significantly affect land use.

The Jordan Cove LNG Project as well as approximately 50 miles of the pipeline route would be within Oregon’s Designated Coastal Zone. The Project would need to obtain a finding from the ODLCD that the Project components within the coastal zone are consistent with the CZMA. To ensure compliance with the CZMA, we are recommending that construction not occur until the Project receives a consistency determination.

5.1.8 Recreation and Visual Resources

5.1.8.1 Recreation

Constructing and operating the Project could temporarily affect recreational use of areas located near the LNG terminal and pipeline. The Project could also affect nearby recreational services. Recreational areas near the LNG terminal could experience a temporary increase in noise. Some views from these areas would now include the LNG terminal and carriers. Individuals using recreational resources in the area could experience increased traffic and greater travel times. Visitors could also find that temporary accommodations (e.g., hotels, camp sites, and RV parks) in the Coos Bay area have less vacancy. During operation, recreational boaters may experience delays due to LNG carriers transiting to and from the LNG terminal; otherwise, no significant impacts are expected to occur to water-based recreation.

Visitors to recreation areas crossed by the pipeline would likely find construction to be an annoyance and an inconvenience; but this impact would be temporary. Recreational service providers may be affected if visitors avoid construction areas. However, due to the assembly line nature of pipeline construction, impacts on a specific area would generally be temporary as pipeline work in an area is completed and activities then move onto another area. Based on the expected impacts to recreation areas and services, we conclude that constructing and operating the Project would affect recreation; however, this effect would not be significant.

5.1.8.2 Visual Resources

The LNG terminal would be visible from numerous viewpoints within the North Bend/Coos Bay area. The most visible components of the LNG terminal would be the LNG storage tanks (180 feet tall) and nighttime lighting. Although adjacent properties have been developed and are currently being used for commercial purposes, the LNG terminal would be a major industrial facility considerably different from adjacent uses, and would permanently and significantly affect the visual character of Coos Bay's northern shoreline. Construction of the pipeline (use of heavy equipment and ground disturbance) and its impact on the viewshed would be temporary. Operation of the pipeline and the maintenance of an easement would permanently affect the viewshed; however, due to the remoteness of the Project area and the presence of other linear infrastructure, powerlines, highways, and roads, which have a similar impact on the viewshed, we conclude that construction and operation of the pipeline would not significantly affect visual resources.

5.1.9 Socioeconomics

Constructing and operating the Project would generate tax revenues for local and state governments. The Project would also create considerable temporary employment opportunities many of which may be filled by local workers. In addition, the purchasing of supplies and materials as well as use of other services would result in a temporary positive impact for local businesses. Constructing the Project would temporarily impact demand for housing (rental housing, hotel and motel rooms, and RV spaces) in the Project area. In the Coos Bay area, constructing both the LNG terminal and the pipeline would significantly impact demand for housing and could result in rent increases and displacement. To reduce this impact, Jordan Cove is constructing a temporary housing facility for contractors. However, we conclude that housing impacts in Coos Bay would experience a temporary significant impact. In other Project areas, housing would also be affected, but this effect would not be significant. The influx of an outside workforce into the Project area during construction would temporarily increase pressure on law enforcement (by increasing crime rates), fire protection, and medical services. Based on the temporary nature of the Project's impacts, we conclude that constructing and operating the Project would not significantly affect the socioeconomic character of the Project area.

With the applicant's proposed construction and operations procedures and mitigation measures in place, we conclude that constructing and operating the LNG and pipeline facilities are not expected to result in significant impacts on socioeconomic resources or services, with the exception of temporary housing availability during construction.

5.1.10 Transportation

Constructing the LNG terminal would require delivery vessels over a 2-year period via a mix of ocean-going vessels and barges. Once construction is complete, LNG carriers would transit to and from the terminal, increasing the total number of deep-draft vessels calling at Coos Bay. The anticipated increases in marine traffic combined with current deep-draft vessel traffic would be less than historic ship traffic through the channel and are, therefore, not expected to significantly affect other marine traffic in Coos Bay. During construction, motor vehicle traffic in the Coos Bay area would increase and, as a result, traffic and commute times in the area would also likely increase. To reduce these increases, Jordan Cove conducted a traffic study of the Coos Bay area and would implement numerous measures to reduce impacts on roadways and facilitate an efficient flow of vehicles. Additionally, during construction, work shifts would be staggered, permanent improvements to a key intersection would be made, manual flagging would be used, and off-site parking lots would be utilized (with workers transported to the site by bus). We have recommended that Jordan Cove entered into traffic development agreements with ODOT, Coos County, and the City of North Bend, as recommended in the *Traffic Impact Analysis* report Furthermore, the use of existing roads along the pipeline route to access construction work areas and to move construction equipment, materials, and personnel would temporarily affect these roadways; however, we conclude that, with mitigation measures in place to reduce impacts on roads and users, constructing and operating the Project would not result in significant impacts on transportation.

5.1.11 Cultural Resources

Cultural resource investigations for the Project are currently incomplete. Surveys that have been completed have identified sites in the vicinity that require monitoring during construction. Additionally, further testing has been recommended for some sites if avoidance cannot be achieved by the Project.

The FERC staff and the applicants have contacted Indian tribes that may attach religious or cultural importance to sites in the APE. We received comments from the CTCLUSI, Coquille, Cow Creek, Grand Ronde, Karuk, Klamath, and Yurok Tribes. The Coquille Tribe is a cooperating agency, while the others have filed motions to intervene. For both Projects (i.e., the Jordan Cove LNG Project and Pacific Connector Pipeline Project), a finalized ethnographic study is in the process of being completed by the applicants.

We have not yet completed the process of complying with Sections 101 and 106 of the NHPA. Additional cultural resource inventories, evaluations, and associated reports are yet to be completed. Consultations with tribes, SHPO, and applicable federal land-managing agencies have also not been concluded. We are recommending that Jordan Cove and Pacific Connector not construct or use any of their proposed facilities, including related ancillary areas for staging, storage, temporary work areas, and new or to-be-improved access roads, until all studies and consultations necessary to complete compliance with the NHPA have been completed. It is expected that the resolution of adverse effects through an MOA and implementation of treatment plans would mitigate impacts at affected historic properties to a less-than-significant finding, should the Project be approved by the Commission.

5.1.12 Air Quality and Noise

5.1.12.1 Air Quality

Air pollutants would be emitted as a result of both construction and operation of LNG marine traffic, the LNG terminal, the Pacific Connector pipeline, and aboveground facilities. During construction, a temporary reduction in ambient air quality may result from emissions and fugitive dust generated by construction equipment. Emissions from construction equipment would be temporary and would not result in a significant impact on regional air quality or result in any exceedance of applicable ambient air quality standards.

The Jordan Cove LNG Project is located in an air attainment area for federal air quality standards. In September 2017, Jordan Cove submitted an air quality permit application to the ODEQ. The Project's Type B state-only NSR permit application demonstrates that applicable requirements have been met. For all pollutants, the impacts at the points of highest concentration during operation of the Jordan Cove facilities are well below the applicable NAAQS and the PSD increments when combined with ambient air quality concentrations.

The Klamath Compressor Station and most of the pipeline route would be located in areas designated as attainment for all federal air quality standards, except for approximately 325 feet of pipeline route that would be located within the Klamath Falls PM_{10} maintenance area. Pacific Connector submitted a standard ACDP initial application to the ODEQ in May 2015, and submitted a revised application in September 2017. For all pollutants, the combined impacts at the points of highest concentration during operation of the Klamath Compressor Station are less than the applicable NAAQS.

Constructing and operating the Project would result in impacts on air quality; however, with implementation of BMPs, we conclude that these impacts would not be significant.

5.1.12.2 Noise

Noise would be generated as a result of both construction and operation of the LNG terminal and aboveground facilities associated with the Pacific Connector pipeline. The NSAs closest to the Jordan Cove LNG terminal are single-family homes in the city of North Bend (NSA1) about 1.3 miles south and directly across Coos Bay from the center of the proposed LNG terminal site and the Horsfall campground located approximately 1.2 miles northeast of the LNG terminal. Based on the large number of residents who live across Coos Bay, the impulsive (i.e., short and intense) noise impacts associated with pile-driving activities, the predicted and perceptible noise impacts on nearby NSAs, the duration of pile-driving activities, as well as the lack of noise mitigation measures proposed by Jordan Cove, we have recommended that Jordan Cove implement additional measures to minimize the noise impacts of pile driving on NSAs. With the implementation of the mitigation measures proposed, in addition to our recommendation, effects resulting from construction of the Jordan Cove LNG terminal would be temporary and would not result in significant impacts on nearby communities.

Operational noise from operating the LNG terminal is predicted to have a sound level below the FERC requirement of 55 dBA L_{dn}. However, we are recommending that Jordan Cove document that its facilities meet our noise standards by filing the results of a noise survey during operation that shows compliance with our noise requirement.

During the construction of the Pacific Connector Project, construction noise would be audible to NSAs near the construction right-of-way. Pipeline construction activities generally would be limited to daytime hours. Due to the assembly-line nature of pipeline construction, activities in any area could occur intermittently over a period lasting from several weeks to a few months. Noise from HDD drilling activities may be above our requirement of 55 dBA L_{dn} at some NSAs without mitigation. To make certain that the mitigation measures implemented at the HDD locations minimize noise at nearby NSAs, we recommend that Pacific Connector file a noise mitigation plan, monitor noise levels, and file weekly noise reports documenting compliance with our noise standard during the drilling activities.

Operation of the Klamath Compressor Station would result in noise impacts on nearby NSAs. In order to reduce these impacts, Pacific Connector would implement mitigation measures to reduce noise from the compressor station to meet our requirement of 55 dBA L_{dn} at nearby NSAs. To ensure that actual operational noise is at or below the predicted noise, and that there would be no significant impact to noise quality at the nearest NSAs, we are recommending that Pacific Connector file the results of a noise survey no later than 60 days after the compressor station is placed in service to demonstrate that noise at nearby NSAs does not exceed our standards. If that level is exceeded, Pacific Connector would need to install additional noise controls to meet that level.

Constructing and operating the Project would result in noise-related impacts; however, with implementation of mitigation measures as well as inclusion of the recommendations made in this EIS, we conclude that the Project would not result in significant noise-related impacts.

5.1.13 Reliability and Safety

As part of the NEPA review, Commission staff must assess whether the proposed facilities would be able to operate safely and securely. As a result of our technical review of the preliminary engineering design and our recommended mitigation, we believe that the facility design proposed by Jordan Cove includes acceptable layers of protection or safeguards that would reduce the risk of a potentially hazardous scenario from developing into an event that could impact the off-site public.

As a cooperating agency, the USDOT assists the FERC by determining whether Jordan Cove's proposed design would meet the USDOT's 49 CFR 193 Subpart B siting requirements. USDOT will provide a Letter of Determination on the Project's compliance with 49 CFR 193 Subpart B. This determination will be provided to the Commission as further consideration to the Commission on its decision to authorize or deny the Project. If the Project is authorized and constructed, the facility would be subject to the USDOT's inspection and enforcement program and final determination of whether a facility is in compliance with the requirements of 49 CFR 193 would be made by the USDOT staff.

As a cooperating agency, the Coast Guard analyzed the suitability of the waterway for LNG marine traffic. Based on its review and its own independent risk assessment, the Coast Guard has determined that the waterway could be made suitable for the type and frequency of LNG marine traffic associated with the proposed Jordan Cove LNG facility. This opinion was contingent upon the availability of additional measures necessary to responsibly manage the maritime safety and security risks. If appropriate resources are not in place prior to LNG carrier movement along the waterway, then the Coast Guard would consider at that time what, if any, vessel traffic and/or facility control measures would be appropriate to adequately address navigational safety and maritime security considerations.

Pacific Connector's pipeline would be built and inspected according to USDOT standards. These standards ensure pipeline safety.

5.1.14 Cumulative Impacts

Construction of the Project, in addition to other projects within the same geographic scopes crossed by the pipeline, would have cumulative impacts on a range of environmental resources, as discussed in section 4.14. We provided information about Project-related impacts and mitigation measures for specific environmental resources and were able to make some general assumptions about other federal projects identified in table 4.14.2.3-1. For the federal projects, there are laws and regulations in place that protect waterbodies and wetlands, threatened and endangered species, and historic properties, and limit impacts from air and noise pollution. Federal land-managing agencies, such as the BLM and Forest Service, have requirements in their LMPs to protect resources on the lands they manage. We have limited information about potential or foreseeable private projects in the region. For some resources, there are also state laws and regulations that apply to private projects. While there would be cumulative impacts on resources when all of the foreseeable projects are combined, the magnitude of that impact would be minimal at the landscape scale. Given the Project BMPs and design features, mitigation measures that would be implemented, federal and state laws and regulations protecting resources, and permitting requirements, we conclude that when added to other past, present, and reasonably foreseeable future actions, the Project, with two exceptions, would not result in significant cumulative impacts on environmental resources. Constructing the Project would result in a temporary significant cumulative impact on housing availability in Coos County and would also result in a permanent significant cumulative impact on the visual character of Coos Bay.

5.2 FERC STAFF'S RECOMMENDED MITIGATION

If the Commission authorizes the Project, we are recommending that the following measures be included as specific conditions in the Commission's Order. These measures would further mitigate the environmental impacts associated with the construction and operation of the proposed Project. The section number in parentheses at the end of a condition corresponds to the section number in which the measure and related resource impact analysis appears in the EIS.

1. Jordan Cove and Pacific Connector shall follow the construction procedures and mitigation measures described in its applications and supplemental filings (including responses to staff data requests), and as identified in the EIS, unless modified by the Order. Jordan Cove and Pacific Connector must:
    a. request any modification to these procedures, measures, or conditions in a filing with the Secretary;
    b. justify each modification relative to site-specific conditions;
    c. explain how that modification provides an equal or greater level of environmental protection than the original measure; and
    d. receive approval in writing from the Director of OEP **before using that modification**.

2. For the LNG terminal, the Director of OEP, or the Director's designee, has delegated authority to address any requests for approvals or authorizations necessary to carry out the conditions of the Order, and take whatever steps are necessary to ensure the protection of life, health, property, and the environment during construction and operation of the Jordan Cove LNG Project. This authority shall include:
    a. the modification of conditions of the Order;
    b. stop-work authority and authority to cease operation; and
    c. the imposition of any additional measures deemed necessary to ensure continued compliance with the intent of the conditions of the Order as well as the avoidance or mitigation of unforeseen adverse environmental impact resulting from project construction and operation.

3. For the pipeline facilities, the Director of OEP, or the Director's designee, has delegated authority to address any requests for approvals or authorizations necessary to carry out the conditions of the Order, and take whatever steps are necessary to ensure the protection of environmental resources during construction and operation of the Pacific Connector Pipeline Project. This authority shall allow:
    a. the modification of conditions of the Order;
    b. stop-work authority; and
    c. the imposition of any additional measures deemed necessary to ensure continued compliance with the intent of the conditions of the Order as well as the avoidance or mitigation of unforeseen adverse environmental impact resulting from project construction and operation activities.

4. **Prior to any construction,** Jordan Cove and Pacific Connector shall file an affirmative statement with the Secretary, certified by a senior company official, that all company personnel, EIs, and contractor personnel will be informed of the EI's authority and have been or will be trained on the implementation of the environmental mitigation measures appropriate to their jobs **before** becoming involved with construction and restoration activities.

5. The authorized facility locations shall be as shown in the EIS, as supplemented by filed site plans and alignment sheets, and shall include the route variations identified in conditions 16-19 below. **As soon as they are available, and before the start of construction,** Jordan Cove and Pacific Connector shall file with the Secretary any revised detailed site plan drawings and survey alignment maps/sheets at a scale not smaller than 1:6,000 with station positions for all facilities approved by the Order. All requests for modifications of environmental conditions of the Order or site-specific clearances must be written and must reference locations designated on these site plan drawings.

   For the pipeline, Pacific Connector's exercise of eminent domain authority granted under NGA Section 7(h) in any condemnation proceedings related to the Order must be consistent with these authorized facilities and locations. Pacific Connector's right of eminent domain granted under NGA Section 7(h) does not authorize it to increase the size of its natural gas pipeline or facilities to accommodate future needs or to acquire a right-of-way for a pipeline to transport a commodity other than natural gas.

6. Jordan Cove and Pacific Connector shall file with the Secretary detailed site plan drawings, alignment maps/sheets, or aerial photographs at a scale not smaller than 1:6,000, identifying all route realignments, facility relocations, changes in site plan layout, staging areas, pipe storage yards, new access roads and other areas that would be used or disturbed and have not been previously identified in filings with the Secretary. Approval for each of these areas must be explicitly requested in writing. For each area, the request must include a description of the existing land use/cover type, documentation of landowner approval, whether any cultural resources or federally listed threatened or endangered species would be affected, and whether any other environmentally sensitive areas are within or abutting the area. All areas shall be clearly identified on the maps/sheets/aerial photographs. Each area must be approved in writing by the Director of OEP **before construction in or near that area.**

   This requirement does not apply to route variations required by the Order, extra workspace allowed by the Commission's *Upland Erosion Control, Revegetation, and Maintenance Plan* and/or minor field realignments per landowner needs and requirements which do not affect other landowners or sensitive environmental areas such as wetlands.

   Examples of alterations requiring approval include all route realignments and facility location changes resulting from:

   a. implementation of cultural resources mitigation measures;

   b. implementation of endangered, threatened, or special concern species mitigation measures;

   c. recommendations by state regulatory authorities; and

d. agreements with individual landowners that affect other landowners or could affect sensitive environmental areas.

7. **Within 60 days of the acceptance of the Authorization/Certificate and before construction begins**, Jordan Cove and Pacific Connector shall each file an Implementation Plan with the Secretary for review and written approval by the Director of OEP. Jordan Cove and Pacific Connector must file revisions to the plan as schedules change. The plan shall identify:

   a. how Jordan Cove and Pacific Connector will implement the construction procedures and mitigation measures described in its application and supplements (including responses to staff data requests), identified in the EIS, and required by the Order;

   b. how Jordan Cove and Pacific Connector will incorporate these requirements into the contract bid documents, construction contracts (especially penalty clauses and specifications), and construction drawings so that the mitigation required at each site is clear to onsite construction and inspection personnel;

   c. the number of EIs assigned, and how the company will ensure that sufficient personnel are available to implement the environmental mitigation;

   d. company personnel, including EIs and contractors, who will receive copies of the appropriate material;

   e. the location and dates of the environmental compliance training and instructions Jordan Cove and Pacific Connector will give to all personnel involved with construction and restoration (initial and refresher training as the Project progresses and personnel change), with the opportunity for OEP staff to participate in the training session(s);

   f. the company personnel (if known) and specific portion of Jordan Cove's and Pacific Connector's organization having responsibility for compliance;

   g. the procedures (including use of contract penalties) Jordan Cove and Pacific Connector will follow if noncompliance occurs; and

   h. for each discrete facility, a Gantt or PERT chart (or similar Project scheduling diagram), and dates for:

      1. the completion of all required surveys and reports;

      2. the environmental compliance training of onsite personnel;

      3. the start of construction; and

      4. the start and completion of restoration.

8. Jordan Cove shall employ at least one EI for the LNG terminal and Pacific Connector shall employ a team of EIs for the pipeline facilities (i.e., at least one per construction spread or as may be established by the Director of OEP). The EIs shall be:

   a. responsible for monitoring and ensuring compliance with all mitigation measures required by the Order and other grants, permits, certificates, or authorizing documents;

b. responsible for evaluating the construction contractor's implementation of the environmental mitigation measures required in the contract (see condition 7 above) and any other authorizing document;

c. empowered to order correction of acts that violate the environmental conditions of the Order, and any other authorizing document;

d. a full-time position separate from all other activity inspectors;

e. responsible for documenting compliance with the environmental conditions of the Order, as well as any environmental conditions/permit requirements imposed by other federal, state, or local agencies; and

f. responsible for maintaining status reports.

9. Beginning with the filing of its Implementation Plan, Jordan Cove shall file updated status reports with the Secretary on a **monthly** basis for the LNG terminal and Pacific Connector shall file updated status reports with the Secretary on a **biweekly** basis for the pipeline facilities until all construction and restoration activities are complete. Problems of a significant magnitude shall be reported to the FERC **within 24 hours.** On request, these status reports will also be provided to other federal and state agencies with permitting responsibilities. Status reports shall include:

a. an update on Jordan Cove's and Pacific Connector's efforts to obtain the necessary federal authorizations;

b. Project schedule, including current construction status of the LNG terminal/each pipeline spread, work planned for the following reporting period, and any schedule changes for stream crossings or work in other environmentally-sensitive areas;

c. a listing of all problems encountered, contractor nonconformance/deficiency logs, and each instance of noncompliance observed by the EI during the reporting period (both for the conditions imposed by the Commission and any environmental conditions/permit requirements imposed by other federal, state, or local agencies);

d. a description of the corrective and remedial actions implemented in response to all instances of noncompliance, nonconformance, or deficiency;

e. the effectiveness of all corrective and remedial actions implemented;

f. a description of any landowner/resident complaints which may relate to compliance with the requirements of the order, and the measures taken to satisfy their concerns; and

g. copies of any correspondence received by Jordan Cove and Pacific Connector from other federal, state, or local permitting agencies concerning instances of noncompliance, and Jordan Cove's and Pacific Connector's response.

10. Pacific Connector shall develop and implement an environmental complaint resolution procedure, and file such procedure with the Secretary, for review and approval by the Director of OEP. The procedure shall provide landowners with clear and simple

directions for identifying and resolving their environmental mitigation problems/concerns during construction of the Project and restoration of the right-of-way. This procedure shall be in effect throughout the construction and restoration periods and two years thereafter. Prior to construction, Pacific Connector shall mail the complaint procedures to each landowner whose property will be crossed by the Project.

a. In its letter to affected landowners, Pacific Connector shall:

    1. provide a local contact that the landowners should call first with their concerns; the letter should indicate how soon a landowner should expect a response;

    2. instruct the landowners that if they are not satisfied with the response, they should call Pacific Connector's Hotline; the letter should indicate how soon to expect a response; and

    3. instruct the landowners that if they are still not satisfied with the response from Pacific Connector's Hotline, they should contact the Commission's Landowner Helpline at 877-337-2237 or at LandownerHelp@ferc.gov.

b. In addition, Pacific Connector shall include in its status report a copy of a table that contains the following information for each problem/concern:

    1. the identity of the caller and date of the call;

    2. the location by milepost and identification number from the authorized alignment sheet(s) of the affected property;

    3. a description of the problem/concern; and

    4. an explanation of how and when the problem was resolved, will be resolved, or why it has not been resolved.

11. Jordan Cove and Pacific Connector must receive written authorization from the Director of OEP before commencing construction of any Project facilities. To obtain such authorization, Jordan Cove and Pacific Connector must file with the Secretary documentation that it has received all applicable authorizations required under federal law (or evidence of waiver thereof).

12. Jordan Cove must receive written authorization from the Director of OEP **prior to introducing hazardous fluids into the Project facilities**. Instrumentation and controls, hazard detection, hazard control, and security components/systems necessary for the safe introduction of such fluids shall be installed and functional.

13. Jordan Cove must receive written authorization from the Director of OEP **before placing into service** the LNG terminal and other components of the Jordan Cove LNG Project. Such authorization will only be granted following a determination that the facilities have been constructed in accordance with the FERC approval, can be expected to operate safely as designed, and the rehabilitation and restoration of the areas affected by the Project are proceeding satisfactorily.

14. Pacific Connector must receive written authorization from the Director of OEP **before placing the pipeline into service.** Such authorization will only be granted following a

determination that rehabilitation and restoration of the right-of-way and other areas affected by the Pacific Connector Gas Pipeline Project are proceeding satisfactorily.

15. **Within 30 days of placing the authorized facilities in service**, Jordan Cove and Pacific Connector shall each file an affirmative statement with the Secretary, certified by a senior company official:

    a. that the facilities have been constructed in compliance with all applicable conditions, and that continuing activities will be consistent with all applicable conditions; or

    b. identifying which of the conditions of the Order Jordan Cove and Pacific Connector have complied with or will comply with. This statement shall also identify any areas affected by the Project where compliance measures were not properly implemented, if not previously identified in filed status reports, and the reason for noncompliance.

16. **Prior to construction,** Pacific Connector shall file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the Blue Ridge Variation into its proposed route between MP 11 and 25. (*section 3.4.2.2*)

17. **Prior to construction,** Pacific Connector shall file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the Survey and Manage Species Variation into the proposed route between MPs 111.5 and 111.6, and provide documentation of consultation with the Forest Service. (*section 3.4.2.7)*

18. **Prior to construction,** Pacific Connector shall file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the East Fork Cow Creek Variation into its proposed route between MPs 109.6 and 109.9, and provide documentation of consultation with the Forest Service. (*section 3.4.2.8)*

19. **Prior to construction,** Pacific Connector shall file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the Pacific Crest Trail Variation into the proposed route between MPs 166.4 and 168.1, and provide documentation of consultation with the Forest Service. (*section 3.4.2.9)*

20. **Prior to construction,** Pacific Connector shall file with the Secretary, for review and written approval by the Director of OEP, the final monitoring protocols and/or mitigation measures for all landslide areas that were not accessible during previous studies. (*section 4.1.2.4*)

21. **Prior to the end of the draft EIS comment period,** Pacific Connector shall consult with the ODEQ regarding existing soil and groundwater contamination at the sites listed in appendix G, and file the results of this consultation, along with any proposed site-specific soil or groundwater handling, management, and disposal procedures. *(section 4.2.2.2)*

22. **Prior to construction,** Pacific Connector shall file a revised *Integrated Pest Management Plan* with the Secretary, for review and written approval by the Director of

the OEP, that specifies that construction equipment will be cleaned after leaving areas of noxious weed infestations and prior to entering BLM-managed lands regardless of contiguous land owner. The revised plan shall also address BLM and Forest Service requirements related to monitoring of invasive plant species on federally managed lands, and documentation that the revised plan was found acceptable by the BLM and Forest Service. (*section 4.4.3.4*)

23. **Prior to construction,** Jordan Cove shall file with the Secretary, for review and written approval by the Director of OEP, its lighting plan. The plan shall include measures that will reduce lighting to the minimal levels necessary to ensure safe operation of the LNG facilities and any other measures that will be implemented to minimize lighting impacts on fish and wildlife. Along with its lighting plan, Jordan Cove shall file documentation that the plan was developed in consultation with the FWS, NMFS, and ODFW. This lighting plan shall also be in compliance with recommendation 59. (*section 4.5.1.1)*

24. **Prior to construction,** Pacific Connector shall file with the Secretary, for review and written approval by the Director of OEP, its final *Fish Salvage Plan*, that addresses methods suitable to collect and salvage all lamprey life stages, to the extent practical, together with documentation that the final *Fish Salvage Plan* was developed in consultations with interested tribes, ODFW, FWS and NMFS. The revised *Fish Salvage Plan* shall also incorporate the applicable measures of the Handling Guidelines for Klamath Basin Suckers. (*section 4.5.2.3*)

25. **Prior to construction**, Pacific Connector shall file with the Secretary, for review and written approval by the Director of OEP, a revised *Hydrostatic Test Plan* that requires that any water withdrawal from a flowing stream does not exceed an instantaneous flow reduction of more than 10 percent of stream flow. (*section 4.5.2.3*)

26. **Prior to construction**, Jordan Cove shall file with the Secretary, for review and written approval by the Director of OEP, a *Marine Mammal Monitoring Plan* that identifies how the presence of listed whales will be determined during construction, and measures Jordan Cove will take to minimize potential noise effects on whales and other marine mammals, and ensure compliance with NMFS underwater noise criteria for the protection of listed whales. *(section 4.6.1.1)*

27. **Prior to construction,** Pacific Connector shall file with the Secretary its commitment to adhere to FWS-recommended timing restrictions within threshold distances of MAMU and NSO stands **during construction, operations, and maintenance** of the pipeline facilities. *(section 4.6.1.2)*

28. **Prior to end of the draft EIS comment period,** Pacific Connector shall file with the Secretary revised alignment sheets that eliminate or relocate TEWA 128.01-W, TEWA 128.96-N, TEWA 142.07-N, and EAR-128.05. *(section 4.6.1.6)*

29. Jordan Cove and Pacific Connector **shall not begin construction until**:

    a. the Commission staff completes formal ESA consultations with the NMFS and FWS; and

b. Jordan Cove and Pacific Connector have received written notification from the Director of OEP that construction and/or implementation of conservation measures may begin. (*section 4.6.1.7*)

30. Jordan Cove and Pacific Connector **shall not begin construction** of the Project **until** they file with the Secretary a copy of the determination of consistency with the Coastal Zone Management Plan issued by the State of Oregon. (*section 4.7.1.2*)

31. **Prior to construction,** Jordan Cove shall file documentation that it has entered into development agreements with ODOT, Coos County, and the City of North Bend, as recommended in the *Traffic Impact Analysis* report. (*section 4.10.1.2*)

32. **Prior to construction of facilities and/or use of any staging, storage, temporary work areas, or new or to-be-improved access roads,** Jordan Cove and Pacific Connector shall file with the Secretary a revised Ethnographic Report describing sites of religious and cultural significance to Indian Tribes and other tribal information as outlined in the FERC staff's October 23, 2018 environmental information request #14, for the review of interested Indian tribes and the FERC staff, and for written approval by the Director of OEP. *(section 4.11.3.1)*

33. Jordan Cove and Pacific Connector shall **not begin construction of facilities and/or use** any staging, storage, or temporary work areas and new or to-be-improved access roads **until**:

    a. Jordan Cove and Pacific Connector each file with the Secretary:

        1. remaining cultural resources inventory reports for areas not previously surveyed;

        2. site evaluations and monitoring reports, as necessary;

        3. final HPMP with avoidance plans;

        4. final UDP; and

        5. comments on the cultural resources reports and plans from the SHPO, applicable federal land managing agencies, and interested Indian tribes.

    b. FERC affords the ACHP an opportunity to comment on the undertaking; and

    c. FERC staff reviews and the Director of OEP approves all cultural resources reports and plans, and notifies Jordan Cove and Pacific Connector in writing that treatment plans may be implemented and/or construction may proceed.

    All materials filed with the Commission containing location, character, and ownership information about cultural resources must have the cover and any relevant pages therein clearly labeled in bold lettering: "**CUI//PRIV - DO NOT RELEASE**." *(section 4.11.5*)

34. **Following the start of pile-driving activities,** Jordan Cove shall monitor daytime pile-driving and file **weekly** noise data reports with the Secretary that identify the noise impact on the nearest NSAs. If any measured daytime noise impacts (L_{max}) at the nearest NSAs are greater than 10 dBA over the L_{eq} ambient levels, Jordan Cove shall:

a. cease pile-driving activities and implement noise mitigation measures; and

b. file with the Secretary evidence of noise mitigation installation and request written notification from the Director of OEP that pile driving may resume. *(section 4.12.2.3)*

35. Jordan Cove shall conduct all pile-driving activities between the hours of 7 a.m. and 7 p.m. **throughout the duration of construction**. *(section 4.12.2.3)*

36. Jordan Cove shall file a full power load noise survey with the Secretary for the LNG terminal **no later than 60 days after** each liquefaction train is placed into service. If the noise attributable to operation of the equipment at the LNG terminal exceeds an L_{dn} of 55 dBA at the nearest NSA, **within 60 days** Jordan Cove shall modify operation of the liquefaction facilities or install additional noise controls until a noise level below an L_{dn} of 55 dBA at the NSA is achieved. Jordan Cove shall confirm compliance with the above requirement by filing a second noise survey with the Secretary **no later than 60 days** after it installs the additional noise controls. *(section 4.12.2.3)*

37. Jordan Cove shall file a full power load noise survey with the Secretary **no later than 60 days after placing the entire LNG terminal into service**. If a full load noise survey is not possible, Jordan Cove shall file an interim survey at the maximum possible horsepower load **within 60 days** of placing the LNG terminal into service and file the full operational surveys **within 6 months**. If the noise attributable to the operation of all the equipment of the LNG terminal exceeds 55 dBA L_{dn} at any nearby NSAs, under interim or full load conditions, Jordan Cove shall file a report on what changes are needed and install additional noise controls to meet the level **within 1 year** of the in-service date. Jordan Cove shall confirm compliance with this requirement by filing a second full power noise survey with the Secretary **no later than 60 days** after it installs the additional noise controls. *(section 4.12.2.3)*

38. **Prior to drilling activities at HDD sites,** Pacific Connector shall file a site-specific noise mitigation plan with the Secretary, for review and written approval by the Director of OEP. During any drilling operations, Pacific Connector shall implement the approved plan, monitor noise levels, and file in its biweekly reports documentation that the noise levels attributable to the drilling operations at NSAs does not exceed 55 L_{dn} dBA. (*section 4.12.2.4*)

39. Pacific Connector shall file a noise survey with the Secretary **no later than 60 days after placing the Klamath Compressor Station in service**. If a full load condition noise survey is not possible, Pacific Connector shall provide an interim survey at the maximum possible horsepower load and provide the full load survey **within six months**. If the noise attributable to the operation of all of the equipment at the Klamath Compressor Station under interim or full horsepower load conditions exceeds an L_{dn} of 55 dBA at any nearby NSAs, Pacific Connector shall file a report on what changes are needed and shall install the additional noise controls to meet the level **within one year** of the in-service date. Pacific Connector shall confirm compliance with the above requirement by filing a second noise survey with the Secretary **no later than 60 days** after it installs the additional noise controls. *(section 4.12.2.4)*

40. **Prior to end of the draft EIS comment period**, Jordan Cove shall file with the Secretary documentation of consultation with USDOT PHMSA staff as to whether the design wind speed for other non-hazardous buildings and structures would be subject USDOT PHMSA requirements. *(section 4.13.1.6)*

41. **Prior to the end draft EIS comment period**, Jordan Cove shall file with the Secretary an analysis that demonstrates the flammable vapor dispersion from design spills would be prevented from dispersing underneath the elevated LNG storage tanks, or the LNG storage tanks would be able to withstand an overpressure due to ignition of the flammable vapor dispersion cloud that disperses underneath the elevated LNG storage tanks. *(section 4.13.1.6)*

42. **Prior to initial site preparation**, Jordan Cove shall file with the Secretary documentation demonstrating it has received a determination of no hazard (with or without conditions) by USDOT FAA for all permanent structures, temporary construction equipment, and mobile objects that exceed the height requirements in 14 CFR 77.9. *(section 4.13.1.6)*

43. **Prior to construction of final design**, Jordan Cove shall file with the Secretary the following information, stamped and sealed by the professional engineer-of-record, registered in Oregon:

    a. site preparation drawings and specifications;

    b. LNG terminal structures, LNG storage tank, and foundation design drawings and calculations (including prefabricated and field constructed structures);

    c. seismic specifications for procured Seismic Category I equipment prior to the issuing of request for quotations;

    d. quality control procedures to be used for civil/structural design and construction; and

    e. a determination of whether soil improvement is necessary to counteract soil liquefaction.

    In addition, Jordan Cove shall file, in its Implementation Plan, the schedule for producing this information. *(section 4.13.1.6)*

44. **Prior to construction of final design,** Jordan Cove shall file with the Secretary consultation with USDOT PHMSA staff as to whether the use of normally closed valves to remove stormwater from curbed areas would meet USDOT PHMSA requirements. *(section 4.13.1.6)*

45. **Prior to commencement of service**, Jordan Cove shall file with the Secretary a monitoring and maintenance plan, stamped and sealed by the professional engineer-of-record registered in Oregon, which ensures the facilities are protected for the life of the LNG terminal considering settlement, subsidence, and sea level rise. *(section 4.13.1.6)*

Conditions 46 through 133 shall apply to the Jordan Cove LNG terminal. Information pertaining to these specific conditions shall be filed with the Secretary for review and written approval by the Director of OEP either: <u>prior to initial site preparation</u>; <u>prior to</u>

construction of final design; prior to commissioning; prior to introduction of hazardous fluids; or prior to commencement of service, as indicated by each specific condition. Specific engineering, vulnerability, or detailed design information meeting the criteria specified in Order No. 683 (Docket No. RM06-24-000), including security information, shall be submitted as critical energy infrastructure information (CEII) pursuant to 18 CFR 388.112. See Critical Energy Infrastructure Information, Order No. 683, 71 Fed. Reg. 58,273 (October 3, 2006), FERC Stats. & Regs. ¶ 31,228 (2006). Information pertaining to items such as offsite emergency response; procedures for public notification and evacuation; and construction and operating reporting requirements will be subject to public disclosure. All information shall be filed a minimum of 30 days before approval to proceed is required.

46. **Prior to initial site preparation**, Jordan Cove shall file an overall Project schedule, which includes the proposed stages of the commissioning plan. *(section 4.13.1.6)*

47. **Prior to initial site preparation**, Jordan Cove shall file procedures for controlling access during construction. *(section 4.13.1.6)*

48. **Prior to initial site preparation**, Jordan Cove shall file quality assurance and quality control procedures for construction activities for both the Engineering Procurement Contractor and Jordan Cove to monitor construction activities. *(section 4.13.1.6)*

49. **Prior to initial site preparation**, Jordan Cove shall specify a spill containment system around the Warm Flare Knockout Drum. *(section 4.13.1.6)*

50. **Prior to initial site preparation**, Jordan Cove shall develop an ERP (including evacuation) and coordinate procedures with the Coast Guard; state, county, and local emergency planning groups; fire departments; state and local law enforcement; and appropriate federal agencies. This plan shall include at a minimum:

    a. designated contacts with state and local emergency response agencies;

    b. scalable procedures for the prompt notification of appropriate local officials and emergency response agencies based on the level and severity of potential incidents;

    c. procedures for notifying residents and recreational users within areas of potential hazard;

    d. evacuation routes/methods for residents and public use areas that are within any transient hazard areas along the route of the LNG marine transit;

    e. locations of permanent sirens and other warning devices; and

    f. an "emergency coordinator" on each LNG marine vessel to activate sirens and other warning devices.

    Jordan Cove shall notify the FERC staff of all planning meetings in advance and shall report progress on the development of its ERP **at 3-month intervals**. *(section 4.13.1.6)*

51. **Prior to initial site preparation**, Jordan Cove shall file a Cost-Sharing Plan identifying the mechanisms for funding all Project-specific security/emergency management costs

that would be imposed on state and local agencies. This comprehensive plan shall include funding mechanisms for the capital costs associated with any necessary security/emergency management equipment and personnel base. Jordan Cove shall notify FERC staff of all planning meetings in advance and shall report progress on the development of its Cost Sharing Plan at **3-month intervals**. *(section 4.13.1.6)*

52. **Prior to construction of final design**, Jordan Cove shall file change logs that list and explain any changes made from the FEED provided in Jordan Cove LNG Project's application and filings. A list of all changes with an explanation for the design alteration shall be provided and all changes shall be clearly indicated on all diagrams and drawings. *(section 4.13.1.6)*

53. **Prior to construction of final design**, Jordan Cove shall file information/revisions pertaining to Jordan Cove's response numbers 8c, 13, 15, 21, 22, 23, 24, 26, 27, 28, and 31 of its December 20, 2018 filing and 6, 9, 10, 11, 17, 19, 32, 34, and 36 of its February 6, 2019 filing which indicated features to be included or considered in the final design. *(section 4.13.1.6)*

54. **Prior to construction of final design**, Jordan Cove shall file drawings and specifications for crash rated vehicle barriers at each facility entrance for access control. *(section 4.13.1.6)*

55. **Prior to construction of final design**, Jordan Cove shall file drawings of the security fence. The fencing drawings shall provide details of fencing that demonstrates it would restrict and deter access around the entire facility and has a setback from exterior features (e.g., power lines, trees, etc.) and from interior features (e.g., piping, equipment, buildings, etc.) that does not allow the fence to be overcome. *(section 4.13.1.6)*

56. **Prior to construction of final design**, Jordan Cove shall file drawings of internal road vehicle protections, such as guard rails, barriers, and bollards to protect transfer piping, pumps, compressors, hydrants, monitors, etc. to ensure that they are located away from roadway or protected from inadvertent damage from vehicles. *(section 4.13.1.6)*

57. **Prior to construction of final design**, Jordan Cove shall file security camera and intrusion detection drawings. The security camera drawings shall show the locations, areas covered, and features of each camera (e.g., fixed, tilt/pan/zoom, motion detection alerts, low light, mounting height, etc.) to verify camera coverage of the entire perimeter with redundancies for cameras interior to the facility to enable rapid monitoring of the facility, including a camera at the top of each LNG storage tank, and coverage within pretreatment areas, within liquefaction areas, within truck transfer areas, within marine transfer areas, and buildings. The drawings shall show or note the location of the intrusion detection to verify it covers the entire perimeter of the facility. *(section 4.13.1.6)*

58. **Prior to construction of final design**, Jordan Cove shall file lighting drawings. The lighting drawings shall show the location, elevation, type of light fixture, and lux levels of the lighting system and shall be in accordance with API 540 and provide illumination along the perimeter of the facility, process equipment, mooring points, and along

paths/roads of access and egress to facilitate security monitoring and emergency response operations. *(section 4.13.1.6)*

59. **Prior to construction of final design**, Jordan Cove shall file a plot plan of the final design showing all major equipment, structures, buildings, and impoundment systems. This lighting plan shall also be in compliance with recommendation 23. *(section 4.13.1.6)*

60. **Prior to construction of final design**, Jordan Cove shall file three-dimensional plant drawings to confirm plant layout for maintenance, access, egress, and congestion. *(section 4.13.1.6)*

61. **Prior to construction of final design**, Jordan Cove shall file up-to-date process flow diagrams (PFDs) and piping and instrument diagrams (P&IDs) including vendor P&IDs. The PFDs shall include heat and material balances. The P&IDs shall include the following information:

    a. equipment tag number, name, size, duty, capacity, and design conditions;

    b. equipment insulation type and thickness;

    c. storage tank pipe penetration size and nozzle schedule;

    d. valve high pressure side and internal and external vent locations;

    e. piping with line number, piping class specification, size, and insulation type and thickness;

    f. piping specification breaks and insulation limits;

    g. all control and manual valves numbered;

    h. relief valves with size and set points; and

    i. drawing revision number and date. *(section 4.13.1.6)*

62. **Prior to construction of final design**, Jordan Cove shall file P&IDs, specifications, and procedures that clearly show and specify the tie-in details required to safely connect subsequently constructed facilities with the operational facilities. *(section 4.13.1.6)*

63. **Prior to construction of final design**, Jordan Cove shall file a car seal philosophy and a list of all car-sealed and locked valves consistent with the P&IDs. *(section 4.13.1.6)*

64. **Prior to construction of final design**, Jordan Cove shall file information to demonstrate the EPC contractor has verified that all FEED HAZOP and LOPA recommendations have been addressed. *(section 4.13.1.6)*

65. **Prior to construction of final design**, Jordan Cove shall file a hazard and operability review prior to issuing the P&IDs for construction. A copy of the review, a list of the recommendations, and actions taken on the recommendations shall be filed. *(section 4.13.1.6)*

66. **Prior to construction of final design**, Jordan Cove shall provide a check valve upstream of the amine contractor column to prevent backflow or provide a a dynamic simulation that shows that upon plant shutdown, the swan neck would be sufficient for this purpose. *(section 4.13.1.6)*

67. **Prior to construction of final design**, Jordan Cove shall specify how Mole Sieve Gas Dehydrator support and sieve material would be prevented from migrating to the piping system. *(section 4.13.1.6)*

68. **Prior to construction of final design**, Jordan Cove shall specify how the regeneration gas heater tube design temperature would be consistent with the higher shell side steam temperatures. *(section 4.13.1.6)*

69. **Prior to construction of final design**, Jordan Cove shall specify a cold gas bypass around the defrost gas heater to prevent defrost gas heater high temperature shutdown during low flow and startup conditions. *(section 4.13.1.6)*

70. **Prior to construction of final design**, Jordan Cove shall demonstrate that the differential pressure (dp) level transmitters on the LNG flash drum would not result in an excess number of false high-high-high level shutdowns. *(section 4.13.1.6)*

71. **Prior to construction of final design**, Jordan Cove shall specify a means to stop LNG flows to the BOG suction drum when the BOG compressor is shutdown to prevent filling the BOG suction drum with LNG. *(section 4.13.1.6)*

72. **Prior to construction of final design**, Jordan Cove shall specify a low instrument air pressure shutdown to prevent loss of control to air operated valves. *(section 4.13.1.6)*

73. **Prior to construction of final design**, Jordan Cove shall evaluate and, if applicable, address the potential for cryogenic feed gas back flow in the event relief valve 30-PSV-01002A/B is open. *(section 4.13.1.6)*

74. **Prior to construction of final design**, Jordan Cove shall include LNG tank fill flow measurement with high flow alarm. *(section 4.13.1.6)*

75. **Prior to construction of final design**, Jordan Cove shall specify a discretionary vent valve on each LNG storage tank that is operable through the Distributed Control System (DCS). In addition, a car sealed open manual block valve shall be provided upstream of the discretionary vent valve. *(section 4.13.1.6)*

76. **Prior to construction of final design**, Jordan Cove shall file the safe operating limits (upper and lower), alarm and shutdown set points for all instrumentation (e.g., temperature, pressures, flows, and compositions). *(section 4.13.1.6)*

77. **Prior to construction of final design**, Jordan Cove shall file cause-and-effect matrices for the process instrumentation, fire and gas detection system, and emergency shutdown system. The cause-and-effect matrices shall include alarms and shutdown functions, details of the voting and shutdown logic, and set points. *(section 4.13.1.6)*

78. **Prior to construction of final design**, Jordan Cove shall file an up-to-date equipment list, process and mechanical data sheets, and specifications. The specifications shall include:

    a. building specifications (e.g., control buildings, electrical buildings, compressor buildings, storage buildings, pressurized buildings, ventilated buildings, blast resistant buildings);
    b. mechanical specifications (e.g., piping, valve, insulation, rotating equipment, heat exchanger, storage tank and vessel, other specialized equipment);
    c. electrical and instrumentation specifications (e.g., power system, control system, safety instrument system [SIS], cable specifications, other electrical and instrumentation); and
    d. security and fire safety specifications (e.g., security, passive protection, hazard detection, hazard control, firewater). *(section 4.13.1.6)*

79. **Prior to construction of final design**, Jordan Cove shall file a list of all codes and standards and the final specification document number where they are referenced. *(section 4.13.1.6)*

80. **Prior to construction of final design**, Jordan Cove shall file complete specifications and drawings of the proposed LNG tank design and installation. *(section 4.13.1.6)*

81. **Prior to construction of final design**, Jordan Cove shall file an evaluation of emergency shutdown valve closure times. The evaluation shall account for the time to detect an upset or hazardous condition, notify plant personnel, and close the emergency shutdown valve(s). *(section 4.13.1.6)*

82. **Prior to construction of final design**, Jordan Cove shall file an evaluation of dynamic pressure surge effects from valve opening and closure times and pump startup and shutdown operations. *(section 4.13.1.6)*

83. **Prior to construction of final design**, Jordan Cove shall demonstrate that, for hazardous fluids, piping and piping nipples 2 inches or less in diameter are designed to withstand external loads, including vibrational loads in the vicinity of rotating equipment and operator live loads in areas accessible by operators. *(section 4.13.1.6)*

84. **Prior to construction of final design**, Jordan Cove shall clearly specify the responsibilities of the LNG tank contractor and the EPC contractor for the piping associated with the LNG storage tank. *(section 4.13.1.6)*

85. **Prior to construction of final design**, Jordan Cove shall file the sizing basis and capacity for the final design of the flares and/or vent stacks as well as the pressure and vacuum relief valves for major process equipment, vessels, and storage tanks. *(section 4.13.1.6)*

86. **Prior to construction of final design**, Jordan Cove shall file an updated fire protection evaluation of the proposed facilities. A copy of the evaluation, a list of recommendations and supporting justifications, and actions taken on the recommendations shall be filed. The evaluation shall justify the type, quantity, and location of hazard detection and

hazard control, passive fire protection, emergency shutdown and depressurizing systems, firewater, and emergency response equipment, training, and qualifications in accordance with NFPA 59A (2001). The justification for the flammable and combustible gas detection and flame and heat detection systems shall be in accordance with ISA 84.00.07 or equivalent methodologies and would need to demonstrate 90 percent or more of releases (unignited and ignited) that could result in an off-site or cascading impact would be detected by two or more detectors and result in isolation and de inventory within 10 minutes. The analysis shall take into account the set points, voting logic, wind speeds, and wind directions. The justification for firewater shall provide calculations for all firewater demands based on design densities, surface area, and throw distance as well as specifications for the corresponding hydrant and monitors needed to reach and cool equipment. *(section 4.13.1.6)*

87. **Prior to construction of final design**, Jordan Cove shall file spill containment system drawings with dimensions and slopes of curbing, trenches, impoundments, and capacity calculations considering any foundations and equipment within impoundments, as well as the sizing and design of the down-comers. The spill containment drawings shall show containment for all hazardous fluids including all liquids handled above their flashpoint, from the largest flow from a single line for 10 minutes, including de-inventory, or the maximum liquid from the largest vessel (or total of impounded vessels) or otherwise demonstrate that providing spill containment would not significantly reduce the flammable vapor dispersion or radiant heat consequences of a spill. *(section 4.13.1.6)*

88. **Prior to construction of final design**, Jordan Cove shall file electrical area classification drawings. *(section 4.13.1.6)*

89. **Prior to construction of final design**, Jordan Cove shall provide documentation demonstrating adequate ventilation, detection, and electrical area classification based on the final selection of the batteries, and associated hydrogen off-gassing rates. *(section 4.13.1.6)*

90. **Prior to construction of final design**, Jordan Cove shall file drawings and details of how process seals or isolations installed at the interface between a flammable fluid system and an electrical conduit or wiring system meet the requirements of NFPA 59A (2001). *(section 4.13.1.6)*

91. **Prior to construction of final design**, Jordan Cove shall file details of an air gap or vent installed downstream of process seals or isolations installed at the interface between a flammable fluid system and an electrical conduit or wiring system. Each air gap shall vent to a safe location and be equipped with a leak detection device that shall continuously monitor for the presence of a flammable fluid, alarm the hazardous condition, and shut down the appropriate systems. *(section 4.13.1.6)*

92. **Prior to construction of final design**, Jordan Cove shall file complete drawings and a list of the hazard detection equipment. The drawings shall clearly show the location and elevation of all detection equipment. The list shall include the instrument tag number, type and location, alarm indication locations, and shutdown functions of the hazard detection equipment. *(section 4.13.1.6)*

93. **Prior to construction of final design**, Jordan Cove shall file a technical review of facility design that:

    a. identifies all combustion/ventilation air intake equipment and the distances to any possible flammable gas or toxic release; and

    b. demonstrates that these areas are adequately covered by hazard detection devices and indicates how these devices would isolate or shutdown any combustion or heating ventilation and air conditioning equipment whose continued operation could add to or sustain an emergency. *(section 4.13.1.6)*

94. **Prior to construction of final design**, Jordan Cove shall file a design that includes hazard detection suitable to detect high temperatures and smoldering combustion products in electrical buildings and control room buildings. *(section 4.13.1.6)*

95. **Prior to construction of final design**, Jordan Cove shall file an evaluation of the voting logic and voting degradation for hazard detectors. *(section 4.13.1.6)*

96. **Prior to construction of final design**, Jordan Cove shall file a list of alarm and shutdown set points for all hazard detectors that account for the calibration gas of the hazard detectors when determining the lower flammable limit set points for methane, ethylene, propane, isopentane, and condensate. *(section 4.13.1.6)*

97. **Prior to construction of final design**, Jordan Cove shall file a list of alarm and shutdown set points for all hazard detectors that account for the calibration gas of hazard detectors when determining the set points for toxic components such as condensate and hydrogen sulfide. *(section 4.13.1.6)*

98. **Prior to construction of final design**, Jordan Cove shall file a drawing showing the location of the emergency shutdown buttons. Emergency shutdown buttons shall be easily accessible, conspicuously labeled, and located in an area which would be accessible during an emergency. *(section 4.13.1.6)*

99. **Prior to construction of final design**, Jordan Cove shall file facility plan drawings and a list of the fixed and wheeled dry-chemical, hand-held fire extinguishers, and other hazard control equipment. Plan drawings shall clearly show the location by tag number of all fixed, wheeled, and hand-held extinguishers and shall demonstrate the spacing of extinguishers meet prescribed NFPA 10 travel distances. The list shall include the equipment tag number, type, capacity, equipment covered, discharge rate, and automatic and manual remote signals initiating discharge of the units and shall demonstrate they meet NFPA 59A. *(section 4.13.1.6)*

100. **Prior to construction of final design**, Jordan Cove shall file drawings and specifications for the structural passive protection systems to protect equipment and supports from cryogenic releases. *(section 4.13.1.6)*

101. **Prior to construction of final design**, Jordan Cove shall file calculations or test results for the structural passive protection systems to protect equipment and supports from cryogenic releases. *(section 4.13.1.6)*

102. **Prior to construction of final design**, Jordan Cove shall file drawings and calculations that demonstrate passive protection is provided in areas where jet fires may result in failure of structural supports. *(section 4.13.1.6)*

103. **Prior to construction of final design**, Jordan Cove shall file a detailed quantitative analysis to demonstrate that adequate thermal mitigation would be provided for each significant component within the 4,000 Btu/ft^2-hr zone from an impoundment, or provide an analysis that assesses the consequence of pressure vessel bursts and boiling liquid expanding vapor explosions. Trucks at the truck transfer station shall be included in the analysis. A combination of passive and active protection shall be provided and demonstrate the effectiveness and reliability. Effectiveness of passive mitigation shall be supported by calculations for the thickness limiting temperature rise and effectiveness of active mitigation shall be justified with calculations demonstrating flow rates and durations of any cooling water would mitigate the heat absorbed by the vessel. *(section 4.13.1.6)*

104. **Prior to construction of final design**, Jordan Cove shall file an evaluation and associated specifications and drawings of how they would prevent cascading damage of transformers (e.g., fire walls or spacing) in accordance with NFPA 850 or equivalent. *(section 4.13.1.6)*

105. **Prior to construction of final design**, Jordan Cove shall file facility plan drawings showing the proposed location of the firewater and any foam systems. Plan drawings shall clearly show the location of firewater and foam piping, post indicator valves, and the location and area covered by, each monitor, hydrant, hose, water curtain, deluge system, foam system, water-mist system, and sprinkler. All areas of the pretreatment area shall have adequate coverage. The drawings shall also include piping and instrumentation diagrams of the firewater and foam systems. *(section 4.13.1.6)*

106. **Prior to construction of final design**, Jordan Cove shall specify that the firewater pump shelter is designed to allow removal of the largest firewater pump or other component for maintenance with an overhead or external crane. *(section 4.13.1.6)*

107. **Prior to construction of final design**, Jordan Cove shall demonstrate that the firewater storage tanks are in compliance with NFPA 22 or demonstrate how API Standard 650 provides an equivalent or better level of safety. *(section 4.13.1.6)*

108. **Prior to construction of final design**, Jordan Cove shall specify that the firewater flow test meter is equipped with a transmitter and that a pressure transmitter is installed upstream of the flow transmitter. The flow transmitter and pressure transmitter shall be connected to the DCS and recorded. *(section 4.13.1.6)*

109. **Prior to construction of final design**, Jordan Cove shall file the settlement results during hydrostatic tests of the LNG storage containers and periodically thereafter to verify settlement is as expected and does not exceed the applicable criteria in API 620, API 625, API 653, and ACI 376. *(section 4.13.1.6)*

110. **Prior to construction of final design**, Jordan Cove shall file drawings of the storage tank piping support structure and support of horizontal piping at grade including pump columns, relief valves, pipe penetrations, instrumentation, and appurtenances. *(section 4.13.1.6)*

111. **Prior to construction of final design**, Jordan Cove shall file the structural analysis of the LNG storage tank and outer containment demonstrating they are designed to withstand all loads and combinations. *(section 4.13.1.6)*

112. **Prior to construction of final design**, Jordan Cove shall file an analysis of the structural integrity of the outer containment of the full containment LNG storage tank demonstrating it can withstand the radiant heat from a roof tank top fire or adjacent tank roof fire. *(section 4.13.1.6)*

113. **Prior to construction of final design**, Jordan Cove shall file a projectile analysis to demonstrate that the outer concrete impoundment wall of a full-containment LNG storage tank could withstand projectiles from explosions and high winds. The analysis shall detail the projectile speeds and characteristics and method used to determine penetration or perforation depths. *(section 4.13.1.6)*

114. **Prior to commissioning**, Jordan Cove shall file a detailed schedule for commissioning through equipment startup. The schedule shall include milestones for all procedures and tests to be completed: prior to introduction of hazardous fluids and during commissioning and startup. Jordan Cove shall file documentation certifying that each of these milestones has been completed before authorization to commence the next phase of commissioning and startup will be issued. *(section 4.13.1.6)*

115. **Prior to commissioning**, Jordan Cove shall file detailed plans and procedures for: testing the integrity of onsite mechanical installation; functional tests; introduction of hazardous fluids; operational tests; and placing the equipment into service. *(section 4.13.1.6)*

116. **Prior to commissioning**, Jordan Cove shall file settlement results from the hydrostatic tests of the LNG storage containers and shall file a plan to periodically verify settlement is as expected and does not exceed the applicable criteria set forth in API 620, API 625, API 653, and ACI 376. The program shall specify what actions would be taken after various levels of seismic events. *(section 4.13.1.6)*

117. **Prior to commissioning**, Jordan Cove shall file the operation and maintenance procedures and manuals, as well as safety procedures, hot work procedures and permits, abnormal operating conditions reporting procedures, simultaneous operations procedures, and management of change procedures and forms. *(section 4.13.1.6)*

118. **Prior to commissioning**, Jordan Cove shall file a plan for clean-out, dry-out, purging, and tightness testing. This plan shall address the requirements of the American Gas Association's Purging Principles and Practice, and shall provide justification if not using an inert or non-flammable gas for clean-out, dry-out, purging, and tightness testing. *(section 4.13.1.6)*

119. **Prior to commissioning**, Jordan Cove shall tag all equipment, instrumentation, and valves in the field, including drain valves, vent valves, main valves, and car-sealed or locked valves. *(section 4.13.1.6)*

120. **Prior to commissioning**, Jordan Cove shall file a plan to maintain a detailed training log to demonstrate that operating, maintenance, and emergency response staff have completed the required training. *(section 4.13.1.6)*

121. **Prior to commissioning**, Jordan Cove shall file the procedures for pressure/leak tests which address the requirements of ASME VIII and ASME B31.3. The procedures shall include a line list of pneumatic and hydrostatic test pressures. *(section 4.13.1.6)*

122. **Prior to introduction of hazardous fluids**, Jordan Cove shall complete and document a pre-startup safety review to ensure that installed equipment meets the design and operating intent of the facility. The pre-startup safety review shall include any changes since the last hazard review, operating procedures, and operator training. A copy of the review with a list of recommendations, and actions taken on each recommendation, shall be filed. *(section 4.13.1.6)*

123. **Prior to introduction of hazardous fluids**, Jordan Cove shall complete and document all pertinent tests (Factory Acceptance Tests, Site Acceptance Tests, Site Integration Tests) associated with the DCS and SIS that demonstrates full functionality and operability of the system. *(section 4.13.1.6)*

124. **Prior to introduction of hazardous fluids**, Jordan Cove shall develop and implement an alarm management program to reduce alarm complacency and maximize the effectiveness of operator response to alarms. *(section 4.13.1.6)*

125. **Prior to introduction of hazardous fluids**, Jordan Cove shall complete and document clean agent acceptance tests. *(section 4.13.1.6)*

126. **Prior to introduction of hazardous fluids**, Jordan Cove shall complete and document a firewater pump acceptance test and firewater monitor and hydrant coverage test. The actual coverage area from each monitor and hydrant shall be shown on facility plot plan(s). *(section 4.13.1.6)*

127. **Prior to introduction of hazardous fluids**, Jordan Cove shall complete and document foam system and sprinkler system acceptance tests. *(section 4.13.1.6)*

128. Jordan Cove shall file a request for written authorization from the Director of OEP **prior to unloading or loading the first LNG commissioning cargo**. After production of first LNG, Jordan Cove shall file weekly reports on the commissioning of the proposed systems that detail the progress toward demonstrating the facilities can safely and reliably operate at or near the design production rate. The reports shall include a summary of activities, problems encountered, and remedial actions taken. The weekly reports shall also include the latest commissioning schedule, including projected and actual LNG production by each liquefaction train, LNG storage inventories in each storage tank, and the number of anticipated and actual LNG commissioning cargoes, along with the

associated volumes loaded or unloaded. Further, the weekly reports shall include a status and list of all planned and completed safety and reliability tests, work authorizations, and punch list items. Problems of significant magnitude shall be reported to the FERC within 24 hours. *(section 4.13.1.6)*

129. **Prior to commencement of service**, Jordan Cove shall file a request for written authorization from the Director of OEP. Such authorization will only be granted following a determination by the Coast Guard, under its authorities under the Ports and Waterways Safety Act, the Magnuson Act, the MTSA of 2002, and the Security and Accountability For Every Port Act, that appropriate measures to ensure the safety and security of the facility and the waterway have been put into place by Jordan Cove or other appropriate parties. *(section 4.13.1.6)*

130. **Prior to commencement of service**, Jordan Cove shall notify the FERC staff of any proposed revisions to the security plan and physical security of the plant. *(section 4.13.1.6)*

131. **Prior to commencement of service**, Jordan Cove shall label piping with fluid service and direction of flow in the field, in addition to the pipe labeling requirements of NFPA 59A (2001). *(section 4.13.1.6)*

132. **Prior to commencement of service**, Jordan Cove shall provide plans for any preventative and predictive maintenance program that performs periodic or continuous equipment condition monitoring. *(section 4.13.1.6)*

133. **Prior to commencement of service**, Jordan Cove shall develop procedures for offsite contractors' responsibilities, restrictions, and limitations and for supervision of these contractors by Jordan Cove staff. *(section 4.13.1.6)*

In addition, conditions 134 through 137 shall apply throughout the life of the Jordan Cove LNG Project.

134. The facility shall be subject to regular FERC staff technical reviews and site inspections on at least an **annual** basis or more frequently as circumstances indicate. Prior to each FERC staff technical review and site inspection, Jordan Cove shall respond to a specific data request including information relating to possible design and operating conditions that may have been imposed by other agencies or organizations. Up-to-date detailed P&IDs reflecting facility modifications and provision of other pertinent information not included in the semi-annual reports described below, including facility events that have taken place since the previously submitted semi-annual report, shall be submitted. *(section 4.13.1.6)*

135. **Semi-annual** operational reports shall be filed with the Secretary to identify changes in facility design and operating conditions; abnormal operating experiences; activities (e.g., ship arrivals, quantity and composition of imported and exported LNG, liquefied and vaporized quantities, boil off/flash gas); and plant modifications, including future plans and progress thereof. Abnormalities shall include, but not be limited to, unloading/loading/shipping problems, potential hazardous conditions from offsite vessels, storage tank stratification or rollover, geysering, storage tank pressure

excursions, cold spots on the storage tank, storage tank vibrations and/or vibrations in associated cryogenic piping, storage tank settlement, significant equipment or instrumentation malfunctions or failures, non-scheduled maintenance or repair (and reasons therefore), relative movement of storage tank inner vessels, hazardous fluids releases, fires involving hazardous fluids and/or from other sources, negative pressure (vacuum) within a storage tank, and higher than predicted boil off rates. Adverse weather conditions and the effect on the facility also shall be reported. Reports shall be submitted **within 45 days after each period ending June 30 and December 31**. In addition to the above items, a section entitled "Significant Plant Modifications Proposed for the Next 12 Months (dates)" shall be included in the semi-annual operational reports. Such information would provide the FERC staff with early notice of anticipated future construction/maintenance at the LNG facilities. *(section 4.13.1.6)*

136. In the event the temperature of any region of the LNG storage container, including any secondary containment and imbedded pipe supports, becomes less than the minimum specified operating temperature for the material, the Commission shall be notified **within 24 hours** and procedures for corrective action shall be specified. *(section 4.13.1.6)*

137. Significant non-scheduled events, including safety-related incidents (e.g., LNG, condensate, refrigerant, or natural gas releases; fires; explosions; mechanical failures; unusual over pressurization; and major injuries) and security-related incidents (e.., attempts to enter site, suspicious activities) shall be reported to the FERC staff. In the event that an abnormality is of significant magnitude to threaten public or employee safety, cause significant property damage, or interrupt service, notification shall be made **immediately**, without unduly interfering with any necessary or appropriate emergency repair, alarm, or other emergency procedure. In all instances, notification shall be made to the FERC staff **within 24 hours**. This notification practice shall be incorporated into the liquefaction facility's emergency plan. Examples of reportable hazardous fluids-related incidents include:

a. fire;

b. explosion;

c. estimated property damage of $50,000 or more;

d. death or personal injury necessitating in-patient hospitalization;

e. release of hazardous fluids for 5 minutes or more;

f. unintended movement or abnormal loading by environmental causes, such as an earthquake, landslide, or flood, that impairs the serviceability, structural integrity, or reliability of an LNG facility that contains, controls, or processes hazardous fluids;

g. any crack or other material defect that impairs the structural integrity or reliability of an LNG facility that contains, controls, or processes hazardous fluids;

h. any malfunction or operating error that causes the pressure of a pipeline or LNG facility that contains or processes hazardous fluids to rise above its maximum allowable operating pressure (or working pressure for LNG facilities) plus the build-up allowed for operation of pressure-limiting or control devices;

i. a leak in an LNG facility that contains or processes hazardous fluids that constitutes an emergency;

j. inner tank leakage, ineffective insulation, or frost heave that impairs the structural integrity of an LNG storage tank;

k. any safety-related condition that could lead to an imminent hazard and cause (either directly or indirectly by remedial action of the operator), for purposes other than abandonment, a 20 percent reduction in operating pressure or shutdown of operation of a pipeline or an LNG facility that contains or processes hazardous fluids;

l. safety-related incidents from hazardous fluids transportation occurring at or en route to and from the LNG facility; or

m. an event that is significant in the judgment of the operator and/or management even though it did not meet the above criteria or the guidelines set forth in an LNG facility's incident management plan.

In the event of an incident, the Director of OEP has delegated authority to take whatever steps are necessary to ensure operational reliability and to protect human life, health, property, or the environment, including authority to direct the LNG facility to cease operations. Following the initial company notification, the FERC staff would determine the need for a separate follow-up report or follow up in the upcoming semi-annual operational report. All company follow-up reports shall include investigation results and recommendations to minimize a reoccurrence of the incident. *(section 4.13.1.6)*

Jordan Cove Energy Project, L.P.

Pacific Connector GAS PIPELINE

September 3, 2019

Ms. Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, D.C. 20426

Re: *Pacific Connector Gas Pipeline, LP* and *Jordan Cove Energy Project L.P.*
Docket Nos. CP17-494-000 and CP17-495-000
Supplemental Response to Comments on Draft Environmental Impact Statement

Dear Ms. Bose:

On September 21, 2017, Jordan Cove Energy Project L.P. ("JCEP") filed an application pursuant to Section 3(a) of the Natural Gas Act, as amended,[1] and Parts 153 and 380 of the regulations of the Federal Energy Regulatory Commission ("Commission"),[2] for authorization to site, construct, and operate certain liquefied natural gas facilities ("LNG Terminal"). On the same day, Pacific Connector Gas Pipeline, LP ("PCGP", and together with JCEP, "Applicants") filed an application pursuant to Section 7(c) of the NGA,[3] and Parts 157 and 284 of the Commission's regulations,[4] for a certificate of public convenience and necessity authorizing PCGP to construct, install, own, and operate a new natural gas pipeline ("Pipeline"). On March 29, 2019, the Commission Staff issued its Draft Environmental Impact Statement ("DEIS") for the Project, establishing a deadline for comments on the DEIS of July 5, 2019.

On July 22, 2019 Applicants submitted their initial response to certain of the comments regarding the DEIS. Applicants are submitting this supplemental response to assist the Commission in its review of all comments filed during the DEIS comment period as part of the preparation of the Final Environmental Impact Statement.

Attachment A

Supplemental Response to Comments on DEIS

Table of Contents

I. *Earthquakes and Tsunamis*

In the Applicants' response to certain of the comments on the DEIS on July 22, 2019, Applicants acknowledged numerous technical comments submitted by the Oregon Department of Geology and Mineral Industries ("DOGAMI") that merited a supplemental response to refute DOGAMI's claims.[5] As the following subsections demonstrate, the analysis reflected in the DEIS is based on current standards and methods and is appropriate and reasonable. DOGAMI's claims to the contrary are incorrect and misinformed. Other state agencies, such as the Oregon Department of Energy,[6] the Oregon Department of Environmental Quality,[7] and the Oregon Department of Land Conservation and Development,[8] have relied on DOGAMI's review and have included issues raised in many of DOGAMI's comments as a concern for permits being granted by each respective agency. Through this response, Applicants explain why the scope of the studies and the designs performed for the Project are accurate and appropriate.

The DEIS contains a comprehensive analysis of earthquake and tsunami risks, and it presents ample support for its main conclusions and recommendations—that (1) identified faults are not likely to cause offset at the LNG Terminal,[9] (2) the LNG Terminal's final design must include consideration of earthquake ground movement,[10] (3) tsunami design elevations are suitable for the LNG Terminal site,[11] and (4) the final Pipeline design must include final monitoring protocols and measures for all landslide areas that were not accessible during previous studies.[12]

In its general comments, DOGAMI claims that key portions of the DEIS were insufficiently prepared, and in some cases were wrong or inadequate, and that this raises questions about FERC's process in developing the DEIS.[13] DOGAMI attacks the DEIS's analysis, conclusions, and recommendations, claiming that the analysis is based on faulty data, faulty engineering, and faulty science. To the contrary, the studies and information that form the base of the analysis presented in the DEIS were prepared by professional engineers using the best modeling techniques available. Tsunami modelling was carried out by two separate engineering firms (Coast & Harbor Engineering and Moffatt & Nichol) using two independently developed, state-of-the-art models that analyzed multiple scenarios. These scenarios were then compared with DOGAMI and NOAA data to further verify results and conclusions for the design of the Project. GeoEngineers preformed the analysis for the Pipeline to develop its landslide analysis using LiDAR mapping and field verification methods that DOGAMI has accepted for other projects.

We strongly disagree with DOGAMI's numerous comments alleging a "lack of familiarity with seismic hazard assessment" and its disparagement of the licensed and qualified professionals

who contributed to the geohazard assessment and prepared the DEIS. FERC Staff reviewed the Applicants' data and analysis, and then used its own expertise and the expertise of other agencies to reasonably, and correctly, reach its conclusions and document those analyses and conclusions in the DEIS.

Many of these concerns rest on DOGAMI's uninformed presumption that JCEP and PCGP failed to address certain comments DOGAMI made on draft versions of the Applicants' resource reports, and not the actual final versions filed with FERC in September 2017. Furthermore, many of DOGAMI's specific comments on the DEIS simply repeat previously provided comments without any diligence to confirm whether the comments remain valid or necessary. For example, DOGAMI repeatedly attacks the DEIS and its underlying analysis for failing to employ LiDAR as a first step in characterizing hazards, but this ignores repeated references to the actual aerial photograph review, LiDAR interpretation, aerial reconnaissance, and ground-based reconnaissance that occurred. DOGAMI questions the design criteria, standards, and referenced studies used in the DEIS and its underlying analysis, but in many instances, DOGAMI fails to verify what standards actually apply, and what studies the DEIS actually uses in its analysis. And unfortunately, many of DOGAMI's comments are focused on isolated words and phrases, taken out of context and characterized as beneath the standard of care that would be employed by qualified professionals. The specific comments addressed below highlight several of these and explain why the DEIS and its underlying analysis contain a thorough review of potential hazards associated with the Project.

Moreover, it appears that DOGAMI has not actually reviewed the final resource reports provided to FERC. Thus, DOGAMI questions the scientific and engineering analyses relating to geologic hazards, but the Applicants understand that DOGAMI has not actually reviewed the underlying scientific and engineering analysis upon which the summaries in the DEIS were based. DOGAMI is aware that its comments were based on outdated reports. In November 2017, DOGAMI provided Applicants with its comments on the April and May 2017 draft versions of the resource reports, and these comments were filed to the FERC docket on December 4, 2017.[14] On December 20, 2017, the Applicants directed DOGAMI to the correct version of the resource reports.[15] Because certain of the scientific and engineering analysis appendices were filed under the FERC guidelines as Critical Energy Infrastructure Information and Controlled Unclassified Information that must be handled as privileged, the Applicants offered DOGAMI the opportunity to enter into a protective agreement to allow DOGAMI access to review the seismic hazard study and geotechnical investigation appendices. These appendices provide additional context to the public resource reports and answered many of the concerns that DOGAMI had raised. DOGAMI never entered into any protective agreement and, to Applicants' knowledge, has not reviewed the underlying studies and investigations that addressed DOGAMI's concerns. In preparing the DEIS, FERC based its analysis on the complete set of resource reports and appendices, and its conclusions are adequately documented.

[14] Comments of DOGAMI, Accession No. 20171204-5022 (Dec. 1, 2017).
[15] Response to DOGAMI Comment Letter of JCEP and PCGP, Accession No. 20171220-5157 (Dec. 20, 2017).

The following subsections address numerous of DOGAMI's specific comments and demonstrate the adequacy of the DEIS's analysis.

A. **Pipeline Seismic Hazard Evaluation**

DOGAMI claims that the pipeline seismic hazard evaluation presented in the DEIS is not sufficiently accurate or detailed.[16] For example, DOGAMI states that the assessment of major earthquake source zones should include intraplate earthquakes.[17] It is correct that the Cascadia subduction zone ("CSZ") is capable of generating both interplate and intraplate earthquakes. Since both originate from the CSZ, and since the DEIS discusses regional earthquakes from the CSZ, there is no deficiency in the analysis.[18] Section 3.2 of PCGP Resource Report 6 contains a more technical discussion of regional seismicity.

DOGAMI notes that major historic earthquakes are not described properly, citing a minor error in the number of events in the year 1873, and requesting a discussion of the completeness and length of record.[19] The DEIS reference to two large earthquakes in 1873 was based on a 2013 version of Resource Report 6, and the final resource report submitted in 2017 correctly reflected the most current data in Section 4.1.1.1, including reference to only one earthquake in the area in 1873. This Section 4.1.1.1 also covers historical seismicity. Magnitude ranges above 4 are of potential engineering significance to a buried pipeline, and the DEIS should be updated to include the current information provided in Section 4.1.1.1 of Resource Report 6.

DOGAMI claims that the assessment is based on an outdated statewide geologic map from 1991, and suggests that OGDC-6 should be used at a minimum.[20] The reference to this 1991 map in the DEIS is immediately followed by a sentence discussing 2009 and 2010 maps from the U.S. Geological Survey, making it plain that GeoEngineers did not base its assessment of geologically mapped faults on an outdated and very small scale statewide geologic map from 1991. The citations included in Section 4.1.2 in Resource Report 6 comprise the accurate and complete set of map references. Sources cited in the DEIS include the USGS Faults and Folds Database (USGS, 2014) DOGAMI mapping including Black and Madin 1995, Personius 2002, Mertzman et al 2007, Mertzman 2008, Hladky and Mertzman 2002, and GeoEngineers interpretation of route specific LiDAR (2015) and DOGAMI LiDAR (as of August 2017).[21] OGDC-6, which DOGAMI suggests, is not cited in the seismic hazards parts of the DEIS or in the underlying analysis in Resource Report 6 because it is not particularly helpful for locating faults. The USGS US Quaternary Fault Map offers the same traces, with more complete information, than DOGAMI's online product OregonHazVu.

[20] Oregon State Agencies Comments at p. 164.
[21] DEIS at p. 4-14.

DOGAMI states that faults should be mapped by study of the high-resolution LiDAR for the entire pipeline route.[22] PCGP agrees and commissioned GeoEngineers to complete a LiDAR fault evaluation of the USGS/DOGAMI Klamath area faults in 2017. Section 4.1.2 of Resource Report 6 describes the accurate and complete review of LiDAR data that supplements the USGS Quaternary fault database. Review of the LiDAR data available from DOGAMI is referenced in Section 4.1.2.3 of the DEIS.[23]

DOGAMI claims that historical seismicity in the Klamath Falls area is not accurately described.[24] Section 4.1.1.1 of Resource Report 6 provides an accurate and complete description of Klamath Basin seismicity. The DEIS narrative[25] is intended for a less technical audience and deliberately focuses on issues that are pertinent to pipeline design and construction.

DOGAMI alleges a lack of in-depth quantitative evaluation of the potential for earthquake induced landslides where expected ground shaking is high enough to potentially trigger such events.[26] Any of the areas identified as known or potential landslide hazard areas on the Geologic Hazards maps in Resource Report 6, Appendix F, could have the potential for being activated by earthquake induced ground shaking, but the potential hazard to the pipeline would not be substantially different than other significant landslide triggers, such as an intense rainfall event. The requested in-depth, quantitative evaluation for every slope along the Pipeline route that can experience strong ground shaking would be an extensive effort requiring subsurface data collection, soil and rock testing, and stability analyses throughout most of the 230-mile pipeline alignment. Subsurface data collection throughout the entire Pipeline alignment is not possible due to the physical limitations of accessing boring equipment to undeveloped right of way on timber covered slopes. The evaluations and mitigation plans provided are consistent with current engineering practice and FERC guidance.

DOGAMI claims that the DEIS overstates the conclusion that welded steel pipelines are not prone to failure during earthquakes.[27] This comment incorrectly characterizes the DEIS. The sentence DOGAMI attacks appears in a discussion on ground shaking,[28] with risks from permanent ground deformation being addressed in subsequent paragraphs. The DEIS clearly indicated potential hazards from seismically induced permanent ground deformation resulting from fault rupture and liquefaction. In particular, the DEIS identified and evaluated the locations of these seismic hazards in Section 4.1.2.3, and included recommendations to mitigate these hazards.[29]

B. **Ground Motion Issues**

DOGAMI submits numerous comments related to ground motion and requests a probabilistic ground motion study for the entire Pipeline using accurate up to date methods and data.[30] The DEIS analysis is already robust and informed on this topic. For example, DOGAMI questions inclusion of a discussion of the distinction between earthquake magnitude and ground motion, claiming that the concept is too basic to be included in an engineering seismology discussion for a major project.[31] Peak horizontal ground acceleration ("PGA") is addressed in Section 4.1.2.3 of the DEIS.[32] This discussion in the DEIS appears specifically intended to be accessible to a lay audience. As such, it includes statements that DOGAMI acknowledges to be correct to illuminate basic distinctions. The Pipeline, like all embedded structures, has Period T=0 seconds, which on an acceleration response spectrum corresponds to the PGA. No other spectral ordinates are important to the Pipeline.

Regarding probabilistic ground motion studies, this section of the DEIS also describes PGAs that have different probabilities of exceedance over different intervals and how they were used in the Probabilistic Seismic Hazard Assessment ("PSHA") for the Project. The second paragraph of this section explicitly cites the probabilistic seismic hazard mapping that the USGS performed and made available for use in building codes and non-building projects that have specific needs like this one.[33] The USGS National Seismic Hazard Maps, and specifically the PGA values, are the results of the USGS PSHA, which responds to DOGAMI's comment.

DOGAMI requests that the DEIS be modified to present the most current recurrence and probability data for Cascadia earthquakes.[34] Section 4.1.1.2 of Resource Report 6 discusses the Cascadia recurrence intervals from current sources. In addition, as discussed therein, Goldfinger et al 2013, 2017 provide the most recent estimates based on paleoseismology offshore. The USGS National Seismic Hazard Maps are the result of a probabilistic seismic hazard assessment that provides coverage for the entire Pipeline, thus meeting DOGAMI's request. Furthermore, the CSZ magnitude cited in DOGAMI's comment is, in fact, the range of magnitudes considered in the source model for seismic hazard curves for the different return periods described in the subsequent paragraph. They are obtained through de-aggregation of the USGS's probabilistic analyses. The large range of magnitude that DOGAMI comments on is inextricably linked to the range of considered recurrence intervals and the nature of probabilistic seismic hazard assessments. It would be incorrect to separate CSZ recurrence or probability from other seismic sources when computing probabilistic PGAs used as input to subsequent ground deformation analyses. DOGAMI requests analysis that is already described in this section of the DEIS and, with further detail, in Resource Report 6. DOGAMI's requests are superfluous. Moreover, DOGAMI's request to consider CSZ-related PGA separately from crustal-related PGA is incorrect.

[30] Oregon State Agencies Comments at pp. 165-167.
[31] Oregon State Agencies Comments at p. 165.
[32] DEIS at p. 4-13 (see paragraph 1).
[33] DEIS at p. 4-13 (see paragraph 2).
[34] Oregon State Agencies Comments at pp. 165-66.

DOGAMI claims that the USGS PSHA mapping for the Pipeline area is not applicable for the Project and that the citation to USGS National Seismic Hazard Map is wrong.[35] For the first claim, the published PSHA is appropriately applicable to this Project, as there is no need to duplicate the national standard PSHA for a pipeline. Regarding the citation, the citation to USGS 2009a (referring to a Quaternary fault and fold database) appears to be in error in the DEIS and in Resource Report 6, and this error should be corrected. However, this error does not support DOGAMI's overall claim that the authors of the analysis have an "apparent lack of familiarity with seismic hazard assessment procedures" and thus "may not be relied on to ensure public safety."

DOGAMI also cites other minor errors and typos to support its claim that the DEIS indicates a lack of familiarity with seismic hazard procedures. For example, DOGAMI notes that the site-specific PGA of 0.5g "does not make sense."[36] DOGAMI is correct that there is a typo in the referenced sentence, one that is easily clarified by referring to Table 2 in Section 4.1.1.4 of the cited Resource Report 6. We concur in recommending that this typo be corrected. The PGA values described in the DEIS and explicitly stated in Table 2 of Resource Report 6 are probabilistic values, as stated in the text.

DOGAMI also claims that the USGS NSHM 2014 PGA data should be used for the ground motion assessment.[37] DOGAMI's referenced USGS probabilistic hazard maps that have not yet been adopted into the Oregon building code. The value stated in the DEIS is based on USGS maps that were in effect at the time the report was prepared and that remain in effect as these responses are being written. The current Oregon Structural Specialty Code is considered an up-to-date method.

DOGAMI cites to a sentence discussing probabilistic ground motion and seismic intensity, claiming that there is no place in modern PSHA discussion for the conflation of the two concepts.[38] Rather than conflating the two concepts, the DEIS text simply creates a relatable point of access to a lay audience in its description of ground shaking and peak horizontal ground acceleration in Section 4.1.2.3.[39] Indeed, in the introductory sentence for this section, the DEIS specifically identifies that "earthquake magnitude and ground motion are two different parameters discussed in relation to CSZ events,"[40] and the DEIS does not conflate the two. With a 1,120-page DEIS, Applicants posit that there is abundant place in this modern PSHA to improve widespread comprehension.

DOGAMI claims that the probabilistic ground motion assessment of the LNG Terminal does not consider certain ground motion parameters that are essential to ensure public safety.[41] DOGAMI states that the DEIS lacks any discussion of structure performance issues in the event

[41] Oregon State Agencies Comments at p. 169.

of a 3 to 5 minute duration of shaking. JCEP completed a site-specific fault and seismic hazard analysis for the LNG Terminal in accordance with 18 CFR 380.12(h)(5). The LNG Terminal is designed to comply with, for example, the most stringent requirements given in ASCE7-05 and ASCE7-10. The LNG Storage Tanks must also satisfy Section 7.2.2 of NFPA 59A (2006).[42] Final design of the soil treatment and foundation design will be in accordance with the latest adopted codes and provided to FERC per recommendations 43 and 45 in Section 5.3 of the DEIS.[43]

DOGAMI questions the credibility of the analysis given a discussion in the DEIS on the correlation between PGA, Mercalli Intensity and Richter magnitude.[44] The DEIS clearly states in its discussion regarding PGA, Mercalli Intensity and Richter magnitude that it is not a direct comparison, but rather relies on an empirical correlation between the accelerations and scales.[45] The next paragraph of the DIES follows with FERC's identification of the seismic design category determination based on ASCE 7-10 and ASCE 7-16.

C. **Fault Identification**

DOGAMI claims that the DEIS's reliance on literature for identifying active faults is itself faulty, and DOGAMI requests that Applicants prepare a detailed evaluation of LiDAR along the Pipeline route for evidence of Quaternary fault followed by field investigation.[46] DOGAMI ignores language in the exact same sentence describing how LiDAR data from DOGAMI was reviewed and interpreted as part of the analysis[47]

DOGAMI also claims that the DEIS overlooks or ignores published information in a way that fails to ensure public safety because it fails to properly evaluate hazard associated with a particular fault near milepost 213 called the Adams Point fault.[48] First, the DEIS is not intended to represent an exhaustive account of the entirety of analysis performed for the geologic hazard evaluation for the Project as presented in Resource Report 6. Second, DOGAMI's claims about the Adams Point fault are incorrect, as it terminates east of the pipeline route as mapped by DOGAMI Open File Report 03-03 (2003). The nearby DOGAMI-mapped, inferred (buried) fault that crosses the route is the southeastern extension of the Stukel Mountain fault, the assessment of which is described in Section 4.1.2.1 of Resource Report 6 and summarized on the same page of the DEIS that DOGAMI cites in its comment.[49] Regarding the alleged oversight of the Adams Point fault near milepost 215, DOGAMI should review that section in Resource Report 6 and further find in Appendix J a summary of the site specific Seismic Reflection Survey of the fault crossing and in Appendix K the fault crossing pipe stress analysis and design. The site-specific geophysical study identified the fault crossing at milepost 212.8-212.9 consistent with the USGS interpreted trace (see Appendix F Geologic Hazards map 44 of 47). This is in contrast to the

DOGAMI (2003) buried fault trace that crosses the route at approximately milepost 213.8 to 213.9, which was not identified by the geophysical.[50]

DOGAMI claims that the evaluation of potentially active faults near the LNG Terminal is inaccurate and incomplete.[51] To the contrary, Section 4.13.1.5 of the DEIS refers to the design requirements of ASCE7-05, ASCE7-10 and NFPA 59A (2001 and 2006), which require site-specific investigation to account for seismicity of "known faults and sources" and "incorporate current seismic interpretations."[52] Applicants used the latest data (2014 USGS Seismic Hazard Maps) available at the time of design. DOGAMI further claims that the DEIS ignores the Charleston Fault.[53] DOGAMI is again incorrect, as the Charleston Fault is included in the 2014 USGS Seismic Hazard Maps and was not ignored in the PHSA. Additionally, no faults were found within the site during field investigations. Results of the site-specific fault and seismic analysis performed for the Project are discussed in Section 4.13.1.5 of the DEIS.[54] These site-specific investigations support the DEIS conclusion that identified faults are not likely to cause offset at the site.

D. **Liquefaction Issues**

DOGAMI claims there are scope-limiting assumptions that cause the liquefactions assessment of the Pipeline route to not adequately ensure public safety.[55] DOGAMI cites a phrase in the DEIS discussing water-saturated soils within the pipeline depth, and then claims that the analysis fails to address liquefaction at depths below the Pipeline trench. However, a plain language reading of the sentence reveals no scope-limiting assumption.[56] DOGAMI requests an analysis of liquefaction potential where the alignment crosses susceptible soils.[57] This precise analysis is discussed in the next paragraph in the DEIS, which describes the liquefaction susceptibility and lateral spreading analysis.[58] This part of the DEIS and Section 4.1.3 of Resource Report 6 present the results of the liquefaction hazards analysis for the entire pipeline alignment.

DOGAMI next claims the lack of references or supporting borehole, geotechnical, or geologic data for analysis of liquefaction potential at stream crossings.[59] GeoEngineers' liquefaction susceptibility evaluation used topography and soil conditions obtained from geological maps, NRCS soil surveys, and, at some sites, geotechnical boring data.[60] This level of detail is adequate for the DEIS to maintain accessibility to a lay audience. The detailed information that DOGAMI claims is missing is more fully provided in Section 4.1.3.2 of Resource Report 6.

---

[50] DEIS at p. 4-14.
[51] Oregon State Agencies Comments at p. 168.

[56] DEIS at p. 4-16.
[57] Oregon State Agencies Comments at p. 167.
[58] DEIS at p. 4-16, 4-17.
[59] Oregon State Agencies Comments at p. 168.
[60] DEIS at p. 4-16.

DOGAMI incorrectly claims that it is impossible to determine whether liquefaction potential assessments are adequate,[61] since the data DOGAMI seeks is provided in the resource report. Resource Report 6 includes a detailed, accurate, and comprehensive liquefaction hazard analysis and mitigation design. Appendix H includes supporting data. Data collection was designed using a multistage screening process. The initial desktop review identified 29 sites, which was winnowed to 20 for site-specific surface and subsurface data collection. Site-specific analyses that conform to the best practices outlined in the National Academies compilation were completed at 8 sites, and 4 of those were evaluated using fully coupled, time-domain, 2D dynamic nonlinear numerical simulation (Atlas Geotechnical 2018).[62] The liquefaction hazard analyses completed for this Project equals or exceeds the standard requested by DOGAMI.

DOGAMI claims that liquefaction hazards at the LNG Terminal receive only cursory treatment.[63] The DEIS specifically recognizes consideration of liquefaction as a key design element for the LNG Terminal[64] and includes a recommendation to specifically require the final design for soil stabilization and foundation design be submitted to the Commission prior to construction.[65] A detailed description of the liquefaction triggering analysis and the methods used in the analysis are provided in Appendix J13.4 of Resource Report 13. The liquefaction triggering analysis applies the recommendations of the National Academies Liquefaction Study Report (NALSR 2016). The final terminal soil stabilization and foundation design will be provided as noted in Staff recommendation 45 in Section 5.2 of the DEIS.[66] This design will be compliant with current codes. As of this date, the 2017 FERC Guidelines require compliance with ASCE 7-05, and the 2014 Oregon Structural Specialty Code (OSSC) requires compliance with ASCE 7-10. Therefore, ASCE 7-05 and ASCE 7-10 are the most current standards required for compliance with the FERC guidelines and applicable building codes in the State of Oregon.

E. **Tsunami Issues**

DOGAMI is concerned that the tsunami analysis and modeling assumptions, results, and mitigation are not clearly documented for runup elevations or subsidence.[67] The DEIS discussion summarizes FERC Staff's evaluation of the modeling provided by JCEP and its independent verification with NOAA and others to confirm the validity of the design.[68] JCEP's modeling was performed by professional engineers recognized as industry experts. The initial Project tsunami modeling was performed by Coast & Harbor Engineering using the SELFE hydrodynamic model. This model is the same model used by DOGAMI. Additionally, JCEP retained Moffatt & Nichol to perform an independent analysis that incorporates the newly available ASCE 7-16 chapter regarding tsunami design. Moffatt & Nichol selected the Mike 21 model suite developed by the

Danish Hydraulic Institute. Data from each of the models plus the DOGAMI published inundation data and the NOAA data provided in the ASCE Tsunami Design Geodatabase were compared and found to show correlation of the design elevation for the site.[69] FERC Staff worked with NOAA, who helped developed Tsunami maps for ASCE 7-16, and NOAA determined that inundation elevations from the MCT event for the LNG Terminal site were consistent with those determined by JCEP. Therefore, FERC Staff correctly agreed in the DEIS that the tsunami elevations that JCEP provided are suitable for the Project site.[70]

Furthermore, the initial modeling methodology and assumptions were coordinated with DOGAMI and FERC.[71] These design assumptions and design factors were used in the SELFE Model[72] and the Mike 21 Model:[73]

- 2,475-year event consistent with a DOGAMI fault scenario L1
- Ground elevations modeled from C-Map, USACE, USGS, site topography surveys, and the proposed ground elevation design of the site[74]
- Initial water surface elevation, MHW Charleston, OR NOAA station +6.46' NAVD88[75]
- Subsidence 7.6' (obtained from DOGAMI deformation grids)[76]
- Modeled wave height increased by factor of 1.3[77]
- Added 1' of freeboard to the adjusted surface elevation

The DEIS notes the assertion that tsunami protection berms, safety critical elements of the facility, point of support elevations, invert levels and underside of essential equipment, would be at least 1 foot above the estimated maximum run-up elevation and most will be far above that elevation.[78] The elevations of the major equipment and areas are clearly detailed and summarized

for the marine facilities, LNG tanks, process areas, impoundment floors, utilities, and building in JCEP Resource Report 13, Table 13.2-1 through Table 13.2-6. Furthermore, provisions for life safety are described in Section 13.39.1.7 of Resource Report 13, describing tsunami evacuation muster points (TEMPs) within the bounds of the LNG Terminal and South Dunes. The elevation of each muster point was determined to maintain an elevation at least equal to the inundation due to a 2,475-year event + 10ft or a 10,000-year event, whichever is greater. The 2,475 year and 10,000-year events are based upon the DOGAMI rupture scenarios L1 and XXL1.

F. **Landslide Issues**

DOGAMI attacks the DEIS statement that landslides can usually be identified on topographical maps or aerial photos based on distinctive contour or vegetative patterns.[79] DOGAMI claims that LIDAR is the only definitive method for finding deep slides in western Oregon.[80] DOGAMI ignores that the cited DEIS reference explicitly states that "topographic maps" was defined as including LiDAR.[81] Furthermore, Section 4.5 of Resource Report 6 provides a detailed description of the landslide mapping process for the entire proposed Pipeline alignment using LiDAR hillshade imagery. Section 4.5.3.4 of Resource Report 6 confirms this, explaining that LiDAR was the primary tool for identifying topographic indicators of landsliding because it can reveal fine details of the landscape. DOGAMI refers to comparison of remote sensitive datasets,[82] but multiple data sets of LiDAR for comparison purposes were not available as of the submittal of Resource Report 6. Moreover, DOGAMI's statement that LiDAR is the only definitive method is itself a misstatement of the conclusions drawn from the Oregon LiDAR pilot study. As stated in SP42 (2009), the conclusion of the LiDAR pilot study was that LiDAR was overwhelmingly better than other available remote sensing data sets. LiDAR is not the only method, nor is it definitive. It is, however, appropriate for use in this analysis, and indeed was used in this hazard assessment.

DOGAMI questions the DEIS analysis of shallow-rapid landslides, where the DEIS states that shallow-rapid landslides are more likely to expose the pipe and result in a loss of support where it crosses a debris slide source area. DOGAMI claims that if the pipe is at the surface, a shallow slide could run into the pipe, and DOGAMI asks that situations where this occurs be defined.[83] DOGAMI appears to misunderstand the issue presented. The statement in the DEIS indicates that shallow-rapid landslides are unlikely to induce long-term strain to a pipeline. As the name of these types of landslides indicates, they are characterized as "rapid." As such, their movement occurs rapidly and typically does not induce strain "long-term." The DEIS discussion goes on to explain that once mobilized into a debris flow, shallow-rapid landslides often have tremendous erosional potential, and that debris flows that originate upslope of the pipeline also have the potential to scour, expose and damage the pipeline by impact.[84] DOGAMI's proposed resolution of this issue—defining situations where shallow slides could run into the pipe, is nonsensical. Pipelines are buried specifically to reduce their exposure to mechanical damage

[84] DEIS at p. 4-19.

including from landslides. Although it is technically true that an above-grade pipeline would be susceptible to impact, PCGP has not proposed to install an above-grade pipeline. Surface facilities, where they exist, are sited away from or protected against debris flows.

DOGAMI attacks the DEIS for relying on the Statewide Information Database for Oregon ("SLIDO"), a compilation of published data, claiming that the compilation ranges from very poor older data from decades ago to the best available modern LiDAR-based data, and DOGAMI requests site-specific evaluations using LiDAR data in order to complete Phase 1 landslide identification.[85] However, the section of the DEIS that DOGAMI references makes no mention of SLIDO data being used.[86] As indicated in the referenced sentence, LiDAR hillshade imagery was used in conjunction with aerial imagery for Phase 1 landslide identification. This is confirmed in Section 4.5.3.4 of Resource Report 6, noting that LiDAR was the primary tool for identifying topographic indicators of landsliding because it can reveal fine details of the landscape.

Similarly, DOGAMI attacks the DEIS analysis, which mentions using the Potential Rapidly Moving Landslide Hazards in Western Oregon (Hofmeister et al. 2002) in PCGP's initial risk assessment.[87] DOGAMI notes that this resource is a preliminary screening tool and, because it is based on outdated datasets, site-specific evaluations including modern methods should be completed using LiDAR data in order to evaluate areas that have potential for shallow landslides.[88] As reflected in the DEIS and the supporting data, the resource DOGAMI suggests should only be used as a preliminary screening tool was indeed only used as a preliminary screening tool. And the modern LiDAR based methods that DOGAMI says should be used were indeed used. Section 4.5.3.4 of Resource Report 6 explains that LiDAR was the primary tool for identifying topographic indicators of landsliding because it can reveal fine details of the landscape. Potential RML hazards were further evaluated based on aerial and ground-based reconnaissance as described in Section 4.1.2.4 of the DEIS and Section 4.5.5 of Resource Report 6.[89]

In other locations, DOGAMI similarly attacks the DEIS analysis, asserting that its conclusions should be supported by modern references and that site-specific evaluations should be completed using LiDAR data to evaluate areas that have potential for shallow landslides.[90] The language that DOGAMI attacks, a discussion of PCGP's analysis along the proposed route, is based on "modern" LiDAR data. Moreover, site specific evaluations were completed based on aerial and ground-based reconnaissance as described in Section 4.5.5 of Resource Report 6.

DOGAMI claims that discussion of areas of potential ground-shaking that might initiate landslides is too limited in scope because it only mentions the Klamath Falls region and the Coos Bay region.[91] DOGAMI states that ground motion maps predict effects much further inland than just the Coos Bay region., and because the entire pipeline route is in a high seismic zone, the

[89] DEIS at p. 4-19, 4-20; PCGP Resource Report 6 at p. 34, Accession No. 20170921-5142 (Sept. 21, 2017).
[90] Oregon State Agencies Comments at p. 182.
[91] Oregon State Agencies Comments at p. 184.

analysis should be revised to reflect that.[92] Table 2 in the main body of Resource Report 6 summarizes ground shaking amplitude along the entire alignment. The term "Coos Bay region" correctly describes the part of the alignment susceptible to ground shaking sufficiently intense to initiate landslides or rockfalls. This statement is consistent with the statement in the opening paragraph of this DEIS section noting that strong ground shaking associated with an earthquake may induce landslide failures at great distances from the earthquake source.[93]

DOGAMI isolates one sentence in the DEIS's landslide discussion—noting that six landslides were identified as posing a moderate to high potential risk and were evaluated further in the field—and claims that this number of landslides is very low compared to what has been recently mapped in areas just north of the pipeline route using LiDAR based mapping.[94] DOGAMI then recommends that the landslide analysis be based on LiDAR data.[95] DOGAMI takes the statement out of context and fails to acknowledge the full breadth of the landslide hazard assessment described in Section 4.5 of Resource Report 6. GeoEngineers identified hundreds of deep-seated landslides and shallow rapid landslide hazards along the PCGP alignment using LiDAR data as well as other published sources, including data from DOGAMI. This is clearly presented in the DEIS, which states that Appendix B, Table B-2 from GeoEngineers (2017a) identified where PCGP's initial proposed route was changed to avoid identified landslides and landslide hazard areas.[96] Table B-2 lists 128 deep-seated landslides identified along the PCGP study corridor. After an iterative routing process to avoid the vast majority of the identified landslides, six landslides were identified as potentially posing a moderate to high risk to the proposed pipeline and were evaluated further in the field. DOGAMI's implication that mapped landslides are ignored in the analysis, and that LiDAR data was not appropriately used, is baseless.

In more than one instance, DOGAMI questions the DEIS's use of qualifiers, such as "generally" and "infrequently," and requests citations to support the statements. In one instance, DOGAMI focuses on an assertion that the mass-movement of rapid-shallow landslides is typically triggered by large, infrequent storm events.[97] DOGAMI notes that "infrequent" is a relative term and asks that it be defined, and the conclusion referenced. DOGAMI similarly attacks the DEIS statement that ridgetops are generally considered to be stable, noting that recent mapping in the coast range has found landslides propagating to and over the ridges.[98] Not all statements that are based on professional judgment and experience require substantiation with peer reviewed citations. In the first instance, because the concept of exceedance intervals is uncommon outside of risk assessment discussions, the word "infrequent" was selected to increase the narrative's accessibility to a lay audience. Quite simply, light rain occurs more frequently than potentially damaging heavy rain. In the second instance, the word "generally" was selected to express the sentiment that this statement is not a rule, and as is the case with all general statements, exceptions may occur.

[97] Oregon State Agencies Comments at p. 182.
[98] Oregon State Agencies Comments at pp. 185 and 186.

DOGAMI questions the DEIS statements that all of the moderate- and high-hazard deep-seated landslides identified along the alignment, and all known hazardous landslides thought to pose a risk to the pipeline, were avoided.[99] DOGAMI asserts that if LiDAR and site-specific landslide hazard mapping was not performed to locate these areas, there are likely many areas missed, and therefore not "all" are identified or avoided.[100] DOGAMI cites an example in the LiDAR image of the route from MP 89 to 90, where the PCGP mapping in Appendix F identified one landslide on the northeast side of the route ridge. DOGAMI asserts that a qualified professional could see on the LiDAR image that landslides are located along both sides of the ridge and on the slope down to the valley towards the northwest.[101]

In rebuttal to this DOGAMI comment, first, Section 4.1.2.4 of the DEIS clearly states that LiDAR was utilized to map and evaluate landslide hazards along the PCGP alignment,[102] and DOGAMI's repeated implications that it was not are baseless. Furthermore, site-specific mapping and site-specific ground-based reconnaissance were also completed. Second, it is unclear what features in the clipped LiDAR image DOGAMI is referring to as landslides. Interpretation of LiDAR imagery requires professional judgment and experience, and landslides mapped using LiDAR interpretation should be ground-truthed. The landslides here were mapped following a comprehensive assessment based on aerial photograph review, LiDAR interpretation, aerial reconnaissance, and ground-based reconnaissance. DOGAMI's comment reflects a preference for relying on interpretation of landslide presence based solely on remote sensing LiDAR imagery, presented as fact, without any additional confirmation in the field. A qualified professional would qualify such interpretations and conclusions with appropriate limitations.

DOGAMI commented on the DEIS statement regarding PCGP's proposed use of Best Management Practices ("BMPs") like well-drained structural fill to limit potential adverse impacts on slope stability for those side slopes segments that are less than 30 percent gradient.[103] DOGAMI claims that focusing on slope gradient alone is insufficient since many deep landslides are on slopes with very low gradients. DOGAMI instead suggests that existing landslides and hazards be located and addressed individually, regardless of slope gradient. DOGAMI misunderstands the discussion regarding the use of slope gradients.[104] The use of slope gradients is not to identify where landslides occur but is used to guide the implementation of BMPs like structural fill to restore the construction corridor to original site grades. Section 4.6 of Resource Report 6 provides a list of the proposed methods for Landslide Hazard Avoidance and minimization of adverse effects. The DEIS appropriately incorporated the landslide hazard avoidance and minimization measures in Section 4.1.2.4 of the DEIS.[105] Additional details regarding specific construction methods across existing low-risk landslides will be provided in the final design package.

II. *Conditional Coastal Zone Management Act Consistency Determination*

Oregon Department of Land Conservation and Development (ODLCD) submitted a comment concerning FERC's longstanding practice of issuing project certificates conditioned on subsequently obtaining CZMA consistency determinations from the relevant states. ODLCD asserts that FERC must know the outcome of the state's consistency review before issuing a certificate order. This is not correct. The D.C. Circuit has held that the CZMA does not prohibit FERC from issuing a certificate conditioned on the applicant receiving a state concurrence before construction may begin:

> "[P]etitioners contend that FERC violated the Coastal Zone Management Act, which provides that a federal permit 'to conduct an activity . . . affecting . . . the coastal zone' shall not be granted 'until the state . . . has concurred with the applicant's certification.' 16 U.S.C. § 1456(c)(3)(A). But FERC's certificate order allows Algonquin to begin construction only after obtaining approval from Massachusetts. Accordingly, it does not authorize the "activity" to which petitioners objected before FERC until after the state 'has concurred.'"[106]

Here, the DEIS recommends a condition that Applicants not begin construction until each files with the Secretary a copy of ODLCD's determination of consistency with the CZMA. Notwithstanding the DEIS's use of the word "should" install of "shall" in the recommended condition, Applicants anticipate that this condition would be binding and prohibit commencement of construction until the CZMA consistency determinations are issued, consistent with FERC's longstanding practice. In sum, because the FERC's approval would be conditioned on the Applicants first obtaining the requisite consistency determinations, the issuance of such a conditional order is consistent with the requirements of the CZMA.

III. *Aquatic and Upland Habitat*

A. **Shade Tree Removal Effects**

Commenters raised concerns that removal of shade trees will have a negative impact on fish, and stated that the DEIS does not address how this impact will be mitigated.[107] They also raised concerns that removal of trees will increase stream temperatures and negatively affect salmon species.[108] Shade tree removal and effects on stream temperatures and fish are addressed in Section 4.3.2.2 of the DEIS.[109] The DEIS analyzes the impacts of the Project on stream temperatures and finds construction and operation of the Pipeline would have no discernable effect on stream temperature.[110] The DEIS also discusses multiple strategies that PCGP would

[110] DEIS at pp. 4-114 through 4-115.

implement to minimize potential impacts, such as reducing the construction right-of-way at waterbody crossings where feasible, locating temporary extra workspace areas 50 feet back from waterbody crossings where feasible, replanting streambanks after construction in accordance with the ECRP, implementing the Large Woody Debris Plan.[111] Additionally, PCGP will use the results of its thermal impact analysis[112] to develop and implement a thermal mitigation plan, replanting riparian areas equal to 1:1 ratio to temporary riparian shading vegetation losses and 2:1 ratio for permanent riparian losses from the 30-foot operational easement clearing. Based on employing the above noted measures, the DEIS appropriately discusses the potential impacts of removing shade trees and provides ample support for its conclusion that impacts from construction and operation of the Pipeline would not result in discernible effects on stream temperature.[113]

B. **Loss of Forested Habitat**

Commenters expressed concerns regarding impacts on forests, specifically "old-growth" and late successional reserve forests/trees.[114] The concerns raised by commenters are already considered in Section 4.4 of the DEIS.[115] Additionally, the DEIS discusses Applicant's Comprehensive Mitigation Plan (CMP),[116] in which Applicants have developed a suite of onsite and offsite strategies to offset removal of forest habitat. These will cover impacts at the LNG Terminal and along the Pipeline. As mentioned in the DEIS, measures include those found in the ECRP,[117] the Leave Tree Protection Plan,[118] the Integrated Pest Management Plan,[119] the Fire Prevention and Suppression Plan,[120] and the SPCC Plan.[121] Approximately 1,400 acres (the area outside of the 30-feet wide permanent easement in forestland) of the construction corridor will be re-planted to trees following construction. PCGP will be committing to voluntarily fund U.S. Forest Service Projects (Appendix F2 of the DEIS) and Bureau of Land Management projects that are designed to enhance wildlife habitat such as fuel reduction projects to minimize risks from wildfires, snag creation, and re-allocation of matrix lands (subject to timber harvest) to protection as late-successional reserves. Based on employing the above noted measures, the DEIS sufficiently considers impacts on forests and contains ample support for its conclusion that constructing and operating the Pipeline would not significantly affect vegetation.[122]

[122] DEIS at p. 4-178.

Comments also expressed concerns regarding impacts on habitat to certain protected or endangered species, such as the marbled murrelet.[123] The DEIS discusses impacts to protected species in Section 4.6.[124] The DEIS also notes that additional habitat mitigation would be completed as part of the project.[125] The DEIS also includes a recommended condition to any FERC order that JCEP and PCGP not begin construction until they receive written notification from the Director of the OEP that construction or implementation of conservation measures may begin.[126] Furthermore, Applicants recently entered into an option agreement with a private timber company to acquire and preserve commercial forestland that would otherwise be subject to harvest under rules of the Oregon Forest Practices Act. Applicants will also be committing to funding programs related to barred owl and marbled murrelet management, programs recommended by the U.S. Fish and Wildlife Service that would aid the recovery of these two species. In sum, PCGP will be committing to habitat mitigation on over 12,000 acres (management and acquisitions), over double the total acreage of habitat removal (all types) over the length of the Pipeline (about 4,500 acres) and more than 5 times the forested acreage along the Pipeline (approximately 2,100 acres) that would be removed.

C. **Impacts to Upland Habitat on the North Spit**

ODFW comments that the Project will likely cause deleterious ecological and have legacy implications for upland habitats on the North Spit.[127] The Comprehensive Mitigation Plan discussed in the DEIS contemplates a Wildlife Habitat Mitigation Plan for the project.[128] JCEP will work with ODFW on appropriate mitigation for the North Spit to be included in the final plan.

IV. ***Wildlife and Aquatic Resources***

A. **Impacts on Fish and Shellfish**

1. Loss of salmon and oyster habitat

Many commenters expressed concern that salmon and oyster habitat in Coos Bay would be degraded as a result of the Project.[129] Potential impacts to salmon and oyster habitat, as well as corresponding mitigation measures, are addressed in Sections 4.5.2.2, 4.5.2.3, and 4.5.2.4 of the DEIS. The DEIS discusses loss of oyster habitat associated with construction of the LNG Terminal and channel improvements, as well as development of the Kentuck project, which is anticipated to replace this habitat since existing oyster and shrimp habitat is present near Kentuck Slough.[130] The DEIS also discusses the impacts of dredging the access channel on the quality of habitat available

[130] DEIS at pp. 2-17, 4-245.

for juvenile salmonids, and mitigation for loss of intertidal and subtidal habitat from dredging.[131] Additionally, 2.7 acres of floodplain habitat would be re-established adjacent to Kentuck Creek and would include stream enhancements including re-alignment of Kentuck Creek through the site. This area is close to the main Coos Bay river channel, which would benefit early marine-rearing juvenile salmonids. The DEIS also discusses the Applicants' Compensatory Wetland Mitigation Plan,[132] is currently under review by the resource agencies, and the Applicants will continue to consult with the ODSL, ODFW, USACE and NMFS in the development of a final Compensatory Wetland Mitigation Plan. Additional BMPs are described in Sections 4.5.2.2 through 4.5.2.4 of the DEIS. Therefore, the DEIS adequately considers impacts to fish and oyster habitat.

a. Effects on fish and shellfish in Coos Bay from dredging

Commenters allege that the DEIS does not sufficiently consider the negative effects of dredging on fish and shellfish from the Project.[133] Effects on fish and shellfish in Coos Bay from dredging is addressed in Section 4.3.2.2 of the DEIS.[134] Overall, the adverse impacts from these activities, to the extent they may occur, are not expected to be substantial and will generally be short-term in duration.[135]

A commenter expressed concern regarding impacts on Dungeness crab (*Metacarcinus magister*) and its habitat in Coos Bay, including impacts from turbidity during construction and maintenance dredging.[136] Effects on aquatic habitat from construction and operation of the LNG Terminal are addressed in Section 4.5.2.2 of the DEIS.[137] The DEIS discusses the Dungeness crabs' extensive use of eelgrass beds,[138] which are not affected by NRI construction. Effects on aquatic habitat, including Dungeness crab, would be minimized by the current in-water work windows (October 1 to February 15) and by maintaining the cutterhead near the bottom if a hydraulic dredge is used.[139] As with all dredging, there would be an initial loss of benthic resources from the dredging of the floor of the bay that would recover over time. Overall habitat structure of the bay would remain essentially unchanged following channel modifications in these areas. Through appropriate BMPs and mitigation, the impacts from turbidity at the NRIs and therefore

---

[139] DEIS at p. 4-247.

to crabs and shellfish will be limited, and the benthic community is expected to recover within a short period after dredging events.[140] The DEIS considers these impacts.

Commenters also expressed concern regarding impacts on Olympia oyster (*Ostrea lurida*) and claimed that the DEIS did not include an Olympia oyster mitigation plan.[141] Effects on shellfish and Olympia oyster from construction of the Pipeline are addressed in Section 4.5.2.3 of the DEIS. In addition to discussing a survey for the Olympia oysters,[142] the DEIS discusses the impact of construction on the oysters as well as other benthic species.[143] Moreover, the DEIS discusses that typical habitat for the Olympia oyster is not common in the bay due to the composition of the bottom areas of the bay.[144] Thus, a specific mitigation plan is not called for. Nevertheless, the DEIS discusses the impact of Project activities as well contingency plans to address potential impacts.[145] Given the above, the DEIS appropriately considers impacts to the Olympia oyster.

b. Changes in channel flow and effects on oysters and oyster farms

Regarding dredging in the Coos Estuary for the Project, a commenter asserts that the DEIS fails to consider the impact of changes to channel flow from the Project, and the resulting impact to oysters, particularly due to harmful algal bacteria on the incoming tide and the sweeping out to sea of larval oysters on the outgoing tide.[146] Project-related effects on tidal flow, tidal range, current velocity, and circulation in Coos Bay are addressed in Section 4.3.2.1 of the DEIS.[147] The DEIS also references modeling completed to determine the extent of these effects, from which it concludes effects would be localized and negligible.[148] Based on results of a two-dimensional hydrodynamic simulation model developed to assess "Without Project" and "With Project" scenarios, it was concluded that the mean tidal range (MHHW – MLLW) remained unchanged by the Project. Tidal currents were determined to remain unchanged for most areas except for a small increase (<0.3 knots) near the Access Channel and <0.7 knot increase in the localized areas around pile dike CB-7.3 and at the eastern and western slopes of the Access Channel. The results of this modeling do not suggest that the Project would alter the existing reach of harmful algal bacteria, or the distribution patterns of larval stages of marine life. The DEIS appropriately addresses the potential impact of changes to channel flow and its impact to oysters.

---

140 These BMPs are describes in Appendix B of the Dredge Pollution Control Plan for the NRIs. Supplemental Information of Jordan Cove Energy Project L.P. at Attachment B Dredging Pollution Control Plans, Accession No. 20190827-5086 (Aug. 27, 2019).

147 DEIS at p. 4-85.
148 *Id.*

c. Impacts on benthic community

Commenters allege that the DEIS does not properly consider Project impacts to the benthic community, and particularly the lack of a definition for benthic recovery.[149] Although no single definition is given for benthic recovery, the DEIS discusses potential impacts to the benthic community in several locations throughout the DEIS. The DEIS considers impacts to benthic community diversity and health,[150] the potential for permanent displacement of some benthic organisms,[151] as well as conditions under which benthic organism re-establishment could occur.[152] The DEIS further considers impacts to the benthic community from sources such as bottom erosion and turbidity,[153] disturbance of habitat,[154] burial,[155] increased suspended sediment,[156] and dredging.[157] Moreover, the DEIS cites several studies and reviews that evaluated effects of dredging on benthic communities in Coos Bay, Yaquina Bay, the lower Columbia River, and elsewhere are cited.[158]

Recovery of affected benthic communities would be cyclic given periodic maintenance dredging that would occur in the channel over decades. The DEIS discusses this maintenance dredging, including frequency, amount of material affected, and disposal of such material.[159] Moreover, the DEIS cites modeling conducted to evaluate the extent of impacts from this maintenance dredging, including impacts to benthic organisms.[160] Given the above, the DEIS appropriately considers impacts to the benthic community, despite providing no explicit definition of recovery.

2. Updated DEIS figure of spatial distribution of shellfish habitat

ODFW comments that the DEIS incorrectly illustrates the major known oyster and shrimp habitat and clamming and crabbing areas in the bay relative to the Project activities in figure 4.5-2, particularly in the mixed communities of bay clams in the area immediately west and north-west of the airport runway.[161] JCEP has updated the DEIS figure 4.5-2 (see below) to incorporate the ODFW 2014 clamming and crabbing areas and the addition of ODFW 1997 primary native oyster habitat in Coos Bay. The data does not identify any crab pots/rings in the four NRI areas. Crabbing areas are depicted in the NRI area 1 and 2 locations because there are crab pots/rings immediately adjacent to those NRI areas. The ODFW 2014 crabbing area within NRI 1 is 2.8 acres and the ODFW 2014 crabbing area within NRI 2 is 4.1 acres.

Jordan Cove Energy Project

Figure 4.5-2

Shrimp and Oyster Habitat and Shellfish Areas in Coos Bay

B. Cooling Water Discharge on Marine Life

Commenters raised concerns that discharge of ballast or cooling water will affect water temperatures in the bay and negatively affect salmon and other marine life.[162] Thermal impacts from LNG carrier ballast water discharge are addressed in Section 4.3.2.1 of the DEIS.[163] The DEIS also discusses modeling by Moffat and Nichols (2017)[164] regarding impacts to water temperature of the slip from the release of engine cooling water. The DEIS adequately evaluates discharge of ballast and cooling water.

C. Impacts on Marine Mammals

Certain commenters expressed concern that the Project could threaten protected marine mammals through ship strikes and shipping noise.[165] Potential Project-related effects on marine mammals, including (but not limited to) ship strikes and underwater noise are addressed in Sections 4.5.2.1 and 4.6.1.1 of the DEIS.[166] The DEIS also discusses mitigation measures for these impacts.[167] Finally, the DEIS references the required Section 7 consultations with FWS and NMFS, which will also consider measures to minimize the risk of adverse impacts, including vessel strikes, to marine mammals.[168] To further increase the awareness of local species and risk factors, the DEIS notes that JCEP would provide a "Ship Strike Avoidance Measures Package" to shippers calling on the LNG Terminal.[169] The DEIS appropriately considers impacts to threatened marine mammals.

D. Impacts on Waterbodies

ODFW comments that variations exist across documents (such as the DEIS, mitigation planning documents, the Applicants' resource reports, and the Applicant-Prepared Draft Biological Assessment), and that inconsistent numbers and differing definitions of "waterbody" make it difficult to assess impacts.[170]

The various documents cited contain minor differences in numbers related to waterbodies for several reasons. As the Applicants obtain landowner permission to conduct wetland and waterbody surveys, and as PCGP incorporates minor route deviations into the pipeline alignment, wetland acreage impacts and waterbody crossing numbers are refined. This accounts for the minor differences in numbers between the documents. The DEIS's analysis of impacts considers the appropriate scope of environmental impacts at these locations, including the implementation of

---

[165] Comment of Whale and Dolphin Conservation, Accession No. 20190703-5199 (July 3, 2019); Oregon State Agencies Comments at pp. 73-74; Comment of Emma Marris, Accession No. 20190621-5008 (June 21, 2019) ("Marris Comments").
[166] DEIS at pp. 4-233 to 4-234, 4-250 to 2-254, 4-319 to 4-320; *see also* Biological Assessment at Section 3.2.
[167] *See, e.g.*, DEIS at p. 4-319.
[168] DEIS at pp. 1-26 to 1-27, 4-309.
[169] DEIS at p. 4-319.
[170] Oregon State Agencies Comments at pp. 82-84.

various BMPs detailed in the environmental documents and applications to protect all wetlands and waterbodies. Moreover, the DEIS discusses the Applicants' statement that construction across waterbodies will occur within the ODFW-recommended in-water work windows (excepting waterbodies where trenchless crossing methods have been proposed).[171] The DEIS's analysis of these impacts is not rendered deficient as a result of minor, insignificant variations in the documents, many of which arise as a result of greater precision over time, particularly given the avoidance, minimization, and mitigation plans discussed in the DEIS.

E. **Wetland Mitigation**

ODFW contends that wetland impacts were underestimated for the Project because Applicants did not consider temporary impacts in its calculations.[172] However, the DEIS appropriately addresses wetland impacts and mitigation. The DEIS discusses both temporary and permanent impacts to wetlands; impacts considered include conversion of wetlands, introduction of non-native species, changes in hydrogeological conditions, vegetation loss, and reduction in hydroregulatory abilities.[173] The DEIS analyzes impacts based not only on wetland type but also on the timeframe of impacts.[174] Additionally, the DEIS references Applicant's Compensatory Wetland Mitigation Plan (CWMP), which addresses both temporary and permanent impacts.[175]

The DEIS acknowledges that USACE and ODSL may require additional mitigation (beyond what is required in the DEIS), and that the adequacy of wetland mitigation for federally jurisdictional wetlands, including the scope and location of mitigation, would ultimately be determined by the USACE.[176] Further, the DEIS executive summary notes that the conclusions in the DEIS are based on several factors, including that the Applicants' CWMP would satisfy the USACE's regulatory requirements to mitigate unavoidable impacts on wetlands and waters of the United States.[177] The DEIS acknowledges that the CWMP is still being reviewed by USACE, ODSL, and other applicable federal and state agencies and that approval of the plan would be prerequisite to issuance of federal and state wetland permits.[178] The DEIS appropriately considers wetland impacts and mitigation.

F. **Eelgrass Mitigation**

ODFW comments that eelgrass avoidance alternatives are not fully investigated and that the eelgrass mitigation plan is incomplete.[179] The DEIS references Applicants' CWMP in discussing eelgrass mitigation.[180] The CWMP discusses details regarding mitigation measures of success and contingencies; however, ODSL and other resource agencies will ultimately determine

[180] *See, e.g.*, DEIS at p. 4-130.

the adequacy of the mitigation plan, the contents of which may change depending on agency consultations. The DEIS acknowledges that the CWMP is still being reviewed by USACE, ODSL, and other applicable federal and state agencies and that approval of the plan would be prerequisite to issuance of federal and state wetland permits.[181] The Applicants will continue to consult with the COE, NMFS, ODSL, and ODFW and other appropriate resource agencies to develop a final wetland mitigation plan. Given the above, the DEIS adequately considers impacts to eelgrass.

V. *Threatened, Endangered, and Other Special Status Species.*

A. **Compliance with Section 7 and Section 10 of the Endangered Species Act**

ODFW claims that the DEIS fails to explain how consultation for impacts from the Project on non-federal lands will occur under Section 10 of the Endangered Species Act ("ESA").[182] ODFW erroneously asserts that consultation under Section 7 of the ESA would be for the federal action and for federal lands only, leaving impacts on non-federal lands for a separate consultation under Section 10.[183] ODFW's comments represent a misunderstanding of the scope of consultation under Section 7 of the ESA for the Project.

Section 7 consultation provides the mechanism by which federal agencies ensure the actions they authorize, fund, or undertake do not jeopardize the existence of any listed species or result in the destruction or adverse modification of designated critical habitat. Section 7(a)(2) of the ESA requires federal agencies to consult with the U.S. Fish and Wildlife Service ("FWS") and the National Marine Fisheries Service ("NMFS"), as appropriate, before taking any action (e.g., permitting) that may affect federally-listed endangered or threatened species or designated critical habitat.[184] Here, the entirety of the LNG Terminal and Pipeline is subject to FERC jurisdiction and authorization, regardless of whether it is located on federal or non-federal lands. As a result, the entire Project is subject to Section 7 consultation. As described in the DEIS, the federal agencies are consulting with FWS and NMFS regarding any federally listed species or critical habitat that may be affected by the Project. There is no qualifier that this Section 7 consultation only reaches federal lands. Indeed, any biological opinion issued for the Project would include an Incidental Take Statement, which would apply to the take of any listed species, regardless of where that take occurred.

Despite ODFW's claim, no Section 10 consultation is required here. Section 10 of the ESA authorizes the FWS and NMFS to issue permits authorizing the take of listed species incidental to otherwise lawful *non-federal* activities upon submission of a habitat conservation plan.[185] The Applicants do not need a Section 10 incidental take permit, and Section 10 of the ESA does not impose any "consultation" obligation on the part of the Applicants or the federal agencies. The ongoing Section 7 consultation with FWS and NMFS will encompass all potential effects to federally-protected species as a result of the Project.

[185] 16 U.S.C. § 1539(a)(1)(A)-(B).

B. **Impacts on Endangered Species**

1. Shortnose sucker (*Chasmistes brevirostris*)

A commenter raised concern that potential mortality to shortnose sucker from electrofishing may occur, and that Project-related erosion would impact the shortnose sucker, such as effects of fertilizer used during revegetation.[186] Impacts from electrofishing are addressed in Section 4.6.1.3 of the DEIS, as are other impacts, such as entrainment and entrapment, acoustic shock and underwater noise, streambank erosion, and herbicide application.[187] The DEIS also references PCGP's Fish Salvage Plan,[188] which details methods to minimize negative impacts from salvage operations.[189] The impacts of fertilizer runoff are discussed in Section 4.3.2.2 of the DEIS.[190] Although the discussion in the DEIS does not directly discuss the shortnose sucker, the application plans discussed in the DEIS address this through the broader minimization of fertilizer runoff.[191]

2. Coho salmon (*Oncorhynchus kisutch*)

Many commenters expressed concern that the Project would harm important habitat, including for species protected under the Endangered Species Act such as Oregon Coast Coho Salmon.[192] Potential Project-related effects on protected species' habitat, including Coho salmon (Oregon Coast Evolutionary Significant Unit [ESU]) are summarized in Section 4.6.1.3 of the DEIS.[193] For example, the DEIS discusses impacts to Coho Salmon and its habitat from pile driving, dredging, increased turbidity, impacts on the benthic community and food sources, entrainment and impingement from engine cooling water operations, blasting, reduced recruitment of large woody debris, and other riparian habitat alterations.[194]

3. Marbled murrelet (*Brachyramphus marmoratus*) and northern spotted owl (*Strix occidentalis caurina*)

Commenters expressed concern regarding clearing of old-growth forest and impacts on spotted owl (NSO) and marbled murrelet (MAMU), their habitat, and the sufficiency of mitigation.[195] Impacts on these species from construction of the Project are addressed in Sections

[193] *See, e.g.*, DEIS at pp. 4-332 to 4-335. The biological assessment has since been issued, and this species is further discussed there in Section 3.5.4.5.
[194] DEIS at pp. 4-334 to 4-335.
[195] *See, e.g.*, Comment of Ronald Crete at p. 3, Accession No. 20190701-5065 (June 28, 2019); Comment of Kristine Cooper Cates at p. 2, Accession No. 20190606-5009 (June 5, 2019).

4.5 and 4.6 of the DEIS.[196] The DEIS discusses impacts to MAMU and NSO habitat, noise impacts, impacts to prey species, and behavioral impacts.[197] Additionally, the DEIS recommends that the Project comply with FWS-recommended timing restrictions concerning MAMU stands and NSO activity centers.[198] The DEIS further recommends that construction not start until consultations with the FWS and NMFS are complete,[199] and notes that these consultations may require further avoidance, reduction, or mitigation measures.[200] Therefore, the DEIS properly discusses impacts to MAMU and NSO, their habitat, and the sufficiency of mitigation.

In addition to the impact minimization measures identified in the DEIS, PCGP is proposing mitigation for permanent impacts to Late Successional Old Growth (LSOG) forest and MAMU habitat.[201] In sum, PCGP is committed to providing habitat mitigation equivalent to approximately 11,500 acres. Of this, approximately 9,000 acres would be management actions on federal lands to accelerate the development of old-growth forests, conversion of matrix land to late-successional reserves, fuel reduction and fire breaks to reduce the threat of habitat loss from wildfires, and snag creation. As stated above in Section III.B, Applicants have made recent commitments for additional forestland preservation and program funding. Based on the additional commitments, over the life of the Project, there would be a net-benefit to obligate LSOG species because the mitigation package would create and preserve far more LSOG habitat than would be removed.[202]

4. Protected Plant Species

Commenters expressed concern regarding Project-related impacts on threatened and endangered plant species, including the sufficiency of mitigation measures.[203] These concerns are addressed in Section 4.6.1.6 of the DEIS.[204] The DEIS discusses impacts to habitat, potential changes in hydrology and soil characteristics, changes to species composition, impacts from invasive species, and fugitive dust.[205] Moreover, the DEIS references PCGP's Federally-listed Plant Conservation Plan, which details avoidance, minimization, and mitigation measures to protect listed plant species.[206] PCGP contracted with local biologist/botanists with expertise in identifying federal and state listed threatened, endangered plants, sensitive flora species, and noxious weeds to conduct surveys for the Pipeline. Given the above, the DEIS appropriately

considers impacts on threatened and endangered plant species, including the sufficiency of mitigation measures.

5. Killer whales (*Orcinus orca*)

Commenters expressed concern regarding the assessment of Project-related effects on killer whale (Eastern Northern Pacific Southern Resident Stock).[207] Project-related effects on killer whale are included in Section 4.6 of the DEIS.[208] The DEIS discusses impacts to the whales from ship strikes, increased carrier traffic, noise, and impacts to critical habitat.[209] Additionally, the DEIS discusses references the 2016 NMFS *Technical Guidance for Assessing the Effect of Anthropogenic Sound on Marine Mammals*,[210] and discusses the impacts of anthropogenic sound not only on marine mammals but also on fish.[211] Moreover, the DEIS recommends that JCEP file a Marine Mammal Monitoring Plan prior to construction.[212] Additionally, JCEP filed an Application for Incidental Harassment Authorization for the Taking of Marine Mammals (IHA) Under Section 101(a)(5)(A) of the Marine Mammal Protection Act, with the NMFS on April 23, 2019.[213] The IHA addresses Project activities expected to result in Take, the type of Incidental Take authorization requested, estimated Take, anticipated impacts, proposed mitigation measures, and proposed monitoring and reporting. JCEP's IHA is under review by NMFS and construction and operation of the Project would be subject NMFS' Incidental Take Authorization and conditions of the Incidental Take Authorization for the protection of marine mammals, including the killer whale.

6. Green sturgeon (*Acipenser medirostris*)

Certain commenters express concern regarding impacts to Green Sturgeon (Southern Distinct Population Segment).[214] Impacts to Green Sturgeon are discussed in Section 4.6 of the DEIS.[215] The DEIS discusses impacts from noise, spills, sedimentation, dredging, construction techniques, and impacts to habitat and concludes most effects would be short-term or localized in nature.[216]

[216] DEIS at pp. 4-335 to 4-337.

7. Western snowy plover (*Charadrius alexandrinus nivosus*)

ODFW expresses concern regarding the Project's impacts to western snowy plover (Pacific Coast Population) nesting and foraging habitat.[217] Impacts to western snowy plover are discussed in Section 4.6.1.2 of the DEIS.[218] The DEIS discusses impacts to habitat from construction, noise, dredging, and increased human presence.[219] As noted in the DEIS, consultation with FWS is required,[220] and the Applicants are working with the agencies to mitigate potential impacts to western snowy plovers and critical habitat.

8. Pacific marten (*Martes caurina*)

ODFW expresses concern about Project impacts to Pacific marten and their habitat.[221] These concerns are addressed in Section 4.6.1.1 of the DEIS[222] The DEIS discusses impacts related to noise, vehicle traffic, impacts to habitat, and increased human presence.[223]

VI. *Reliability and Safety*

Many commenters assert that Project activities would present significant potential safety risks.[224] Concerns regarding public safety are discussed in Sections 4.13 of the DEIS.[225] As described extensively in the DEIS, Applicants will construct and operate their respective facilities in compliance with the requirements of the U.S. Department of Transportation (USDOT) and the Pipeline and Hazardous Materials Safety Administration (PHMSA).[226]

As noted in the DEIS, the Project would be subject to safety standards under both USDOT and the USCG,[227] which would govern the design, construction, and operation of the facilities.[228] The DEIS also references the USCG's May 2018 Letter of Recommendation, which recommended that the Coos Bay Channel is suitable for accommodating the type and frequency of LNG marine traffic associated with this project from a maritime and navigational safety standpoint.[229] Likewise, the DEIS indicates that USDOT monitors the construction and operation of natural gas facilities to determine compliance with USDOT standards.[230] The DEIS further explains that USDOT will issue a Letter of Determination (LOD) regarding whether the proposed LNG facility

[229] DEIS at pp. 4-709 to 4-710, 4-780.
[230] DEIS at p. 1-15.

will be capable of complying with USDOT's siting regulations.[231] The Commission may rely on the conclusions of USDOT, the Coast Guard, and PHMSA in conducting its independent assessments.[232] Further, the Commission may rely on future coordination between the Applicants and other federal agencies in its NEPA assessment.[233] Moreover, the DEIS contains multiple recommendations to enhance the reliability and safety of, and minimize risk from, the Projects.[234] Given the above, the DEIS appropriately discusses safety risks. Specific safety concerns are addressed in more detail below.

A. **LNG Terminal**

1. Safety hazards

One commenter asserts that the DEIS did not disclose what would happen if risks occurred, beyond vague descriptions, and the DEIS did not describe any safety hazard; only that safety hazards are mitigated; and the commenter asserted that conclusions in the DEIS regarding the safety to the public from the LNG Terminal are vague, incorrect, and misleading.[235] Section 4.13.1 of the DEIS assesses safety hazards associated with the LNG Terminal. The DEIS discusses a range of hazards, including vessel hazards,[236] potential releases,[237] fires,[238] seismic events (including earthquakes and tsunamis),[239] meteorological events (including hurricanes and tornadoes),[240] landslides and other natural hazards,[241] and potential transportation impacts.[242] Additionally, the DEIS identifies and describes historical records of both LNG marine vessel transport and LNG facility operations.[243] The DEIS's analysis includes a discussion of regulatory oversight, USDOT siting requirements, security requirements, preliminary engineering review of the facility design, and recommended mitigation measures.[244] As such, the DEIS adequately identifies safety hazards associated with the LNG Terminal.[245]

2. Unconfined vapor clouds

Commenters raise questions regarding the adequacy of modeling used to measure vapor cloud dispersion at the LNG Terminal and assert that the risks of unconfined vapor cloud

---

[244] DEIS at pp. 4-698 to 4-755.
[245] DEIS at p. 4-781.

explosions are not adequately accounted for.[246] The DEIS addresses these vapor cloud issues and notes that potential incidents, such as vapor cloud explosions, are considered in determining compliance with USDOT requirements.[247] The DEIS's analysis recognizes that JCEP will have to demonstrate to USDOT that the LNG Terminal will meet the USDOT siting standards and the USDOT's LOD will serve as one of the considerations for the Commission to deliberate in its decision to authorize or deny any application.[248]

The DEIS discusses JCEP's facility siting hazard analysis,[249] and impacts from flammable vapors are included in that analysis. That analysis also includes overpressure analysis for the ignition of flammable refrigerant vapors from design spills, which JCEP completed using USDOT-approved modeling tools that are used consistently among LNG applicants to demonstrate siting compliance with 49 CFR Part 193 requirements.

As noted above, USDOT reviews LNG applications to determine whether a proposed LNG facility complies with the safety standards contained in 49 CFR Part 193, Subpart B.[250] JCEP has submitted the information required by USDOT for this review and anticipates receiving an LOD 30 days prior to FERC's issuance of the Final EIS confirming that the LNG Terminal meets the siting requirements of 49 CFR Part 193. As such, the DEIS appropriately concludes that the USDOT will assist FERC by determining whether the Jordan Cove LNG Project's proposed design would meet USDOT siting requirements,[251] and based on adherence to USDOT standards, the Project would not significantly affect public safety.[252]

3. Leaks and fires

Commenters expressed concerns regarding potential leaks of combustible gases from the Project and fires resulting from releases of LNG.[253] These concerns are addressed in Sections 4.13.1 and 4.13.2 of the DEIS. As discussed above, USDOT will assist FERC in determining if safety standards are met prior to issuance of any Certificate Authorization for the Project. These standards include provisions to minimize the risk from spills of any flammable mixture of vapors,[254] and Section 4.13.1.1 of the DEIS provides a discussion of the LNG safety regulations followed in the design of the Project and the regulatory review and approval framework.[255]

Additionally, Section 4.13.1.5 of the DEIS describes LNG Terminal design, monitoring systems, and emergency response measures to minimize the risk of such potentially hazardous

---

[255] DEIS at pp. 4-698, 4-699.

scenarios at the LNG Terminal. The DEIS discusses spill containment, spacing and plant layout, ignition controls, hazard detection, emergency shutdown, depressurization systems, hazard controls, passive cryogenic and fire protection, and firewater systems incorporated into the LNG Terminal design.[256] The DEIS includes a review of JCEP's proposed hazard mitigation systems included in its Certificate Application and discusses how the measures would meet NFPA 72, ISA Standard 12.13, and other recommended and generally accepted good engineering practices.[257] Moreover, the DEIS recommends in Section 4.13.1.6 additional requirements that are anticipated to be conditions of any Certificate Authorization issued for the Project, subjecting Project design of hazard detection and monitoring systems to further study and final design review and approval by FERC.[258]

Additionally, the DEIS discusses the Project's Emergency Response Plans (ERPs).[259] The DEIS explains that the Energy Policy Act of 2005 requires an ERP be prepared in consultation with the USCG, as well as state and local agencies, and be approved by the FERC prior to any approval to begin construction of an LNG terminal.[260] Moreover, the ERP establishes the procedures for responding to specific emergencies that could occur at the LNG Terminal as well as procedures for emergencies that could affect the public.[261] Section 4.13.1.5 summarizes the required contents of the ERP and elements included in JCEP's draft ERP submitted with its Certificate Application to address emergency events and potential release scenarios. For PCGP, the DEIS discusses the requirements of the pipeline ERP and references the ERP previously submitted by PCGP.[262] The DEIS further discusses safety measures associated with PCGP in Section 4.13.2.1. This includes a review of pipeline burial depth, compliance with USDOT regulations, as well as PCGP's Fire Prevention and Suppression Plan.[263]

4. Emergency response

Commenters express concern about the Project's impact on emergency response capabilities, including concerns regarding response capacity and the adequacy of access to, and escape from, the LNG Terminal site and workforce housing area.[264] These concerns are adequately addressed in the DEIS. As noted above, the DEIS explains that prior to construction, JCEP must develop an ERP (including evacuation) and coordinate procedures with the USCG and other appropriate federal, state, county, and local agencies. The DEIS discusses that this plan will include at a minimum: a) designated contacts; b) scalable notification procedures; c) evacuation

[264] McLaughlin Comments at p. 4; WELC Comments at p. 53

routes/methods; d) locations of permanent sirens and other warning devices; and e) emergency coordinators.[265]

Additionally, the DEIS includes several recommendations to further account for the sufficiency of emergency response measures, including notifications for all planning meetings reports on progress on the development of the ERP at 3-month intervals.[266] The DEIS also explains that JCEP would also be required to develop a cost-sharing plan that discusses resources and reimbursements provided by JCEP to cover state and local safety and emergency management and that must include the LNG Terminal operator's letter of commitment with agency acknowledgement for each state and local agency designated to receive resources.[267]

ODOE raised concern that funding to the Coos County Sheriff's Office has been suspended, preventing its participating in emergency planning activities.[268] JCEP is re-engaging with the Sheriff's Office for the exclusive purposes of emergency planning. In addition, meetings with ODOE are being held to develop an engagement plan to meet with the other County planning groups and to address the issues raised by ODOE that include ERP and security plans for Project construction, operation, blasting, and for the temporary worker housing.[269]

Based on employing all of the above noted measures, the DEIS contains ample support for its conclusion that the Project would not significantly affect public safety.

5. Hazard zones

Commenters raise concerns regarding inadequate analysis of impacts in hazard zones, especially to schools and residential areas.[270] These impacts are appropriately addressed in the DEIS. The DEIS explains that the Project must comply with USDOT siting requirements;[271] as stated therein, USDOT will issue a LOD to the Commission after USDOT completes its analysis of whether the proposed facilities would meet the USDOT siting standards.[272] The DEIS describes the evaluation in the LOD, including hazard modeling results and endpoints used to establish exclusion zones, as well as JCEP's evaluation on potential incidents and safety measures incorporated in the design or operation of the facility specific to the site that have a bearing on the safety of plant personnel and surrounding public. The LOD will serve as one of the considerations for the Commission to deliberate in its decision to authorize or deny an application.[273]

[269] Oregon State Agencies Comments at p. 11-17.
[270] Comment of Wim de Vriend at pp. 5, 27 to 37, Accession No. 20190419-5008 (Apr. 18, 2019) ("de Vriend April Comments"); Comment of Janet Lea at p. 1, Accession No. 20190708-5011 (Jul. 5, 2019); Comment of Martha Neuringer at p. 1, Accession No. 20190708-5033 (Jul. 5, 2019).
[271] DEIS at 4-699 to 4-701.
[272] DEIS at 4-702.
[273] DEIS at p. 4-702.

The DEIS also discusses the siting standards of the USCG. In the DEIS, FERC Staff conduct a hazard analysis for zones of concern for potential impacts from LNG vessel traffic, including to schools and other areas.[274] Additionally, the DEIS references the Coast Guard's May 2018 LOR, which recommended that the Coos Bay Channel is suitable for accommodating the type and frequency of LNG marine traffic associated with this project from a maritime and navigational safety standpoint.[275] The DEIS further discusses that the May 2018 LOR was based on implementation of strategies and risk management measures identified by the USCG in its Waterway Suitability Assessment.[276] The Commission may rely on the conclusions of USDOT and USCG in conducting its independent assessments.[277] Further, the Commission can rely on future coordination between the Applicants and other federal agencies in its NEPA assessment.[278] Therefore, the DEIS appropriately considers impacts in hazard zones, including to school and residential areas.

6. Industry Standards.

Commenters allege that JCEP does not meet certain Society of International Gas Tanker and Terminal Operators (SIGTTO) standards relating to safe distances from populated areas, timely escape routes for LNG carriers in emergencies, avoiding moorage on the outside of a channel curve, and avoiding long inshore channels.[279] The SIGTTO Information Paper 14 (Information Paper) referenced by commenters was prepared and published more than 20 years ago, and it is not an industry or regulatory standard, as suggested by commenters; rather, it is an "information paper" with "views on risks, navigation and cargo operations." JCEP is a member of SIGTTO and adheres to its principles. The Information Paper concentrates on issues when a port is being designed where ports do not yet exist and are being developed.[280] The Port of Coos Bay is not within this category. However, JCEP, a member of SIGTTO, used the paper's concepts in addressing risk.

In the United States, regulatory and agency oversight of LNG facilities far exceeds the views in the Information Paper. Federal and state authorities have established regulatory requirements and standards for LNG facilities in the United States based on extensive studies, risk evaluation, and analysis. The DEIS's analysis of the Project's compliance with these standards has been discussed above; however, specific responses to issues raised by commenters are provided below:

[280] Site selection and design for LNG ports and jetties: With views on risk limitation during port navigation and cargo operations. 1997. Society of International Gas Tanker and Terminal Operators.

Safe distances from populated areas

In Section 4.13.1, the DEIS explains that the Project must comply with the siting requirements of both USDOT and USCG.[281] The DEIS further explains that USDOT will issue a LOD to the Commission after USDOT completes its analysis of whether the proposed facilities would meet the USDOT siting standards.[282] The DEIS describes the evaluation in the LOD, including hazard modeling results and endpoints used to establish exclusion zones, as well as JCEP's evaluation on potential incidents and safety measures incorporated in the design or operation of the facility specific to the site that have a bearing on the safety of plant personnel and surrounding public; the LOD will serve as one of the considerations for the Commission to deliberate in its decision to authorize or deny an application.[283] Additionally, the DEIS discusses a hazard analysis for zones of concern for potential impacts from LNG vessel traffic, including for populated areas.[284] Therefore, the DEIS adequately considers safety impacts to populated areas.

Timely escape routes for LNG carriers in emergencies including earthquakes

As noted above, the DEIS explains that prior to construction, JCEP must develop an ERP (including evacuation) and coordinate procedures with the USCG and other appropriate federal, state, county, and local agencies. The DEIS discusses that this plan must include evacuation routes/methods.[285] The DEIS adequately considers escape routes for LNG carriers.

Channel design, including avoiding long inshore channels and avoiding moorage on the outside of a channel curve

Section 4.13.1.3 of the DEIS explains that USCG has regulatory authority over navigational safety, LNG marine vessel engineering and safety standards, and marine transfer areas.[286] The DEIS references the Coast Guard's May 2018 LOR, which recommended that the Coos Bay Channel is suitable for accommodating the type and frequency of LNG marine traffic associated with this project from a maritime and navigational safety standpoint.[287] The DEIS also discusses that the May 2018 LOR was based on implementation of strategies and risk management measures identified by the USCG in its Waterway Suitability Assessment, which would help ensure the waterway is suitable for LNG carrier traffic.[288] Moreover, the DEIS discusses modifications to the channel in order to reduce risks from vessel passage.[289] Therefore, the DEIS properly considers impacts of channel design.

---

[281] DEIS at pp. 4-699 to 4-710.
[282] DEIS at pp. 4-702.
[283] DEIS at p. 4-702.
[284] DEIS at pp. 4-707 to 4-709.
[285] DEIS at pp. 4-753 to 4-754, 4-756 to 4-757.
[286] DEIS at pp. 4-702 to 4-710.
[287] DEIS at pp. 4-709 to 4-710, 4-780.

[289] *See, e.g.*, DEIS at p. 2-10.

Based on FERC Staff's consideration of the USDOT's LOD and the USCG's LOR in the Commission's decision to authorize or deny an application, the DEIS contains ample support for its conclusion that the Project would not significantly affect public safety.

B. **LNG Vessels**

1. Navigation conflicts and safety

Commenters raised concerns regarding the effects of LNG vessels on navigation safety, and conflicts with other boats/vessels navigating the channel.[290] These concerns are addressed in Section 4.13.1 of the DEIS. The DEIS discusses JCEP's WSA, which analyzes the public safety and security implications of the Project from LNG marine traffic both in the waterway and when in port, as well as USCG's approval of JCEP's WSA.[291] Additionally, Section 4.13.1.3 of the DEIS explains that USCG has regulatory authority over navigational safety, LNG marine vessel engineering and safety standards, and marine transfer areas.[292] The DEIS references the USCG's May 2018 LOR, which recommended that the Coos Bay Channel is suitable for accommodating the type and frequency of LNG marine traffic associated with this project from a maritime and navigational safety standpoint.[293] In sum, the DEIS adequately considers potential impacts from LNG vessel traffic on navigational safety and use of Coos Bay.

2. Airport safety

Commenters express concern regarding the LNG Terminal's proximity to the Southwest Oregon Regional Airport in North Bend and assert that the LNG Terminal would threaten aviation safety.[294] These concerns are addressed in Section 4.13.1.5 of the DEIS.[295] The DEIS describes applicable FAA regulations, JCEP's notice to the FAA of the Project, structures associated with the LNG Terminal exceeding 200 feet, JCEP's commitment to continue to investigate measures to eliminate or mitigate presumed hazards, and potential mitigation measures.[296] Additionally, the DEIS includes a recommendation that JCEP should file documentation of receipt of no hazard determinations from the FAA prior to initial site preparation, without which the Project will not proceed as currently envisioned.[297] Given the above, the DEIS appropriately considers impacts to aviation safety.

[296] DEIS at pp. 4-749 to 4-752.
[297] DEIS at pp. 4-751, 4-755.

3. Security Zones and Exclusion Zones

A commenter expresses concern regarding the implementation of security zones for vessels in the channel and of exclusion zones applicable to the LNG Terminal under 49 CFR Subpart B.[298] These issues are already addressed in the DEIS. The DEIS discusses JCEP's WSA, which analyzes the public safety and security implications of the Project from LNG marine traffic both in the waterway and when in port, as well as USCG's approval of JCEP's WSA.[299] As identified in the WSA, a moving Safety/Security zone shall be established around the LNG vessel extending 500-yards around the vessel but ending at the shoreline; vessels are not excluded from entering the security zone but may not enter the Safety/Security zone without first obtaining permission from the USCG Captain of the Port (COTP).[300] Additionally, the WSA discusses how escort resources will be used to contact and control vessel movements such that the LNG carrier is protected.[301] Moreover, Section 4.13.1.3 of the DEIS explains that USCG has regulatory authority over navigational safety, LNG marine vessel engineering and safety standards, and marine transfer areas.[302] The DEIS references the USCG's May 2018 LOR, which recommended that the Coos Bay Channel is suitable for accommodating the type and frequency of LNG marine traffic associated with this Project from a maritime and navigational safety standpoint.[303]

To assist with vessel traffic management, JCEP would provide a Vessel Traffic Information System (VTIS) that will cover Coos Bay. The VTIS would be able to deconflict the waterway for all waterway users. Because the LNG carriers would be able to provide long-term forecasts of their entry and exit times, the VTIS would coordinate with all waterway users to avoid conflicts and emergency conditions. Inbound LNG carriers would have fewer entry limits than loaded LNG carriers and are more flexible as to entry conditions. The LNG carrier crossing of the sand bar during high tides is only in the case of the departing laden LNG carrier. Arriving vessels have no such tidal restrictions and hence are more flexible. The VTIS operator would be able to communicate directly with fishing vessels, the USCG, and deep-draft shipping to ensure a smooth and coordinated waterway. This system currently does not exist in Coos Bay. Similar systems are in other ports, and they operate effectively to coordinate and deconflict vessel traffic in a waterway. The Coos Bay Pilots, who have been piloting ships into Coos Bay for years, do not anticipate any impact to the current recreational and commercial fishing fleet in Coos Bay with the additional LNG vessel traffic.

The DEIS considers exclusion zones among the siting requirements discussed in Section 4.13.1.2. The DEIS explains that the Project must comply with the siting requirements of USDOT.[304] Additionally, the DEIS explains that USDOT will issue a LOD to the Commission after USDOT completes its analysis of whether the proposed facilities would meet these USDOT

---

[298] WELC Comments at pp. 20 to 21.
[299] DEIS at pp. 1-14, 4-705 to 4-707.

[304] DEIS at pp. 4-699 to 4-702.

siting standards.[305] The DEIS describes the evaluation in the LOD, including hazard modeling results and endpoints used to establish exclusion zones, as well as JCEP's evaluation on potential incidents and safety measures incorporated in the design or operation of the facility specific to the site that have a bearing on the safety of plant personnel and surrounding public; the LOD will serve as one of the considerations for the Commission to deliberate in its decision to authorize or deny an application.[306] Therefore, the DEIS adequately assesses security zones and exclusion zones.

In addition, on August 2, 2019, JCEP filed with FERC documentation of its continued efforts toward a landowner agreement to address the exclusion zone beyond the LNG Terminal western property line and over the Henderson Property.[307] JCEP is committed to ongoing negotiations with the landowner for legal control over the LNG Terminal exclusion zone, and will provide FERC with a copy of the final agreement.

4. Regulatory Oversight

One commenter expressed concern regarding regulatory oversight of LNG vessels.[308] Regulatory oversight of LNG vessels is addressed in Section 4.13.1.3 of the DEIS.[309] The DEIS identifies USCG regulatory authority over LNG marine vessels, and applicable United States and international security requirements.[310] Additionally, the DEIS discusses JCEP's WSA, which analyzes vessel route, port characterization, and risk management strategies, as well as USCG's review and approval of JCEP's WSA.[311] The DEIS adequately addresses regulatory oversight of LNG vessels in transit and at berth in the DEIS.

C. **Pipeline Safety**

1. Pipeline leaks and rupture

Commenters express concern regarding natural gas leaks from the Pipeline and pipeline rupture.[312] These concerns are addressed in Section 4.13.2 of the DEIS. As described in the DEIS, Applicants must construct and operate their respective facilities to comply with the requirements of the USDOT and PHMSA.[313] Additionally, the DEIS discusses how USDOT has the exclusive authority to promulgate federal safety standards for the transportation of natural gas.[314] The DEIS further discusses safety standards for the Pipeline, such as maximum allowable operating pressures based on nearby population density, pipeline burial depth requirements, and development of

313 *See, e.g.*, DEIS at pp. 4-752, 4-769, and 4-779 to 4-780.
314 DEIS at p. 4-769.

emergency response plans.[315] Additionally, in Sections 4.13.2.2 and 4.13.2.3, the DEIS examines pipeline accident data.[316] As stated therein, the available data show that natural gas transmission pipelines continue to be a safe, reliable means of energy transportation.[317]

The DEIS also discusses various protective measures that the PCGP will implement to mitigate the risk of leaks or rupture. To prevent natural gas leaks along the Pipeline, PCGP would conduct periodic corrosion/leak surveys along a corridor centered on the Pipeline, which will be up to 10 feet wide and will be maintained in an herbaceous state. Trees that are located within 15 feet of the Pipeline will be cut and removed from the right-of-way.[318] In addition, the Pipeline would be protected from corrosion using a cathodic protection (CP) system, which would be installed following construction. The CP system would generally consist of a number of sites where a rectifier/anode bed is installed and electrically connected by a conductor to the Pipeline.[319] The Project Corrosion Control Plan[320] contains additional information on PCGP's corrosion control methods and cathodic protection system.[321] Monitoring and maintenance of the cathodic protection system would be accomplished in compliance with the appropriate regulations at least once per calendar year but with intervals not to exceed 15 months. Problems detected through the monitoring program would be corrected promptly and checked in a follow-up survey no later than 12 months after the initial discovery. Recording and transmitting pressure and temperature data would be controlled and/or monitored by the gas control monitoring system.

In addition, in-line inspection tools, known as smart pigs, would be launched/received by equipment located at each end of the Pipeline (i.e., the Jordan Cove Meter Station and the Klamath Compressor Station).[322] There would also be pig launcher/receiver equipment co-located at Block Valve Assemblies to facilitate periodic in-line inspections using smart pigs. Use of pigs, the cathodic protection system, and periodic aboveground inspections would reduce the remote possibility of unintentional natural gas releases.

Based on employing all of the above noted measures, the DEIS contains ample support for its conclusion that the Project would not significantly affect public safety.

2. Valve Assemblies

Commenters raise concern regarding USDOT pipeline safety regulations and distances between block valve assemblies and mainline block valves.[323] These requirements are already considered in the DEIS. A mainline valve (MLV) is a block valve installed in-line (as part) of the pipeline. A block valve assembly (BVA) includes the MLV and appurtenances such as the valve

[315] DEIS at pp. 4-770 to 4-771, 4-774 to 4-775.
[316] DEIS at pp. 4-776 to 4-780.
[317] DEIS at p. 4-780.
[318] DEIS at p. 2-71.
[319] DEIS at pp. 2-42, 4-426.

[321] DEIS at p. 2-69.
[322] DEIS at p. 2-21.
[323] Comment of Clarence and Stephany Adams at pp. 3 to 4, Accession No. 20190703-5053 (July 3, 2019).

operator, bypass and blowdown valves and piping, and instrumentation. Pipe class and MLV locations must comply with the 49 CFR Section 192, in particular 49 CFR Section 192.5 Class Locations and 49 CFR Section 192.179 Transmission line valves.[324] PCGP agrees with commenters who cite the required maximum distances that a sectionalizing block valve (MLV) must be placed, as stated in 49 CFR Section 192.179. For example, 49 CFR Section 192.179 (a)(3) states "Each point on the pipeline in a Class 2 location must be within 7-1⁄2 miles (12 kilometers) of a valve." The DEIS explains that the Pipeline would be constructed in accordance with such USDOT regulations.[325]

To perform the compliance assessment, the beginning and ending location of each class segment is compared to the location of both the upstream and downstream MLV, to assure that every point within a class segment is within the maximum allowed distance to at least either the upstream or downstream MLV. If the distance is greater than the maximum allowed, then the MLV location must be revised or additional MLV added until all points are within the maximum allowed distance of an MLV. PCGP notes that due to the incorporation of re-routes into the originally proposed Pipeline alignment, and preservation of original mileposting as reference points, using milepost designations to determine miles of pipeline is inaccurate. Rather, a measured method for determining mileage should be used to obtain a linear distance between valve locations. Additionally, the Applicants filed a proposed list of modifications to the Project which included relocations of four MLV's (see Applicant Response to DEIS date July 5, 2019, Attachment A, Appendix 3).[326] These revisions have been reviewed to ensure the design complies with the requirement of 49 CFR Section 192.179.

3. Wildfire and Extreme Fire Danger Concerns

Commenters raise concerns related to wildfires and extreme fire dangers generally in the Project area.[327] The DEIS adequately evaluated these concerns and determined that PCGP would, among other things, meet or exceed USDOT pipeline burial depth requirements, develop an ERP including procedures to minimizes hazards in the event of an emergency, and would have facilities along the Pipeline to aid in protecting the Pipeline from wildfires.[328] Concerns regarding drought and wildfire are addressed through PCGP's implementation of the procedures detailed in its Fire Prevention and Suppression Plan[329] and the Prescribed Burning Plan[330], which follow Oregon Department of Forestry requirements, and which were analyzed in the DEIS.[331] In addition, many landowner agreements, especially those with timber companies, contain requirements for fire plans.

[324] DEIS at pp. 4-769 to 4-771.
[325] DEIS at p. 2-45.

[327] Comment of Regna Merritt on behalf of 978 petition signees, Accession No. 20190627-5082 (June 27, 2019).
[328] DEIS at pp. 4-774 to 4-776.
[329] Plan of Development at Appendix K.
[330] Plan of Development at Appendix R.
[331] DEIS at pp. 2-70, 4-776.

Another commenter asserts that by creating a continuous corridor of early seral vegetation and by facilitating additional fire exclusion and fire suppression through LSRs, the Pipeline will increase fire hazards and wildfires in the area that inhibit the retention of late-successional habitat characteristics; further, the commenter claims that the Umpqua National Forest is the only land management area that presents mitigation measures that would lower the risk of loss of forest stands to high intensity fire with proposed thinning and off-site pine removal.[332] These concerns are already addressed in the DEIS. PCGP is unaware of any scientific support indicating that the Pipeline route through LSRs would increase fire hazards. In descriptions for the proposed mitigation projects on the Umpqua National Forest, the DEIS notes that the Forest Service states that the Pipeline corridor would increase fire suppression complexity, but that it would also provide a fuel break.[333] Additionally, some of the proposed mitigation projects identify that fuels reduction adjacent to the Pipeline would increase the effectiveness of the Pipeline corridor as a fuel break. Commenter is correct that the Umpqua National Forest is the only National Forest that has provided mitigation specifically for fuels reduction and/or a fuel break.[334]

Further, the DEIS discusses Applicants' voluntary compensatory mitigation proposals for BLM lands.[335] Within the list of voluntary mitigation projects, there are several focused on fire suppression and fuels reduction, and they are spread across the Coos Bay, Roseburg and Medford BLM districts.

Commenters raise concern of pipeline failures leading to fires, and fire response time in remote areas and areas of steep terrain[336]. Additionally, commenters expressed concern regarding the impacts of a wildfire over the buried pipeline and block valves.[337] The DEIS already addresses these concerns. See the above discussion for a description of leak detection, corrosion control, and inspection measures to be implemented by PCGP during operation of the Pipeline to minimize the potential for pipeline leaks. In addition, block valves are protected because the site ground cover is crushed rock (gravel) and is free of vegetation, which provides separation between a possible wildfire and the main piping arrangement that exists above ground."

The DEIS recognizes that the Pipeline would be in areas where forest fires could occur.[338] The DEIS further discusses PCGP's proposal to meet or exceed USDOT pipeline burial depth requirements (found in 49 CFR Part 192), installing the Pipeline with at least 36 inches of cover in Class I locations with normal soils and at least 24 inches of cover in consolidated rock areas.[339] In the event a fire was to occur on the surface in the vicinity of the Pipeline, the presence of the Pipeline would not increase fire hazards.

[332] Comment of Klamath Siskiyou Wildlands Center at p. 9, Accession No. 20190611-5153 (July 11, 2019).
[333] DEIS at p. 4-450.
[334] Other National Forests have proposed projects that would thin forest, but not specifically to manage or control fires; typically proposed to increase late successional characteristics in a stand
[335] DEIS at p. 1-8.
[336] Marris Comments at 7.
[337] Oregon Women's Land Trust at pp. 4-5, Accession No. 20190702-5054 (July 2, 2019).
[338] DEIS at p. 4-774.
[339] DEIS at p. 4-774.

The DEIS explains how fires on the surface are not a direct threat to underground natural gas pipelines because of the insulating effects of soil cover over the pipeline; soil is a poor conductor of heat with thermal conductivity values ranging from 0.44 to 1.44 Btu/ft-hr-°F, and the heat capacity of most soils is 0.20 to 0.25 Btu/lb-°F.[340] Additionally, the 30-foot wide operational corridor would be maintained with a low fuel, low shrub canopy to allow aerial inspection and ground-based inspection. The operational/maintained corridor would be planted in native grasses, low growing plants, and shrubs and would closely approximate the bio regime and fuel load condition of a dense chaparral forest (California, Chaparral Institute 2017). According to Figure 2.5(C) in "Wildland Fire in Ecosystems Effects of Fire on Soil and Water," soil temperatures during a High Severity chaparral wild fire typically do not exceed ~175° F at a depth of 2 inches (Forest Service 2005). The amount of moisture present in the soil along the maintained corridor would have no effect on the deeper (>2 inches) soil temperature profiles due to the short-duration burn time and fast moving characteristics of a wildfire in the low canopy environment within the operational/maintained corridor. Given the above, the DEIS sufficiently considers fire risk to pipeline integrity.

VII. *Engineering and Design*

1. LNG Terminal Design

One commenter expresses concerns regarding the safety implications of the mechanical design of the LNG facility, particularly the reliability of the mechanical design.[341] These concerns are already adequately addressed in the DEIS. Section 4.13.1.5 of the DEIS contains a review of the preliminary engineering designs and discusses public information related to reliability and mechanical design of the LNG Terminal[342] Moreover, the DEIS refers to industry codes and standards for the design, fabrication, construction, and installation of piping and equipment and specifications for the facility and includes recommendations not only to ensure industry codes and standards are incorporated in the facility design but also to verify that the equipment is being properly maintained during the life of the facility.[343] Given the above, the DEIS adequately assesses the reliability of the mechanical design and makes provisions to assure use of the proper design and technology throughout the life of the Project.

One commenter expressed concern regarding the LNG Terminal's ability to shut down in an emergency, and any relevant safety implications.[344] These concerns are sufficiently addressed in the DEIS. In Section 4.13.1.5, the DEIS addresses the LNG Terminal's emergency shutdown and depressurization systems.[345] The emergency shutdown system is subject to 49 CFR Part 193 compliance and FERC Staff's recommendations in the DEIS[346] detail further review of final design requirements. JCEP anticipates that the Staff Recommendations in Section 4.13.1.6 of the DEIS would be conditions of any Certificate issued for the LNG Terminal. JCEP would comply with

[340] DEIS at p. 4-755.
[341] WELC Comments at p. 17.
[342] DEIS at pp. 4-713 to 4-719.
[343] DEIS at pp. 4-715 to 4-719.
[344] WELC Comments at p. 20.
[345] DEIS at pp. 4-719 to 4-720.
[346] DEIS at p. 4-762.

the conditions of the Certificate to enhance the reliability and safety of the facility and to mitigate the risk of impact on the public. Therefore, the DEIS sufficiently analyzes the Project's emergency shutdown system.

2. Shipping Channel Modifications

One commenter asserts that there is no evidence to suggest that the four modifications to the shipping channel are necessary or would serve to enhance the channel.[347] These modifications are appropriately considered in the DEIS. As stated in the DEIS, JCEP proposes to excavate four submerged areas in Coos Bay along the vessel access route to improve navigational reliability.[348] Section 4.13.1.3 of the DEIS explains that USCG has regulatory authority over navigational safety, LNG marine vessel engineering and safety standards, and marine transfer areas.[349] The DEIS references the USCG's May 2018 LOR, which recommended that the Coos Bay Channel is suitable for accommodating the type and frequency of LNG marine traffic associated with this project from a maritime and navigational safety standpoint.[350] The DEIS notes that the LNG Terminal would be able to produce up to 7.8 million metric tons per annum of LNG.[351] In order to export this volume using the size of vessels anticipated to call on the LNG Terminal, JCEP identified the need to expand the weather window in which these LNG vessels could transit Coos Bay.[352]

PROPERTY OWNER CERTIFICATION AND CONSENT

I hereby certify that the Oregon Department of State Lands is the manager of those submerged and submersible non-trust lands in Coos Bay owned by the State of Oregon. I hereby approve Jordan Cove LNG, LLC to file land use applications with the City of Coos Bay ("City"), the City of North Bend, and Coos County ("County") for the following land use authorizations for uses and activities to be located and/or undertaken within our area of ownership, as depicted on attached Exhibit 1:

(1) Post-acknowledgment amendments to the Coos Bay Estuary Management Plan ("CBEMP") map at three Coos Bay locations in the City of Coos Bay and unincorporated Coos County depicted in Exhibit 1 to these Applications ("Navigation Reliability Improvement Sites" or "NRI Sites") to change the zoning designation of 59-CA, 2-NA, and 3-DA, to DDNC-DA;

(2) A post-acknowledgment amendment of the CBEMP, which is part of the Coos County Comprehensive Plan ("CCCP"), to take a reasons exception to Statewide Planning Goal ("Goal") 16 text amendment adopted of the CBEMP, which is part of the Coos County Comprehensive Plan ("CCCP"), in the form of a reasons exception to Statewide Planning Goal ("Goal") 16 to authorize the rezone of the NRI Sites to DDNC-DA;

(3) An amendment of the text of the Coos County Zoning and Land Development Ordinance ("CCZLDO") to clarify that the DDNC-DA designation is appropriate for application to area adjacent to, and not only within, the designated federal navigation channel;

(4) Administrative conditional use permit to authorize new and maintenance dredging at the NRI Sites in the DDNC-DA zone, as this Application proposes to amend those sites.

(5) Administrative authorization from the City of North Bend for the installation of temporary dredge material transport lines, an off-loading facility, and the placement of dredged material in an Industrial zone designation.

Jordan Cove Energy Project, L.P.

October 11, 2019

Ms. Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street, N.E.
Washington, D.C. 20426

Re: OEP/DG2E/Gas Branch 3
Jordan Cove Energy Project L.P.
Docket No. CP17-495-000
Response to October 4, 2019 Data Request

Dear Ms. Bose:

On September 21, 2017, Jordan Cove Energy Project L.P. ("JCEP") filed an application pursuant to Section 3(a) of the Natural Gas Act, as amended,[1] and Parts 153 and 380 of the regulations of the Federal Energy Regulatory Commission ("Commission"),[2] for authorization to site, construct, and operate certain liquefied natural gas facilities.

On October 4, 2019, the Commission issued an Environmental Information Request ("October 4 Data Request"). JCEP is submitting a complete response to the October 4 Data Request in the narrative and attachments included herewith.

Should you have any questions, please contact me at neades@pembina.com or 832-255-3841.

Sincerely,

/s/ Natalie Eades

Jordan Cove Energy Project L.P.

Request

In order to address concerns expressed by the Bureau of Land Management (BLM) regarding the feasibility of installing the proposed industrial waste water pipeline (IWWP) along the Trans-Pacific Parkway, please provide a map of the proposed IWWP at a horizontal scale of 1" = 200'. This map should indicate landownership and illustrate topographic features, such as sand dunes and wetlands. This map should also depict the adjacent Trans-Pacific Parkway and North Spit rail spur as well as all existing utilities (water, power, fiber optics, etc.). Confirm sufficient space is present within the existing easement to successfully accommodate construction and operation of the IWWP by indicating on the aforementioned map (or other drawing) all required workspaces. Also, in an accompaniment to the map, describe IWWP construction methods (general and special). If sufficient space is unavailable within the existing easement, describe facility/route alternatives, including any impact on BLM or U.S. Department of Agriculture Forest Service (Forest Service) administered lands. Specifically, at a minimum, describe the feasibility of an alternative pipeline route that would avoid the BLM parcel located north of the terminal site and would locate a portion of the IWWP within the proposed Access and Utility Corridor. Lastly, document consultation with the BLM and Forest Service regarding the proposed IWWP location, construction feasibility, and any potential alternative facilities/routes.

Response:

Please see Attachment 1 for details regarding construction of the industrial wastewater pipeline ("IWWP" or "IWP" on the attachments). The horizontal scale provided in Attachment 1 is greater than 1" = 200'. Attachment 1 also shows topographic features, the Trans-Pacific Parkway, the rail line and utilities. Please see Attachment 2 for land ownership with existing and proposed easement information. JCEP has confirmed that there is sufficient space for construction, operation and maintenance of the IWWP within the existing 100-foot wide Trans-Pacific Parkway right-of-way easement created and established for transportation and utility purposes. Therefore this response does not include plans for future work nor potential facility/route alternatives. No feasible alternative routes have been identified. Attachment 1 will be updated prior to construction to include the latest wetland delineations and construction requirements; no centerline changes are anticipated, however. JCEP discussed the permitting of the proposed IWWP with BLM through teleconferences in August and September 2019.

JCEP anticipates using typical municipal utility construction techniques, including trenching, pipe placement, and backfill. Construction and major maintenance activities would utilize the width between the railroad tracks and up to one lane of Trans-Pacific Parkway. Minor maintenance would utilize the proposed 20-foot wide IWWP easement within the existing 100-foot easement shown on Attachment 2. The trench width for the IWWP is expected to be 36 inches to 48 inches with a minimum burial depth of 36 inches, as on in sheet D-1 included in Attachment 1. JCEP notes that some traffic flagging and signaling will be necessary, but this is not depicted on the plan sheets in Attachment 1.

OVERVIEW MAP
NTS

GENERAL NOTES:

1. CONTRACTOR TO OBTAIN ALL PERMITS FOR RAIL CROSSING AND RETAIN COPY OF PERMITS ON SITE AT ALL TIMES.
2. CONTRACTOR TO OBTAIN COOS COUNTY CONSTRUCTION PERMIT TO WORK WITHIN THE TRANSPACIFIC PARKWAY RIGHT OF WAY.
3. THIS IS A PREVAILING WAGE PROJECT.
4. OWNER TO PAY ALL PERMIT FEES.
5. ALL WORK SHALL CONFORM TO THE APPLICABLE SECTIONS OF THE ODOT STANDARD SPECIFICATIONS AND THE CONTRACT PLANS AND SPECIFICATIONS. IN THE ABSENCE OF PLAN AND SPECIFICATION DEFINITION, THE MORE STRINGENT SHALL GOVERN IN CASE OF CONFLICT.
6. TRAFFIC CONTROL SHALL COMPLY WITH THE OREGON TRAFFIC CONTROL HANDBOOK LATEST EDITION.
7. ATTENTION: OREGON LAW REQUIRES YOU TO FOLLOW THE RULES ADOPTED BY THE OREGON UTILITY NOTIFICATION CENTER. THOSE RULES ARE SET FORTH IN OAR 952-001-0010 THROUGH 952-001-0090. YOU MAY OBTAIN COPIES OF THE RULES BY CALLING THE CENTER. (NOTE: THE TELEPHONE NUMBER FOR THE OREGON UTILITY NOTIFICATION CENTER IS 503 232-1987.)
8. CONTRACTOR TO CALL "ONE CALL" UTILITY LOCATION NUMBER 1-800-332-2344 OR (811) FOR FIELD LOCATION PRIOR TO EXCAVATION.
9. CONTRACTOR TO FIELD VERIFY THE DEPTH AND LOCATION OF ALL UTILITIES PRIOR TO EXCAVATION AND SHALL NOTIFY THE ENGINEER IMMEDIATELY OF ANY DISCREPANCIES. UTILITY ELEVATIONS SHOWN IN PROFILE ARE ESTIMATED AND SHALL BE FIELD VERIFIED BY THE CONTRACTOR.
10. IF MATERIALS CONTAINING ASBESTOS ARE ENCOUNTERED ON THIS PROJECT. CONTRACTOR SHALL BE FULLY RESPONSIBLE FOR PROPER IDENTIFICATION OF MATERIALS, SAFE HANDLING, AND PROPER DISPOSAL. ALL APPLICABLE FEDERAL, STATE AND LOCAL RULES, LAWS AND GUIDELINES MUST BE STRICTLY ADHERED TO OVER THE COURSE OF CONSTRUCTION. CONTRACTOR SHALL COORDINATE AND PAY FOR PERMITS, FEES, INSPECTIONS, ETC. WITH APPROPRIATE REGULATORY AGENCIES. CONTRACTOR TO PROVIDE SAFE TRANSPORT TO DISPOSAL FACILITIES.
11. COMPACTION REQUIREMENTS UNLESS OTHERWISE NOTED:

LAYER	RATE	TEST
SUBGRADE	95%	T99
CRUSHED ROCK	95%	T99
ASPHALT	91%	

12. MAINTAIN ALL SIGNS AND MARKERS AND RESTORE PAVEMENT STRIPING AS NEEDED TO ORIGINAL OR BETTER CONDITION.
13. PROTECT MAILBOXES AND RETURN TO EXISTING LOCATION.
14. RESTORE ALL SURFACE MATERIALS TO ORIGINAL OR BETTER CONDITION. LANDSCAPE MATERIALS TO MATCH EXISTING TO THE GREATEST EXTENT POSSIBLE.
15. CONTRACTOR TO LOCATE EXISTING WATER TO ENSURE HORIZONTAL AND VERTICAL SEPARATION AS REQUIRED.
16. ALL ABANDONED UTILITY APPURTENANCES SHALL BE REMOVED TO WITHIN 36" OF THE GROUND SURFACE AND LIVE PIPE SYSTEMS. ABANDONED PIPES SHALL BE ABANDONED IN PLACE WITH ALL PORTALS CAPPED OR PLUGGED.
17. CONTRACTOR SHALL PROTECT ALL STORM SEWERS WITH INLET SEDIMENT BARRIERS, AND INSTALL OR PROVIDE EROSION AND SEDIMENT CONTROL MEASURES IN ACCORDANCE WITH BEST MANAGEMENT PRACTICES.
18. ROADWAY MATERIALS SHALL BE RESTORED TO MATCH OR EXCEED EXITING DIMENSIONS WITH MATERIALS MEETING ODOT SPECIFICATIONS. MATERIAL GRADATIONS AND TEST DATA SHALL BE SUBMITTED AND APPROVED PRIOR TO CONSTRUCTION.
19. CONTRACTOR TO PRESSURE TEST ALL NEW PIPE AT 150 LBS.
20. INSTALL THRUST BLOCKS, TOGETHER WITH JOINT RESTRAINT SYSTEMS, ON ALL FITTINGS OR PRESSURE POINTS PRIOR TO TESTING PIPE. FOLLOW RESTRAINED JOINT TABLE FOR PIPE LENGTH TO BE RESTRAINED FROM EACH FITTING. ON TEMPORARY OR EXISTING FITTINGS, ONLY THRUST BLOCKS WILL BE REQUIRED. ALLOW THRUST BLOCKS 5 DAYS TO CURE PRIOR TO TESTING. INSTALL PORTS AND VALVES AS NEEDED FOR TESTING PURPOSES.
21. THE CONTRACTOR SHALL MAKE HIS OWN ARRANGEMENTS FOR STAGING AREAS.
22. THE CONTRACTOR SHALL MAKE HIS OWN ARRANGEMENTS FOR DISPOSAL OF EXCESS MATERIALS. MATERIALS TO BE DISPOSED OF OFFSITE SHALL BE BY WRITTEN AGREEMENT BETWEEN PARTIES AND/OR PERMITS FROM APPROPRIATE AGENCIES, AND THE CONTRACTOR SHALL PROVIDE A COPY OF THE AGREEMENT/PERMITS TO THE ENGINEER.

RESTRAINED JOINT TABLE

	RESTRAINT LENGTH (B-BRANCH, R-RUN)
FITTING	16"
PIPE END	175'
TEE	R-20' B-23'
90° ELBOW	50'
45° ELBOW	22'
22.5° ELBOW	10'
11.25° ELBOW	5'

RESTRAINED JOINT TABLE NOTES:

1. RESTRAINED JOINT FITTINGS ARE TO BE INSTALLED IN ADDITION TO TRUST BLOCKS. THRUST BLOCKS AND MECHANICAL JOINT RESTRAINT ARE TO BE PROVIDED AT ALL POINTS WITH UNBALANCED FORCES.
2. THIS RESTRAINED JOINT TABLE IS VALID FOR A MINIMUM OF 3' COVER, 95% COMPACTION, 150 PSI TEST PRESSURE, AND SAFETY FACTOR 1.5.
3. PIPE BEDDING AND PIPE ZONE MATERIALS, AROUND AN ON EACH SIDE OF THE RESTRAINED PIPE FOR THE MINIMUM DISTANCE SHOWN IN THE JOINT RESTRAINT TABLE, SHALL BE 3/4"-0 COMPACTED TO 95% RELATIVE DENSITY.
4. NEW WATER LINE SHALL BE RESTRAINED TO COMPENSATE FOR ALL UNBALANCED FORCES AND FOR EACH FITTING INSTALLED.
5. RESTRAINED JOINTS SHALL BE SERIES 2800 FOR C905 PVC AND SERIES 2000 FOR C900 PVC, AS MANUFACTURED BY EBAA IRON OR APPROVED EQUAL.
6. A COMPACTION TEST SHALL BE TAKEN AT LOCATION DIRECTED FOR EACH FITTING.
7. WHERE RESTRAINT LENGTH CANNOT BE MET OR WHERE TEMPORARY PLUGS OR FITTINGS ARE REQUIRED PROVIDE THRUST BLOCKS TO PREVENT PIPE MOVEMENT.

Document Content(s)

Jordan Cove Energy Project L.P.

Resource Report No. 1

General Project Description

Jordan Cove Energy Project

September 2017

contracts roll off on GTN and Ruby, there is ample supply from those two systems when gas is needed.

Pipeline transmission system subscription (volume reserved within the pipeline total capacity) and available capacity are provided in Table 1.2-1. This table depicts the shortage of available gas subscription capacity of the Williams Northwest Pipeline ("NWP") system and how it is not sufficient for the Project demand. While NWP can supply gas from Sumas for delivery at Stanfield, the amount of available capacity for Stanfield Delivery (227,846 Dth/d) is substantially less (approximately 80% less) than the required feedstock for the terminal (1,200,000 Dth/d). NWP can also deliver gas from the U.S. Rockies, however, this supply is highly seasonal. During summer, there is approximately 536,040 Dth/d available; during the peak winter months, this capacity is almost fully utilized (as an example, on Feb 1, 2017, only 70,000 Dth/d were available).

A connection from a point near the intersections of the Ruby Pipeline and the GTN Pipeline would provide more than sufficient capacity to access the aforementioned gas markets utilizing existing infrastructure and avoiding impacts to domestic use of the gas resources.

Table 1.2-1

Pipeline Capacity Available for New Long-Term Contracts

		Operating Capacity	**Subscribed Capacity**	**Available Capacity**
		Dth/d	**Dth/d**	**Dth/d**
Ruby Pipeline				
	Opal Receipt	1,500,000	819,534	680,466
Williams Northwest (NWP)				
	Sumas Receipt	1,314,750	1,113,815	200,935
	Opal- Stanfield (summer)	655,000	118,960	536,040
	Opal- Stanfield (winter)	655,000	584,993	70,007
	Stanfield Delivery	244,560	16,714	227,846
GTN				
	Kingsgate Receipt	2,812,440	2,047,243	765,197

Data extracted from EBB's of GTN, NWP and Ruby effective 08/21/2017 and Opal – Stanfield (winter) extracted from NWP's EBB effective 02/01/2017.

1.2.3 Current LNG Terminal Proposal

The design of the proposed LNG Terminal reflects several enhancements from the prior proposal in Docket No. CP13-483-000. These changes will result in an enhanced system design and a reduction in overall environmental impacts. Hydrocarbon processing and combustion, including pre-treatment, will be located on Ingram Yard in an effort to create a more efficient footprint and operating aspects of the facility. The LNG Terminal will now utilize a direct drive configuration by relocating the gas turbines adjacent to the refrigerant compressors, thereby eliminating the need for the South Dunes Power Plant and associated transmission line, making the facility simpler, more efficient, and easier to operate. The workforce housing facility has been consolidated onto the South Dunes Site reducing land and traffic impacts in the area of the previously proposed location at the North Point Site in North Bend adjacent to the suburb of Simpson Heights. The Southwest Oregon Regional Safety Center ("SORSC") building has been relocated to the northeast portion of the South Dunes Site and the Fire Department has been relocated to the Access and Utility Corridor, both relocations further reducing land and wetland impacts while improving emergency response time.

The Project under Docket No. CP13-483-000 included the 420-megawatt ("MW") South Dunes Power Plant. Within the current proposal, the Project proposes to use direct combustion-turbine liquefaction-drive instead of motor liquefaction-drive driven by electric power provided by the South Dunes Power Plant. A direct drive configuration is simpler, more efficient and easier to operate; and results in a number of reductions in environmental impact, including:

- Eliminates hydrocarbon processing combustion equipment from the South Dunes Site, which results in a single compact and consolidated facility process area on Ingram Yard;
- Eliminates the need for a railroad spur road overpass, reducing wetland impacts;
- Reduces combustion-turbine count from six to five, and maintains, and in some cases reduces, point source air emissions from the existing conditions permitted by the Oregon Department of Environmental Quality ("ODEQ");
- Reduces water consumption by 1 million gallons per day by eliminating the need for gas turbine water injection;
- Increases the distance from the nearest noise-sensitive receptors;
- Eliminates impacts on estuarine wetlands on the South Dunes Site;
- Allows for relocation of the workforce housing facility to the South Dunes Site addressing community concerns and significantly reducing workforce traffic movements on U.S. Highway 101 ("US 101") during the working week; and
- Allows for the relocation of the SORSC building to the northeast corner of the South Dunes Site and the elimination of 1 acre of wetland impacts.

In addition to the above enhancements, the following changes have been made to the design and construction of the LNG Terminal:

- Fire and other emergency incident response time has been improved by splitting the Fire Department building from the SORSC building and relocating the fire department to the Access and Utility Corridor from the South Dunes Site.
- The design now incorporates black-start capability reducing impacts from the Project on local utilities by eliminating the need to draw and export electricity from the local grid for operations, except the SORSC building. Limited temporary construction power within the capacity of the existing grid system will be utilized.
- The expansion of the Kentuck Mitigation Site from 33 acres to a more comprehensive Kentuck Project encompassing over 100 acres of wide-ranging habitat of mudflats, salt marsh, willowed scrub/shrubs and fish structures addressing a number of the key limiting factors Coho salmon face in this region, which will assist in the species' removal from the endangered species list
- The excavation of four submerged areas lying adjacent to the federally-authorized Coos Bay Navigation Channel ("Channel"). These minor enhancements (approximately 700,000 cubic yards) will allow for transit of LNG vessels of similar overall dimensions to

Re: Jordan Cove -- Withdrawal of Application for Exemption

Dear Mr. Cornett:

By letter dated June 14, 2018, Jordan Cove Energy Project L.P. ("JCEP") submitted to the Oregon Department of Energy ("ODOE") an Application for Exemption from a Site Certificate for a high-efficiency cogeneration energy facility to be constructed at its proposed Liquefied Natural Gas Terminal in Coos Bay, OR (the "LNG Terminal"). This letter is to inform you that JCEP is withdrawing that Application for Exemption.

JCEP has made a minor modification to the LNG Terminal such that the nominal electric generating capacity is less than 25 megawatts. Consequently, the LNG Terminal does not meet the definition of an "energy facility" in ORS 469.300(11)(a) and is below the Energy Facility Siting Council's jurisdictional threshold applied to state jurisdictional energy facilities. Therefore, there is no basis (or need) for JCEP to request, or the Siting Council to issue, an exemption. As a result, please consider our Application for Exemption from a Site Certificate withdrawn.

Thank you for your assistance and that of your staff.

Sincerely,

Mike Koski
VP, External Affairs

Re: Industrial Emissions Evidentiary Letter

Dear Mr. Pfeiffer:

Please accept this letter into the record on behalf of the Jordan Cove Energy Project L.P. (Jordan Cove or JCEP) in support of the application for land use approvals for Jordan Cove's proposed liquefied natural gas (LNG) export terminal, hereinafter referred to as "the Project." The Project includes all supporting and integrated components as described in the application.

The purpose of this letter is to explain the source and types of potential industrial emissions at the Project and how they will be mitigated for. The Coos County Zoning and Land Development Ordinance (CCZLDO) Section 4.11.445(4) requires industrial uses as a part of regular operations not cause emissions of smoke, dust or steam that could obscure visibility within airport approach surfaces, unless mitigation measures will reduce the safety risk or incompatibility with airport operations to an insignificant level.

I am a Technical Project Lead in the Energy Division at Black and Veatch Corporation. Black and Veatch has extensive experience designing and constructing Import and Export LNG facilities. As the Technical Project Lead I am responsible for directing the overall design of the Jordan Cove facility. Formerly I was an Instrument & Controls Project Lead with Black and Veatch. I hold a Bachelor's of Science degree in Industrial Engineering from Penn State University. I have 46 years of experience in the Oil and Gas sector. I am a registered Professional Engineer (Texas, Louisiana). For the past 10 years I have worked on designing LNG Import and Export facilities in the United States. With this education and experience I believe I am qualified to explain the source of industrial emissions and types of mitigation for industrial emissions from the Project.

The likely sources of industrial emissions are: (1) dust during construction due to mobile equipment use, construction equipment and vehicle travel, (2) minimal thermal plumes from the off Thermal Oxidizers in the gas processing facility during operation. There are no visible or steam plumes from the facility. The Project will not generate any smoke. Each of these are assessed separately below.

As explained in Resource Reports 2 and 9, submitted to FERC in May 2013, the Project will mitigate dust during construction by using best management practices. These typically include watering areas of sand or dust at regular intervals. Also note that the water table in this area is very high which results in a high moisture content of the material being handled. This also reduces dust emissions.

As explained in Resource Report 2, Water Use and Quality, Section 2.1.5 Water Use:

> The CBNBWB also has two raw water lines, one for each of the well fields on the North Spit. One raw water line runs from the well field located to the north of the former linerboard mill site and was the source of water to the mill. A second raw water line connects a well field located to the west of the Project site and to the north of the Trans-Pacific Parkway to a water treatment plant. Prior to the construction of the potable water line, this plant provided the potable water on the North Spit. JCEP is planning on extending the raw line (before it gets to the treatment plant) to the Project site and use that water for the concrete batch plant, compaction during site grading (if required), dust suppression during construction, and to supplement the potable water available for hydrostatic testing (described further in Section 2.3.4) and any other construction activity requiring water.

Construction related dust and suppression is explained in Resource Report 9, Air and Noise Quality, Section 9.3.1.1:

> Air quality impacts associated with construction projects generally can be classified as: impacts associated with fugitive dust generation; and impacts associated with the operation of equipment during construction activities that may result in a minor, temporary increase in emissions.
>
> Fugitive dust generation may result from construction activities such as land clearing, grading, excavation, and concrete placement, along with vehicular traffic on paved and unpaved roads. The magnitude of fugitive dust generation will be primarily a function of the area of construction, silt and moisture contents of the soil, wind speed, frequency of precipitation, amount of vehicle traffic, vehicle types and paved roadway characteristics. Fugitive dust may be produced during all phases of construction. Emissions will be greater during the drier summer months and in areas of fine-textured soils. During these periods, dust suppression techniques, such as watering, will be used in these areas to minimize the impacts of fugitive dust on sensitive areas. Fugitive emissions during the construction activities alone will not require a permit.
>
> Air quality impacts are also associated with the operation of gasoline or diesel fueled engines in land clearing/grading equipment, cranes, bulldozers, and various types of trucks and cars. The engines will emit relatively small amounts of air emissions. Construction of the LNG Terminal is expected to last about 42 months. Other construction-related emissions include compactors, pavers, welding, brazing, soldering, solvent cleaning, grinding, cutting, etc.

TRC Environmental Corporation explains the source and volume of plumes in the Thermal Plume Study (Applicant's Exhibit 27, 1-4):

> The total combined volumetric flow rate from the two thermal oxidizers is 4% of the total flow from the five combustion turbines. Thus, it is expected that the plume vertical velocity generated from the thermal oxidizers will be substantially lower in magnitude than the plume vertical velocity from the combustion turbine stacks.

It is important to note, that the thermal oxidizers only contribute 4% of the total flow or plume. The remainder of the plume is generated by sources that are not part of this land use application.

Each of the two thermal oxidizers will have a thermal plume exiting the 3.5 feet diameter stack at 63.6 feet/second velocity. The stack outlet is 75 feet above grade or at an elevation 121 feet NAVD 88. The following is a table of the expected Exhaust Characteristics for the thermal oxidizers.

Exhaust Parameter	
Exhaust Height (ft above grade)	75
Exhaust Height (m above grade)	22.86
Exhaust Temperature (deg F)	980
Exhaust Flow (acfm)	36,744
Exhaust Velocity (ft/sec)	63.6
Exhaust Velocity (m/sec)	19.40
Inner Diameter (ft)	3.50
Inner Diameter (m)	1.07
Stack Base Elevation (ft)	48
Stack Locations (UTM NAD83)	399,180.6 m East 4,809,908.2 m North 399,253.7 m East 4,809,910.4 m North

The thermal plume from the thermal oxidizers will not cause a significant safety risk or be incompatible with airport operations. I reach this conclusion for three reasons. First, the thermal oxidizers are not directly under the flight path. See Applicant's Figure 15. Second, as explained in the Thermal Plume Study, "[u]nder these more typical meteorological conditions the CASA threshold would not be expected to be exceeded other than in the area directly above the South Dunes Power Plant exhausts." Exhibit 27, 1-10. As explained above, the thermal oxidizers are not under the flight path and only contribute 4% of the plume. Therefore, since the entire plume (including 96% from other sources) is expected to meet CASA standards in the flight path, the emissions from the thermal oxidizers would as well. Third, even when the CASA threshold is exceeded in the general direct airspace above the power plant, it quickly dissipates at less than 1.0m/s in the direct flight path to the airport. Exhibit 27, 1-9.

It is my professional opinion that the Jordan Cove Project, if constructed and operated consistent with the mitigation measures detailed in this letter, will not adversely affect airport approach surfaces.

Should you have any further questions please do not hesitate to contact me at 913-458-6235.

Sincerely,

Carl A. Himes Jr.

Air and Noise Quality

Jordan Cove Energy Project

September 2017

Responses to Agency Comments

Agency	Agency Comment #	Agency Comment	Response Summary
FERC	1	Include any cultural sites and recreational areas that could be impacted by Project-related noise as NSAs in the analysis.	REC 1 included in discussion and tables.
FERC	2	The modeled concentrations presented in Table 9.2-10 (Cumulative Modeled Impacts) appear to differ from the modeled concentrations presented in Table 9.2-9 for the same pollutant and averaging period. In addition, the total impact presented in Table 9.2-10 appears to differ from the sum of modeled concentrations plus background in several cases. Include an updated version of Table 9.2-10 (and/or Table 9.2-9) to correct any errors, or include an explanation of the apparent discrepancies	Updated values were provided. In addition clarification that the values presented in Table 9.2-9 are the highest concentrations whereas the values in Table 9.2-10 are the form of the standards.
FERC	3	Include citations for the emission factors used in Appendix F.9 for emissions from LNG vessels and tugboats.	Citations for the emission factors were added for vessels and tugs.
FERC	4	Include the times of day when Jordan Cove would perform construction activities for the LNG terminal. In addition, indicate if construction would take place on weekends and federal holidays.	See section 9.4.1.2
FERC	5	Include a table that identifies the equipment needed for construction of the LNG Terminal. The table should include the type of equipment, number of equipment/vehicles, and associated sound power level or sound pressure level at a reference distance (e.g., 50 feet).	See Table 9.4-1
FERC	6	Include the noise levels from blowdown facilities, venting, or flaring at the terminal site. Describe the expected types, estimate the average number of yearly events by type, and estimate the duration. Indicate whether noise mitigation would be installed, and estimate the noise impact at the nearest NSAs.	See Section 9.4.2.2
FERC	7	Include an evaluation and quantification of noise impacts from pile driving and dredging operations at the nearest NSAs in L_{dn}. Indicate if these operations would be 24 hours and identify the length of time dredging would occur. Provide supporting documents, calculations, and a list of all assumptions used to estimate the noise impacts.	See Sections 9.4.1.2 and 9.4.1.3
FERC	8	Include an evaluation and quantification of noise impacts from sound pressure waves generated within the water due to pile driving and dredging operations, as well as noise due to the operation of the tugs and LNG vessels. Quantify sound pressure levels in the aquatic environment (in dB re: 1μPa) to a distance of 1	See Sections 9.4.1.2 and 9.4.1.3

Agency	Agency Comment #	Agency Comment	Response Summary
		mile and discuss impacts to all threatened and endangered aquatic species, marine mammals, and commercial and recreational fish species.	
FERC	9	Include Appendix G.9, including a table of sound sources associated with LNG Terminal operation presented in terms of both octave band and broadband sound levels. Appendix G.9 should also include a table of all proposed noise mitigation measures, providing their associated octave band insertion loss or transmission loss values.	A table of proposed mitigation measures with their associated insertion losses was not provided in Appendix G9 because no additional mitigation measures were required to meet the noise limit. Noise impacts were prevented through selection of a site distant from sensitive receivers. Noise reductions are inherent to the design through equipment selection meeting acoustical limits. Vapor barrier walls and topography also attenuate sound levels produced by the facility but are not specifically noise mitigation measures with insertion losses of a certain magnitude or any goal requirement for reduction.
FERC	10	Include a table listing the construction equipment needed to widen and/or modify the Coos Bay Channel as part of the Pilots Project. The table should include the type of equipment, number of equipment/vehicles, and their associated sound power level or sound pressure level at a reference distance (e.g., 50 feet).	See Section 9.4.1.3. A table was not included since only two types of dredges are being used and they are described in the text.
FERC	11a	Estimate potential in-air and underwater noise impacts associated with the construction activities and equipment needed to widen and/or modify the Coos Bay Channel as part of the proposed Pilots Project	See Section 9.4.1.3
FERC	11b	Estimate potential in-air and underwater noise impacts associated with the construction activities and equipment needed to widen and/or modify the Coos Bay Channel as part of the proposed Pilots Project	See Section 9.4.1.3
FERC	12	Provide concurrence from the State of Oregon that its noise regulations (OAR 340-035-0035) are not directly applicable to the construction and operational noise levels generated by the Project.	JCLNG is coordinating with DEQ.
EPA	13	The EPA recommends the EIS provide a detailed discussion of ambient air conditions (baseline or existing conditions), National Ambient Air Quality Standards, criteria pollutant nonattainment areas, and potential air quality impacts of the proposed project (including cumulative and indirect	The existing conditions and potential air quality impacts of the proposed project have been evaluated in the ACDP Application and the RR9. The ACDP application is included as Appendix A.9.

Agency	Agency Comment #	Agency Comment	Response Summary
		impacts). Such an evaluation is necessary to assure compliance With State and Federal air quality regulations, and to disclose the potential impacts from temporary or cumulative degradation of air quality.	
EPA	14	The EPA recommends the EIS describe and estimate air emissions from potential construction, operation, and maintenance activities, including emissions associated with LNG carriers at berth. The analysis should also include assumptions used regarding the types of fuel burned and/or the ability for carriers to utilize dockside power (i.e. cold ironing). Emissions at berth are of particular relevance because the deep draft LNG carriers would be required to remain docked between high tides. We also recommend proposing mitigation measures in the EIS to address identified emissions impacts.	Air emissions from construction, operation, and LNG carrier emissions have been quantified and addressed in the ACDP Application and the RR9. The carriers burn two types of fuel and will not use dockside power. Carrier emissions and operations are described in Appendix F.9.

JCEP LNG TERMINAL PROJECT

Resource Report 9 – Air and Noise Quality

Minimum FERC Filing Requirement:	Resource Report Section:
1. Describe the existing air quality, including background levels of nitrogen dioxide and other criteria pollutants that may be emitted above EPA-identified significance levels. (§ 380.12(k)(1)).	Section 9.1
2. Quantitatively describe existing noise levels at noise-sensitive areas such as schools, hospitals, or residences and include any areas covered by relevant state or local noise ordinances: • Report existing noise levels as the L_{eq} (day), L_{eq} (night), and L_{dn} and include the basis for the data or estimates. • For existing compressor stations, include the results of a sound level survey at the site property line and nearby noise-sensitive areas while the compressors are operated at full load. • For proposed new compressor station sites, measure or estimate the existing ambient sound environment based on current land uses and activities. • Include a plot plan that identifies the locations and duration of noise measurements, the time of day, weather conditions, wind speed and direction, engine load, and other noise sources present during each measurement. (§ 380.12(k)(2)).	Section 9.3 Figure 9.3-1 Tables 9.3-1, 9.3-2, and 9.3-3
3. Estimate the impact of the project on air quality, including how existing regulatory standards would be met. • Provide the emission rate of nitrogen oxides from existing and proposed facilities, expressed in pounds per hour and tons per year for maximum operating conditions, include supporting calculations, emission factors, fuel consumption rates, and annual hours of operation. • For major sources of air emissions (as defined by the Environmental Protection Agency), provide copies of applications for permits to construct (and operate, if applicable) or for applicability determinations under regulations for the prevention of significant air quality deterioration and subsequent determinations. (§ 380.12(k)(3)).	Section 9.2 Tables 9.2-1, 9.2-2, 9.2-3, 9.2-4, 9.2-5, 9.2-6, 9.2-7, and 9.2-8
4. Provide a quantitative estimate of the impact of the project on noise levels at noise-sensitive areas, such as schools, hospitals, or residences. • Include step-by-step supporting calculations or identify the computer program used to model the noise levels, the input and raw output data and all assumptions made when running the model, far-field sound level data for maximum facility operation, and the source of the data. • Include sound pressure levels for unmuffled engine inlets and exhausts, engine casings, and cooling equipment; dynamic insertion loss for all mufflers; sound transmission loss for all compressor building components, including walls, roof, doors, windows and ventilation openings; sound attenuation from the station to nearby noise-sensitive areas; the manufacturer's name, the model number, the performance rating; and a description of each noise source and noise control component to be employed at the proposed compressor station. For proposed compressors the initial filing must include at least the proposed horsepower, type of compression, and energy source for the compressor. • Far-field sound level data measured from similar units in service elsewhere, when available, may be substituted for manufacturer's far-field sound level data. • If specific noise control equipment has not been chosen, include a schedule for submitting the data prior to certification. • The estimate must demonstrate that the project will comply with applicable noise regulations. (§ 380.12(k)(4)).	Section 9.4

Resource Report 9 – Air and Noise Quality	
Minimum FERC Filing Requirement:	**Resource Report Section:**
5. Describe measures and manufacturer's specifications for equipment proposed to mitigate impact to air and noise quality, including emission control systems, installation of filters, mufflers, or insulation of piping and buildings, and orientation of equipment away from noise-sensitive areas. (§ 380.12(k)(5)).	Section 9.2 Section 9.4

INFORMATION RECOMMENDED OR OFTEN MISSING	See the Following Resource Report Section:
1. Include climate information as part of the air quality information provided for the project area.	Section 9.1
2. Identify potentially applicable federal and state air quality regulations.	Section 9.1
3. Provide construction emissions (criteria pollutants, hazardous air pollutants, greenhouse gases) for proposed pipelines and aboveground facilities.	Section 9.2 Tables 9.2-1, 9.2-2, 9.2-3, 9.2-4, 9.2-5, and 9.2-6
4. Provide copies of state and federal applications for air permits.	Appendix A.9
5. Provide operation and fugitive emissions (criteria pollutants, hazardous air pollutants, greenhouse gases) for pipelines and aboveground facilities.	Section 9.2 Table 9.2-7 and 9.2-8
6. Identify temporary and permanent emissions sources that may have cumulative air quality effects in addition to those resulting from the project.	Section 9.2
7. Describe the existing noise environment and ambient noise surveys for compressor stations, liquefied natural gas facilities, meter and regulation facilities, and drilling locations.	Section 9.3
8. Identify any state or local noise regulations applicable to construction and operation of the project.	Section 9.3
9. Indicate whether construction activities would occur over 24-hour periods.	Section 9.4
10. Discuss construction noise impacts and quantify construction noise impacts from drilling, pile driving, dredging, etc.	Section 9.4
11. Quantify operation noise from aboveground facilities, including blowdowns.	Section 9.4
12. Describe the potential for the operation of the proposed facilities to result in an increase in perceptible vibration and how this would be prevented.	Section 9.4
13. Identify temporary and permanent noise sources that may have cumulative noise effects in addition to those resulting from the project.	Section 9.4

9. INTRODUCTION

Jordan Cove Energy Project L.P. ("JCEP") is seeking authorization from the Federal Energy Regulatory Commission ("FERC" or "Commission") under Section 3 of the Natural Gas Act ("NGA") to site, construct, and operate a natural gas liquefaction and liquefied natural gas ("LNG") export facility ("LNG Terminal"), located on the bay side of the North Spit of Coos Bay, Oregon. JCEP will design the LNG Terminal to receive a maximum of 1,200,000 dekatherms per day ("Dth/d") of natural gas and produce a maximum of 7.8 metric tonnes per annum ("mtpa") of LNG for export. The LNG Terminal will turn natural gas into its liquid form via cooling to about -260ºF, and in doing so it will reduce in volume to approximately 1/600th of its original volume, making it easier and more efficient to transport.

In order to supply the LNG Terminal with natural gas, Pacific Connector Gas Pipeline, LP ("PCGP") is proposing to contemporaneously construct and operate a new, approximately 229-mile-long, 36-inch-diameter natural gas transmission pipeline from a point of origin near the intersection of the Ruby Pipeline LLC ("Ruby") and Gas Transmission Northwest LLC ("GTN") systems to the LNG Terminal ("Pipeline," and collectively with the LNG Terminal, the "Project"). PCGP will submit a contemporaneous application to FERC that will include its own set of resource reports with references to certain materials in the LNG Terminal resource reports.

This Resource Report 9 contains a discussion of, and an evaluation of, the potential impacts to air and noise within the JCEP Project Area.

9.1 AIR QUALITY

9.1.1 Regional Climatology

The State of Oregon is divided into nine (9) climate zones as established by the National Centers for Environmental Information ("NCEI"). The JCEP Project Area lies in the southern part of Zone 1 – The Oregon Coast. The coastal zone is characterized by wet winters, relatively dry summers, and mild temperatures year round. Terrain features include the coastal plain, which extends from less than a mile to a few tens of miles in width, numerous coastal valleys, and the Coast Range, whose peaks range from 2,000 to 5,500 feet above sea level ("ASL").

The Zone's heaviest precipitation occurs mainly during the winter months when moist air masses move off the Pacific Ocean onto land. Normal annual precipitation at the Southwest Oregon Regional Airport, formerly the North Bend Municipal Airport, which is located just across Coos Bay from the JCEP Project Area, is approximately 65 inches. Normal annual snowfall is approximately one inch. The highest monthly precipitation values occur during the months of November, December, and January.

The mean maximum temperature is approximately 60°F, the mean minimum temperature is approximately 46°F, and the mean temperature is approximately 53°F. Temperatures of 90°F or higher occur less than once per year, on average, and freezing temperatures are infrequent, with killing frosts being even less frequent. There is a 60% chance of the frost free period extending to 251 days.

Strong winds occur occasionally, usually in advance of winter storms, and can exceed hurricane force. Strong winds have been known to cause significant damage to structures and vegetation. Such events, however, are typically short-lived, and last less than one day. Partly cloudy skies are prevalent during the summer. Winter skies are typically cloudy. As a result of the persistent cloudiness, total solar radiation is lower in Zone 1 than it is in any other climatic zones of Oregon.

9.1.2 Regulatory Requirements for Air Quality

The Clean Air Act (CAA) of 1970, 42 United States Code ("USC") § 7401 *et seq.,* amended in 1977 and 1990, is the basic federal statute governing air quality. The provisions of the CAA that are potentially relevant to construction and operational emission sources include the following:

- National Ambient Air Quality Standards ("NAAQS");
- New Source Review ("NSR");
- New Source Performance Standards ("NSPS");
- National Emission Standards for Hazardous Air Pollutants ("NESHAP");
- CAA Title V Operating Permits;
- Chemical Accident Prevention;
- Mandatory Greenhouse Gas Reporting Rule; and
- General Conformity.

9.1.2.1 National Ambient Air Quality Standards

The CAA defines National Ambient Air Quality Standards ("NAAQS") for six criteria pollutants. The six criteria pollutants include nitrogen dioxide (NO_2), carbon monoxide (CO), particulate matter (PM_{10} and $PM_{2.5}$), sulfur dioxide (SO_2), ozone (O_3), and lead (Pb). The NAAQS were developed to protect human health (primary standards) and human welfare (secondary standards). Oregon has adopted the NAAQS. The NAAQS for the six criteria pollutants are provided in **Table 9.1-1** and **Table 9.1-2**.

Table 9.1-1 National and Oregon Ambient Air Quality Standards

Pollutant	Value	Description of Standard
PM_{10}	150 µg/m³	24-hour concentration (not to be exceeded more than once per year on average over 3 years)
$PM_{2.5}$	35 µg/m³	24-hour concentration (98th percentile averaged over 3 years)
	12 µg/m³	Annual mean concentration (averaged over 3 years)
SO_2	75 ppb	1-hour concentration (99th percentile of 1-hour daily maximum concentrations, averaged over 3 years)
	500 ppb	3-hour concentration (not to be exceeded more than once per year)
	100 ppb	24-hour concentration (not to be exceeded more than once per year)(1)
	20 ppb	Annual concentration(1)
CO	35 ppm	1-hour concentration (not to be exceeded more than once per year)
	9 ppm	8-hour concentration (not to be exceeded more than once per year)
O_3	0.070 ppm	8-hour concentration (annual fourth-highest daily maximum, averaged over 3 years)
NO_2	100 ppb	1-hour concentration (98th percentile of 1-hour daily maximum concentrations, averaged over 3 years)
	53 ppb	Annual mean concentration
Pb	0.15 µg/m³	Rolling 3 month average (not to be exceeded)

Key:
µg/m³ = Micrograms per cubic meter.
PM_{10} = particulate matter less than 10 micrometers aerodynamic diameter.
$PM_{2.5}$ = particulate matter less than 2.5 micrometers aerodynamic diameter.

(1) EPA revoked 24-hour and annual SO_2 standards in 2010, however Oregon regulations include the 24-hour and annual SO_2 standards.

Table 9.1-2 National Secondary Ambient Air Quality Standards

Pollutant	Value	Description of Standard
PM_{10}	150 µg/m³	24-hour concentration (not to be exceeded more than once per year on average over 3 years)
$PM_{2.5}$	35 µg/m³	24-hour concentration (98th percentile averaged over 3 years)
	15 µg/m³	Annual mean concentration (averaged over 3 years)
SO_2	0.5 ppm	3-hour concentration (not to be exceeded more than once per year)
O_3	0.070 ppm	8-hour concentration (annual fourth-highest daily maximum, averaged over 3 years)
NO_2	53 ppb	Annual mean concentration
Pb	0.15 µg/m³	Rolling 3 month average (not to be exceeded)

9.1.2.2 Attainment Status

Areas in which the NAAQS are violated are designated as “non-attainment” areas for the relevant air pollutants. Areas that are in compliance with the NAAQS are designated as “attainment” areas for the relevant air pollutants. Areas with insufficient data available are designated as “attainment/unclassified” areas. The air quality in the JCEP Project Area does not violate any NAAQS and is, therefore, designated as an attainment/unclassified area.

9.1.2.3 New Source Review ("NSR")/Prevention of Significant Deterioration Permits ("PSD")

The EPA has established separate air quality programs for pre-construction review of certain large projects. Federal pre-construction review for affected sources located in non-attainment areas is commonly referred to as Non-Attainment New Source Review ("NANSR"). Federal pre-construction review for affected sources located in attainment/unclassifiable areas is known as Prevention of Significant Deterioration (PSD). The pre-construction review process is intended to prevent a new source from causing existing air quality to deteriorate below acceptable levels. Because the proposed JCEP Project Area location is currently designated as attainment/unclassifiable for each NAAQS, the determination must be made if the LNG Terminal is a PSD major source and is thus subject to the PSD pre-construction review program.

ODEQ's NSR program was approved by the EPA in the early 1980's. The program regulates construction and modification of larger or major sources in Oregon. The program is a unique State Implementation Plan ("SIP")-approved program that utilizes Plant Site Emission Limits ("PSEL") and Baseline Emission Rates for regulating source emissions, as well as determining when new and modified sources are subject to New Source Review ("NSR"). The Oregon Administrative Rules ("OAR") (OAR 340-200-0020) define a federal major source as any source with a potential to emit listed pollutants in amounts equal to or greater than 250 tons per year ("tpy") or 100 tpy for 28 specific source categories identified in OAR 340-200-0020(66)(c). Sources which do not meet the definition of federal major source but which have emissions greater than significant emission rates ("SER") must meet State NSR requirements. The PSD and State NSR requirements are contained in OAR Chapter 340, Division 224.

JCEP submitted an air quality permit application to the Oregon Department of Environmental Quality ("ODEQ") on March 29, 2013. The air quality permit application demonstrated that the LNG Terminal would be in compliance with all applicable air quality regulations and ambient air quality standards. As such, ODEQ issued PSD Air Contaminant Discharge Permit (ACDP) 06-0118-ST-01 to the JCEP on June 16, 2015. ACDP 06-0118-ST-01 covers the LNG Terminal and the previously proposed South Dune Power Plant facility. Because the design of the facility has changed (i.e., the South Dunes Power Plant facility is no longer included), the LNG terminal no longer meets the criteria for and definition of a federal major source (i.e., JCEP is no longer classifiable as one of the 28 listed sources and the facility's annual potential to emit is less than the 250 tpy limit for unlisted sources). The facility is, therefore, no longer subject to the PSD pre-construction permitting program. JCEP is submitting a Type B State NSR application to ODEQ to obtain a Standard ACDP for approval to construct and operate the terminal. A copy of the air permit application is provided as **Appendix A.9**.

9.1.2.4 New Source Performance Standards ("NSPS")

The New Source Performance Standards ("NSPS"), found in 40 CFR 60, establish requirements for new, modified, or reconstructed emission units in specific source categories. The LNG Terminal includes certain emission units, storage tanks, and process equipment that would be applicable to specific NSPS as summarized in **Table 9.1-3**.

Table 9.1-3 NSPS Affected Sources

Source Type	Number of Sources	Rated Capacity		Fuel Type	Annual Hours Of Operation	Applicable NSPS
Combustion Turbine	5	524.1	MMBtu/hr	Natural Gas	8,760	Subpart KKKK
Thermal Oxidizer	1	110	MMBtu/hr	Natural Gas	8,760	N/A
Auxiliary Boiler	1	296.2	MMBtu/hr	Natural Gas	876	Subpart Db
Black Start Engine	2	4,376	hp	Diesel	200	Subpart IIII
Backup Engine	2	1,073	hp	Diesel	200	Subpart IIII
Enclosed Marine Flare	1	0.74	MMBtu/hr	Natural Gas	8,760	N/A
Multipoint Ground Flare	1	2.13	MMBtu/hr	Natural Gas	8,760	N/A
Firewater Pump Engine	3	700	hp	Diesel	200	Subpart IIII

40 CFR 60 Subpart Db

The Standards of Performance for Industrial, Commercial, and Institutional Steam Generating Units apply to the Auxiliary Boiler. The requirements of 40 CFR 60 Subpart Db include emission limits, performance testing, monitoring, recordkeeping, and reporting.

40 CFR 60 Subpart IIII

The Standards of Performance for Stationary Compression Ignition Internal Combustion Engines constructed after July 15, 2005, apply to the diesel-fired generator engines, back up engines, and firewater pump engines. The requirements of 40 CFR 60 Subpart IIII include emission standards, fuel sulfur content, monitoring, and recordkeeping.

40 CFR 60 Subpart KKKK

The Standards of Performance for Stationary Combustion Turbines constructed after February 18, 2005, apply to the combustion turbines. The requirements of 40 CFR 60 Subpart KKKK include emission limits, performance testing, monitoring, recordkeeping, and reporting.

40 CFR 60 Subpart OOOOa

The Standards of Performance for Crude Oil and Natural Gas Production, Transmission, and Distribution for which construction, modification, or reconstruction commenced after September 18, 2015, will not apply to any process equipment at the LNG Terminal. The requirements of 40 CFR 60 Subpart OOOOa do not apply to the LNG storage tanks, because the LNG storage tanks will not contain the products covered by Subpart OOOOa, and the tanks will not have the potential to emit six tpy of Volatile Organic Compound (“VOC”) emissions. In addition, the facility operations do not meet the definition of ‘natural gas processing plant’ so pneumatic controllers and components in VOC and wet gas service would be not be subject to Subpart OOOOa. Proposed compressors for the BOG fuel gas system will be centrifugal compressors with dry seals, which are not an affected source type under Subpart OOOOa.

9.1.2.5 National Emission Standards for Hazardous Air Pollutants ("NESHAPs")/Maximum Achievable Control Technology ("MACT")

NESHAPs, codified in 40 CFR Part 61 and Part 63, regulate the emission of hazardous air pollutants ("HAPs") from existing and new sources. Part 61 was promulgated prior to the 1990 CAA Amendments and regulates only eight types of hazardous substances, which include: asbestos, benzene, beryllium, coke oven emissions, inorganic arsenic, mercury, radionuclides, and vinyl chloride. The LNG Terminal would not operate any processes that are regulated by Part 61. As a result, the requirements of Part 61 are not applicable.

The 1990 CAA Amendments established a list of 189 additional HAPs, which necessitated the need for issuing standards under Part 63. Known as the MACT standards, Part 63 regulates HAP emissions from major sources of HAPs and specific source categories that emit HAPs, as well as certain minor or "area" sources of HAPs. Part 63 defines a stationary source with the potential to emit 10 tpy of any single HAP and/or 25 tpy of HAPs in aggregate as a major source of HAPs. Potential HAP emissions from operations are included in the potential to emit analysis.

Based on potential HAP emissions, the LNG Terminal will be a HAPs area source. HAP emissions are provided in **Table 9.1-4**. Supporting calculations are provided in **Appendix B.9 Stationary Source Emission Unit Inventory and Emission Calculations**.

Table 9.1-4 Potential HAP Emissions – Operations

Air Pollutant	Potential Emissions
Total HAPs	8.1 tons/year
Single Highest HAP (n-hexane)	3.3 tons/year

40 CFR 63 Subpart ZZZZ

The National Emission Standard for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines applies to the diesel-fired generator engines, back-up engines, and firewater pump engines. According to Subpart ZZZZ, new stationary reciprocating internal combustion engines located at a HAPs area source must meet the requirements of Subpart ZZZZ by meeting the requirements of 40 CFR 60 Subpart IIII. No further requirements apply for such engines under Subpart ZZZZ. The diesel-fired generator engines, back-up engines, and firewater pump engines would meet the requirements of 40 CFR 60 Subpart IIII and thus meet the requirements of 40 CFR 63 Subpart ZZZZ.

9.1.2.6 Title V Operating Permit

Title V of the CAA requires sources that have the potential to emit more than 100 tpy of any criteria pollutant, are a major source of HAPs, or are subject to certain NSPS or NESHAP subparts to obtain a Title V Operating Permit. The authority to issue Title V Operating Permits has been delegated to ODEQ by the EPA.

9.1.2.7 Chemical Accident Prevention

Section 112r of the 1990 CAA Amendments requires the EPA to publish regulations and guidance for chemical accident prevention at facilities for substances with the greatest risk of harm from accidental release. The chemical accident prevention provisions, referred to as the Risk Management Plan (RMP) Rule are codified in 40 CFR Part 68. A RMP must be prepared if a facility stores a regulated substance in a quantity greater than certain thresholds. The RMP regulated flammable substances list includes methane, ethane, ethylene, propane and pentane, each with a threshold quantity of 10,000 pounds. The LNG Terminal will process and/or store these substances in quantities greater than 10,000 pounds each. Applicability would be determined based on the final facility design. Flammable substances used as fuel or held for sale as fuel at a retail facility are not covered under the Risk Management Program. It is likely an RMP will be required for the flammable substances used as refrigerants because all natural gas handled at the facility will be combusted on site as fuel or sold for export. If an RMP is required, JCEP will prepare and submit an RMP plan to the EPA prior to introduction of hydrocarbons.

The RMP applies only to stationary sources and does not apply to transportation, including storage incident to transportation. Transportation includes, but is not limited to, transportation subject to oversight or regulation under 49 CFR Parts 192 (federal safety standards for transportation of natural and other gas by pipeline), 193 (federal safety standards for liquefied natural gas facilities), or 195 (federal safety standards for transportation of hazardous liquids by pipeline), or a state natural gas or hazardous liquid program for which the state has in effect a certification to the U.S. Department of Transportation ("DOT") under 49 USC § 60105. Because the LNG storage tanks are regulated under 49 CFR Part 193, the LNG storage tanks are not subject to RMP requirements under 40 CFR Part 68.

9.1.2.8 Mandatory Greenhouse Gas ("GHG") Reporting

The EPA established mandatory GHG reporting under 40 CFR 98. These regulations prescribe the sources for which GHG emissions must be reported and the manner in which GHG emissions are to be monitored, calculated, and quality assured for different source categories. Facilities with GHG emissions above the reporting threshold of 25,000 tonnes of carbon dioxide equivalent (CO_2e) per calendar year are required to report GHG emissions under 40 CFR 98. Additionally, a GHG Monitoring Plan which includes data collection requirements, GHG calculation methodology, and data quality assurance procedures would be required. Jordan Cove will have GHG emissions in excess of the reporting threshold for the mandatory GHG reporting rule.

9.1.2.9 Applicable State Regulations

The following ODEQ regulations (OAR) were evaluated for applicability:

- Division 200 General Air Pollution Procedures and Definitions;
- Division 202 Ambient Air Quality Standards and PSD Increments;
- Division 204 Designation of Air Quality Areas
- Division 208 Visible Emissions and Nuisance Requirements;
- Division 210 Stationary Source Notification Requirements;

- Division 212 Stationary Source Testing and Monitoring;
- Division 214 Stationary Source Reporting Requirements;
- Division 216 Air Contaminant Discharge Permits;
- Division 218 Oregon Title V Operating Permits;
- Division 220 Oregon Title V Operating Permit Fees;
- Division 222 Stationary Source Plant Site Emission Limits;
- Division 224 New Source Review;
- Division 225 Air Quality Analysis Requirements;
- Division 226 General Emission Standards;
- Division 228 Requirements For Fuel Burning Equipment and Fuel Sulfur Content; and
- Division 246 Oregon State Air Toxics Program.

The Project has applied for a Type B State NSR Standard Air Contaminant Discharge Permit because emissions of PM, PM_{10}, $PM_{2.5}$, NO_X, CO, SO_2, VOC, and H_2SO_4 will each exceed significant emission rates, but will be less than the PSD threshold.

9.1.3 Ambient Air Quality

The existing ambient air quality must be characterized to understand the potential impact of the LNG Terminal. The only monitors for CO, NO_2, and SO_2 in the state are in Portland, which is approximately 260 kilometers (km) northeast of the LNG Terminal site. The monitor selected for PM-10 is outside of Eugene in Lane County, which is approximately 120 km northeast of the LNG Terminal site. The monitor selected for PM-2.5 and ozone is located in Cottage Grove in Lane County, which is 110 km northeast of the LNG Terminal site. All monitoring sites show compliance with the ambient air quality standards as shown in **Table 9.1-5**.

Table 9.1-5 Existing Ambient Air Quality Data

Pollutant	Averaging Period	Ambient Air Quality	National Ambient Air Standard	State Ambient Air Standard	Monitoring Period	Site
SO_2	1-hour	4 ppb	75 ppb	75 ppb	2013-2015	41-051-0080
	3-hour	8 ppb	500 ppb	500 ppb	2015	
	24-hour(1)	2 ppb	N/A	100 ppb	2015	
	Annual(1)	0 ppb	N/A	20 ppb	2015	
NO_2	1-hour	29 ppb	100 ppb	100 ppb	2013-2015	41-051-0080
	Annual	9 ppb	53 ppb	53 ppb	2015	41-051-0080
CO	1-hour	2.4 ppm	9 ppm	9 ppm	2015	41-051-0080
	8-hour	1.9 ppm	35 ppm	35 ppm	2015	41-051-0080
PM-10	24-hour	53 µg/m^3	150 µg/m^3	150 µg/m^3	2015	41-039-0059
PM-2.5	24-hour	22 µg/m^3	35 µg/m^3	35 µg/m^3	2013-2015	41-039-9004
PM-2.5	Annual	8.2	12 µg/m^3	12 µg/m^3	2015	41-039-9004

Pollutant	Averaging Period	Ambient Air Quality	National Ambient Air Standard	State Ambient Air Standard	Monitoring Period	Site
Ozone	8-hour	0.061	0.070 ppm	0.070 ppm	2013-2015	41-039-9004

(1) EPA revoked 24-hour and annual SO_2 standards in 2010, however Oregon regulations include the 24-hour and annual SO_2 standards.

The above monitors are located within or nearby the two largest cities in Oregon (*i.e.*, Portland and Eugene). These areas have a substantially larger population than the Coos Bay area and therefore have a significantly higher density of industrial facilities and mobile source air emissions compared to the LNG Terminal. Thus, these monitors would be considered to conservatively represent the ambient air quality within the LNG Terminal. This is confirmed when the monitored data are compared to the NW AIRQUEST model output for the LNG Terminal location as provided in **Table 9.1-6**. The NW AIRQUEST modeling is the result of regional photochemical grid modeling combined with observational air quality data for the period of 2009-2011. The result is a hybrid dataset that allows for an estimate of air quality anywhere within the modeled domain, including Coos Bay (*i.e.*, data extracted for 43.42981, -124.2542).

Table 9.1-6 Existing Ambient Air Quality Data Comparison

Pollutant	Averaging Period	Monitored Ambient Air Quality	NW AIRQUEST Database	National Ambient Air Standard	State Ambient Air Standard
SO_2	1-hour	4 ppb	1.2 ppb	75 ppb	75 ppb
	3-hour	8 ppb	1.1 ppb	500 ppb	500 ppb
	24-hour(1)	2 ppb	1.1 ppb	N/A	100 ppb
	Annual(1)	0 ppb	0.4 ppb	N/A	20 ppb
NO_2	1-hour	29 ppb	8.4 ppb	100 ppb	100 ppb
	Annual	9 ppb	1.0 ppb	53 ppb	53 ppb
CO	1-hour	2.4 ppm	0.659 ppm	9 ppm	9 ppm
	8-hour	1.9 ppm	0.516 ppm	35 ppm	35 ppm
PM-10	24-hour	53 µg/m^3	35 µg/m^3	150 µg/m^3	150 µg/m^3
PM-2.5	24-hour	22 µg/m^3	9.9 µg/m^3	35 µg/m^3	35 µg/m^3
PM-2.5	Annual	8.2 µg/m^3	6.7 µg/m^3	12 µg/m^3	12 µg/m^3
Ozone	8-hour	0.061 ppm	0.046 ppm	0.070 ppm	0.070 ppm

(1) EPA revoked 24-hour and annual SO_2 standards in 2010, however Oregon regulations include the 24-hour and annual SO_2 standards.

Pre-construction monitoring is not required for Type B State NSR projects.

9.1.4 Ambient Area Air Quality Analysis

An ACDP application for the LNG Terminal requires a demonstration that compliance is achieved with all applicable air quality standards. An ambient air quality impact analysis (dispersion modeling) was performed consistent with the requirements and procedures described in the Guideline on Air Quality Models (EPA 2017), Oregon Administrative Rules, and the Federal Land Managers' Air Quality Related Values work group ("FLAG") (NPS 2010).

Other guidance was used, as appropriate, such as the Guidance on the Development of Modeled Emission Rates for Precursors ("MERPs") (EPA 2016) and the New Source Review Workshop Manual (EPA 1990).

An Air Quality Modeling Protocol was approved by ODEQ in July 2017 and was based on a modeling discussion held with ODEQ on March 13, 2017. Using the approved modeling protocol, an ambient air quality impact analysis was conducted to demonstrate compliance with the NAAQS.

The ambient air quality analysis used the following approach:

- The results from the ambient air quality analysis are compared to the Class II modeling significant impact levels ("SILs") on a pollutant and averaging period basis.
- If the LNG Terminal's impacts are less than the SILs and there is sufficient "headroom" between the existing background air quality levels and the ambient air quality standard, then the NAAQS are considered to be protected.
- If the LNG Terminal's impacts are greater than the SILs, then the LNG Terminal's emission rates must be further analyzed to demonstrate compliance with all applicable PSD increments and NAAQS. Compliance with the applicable PSD increments must be demonstrated as part of the ACDP permit application.

The results of this analysis are provided in Section 9.2.2.1.

9.1.4.1 Model Selection and Methodology

The most recent version of the AERMOD modeling system (version 16216r) available was used to generate impacts for the ambient air quality impact analysis. AERMOD is the EPA preferred model for near-field (*i.e.*, <50 km) analyses.

The inputs and methodology used for the ambient air quality analysis are based on standard modeling practice and applicable guidance, which are summarized herein:

- The surface data used in the analysis is the five most-recent complete years of data collected at the Southwest Oregon Regional Airport (call sign KOTH), located at 43.419°N, 124.243°W, which is approximately 2 km southeast of the LNG Terminal site. Upper air data from McNary Field in Salem, OR (44.92°N, 123.02°W) will also be used, which is approximately 197 km northeast of the LNG Terminal site. The period of meteorological data that was used is January 1, 2012 to December 31, 2016.
- Ground-level concentrations will be calculated within a nested, Cartesian receptor grid. The nested grids will cover an area extending up to 50 km from the proposed facility, but truncated over the Pacific Ocean. The proposed grids will be defined as follows:
    - receptors spaced every 25 m along the facility fence line;
    - receptors spaced every 25 m that extend 100 m from the facility fence line;
    - receptors spaced every 100 m that extend from 100 m to 3 km;
    - receptors spaced every 250 m that extend from 3 km to 5 km;
    - receptors spaced every 500 m that extend from 5 km to 20 km; and
    - receptors spaced every 1,000 m that extend from 20 km to 50 km.
- Treatment of downwash with BPIPPRM (version 04274).

- Evaluation of LNG Terminal operations for both normal operation and startup and shutdown (SU/SD).
- Evaluation of offsite stationary and mobile source emissions (*i.e.*, other permitted sources, LNG carriers, and support vessels) during carrier transiting, hotelling and loading combined.
- Assessment of LNG Terminal impacts compared to the applicable PSD SILs and, if above, compared to the applicable NAAQS.

9.1.4.2 Class I Areas

FERC guidance recommends an analysis of project impacts on Class I areas if there are PSD Class I areas within 100 km, the project is subject to PSD review, or comments are anticipated. There are no federal PSD Class I areas located within 100 km of the LNG Terminal site, but there are five within 200 km of the LNG Terminal site. The closest Class I area is the Kalmiopsis Wilderness Area, which is located approximately 110 km south of the LNG Terminal site.

Compliance with the Class I PSD Increments is assessed in the state NSR permit application. The state NSR permit application does not require an analysis of air quality related values ("AQRVs") for State NSR sources, but a screening level analysis was performed for completeness. The FLAG guidance for air AQRV analyses recommends the use of the Q/D screening approach to determine if visibility impacts are likely to result from a project. This screening analysis is based on the distance from the source to the Class I area and the annualized, maximum daily emissions of AQRV-impacting pollutants. If the Q/D analysis results are less than or equal to the screening factor of 10, then FLM agencies do not require any further Class I AQRV impact analyses.

Using the calculations summarized in **Appendix C.9 Q/D Emission Calculations** for the visibility-impairing pollutants of NOx, SO_2, PM, and H_2SO_4 the calculated Q value is 849 tons per year. Using the shortest distance of 110 km, the Q/D value is calculated to be 7.7, which is below the threshold value of 10. FLM concurrence with these calculations and that additional Class I modeling is not required is also provided in **Appendix C.9**.

9.1.4.3 Source Parameters and Emissions

The main criteria air pollutant emission sources from the LNG Terminal would consist of five compressor-direct drive combustion turbines, a thermal oxidizer for the gas conditioning system, an auxiliary boiler, two diesel black-start generator engines, two diesel back-up engines, three firewater pump engines, one marine flare, and a combined (warm and cold) multipoint ground flare. The modeled emission rates and stack parameters for normal operations are presented in **Table 9.1-7**.

Table 9.1-7 LNG Terminal Emission Rates and Stack Parameters

Emission Units	Stack Parameters				Potential Emission Rates Per Unit			
	Temperature (°F)	Velocity (ft./sec)	Stack Diameter (ft.)	Stack Height (ft.)	NO_X (lb./hr.)	$PM_{10}/PM_{2.5}$ (lb./hr.)	SO_2 (lb./hr.)	CO (lb./hr.)
Combustion Turbine with Duct Firing	243	71	10	119	3.8	5.4	1.64	4.6
Auxiliary Boiler	330	49	6	100	2.18	2.20	0.83	2.66
Thermal Oxidizer	1,600	42	9.5	131	14.44	0.88	4.53	8.79
Marine Flare	1,832	30	45	100	0.05	0.023	0.0023	0.23
Ground Flare (warm and cold)	Ambient	Negligible	259' x 227'	85	0.14	0.065	0.0067	0.66
Fire Water Pump (1)	948.3	193	0.67	18	5.31	0.30	0.0071	2.68
Backup Generator (1)	952.5	287	0.67	13	16.63	0.19	0.012	1.42
Black Start Generator (1)	873.6	177	1.67	18	7.43	0.23	0.044	1.04

(1) The emission sources are intermittent and will operate less than 200 hours per year. The modeled emission rates are based on annualized emissions.

The LNG Terminal will also have associated marine vessels (*i.e.,* LNG carriers and tugboats) that will be moored at the berth during loading of the LNG from the LNG storage tanks. Emissions and exhaust parameters from the LNG carriers are included in the cumulative modeling analysis starting from the process of transit, berthing, to hotelling and LNG loading and finally to connecting the towlines and de-berthing.

9.1.5 Along the Waterway

Approximately 110 to 120 LNG carriers per year would transit to the LNG Terminal. Tugs would be provided by JCEP to be used in the transit and berthing (and de-berthing) of the LNG carriers. The tugs would be berthed adjacent to the LNG ship berth to be ready when called upon. Emissions and exhaust parameters from the LNG carriers are included in the preliminary ambient air quality analysis as an emission source for cumulative impact demonstration modeling starting from the transit to the process of berthing, to hoteling and LNG loading and finally to connecting the towlines and de-berthing.

9.2 ENVIRONMENTAL CONSEQUENCES – AIR QUALITY

9.2.1 Construction Related Emissions

Air quality impacts associated with the construction of the LNG Terminal can be classified as impacts associated with fugitive dust emissions (PM emissions suspended in air) during site preparation and impacts associated with operating fossil fuel burning equipment. The construction of the LNG terminal would result in a temporary increase in emissions.

Emissions of criteria pollutants, including nitrogen oxides (NO_X), CO, PM, VOCs, and SO_2, along with GHGs (*i.e.*, carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O)) would result from the combustion of fossil fuels. These emissions would be released in the exhaust of the equipment used in land clearing/grading equipment, cranes, bulldozers, and various types of trucks and cars. Other construction-related emissions include compactors, pavers, welding, brazing, soldering, solvent cleaning, grinding, cutting, etc.

Fugitive dust emissions would result from construction activities such as land clearing, grading, excavation, and concrete placement, along with vehicular traffic on paved and unpaved roads. The magnitude of fugitive dust emissions would primarily be a function of the area of construction, silt and moisture contents of the soil, wind speed, frequency of precipitation, amount of vehicle traffic, vehicle types, and paved roadway characteristics. Fugitive dust emissions would be produced during all phases of construction. Emissions would be greater during the drier summer months and in areas of fine-textured soils. During these periods, dust suppression techniques, such as watering, would be used in these areas to minimize the impacts of fugitive dust on sensitive areas. The potential emissions from construction are provided in **Table 9.2-1, Table 9.2-2, Table 9.2-3, Table 9.2-4, and Table 9.2-5**. Supporting calculations are provided in **Appendix E.9 Construction Emission Inventory and Emission Calculations**.

Table 9.2-1 Pollutant Emissions Summary – Construction Year 1

Construction activities would take place over multiple years. **Table 9.2-6** provides a summary of the total emissions of criteria pollutants and GHGs for construction by year. The construction emission totals during year five include operation of the LNG Terminal equipment for commissioning. Supporting calculations are provided in **Appendix E.9 Construction Emission Inventory and Emission Calculations**.

Table 9.2-6 Total Construction Emissions by Year

Construction Year	Emissions (tons/year)							
	NO_X	SO_2	CO	PM_{10}	$PM_{2.5}$	VOC	GHG	HAPS
Year 1	351	0.35	120	268	39	23	53,397	7.4
Year 2	404	0.43	184	310	100	32	66,708	11.0

Year 4	43	0.08	81	18	17	10	13,615	3.7
Year 5	72	20.94	85	209	68	71	925,856	4.1

9.2.2 Operational Emissions

The operation of the LNG Terminal would include operating the compressor-direct drive combustion turbines, a thermal oxidizer for the gas conditioning system, an auxiliary boiler, diesel generator engines, diesel backup engines, flares, and firewater pump engines. The LNG Terminal equipment would combust fossil fuels and would release combustion emissions that include NO_X, CO, PM, VOCs, SO_2, and GHGs. Enclosed ground flares would be used to burn gas released from the process during emergencies or while purging equipment in preparation for maintenance, and LNG tanker conditioning activities. Fugitive VOC and GHG emissions, emissions that could not reasonably pass through an exhaust stack, would also result from evaporative losses from valves, connectors, open ended lines, pressure relief valves, and storage vessels. The potential annual emissions from operations are provided in **Table 9.2-7** and fugitive emissions are provided in **Table 9.2-8**. Supporting calculations are provided in **Appendix B.9 Stationary Source Emission Unit Inventory and Emission Calculations**.

Table 9.2-7 Pollutant Emissions Summary – Operations

Source	Emissions (tons/year)							
	NO_X	CO	$PM_{2.5}$	PM_{10}	VOC	SO_2	HAP	GHG (as CO_2e)

Table 9.2-8 Fugitive Emissions

Pollutants	Annual Emissions (tons/year)		
	LNG Tanks	Equipment Leaks	Total
VOC	0.11	7.87	7.98
CO_2	0.00	1.64	1.64
CH_4	23.06	501.52	524.58
N-Hexane	0.03	1.75	1.77

9.2.2.1 PSD Class II Impacts

The results from the ambient air quality analysis are compared to the Oregon Class II modeling significant impact levels (SILs) on a pollutant and averaging period basis in **Table 9.2-9**. These results are the maximum of either the normal operating scenario or the startup/shutdown scenario. For those pollutants and averaging periods with impacts greater than the SILs, additional modeling was conducted that included an offsite stationary and mobile source emission inventory (*i.e.*, other permitted sources, LNG carriers, and support vessels during carrier transiting, hoteling and loading). The results of this cumulative ambient air quality analysis are added to representative background values and compared to the NAAQS in **Table 9.2-10**.

The results of the preliminary air quality modeling indicate that all CO and 3-hr, 24-hr, and annual SO_2 impacts are less than the Class II SILs and, therefore, no further modeling is required. The remaining pollutants and averaging times were further modeled with the above-mentioned offsite stationary and mobile source inventory. The results of the cumulative modeling analysis indicate compliance with all NAAQS.

A demonstration of compliance with both the NAAQS and PSD Increments is required for the ACDP application. Compliance with the PSD Increments is addressed in the permit application included as **Appendix A.9**.

Table 9.2-9 LNG Terminal-Only Maximum Modeled Impacts

Pollutant	Averaging Period	Maximum Modeled Concentration(1) (μg/m^3)	Oregon Class II SIL (μg/m^3)
CO	1-hour	108.0	2000.0
	8-hour	16.2	500.0
NO_2(2)	1-hour	**50.5**	8.0
	Annual	**3.4**	1.0
PM_{10}	24-hour	**8.1**	1.0
	Annual	**1.1**	0.2
$PM_{2.5}$(3)	24-hour	**8.1**	1.2
	Annual	**1.1**	0.3
SO_2	1-hour	**11.5**	8.0
	3-hour	5.7	25.0

Pollutant	Averaging Period	Maximum Modeled Concentration(1) (μg/m³)	Oregon Class II SIL (μg/m³)
	24-hour	2.5	5.0
	Annual	0.3	1.0

(1) Modeled concentrations are the overall maximum values at any receptor. Modeled concentrations shown in **bold** type exceed the Class II SILs and additional analysis of impacts is required. See Table 9.2-10 for these pollutants.
(2) The reported NO_2 modeled concentration assumes 100% conversion of NOx to NO_2.
(3) Direct $PM_{2.5}$ only.

Table 9.2-10 Cumulative Modeled Impacts (in the Form of the Standard(1))

Pollutant	Averaging Period	Modeled Concentration(1) (μg/m³)	Background (μg/m³)	Total Impact (μg/m³)	NAAQS (μg/m³)
NO_2(2)	1-hour	132.3	16.0	148.3	188.0
	Annual	4.1	1.9	6.0	100.0
PM_{10}(3)	24-hour	9.3	35.0	44.3	150.0
	Annual	1.4	n/a	1.4	n/a
$PM_{2.5}$(4)	24-hour	6.9	9.9	17.2	35.0
	Annual	1.3	6.7	8.4	12.0
SO_2	1-hour	30.1	3.1	33.2	196.0

(1) Modeled concentrations are in the form of the NAAQS:
  a. The modeled 1-hour NO_2 concentration is the 98th percentile of 1-hour daily maximum concentrations, averaged over three years
  b. The modeled annual NO_2 is the maximum concentration at any receptor
  c. The modeled 24-hour PM10 concentration is not to be exceeded more than once per year on average over three years
  d. The modeled 24-hour $PM_{2.5}$ concentration is the 98th percentile averaged over three years
  e. The modeled annual $PM_{2.5}$ concentration is the maximum concentration at any receptor
  f. The modeled 1-hour SO_2 concentration is the 99th percentile of 1-hour daily maximum concentrations, averaged over 3 years
(2) The reported NO_2 modeled concentration is based on the ARM2 method in AERMOD.
(3) PM_{10} has a Class II SIL defined in OAR 340, but no associated NAAQS.
(4) Includes an estimated secondary component of 0.39 μg/m³ as described in the ACDP application.

9.2.2.2 PSD Class I Impacts

The air quality related values (AQRVs) that are applicable at PSD Class I areas, such as regional haze and acid deposition, were screened using the FLAG 2010 Q/D approach. Q/D is the sum of certain pollutant emissions (tpy) divided by distance (km) from the Class I area. A Q/D ≤ 10 indicates no further analysis of AQRVs is required.

Section 9.1.4.2 provides the Q/D calculation, which results in a value well under the threshold value of 10. This approach and calculation has been confirmed with the appropriate FLMs. Compliance with the Class I PSD increments is demonstrated as part of the ACDP permit application.

9.2.2.3 Secondary Formation

Ozone is formed through a series of complex reactions between precursor pollutants (*e.g.*, NOx and VOC) that take place in the atmosphere in the presence of sunlight. Generally, ozone is considered a regional pollutant due to substantial international and regional transport of both ozone and precursor emissions. Secondary formation from NOx and SO_2 to particulate $PM_{2.5}$ is also formed through complex reactions in the atmosphere that depend on factors such as temperature, humidity, ammonia, etc. The LNG Terminal area is in attainment of the EPA standards for ozone and $PM_{2.5}$.

The final ambient air quality impact analysis includes an evaluation of potential secondary formation for ozone and $PM_{2.5}$ from the LNG Terminal emissions using the EPA document Guidance on the Development of Modeled Emission Rates for Precursors (MERPs) (EPA, 2016). The ACDP permit application report contains a discussion of the final approach. Based on this final approach and the LNG Terminal emissions, the LNG Terminal will have secondary formation of ozone and $PM_{2.5}$ that is considered insignificant.

9.2.2.4 Along the Waterway

Different types of LNG carriers would transit to the LNG Terminal site; steam turbine vessels firing fuel oil, steam turbine vessels firing natural gas, dual-fuel diesel electric ("DFDE") vessels, totally approximately 110 to 120 LNG carriers per year. The worst case potential emissions, assuming 120 calls per year for each type of LNG carrier, were calculated and are provided in **Table 9.2-11**. Supporting calculations are provided in **Appendix F.9 Marine Vessel Emission Inventory and Emission Calculations.**

Table 9.2-11 Worst Case Potential Emissions Summary – Marine Vessels

Source	Emissions (tons/year)						
	NO_X	CO	$PM_{2.5}$	PM_{10}	VOC	SO_2	GHG (as CO_2e)
Steam Turbine Vessels – Fuel Oil	28.10	2.98	3.31	3.31	0.17	9.5	14,653.02
Steam Turbine Vessels – Natural Gas	14.90	6.69	0.60	0.60	0.44	0.11	10,394.41
DFDE Vessels	48.68	36.68	2.06	2.06	9.47	3.57	8,756.88
Tugboats	9.51	17.68	0.317	0.317	1.00	2.6	3736.15

In the unlikely event of an LNG spill on the ground or another warm surface, the LNG would boil quickly and vaporize. The vapor would be primarily methane, which is not a criteria pollutant. Without an ignition source and specific flammability limit conditions, the methane would disperse in the air, which in turn would cause a temporary degradation of ambient air quality. Natural gas burns with a visible flame and has narrow flammability limits, combusting only in air-to-fuel proportions of 5-15%. Below 5% the mix is too lean to burn and above 15% the mix is too rich to burn. Pools of liquefied natural gas do not ignite as readily as pools of gasoline or diesel fuel. The auto-ignition temperature of methane is 1004° F, significantly higher than gasoline (495° F) or diesel (600° F). So while open flames and sparks can ignite natural gas, many hot surfaces such as a car muffler will not. Methane vapors in open air exhibit a very slow flame speed of about 4 mph. Methane is also considered a greenhouse gas and the release of an amount of methane may contribute to global warming. Methane vapor release effects would likely be confined to along the LNG ship transit route and would not affect any sensitive receptors outside of that zone. Consequently, an LNG spill without ignition of the vapor is not anticipated to have a long-term adverse effect on air quality.

If the vapor from an LNG spill were to come in contact with an ignition source and meet the specific flammability limit conditions, it is likely that products of combustion would degrade the local air quality particularly downwind of the LNG spill. The incomplete products of the combustion of methane include criteria pollutants, ozone precursors, and carbon particulates. While the types and amounts of air contaminants from burning vapor due to an LNG spill would depend on a number of factors, the emissions would be limited to a localized area and would be temporary, and would not result in significant effects on air quality.

9.2.3 Mitigation

During construction, ambient air quality will be affected by emissions and fugitive dust generated by construction equipment. Fugitive dust and emissions from construction activities generally do not result in a significant increase in regional pollutant levels, although local pollutant levels could intermittently increase during the construction phase of this project. Fortunately the LNG Terminal would be located in an area zoned for industrial use and is void of permanent residents. Sensitive receptors, such as children, elderly, and infirm are not expected to be near the project area where localized construction emissions will occur.

Regardless, the LNG Terminal would utilize techniques to minimize the air quality impacts during construction and operation of the LNG Terminal. Construction activities must comply with the Oregon DEQ Regulations for dust control in OAR 340-208-0210 and JCEP will operate according to the Erosion and Sediment Control Plan. During construction of the LNG Terminal dust control mitigation measures would include one or more of the following:

- Dust suppression techniques, such as watering, which would reduce fugitive PM emissions from construction activities such as material storage, land clearing, grading, excavation, and concrete batching;
- Wheel washing stations, as necessary, to prevent tracking of materials onto public roads;
- Street sweepers, as needed, to clean any inadvertent materials tracked onto public roads near the project site;
- Material hauling operations will endeavor to prevent spillage. Methods can include covering loads, limiting fill height in trucks, and proper training of operators;
- Excavated materials being hauled off-site on public roads will be covered; and
- Enclosing cement storage silos at the Batch Plant.

Speed will be limited to 15 mph for non-earthmoving equipment on the site in active construction areas to ensure personnel safety and reduce emissions. However, speed will only be limited by the safe travel speed of the haul road and equipment for earthmoving operations. Unnecessarily constraining haul speeds would lengthen the project and cause additional fugitive emissions from extended support operations and supervision. Wind fencing is not an appropriate dust mitigation measure for the Terminal Site design and construction process and would cause unnecessary burdens for the project.

The LNG Terminal would minimize vehicular and crankcase emissions from gasoline and diesel engines by complying with applicable EPA mobile and stationary source emissions performance standards and by using engines manufactured to meet these standards. Additionally, the LNG Terminal will minimize emissions using the following techniques:

- KBJ (EPC Contractor) will self-perform the majority of the construction activities for the LNG terminal and will utilize their company-owned fleet. The average age of the fleet is 6 years old. MOVES emission factors used to create the emissions estimates for the construction of the LNG Terminal used national average emission rates from similar equipment. The equipment in the KBJ fleet are newer than the national average and therefore are likely more efficient and the emissions calculated in Table 9.2-6 provide a conservative estimate of project-related emissions.
- Local subcontractors and outside rental equipment owners will comply with federal, state, and local laws;
- Performing regular maintenance of the emission units, which maintains efficient combustion. Efficient combustion reduces the fuel required to operate the emission units and thus reduces combustion emissions. The maintenance program for the KBJ equipment includes daily inspections, 500 operation hour preventative maintenance, engine oil analysis, and equipment specific activities;
- Operating equipment only within the manufacturer's guidelines;
- Equipment will not be modified or retrofitted without manufacturer involvement to ensure warranty and liability criteria are met;
- Combustion of ultralow sulfur diesel (ULSD) in heavy construction, diesel-burning equipment;
- Use of industry recognized standard emissions controls on stationary construction equipment;
- Following the KBJ Idling Policy, which includes requirements such as not allowing construction vehicles and equipment to idle for more than a set amount of time if the vehicle or equipment is not in motion to reduce fuel consumption, which reduces NO_X, CO, PM, VOCs, SO_2, and GHGs emissions; and
- Reducing roadway traffic congestion and minimizing vehicle trips through implementation of the Traffic Impact Study included in the Resource Report 8. Some traffic congestion and emissions reduction techniques include utilizing on-site and off-site parking and locating the Batch Plant and laydown areas in the North Spit to avoid excessive traffic through the project area.

When construction is commenced the decision to use alternative fuels to reduce emissions would be based on technical, operational, commercial, and resource availability considerations. KBJ does not own alternative fuel equipment, however, KBJ's newer fleet and rigorous equipment maintenance program and policies will help ensure maximum fuel efficiency and minimize emissions. Also, alternative fuel infrastructure is not widely available in the area to support a project of this magnitude.

During operations of the LNG Terminal air pollution mitigation measures will include:

- The combustion turbines will be equipped with post-combustion emission controls (catalytic oxidizers and selective catalytic reduction), which reduces NO_X, CO, and VOC emissions;
- The auxiliary boiler will be equipped with post-combustion emission controls (catalytic oxidizers and selective catalytic reduction), which reduces NO_X, CO, and VOC emissions;

- The combustion turbines will fire natural gas for facility startup and boil-off gas during normal operations, which reduces the consumption of diesel fuel;
- The HRSG steam will be used to drive a steam generator, providing ancillary power to the facility which reduces the need for additional power to be produced or purchased for the LNG Terminal;
- Tier 2 and Tier 3 stationary engines are specified which comply with emission limits for PM, NO_X and NMHC;
- Performing regular maintenance of the emission units, which maintains efficient combustion. Efficient combustion reduces the fuel required to operate the emission units and thus reduce the amount of combustion emissions emitted; and
- A halon-free, fire-suppression system. This system would remove the possibility of a release of ozone-depleting substances.

9.3 NOISE QUALITY

At any location, both the amplitude and frequency of environmental noise may vary considerably over the course of the day and throughout the week. This variation is caused in part by changing weather conditions and the effects of seasonal vegetative cover, in addition to human activities. There are two measures used by federal agencies to relate the time-varying quality of environmental noise. The A-weighted equivalent continuous noise level (L_{eq}) for 24 hours ($L_{eq(24)}$) is the level of steady sound with the same total energy as the time-varying sound of interest averaged over a 24-hour period. The day-night average noise level (L_{dn}) is the $L_{eq(24)}$ with 10 dBA added to the nighttime sound levels between the hours of 10 p.m. and 7 a.m. to account for people's greater sensitivity to sound during nighttime hours.

Another way of judging potential noise impact is the amount of increase over existing levels of noise at receptors around a site. In general, an increase of 3 decibels (dB) is barely detectable by the human ear and an increase of 5 dB is considered slightly significant. Increases of greater than 10 dB are generally considered significant, being perceived as an apparent doubling of loudness.

9.3.1 Ambient Noise Levels

The LNG Terminal is located in an area along the northern shore of Coos Bay, approximately one mile north of the Cities of North Bend and Coos Bay. The surrounding area consists of sand dunes interspersed with lower flat marsh areas, water bodies, and grassy fields. The sand dunes are covered with dense stands of vegetation, except where it has been affected by human activities.

There are no NSAs within one mile of the LNG Terminal site. This is a significant buffer that should greatly reduce the potential for any noise impacts. Two noise surveys previously have been conducted in the area: one in 2005, and the other in 2013, both of which identified two NSAs. A new sound level survey was performed in May 2017. There are a few campgrounds within 1.3 miles of the LNG Terminal site, which were also considered as part of the noise survey and identified as an additional NSA. The previously identified NSAs have been retained and an additional NSA, NSA 3, has been added to address the campground facilities to the north of the LNG Terminal. The noise survey results are summarized below.

All NSAs and distances to the LNG Terminal are shown on **Figure 9.3-1**. In order to evaluate the impact of the Project on the nearby recreation area, an additional noise receptor point has been included in the evaluation. As this location is not necessarily an NSA, it has been designated REC 1. **Table 9.3-1** shows the receptors, directions to the receptors, and approximate distance from the center of the liquefaction area. The following are the noise receptor locations included in the noise impact evaluation for the project:

- NSA 1 consists of single-family residences in a subdivision about 1.3 miles south of the LNG Terminal in the City of North Bend along the south side of the bay adjacent to the airport. The subdivision is bordered on the north by Colorado Avenue and on the west by Arthur Street.
- NSA 2 is a group of single-family residences, located approximately 2.2 miles east on Russell Point.
- NSA 3 is the Horsfall campground, the closest campground to the LNG Terminal site, located approximately 1.2 miles northeast of the LNG Terminal site.
- REC 1 is the recreation area located to the west and northwest of the LNG Terminal site.

Table 9.3-1 Receptor Distances and Directions from the LNG Terminal Equipment

Receptor	Description	Direction to Receptor	Distance, miles
NSA 1	Residential	South	1.3
NSA 2	Residential	East	2.2
NSA 3	Campground	Northeast	1.2
REC 1	Recreation Area	West	0.7

9.3.1.1 Summary of Previous Noise Surveys

The sound level measurement locations near the two previously identified NSAs were as follows:

- NSA 1: at the corner of Colorado Avenue and Arthur Street adjacent to a subdivision on the south side of the bay; and
- NSA 2: off East Bay Street about 90 feet east of US 101.

Previous noise surveys were conducted in 2005 and 2013:

- Between 1700 hours on August 31, 2005, and 1700 hours on September 1, 2005; and
- Between 1000 hours on April 11, 2013, and 0900 hours on April 18, 2013.

Table 9.3-2 summarizes the previously-measured results and shows the results of the 2017 sound level survey, which included NSA 3 and REC 1. The data are fairly consistent among the surveys.

Table 9.3-2 Summary of Existing Noise Levels at NSAs

Receptor	2005 $L_{eq(1\text{-}hr)}$	2005 L_{dn}	2013 $L_{eq(1\text{-}hr)}$	2013 L_{dn}	2017 $L_{eq(1\text{-}hr)}$	2017 L_{dn}
NSA 1	35.1 – 53.8	53.7	31.9 – 57.6	47.4 – 51.6	33.2 – 58.9	52.7
NSA 2	48.7 – 66.4	65.7	42.6 – 63.7	59.8 – 62.2	52.8 – 67.7	65.2
NSA 3	--	--	--	--	34.8 – 67.6	56.3
REC 1	--	--	--	--	42.4 – 61.2	55.2

The primary sources of man-made noise in the area included vehicle traffic on the Trans-Pacific Parkway and US Highway 101, recreational vehicle use in the Oregon Dunes National Recreation Area, and boat traffic in Coos Bay. Natural sounds included birds, insects and wind. At REC 1, ocean surf sounds are a significant and continuous source of ambient sounds. Occasional aircraft could be heard at the Southwest Oregon Regional Airport just across the bay from the site. A generator was operating at the wastewater treatment plant near NSA 1 during the first day of the 2017 monitoring. Noise levels at existing NSAs nearest the LNG Terminal site are controlled primarily by vehicular traffic. Noise levels experienced at the NSAs are similar in level to those in suburban areas where traffic is the primary source of noise.

9.3.1.2 2017 Noise Survey

The results of the updated noise survey are shown in **Table 9.3-3**. The Baseline Environmental Noise Survey Report in **Appendix D.9** provides the details of the baseline ambient noise survey, including weather conditions, site observations, survey methodology and results. The data shown in **Table 9.3-3** have been processed to remove periods of high wind, as discussed in **Appendix D.9**.

Table 9.3-3 Baseline Sound Level Measurement Results at NSAs

Receptor	Distance to Receptor, miles	Direction	Duration HH:MM	Daytime L_{eq}, dBA	Nighttime L_{eq}, dBA	Ambient L_{dn}, dBA
NSA 1	1.3	South	29:48	51.7	43.9	**52.7**
NSA 2	2.2	East	32:39	62.7	57.5	**65.2**
NSA 3	1.3	Northeast	32:03	57.9	40.3	**56.3**
REC 1	0.7	West	31:50	51.1	48.3	**55.2**

9.3.1.3 Ambient Underwater Noise Levels

Ambient underwater noise levels range from about 74 dB to 100 dB re 1 µPa in the open ocean with no ship traffic nearby, to about 115 dB to 135 dB re 1 µPa in large marine inlets with some recreational boat traffic (CaDOT 2009). Existing shipping traffic in the Coos Bay area means that ambient underwater noise levels are expected to correspond to this latter range in the presence of shipping, but may be lower at times corresponding to reduced boat traffic activity.

9.3.2 Applicable Standards and Ordinances

9.3.2.1 Federal Guidelines

The only federal noise guidelines applicable to the LNG Terminal are those of the FERC. The FERC guidelines (18 CFR § 380.12) limit generated sound to an L_{dn} level no greater than 55 dBA at the nearest NSA, such as a residence, school, campground, or hospital, during facility operations. If it is projected that the sound criteria could be exceeded at any nearby NSA, it will be necessary to develop noise mitigation measures which would be implemented to reduce the noise impacts of the operations and achieve the sound criteria.

Due to the 10 dBA nighttime penalty added when calculating the L_{dn}, the actual constant noise level required to produce an L_{dn} of 55 dBA is approximately 48.6 dBA. Therefore, compliance with the FERC guideline of an L_{dn} of 55 dBA at the nearest pre-existing NSA requires that the LNG facility be designed such that the actual continuous operational noise levels do not exceed 48.6 dBA at any NSA. For noise sources which are not continuous, such as flaring, the L_{dn} calculation will depend on the specific hours of operation of each noise source.

The National Marine Fisheries Service (NMFS) provides interim guidance on underwater noise thresholds for behavioral disturbance for marine mammals (NMFS 2012), and guidance on thresholds for the onset of permanent threshold shift (PTS), which represents non-recoverable hearing damage (NMFS 2016). For the LNG Terminal, the proposed in-water activities are not considered to present any realistic potential for PTS to marine mammals. Recommended sound exposure guidelines for fish and sea turtles are provided in Popper, et al. (2014).

The NMFS interim underwater thresholds for marine mammal behavioral effects are 160 dB (rms) referenced to 1 micro Pascal (re 1 µPa), for impulsive noise sources such as impact pile driving. For continuous in-water noise sources such as the noise from vibratory pile driving or dredging, the interim threshold for behavioral effects is 120 dB (rms) re 1 µPa.

9.3.2.2 State Guidelines

The ODEQ noise standards are contained in OAR, Chapter 340, Division 35 – Noise Control Regulations. The OAR noise regulations are not directly applicable to the operational noise from the LNG Terminal site.

9.3.2.3 Local Guidelines

The City of North Bend has a noise ordinance that prohibits the “making of unnecessary noise” but the ordinance has no specific numerical limits (North Bend City Code, Section 9.04.030). Daytime construction noise between the hours of 7 a.m. to 6 p.m. is exempt. Coos County does not have a noise ordinance. The project is located in Coos County.

9.4 ENVIRONMENTAL CONSEQUENCES - NOISE

9.4.1 Facility Construction Noise and Mitigation

9.4.1.1 General Construction

Noise could affect the local environment during construction and operation of the LNG Terminal. Noise associated with construction activities will be intermittent, as equipment is operated on an as-needed basis. During the site grading and filling operations, the equipment may be operated on a schedule of two 10-hour shifts, per day, with two daytime hours and two nighttime hours used as the shift change break. Construction will not result in generation of or exposure of persons to excessive noise or vibration levels. Site investigations and soil characterization has not identified the need for blasting as the entire the LNG Terminal area is predominantly sand.

Construction noise was estimated based on equipment needed to construct a project of this magnitude. The sound level due to each piece of equipment was estimated using the Federal Highway Administration's Roadway Construction Noise Model (RCNM). **Table 9.4-1** shows a schedule of the equipment expected to potentially be in simultaneous operation, along with the maximum sound level, L_{max}, at 50 feet, the usage percentage, and the expected L_{eq} at 50 feet considering the usage percentage.

The Lmax is the maximum sound level during a given period using either the slow or fast time constant. The Lmax is a very different metric than the Leq that is used to characterize steady state sound levels and direct comparison is usually inappropriate. High Lmax sound levels can be experienced even in otherwise quiet locations due to short-term events such as wind gusts.

Table 9.4-1 Proposed General Construction Equipment

Equipment Type	Make/ Model	RCNM Category	Usage (%)	L_{max} at 50 ft, dBA	L_{eq} at 50 ft, dBA	# of Units Operating Simultaneously	Operating Shift
Pickup Trucks	Ford F-150	Pickup Truck	40%	75.0	71.0	35	Day
Large Trucks	Ford F-350	Pickup Truck	40%	75.0	71.0	61	Day
Offroad Trucks	Caterpillar 740	Dump Truck	40%	76.5	72.5	3	Day/Night
RT Cranes	Grove RT770E	Crane (mobile or stationary)	16%	80.6	72.6	42	Day
Dozers	Caterpillar D6	Dozer	40%	81.7	77.7	7	Day/Night
Forklifts	Xtreme XR3034	Front End Loader	40%	79.1	75.1	43	Day
Loaders	Caterpillar 966F	Front End Loader	40%	79.1	75.1	3	Day/Night
Tractors	Caterpillar Challenger 65	Tractor	40%	84	80.0	3	Day/Night
Lifts / Hoists	80' Manlift	Man Lift	20%	74.7	67.7	63	Day

Equipment Type	Make/ Model	RCNM Category	Usage (%)	L_{max} at 50 ft, dBA	L_{eq} at 50 ft, dBA	# of Units Operating Simultaneously	Operating Shift
Rollers	Caterpillar 563 - 84"	Roller	20%	80.0	73.0	2	Day/Night
Scrapers	Caterpillar 657	Scraper	40%	83.6	79.6	1	Day/Night
Motor Graders	Caterpillar 14H	Grader	40%	85	81.0	1	Day/Night
Backhoes	Caterpillar 330, John Deere 330	Backhoe	40%	77.6	73.6	3	Day/Night
Compressors	Air Compressor (185 CFM)	Compressor (air)	40%	77.7	73.7	18	Day
Generators / Light Plants	Portable Light Plant	Generator	50%	80.6	77.6	11	Night
Welders	Welder (400-450 Amp)	Welder/ Torch	40%	74.0	70.0	30	Day
Crawler Cranes	Manitowoc 999	Crane	16%	80.6	72.6	13	Day
Augers/Soil Mix Equipment	Soilmec SR 90 Rotary Drill	Soil Mix Drill Rig	50%	80	77.0	17	Day
Pumps	Centrifugal Pump (10")	Pumps	50%	80.9	77.9	1	Day/Night
Excavator	Caterpillar 390F L	Excavator	40%	80.7	76.7	0	Day/Night
Concrete Pumps	BSA 14000 Series	Concrete Pump Truck	20%	81.4	74.4	3	Day

Both daytime and nighttime construction levels were calculated based on planned equipment usage for the currently planned equipment allocation for each of the five years of construction. The highest levels were calculated for year three. These are the levels that were used to model construction noise. This equipment schedule was used to develop overall construction sound power levels for peak construction activities of 129 dBA during the day and 125 dBA at night. The frequency spectrum used was based on measurements of an active construction site, and is representative of a combination of various types of diesel-engine powered equipment.

A construction noise model was developed using CadnaA version 2017, a commercial noise modeling package developed by DataKustik GmbH. The derived total day and night construction sound power spectra were included in the noise model as area sources, uniformly distributed throughout the general construction work area at an average height above grade of 10 feet. The noise model was then used to predict the construction sound level contributions at the closest NSAs.

The predicted sound levels at the nearest NSAs during general construction activities are summarized in **Table 9.4-2** and **Figure 9.4-1**. There are two daytime and two nighttime hours during which there are no planned construction activities to allow the crew to change shifts. Construction activities and equipment are different during the daytime and nighttime periods. Table 9.4-2 shows both the A-weighted construction sound level contribution predicted for activities occurring during the day and separately for those occurring at night. The daytime period average uses the construction contribution (from daytime activities) averaged over 13 of 15 daytime hours, and the nighttime period average is the nighttime activity contribution averaged over 7 of 9 nighttime hours. Thus the daytime and nighttime average levels are 0.6 and 1.1 dBA lower than the respective construction contributions would be for full 15 hour and 9 hour periods, because there is no construction contribution during the shift-change hours.

Table 9.4-2 Predicted General Construction Sound Levels at Receptors
All levels shown are A-weighted Decibels, re: 20 μPa

Receptor	Predicted A-Weighted Construction Contribution During Activities, dBA		Predicted Period Average Sound Level, dBA (Includes adjustments for idle shift-change hours)			Existing Ambient Level, dBA	Future Combined Level, dBA	Increase Over Existing Ambient, dB
	Day	Night	Day, L_d	Night, L_n	L_{dn}	L_{dn}	L_{dn}	
NSA 1	49.1	45.1	48.5	44.0	51.5	52.7	55.2	2.5
NSA 2	39.1	35.1	38.5	34.0	41.4	65.2	65.2	0.0
NSA 3	42.5	38.5	41.9	37.4	44.8	56.3	56.6	0.3
REC 1	49.5	45.5	48.9	44.4	51.8	55.2	56.8	1.6

As shown in Table 9.4-2, the sound levels due to general construction noise are less than 52 dBA L_{dn} at all NSAs and the predicted increase over ambient conditions is between 0 and 3 dB. Noise impacts due to general construction equipment are not expected to be significant at any of the receptor locations, including the NSAs and REC 1, the recreational area receptor.

9.4.1.2 Pile Driving

Pile driving is expected to take place between July 2019 and July 2021 over two 10-hour shifts per day, six days per week (i.e. not on Sundays or major holidays). Up to 14 concurrent diesel impact pile hammers will be used during construction of the facility to drive approximately 3,600 pipe piles in the plant facility area. Up to six vibratory hammers will be in use to install roughly 11,800 sheet piles.

The pipe piles range from 24 inches to 72 inches in diameter. Maximum sound pressure level data from a pile driving equipment manufacturer for each size pile was used for the analysis. Vibratory pile drivers were modeled using an L_{max} level of 101 dBA at a distance of 50 feet with a usage factor of 20 percent based on RCNM data. These data are shown in Table 9.4-3, below.

Table 9.4-3 Pipe Pile Driving Equipment Sound Levels and Operating Parameters

Pile Diameter (Inches)	Sound pressure level at 23 feet, dBA L_{max}	Est. Total Piles	Est. Piling Hammer Blows Required	Rig Scheduled Deployed Time, Days	Est. Pile Driving Usage Factor
18 – 24	106	1468	255,476	717	0.12%
30 – 36	110	1581	569,847	717	0.26%
48	114	261	147,987	350	0.14%
60 – 72	116	284	179,093	350	0.17%

As pile driving is an impact noise source with a large variation between the maximum and long-term average sound levels, the sound level contribution at the NSAs has been calculated using both the L_{eq} / L_{dn}, as well as the L_{max}. As the pile driving events are not synchronized, the L_{max} presented is the highest single L_{max} level for any single pile driver. The overall L_{eq} shows the cumulative long term average sound level due to pile driving activities for 14 impact pile driving rigs and 6 vibratory pile driving rigs in operation, simultaneously.

The pile rigs were distributed in the model based on the pile driving schedule such that areas that will require larger numbers of piles were assigned more pile driving sources. The impact pile sources were modeled at an elevation equal to half of the average pile length for each hammer diameter and location.

For each impact pile hammer size, a usage factor was developed based on an average pile driving time for each pile size. A total pile impact sound level period of 200 milliseconds per blow was assumed. Each of these is an estimate as the pile driving rate depends on the specific soil composition and conditions at each pile driving location. The usage factor for each rig type was used to calculate the long-term L_{eq} sound levels from the manufacturer L_{max} levels.

There will be two daytime and nighttime hours during which there are no planned pile driving activities due to the crew shift change. Table 9.4-3 shows both the A-weighted pile driving sound level contribution predicted for pile driving activities along with the daytime and nighttime period averages. The pile driving noise is expected to be the same during daytime and nighttime, so there is a single level for the pile driving noise contribution during activities. The daytime and nighttime average levels are 0.6 and 1.1 dBA lower, than the pile driving contribution during activity due to these shift-change hours.

Table 9.4-4 shows that the predicted L_{max} sound levels for pile driving at the receptors will range from 55 to 69 dBA. While most regulatory agencies use L_{dn} as the favored metric to assess noise annoyance and compliance, both the World Health Organization (WHO) and the American Public Transit Association (APTA) have also issued noise goals in terms of L_{max}.

WHO's criterion is a nighttime level designed to be protective of people sleeping with windows open, and is set as a nighttime L_{max} of 60 dBA (WHO 1999). APTA's criteria are to protect from annoyance due to airborne noise from train operations. The L_{max} criteria are 70 dBA for single family homes in low density areas, 65 dBA for "quiet" outdoor recreational areas, and 60 dBA for amphitheaters (APTA 1981). The predicted L_{max} levels at the NSAs are all below 65 dBA, as shown in Table 9.4-4.

Table 9.4-4 Predicted Pile Driving Noise Levels at Receptors

Receptor	Predicted A-Weighted Pile Driving Contribution During Activities, dBA	Predicted Period Average Sound Levels, dBA (Includes adjustments for idle shift-change hours)			Existing Ambient Level, dBA L_{dn}	Future Combined Level, dBA L_{dn}	Increase Over Existing Ambient, dB	Predicted Maximum Level, dBA L_{max}
	Day/Night	Day, L_d	Night, L_n	L_{dn}				
NSA 1	54.1	53.5	53.0	59.5	52.7	60.3	7.6	64.7
NSA 2	39.5	38.9	38.4	44.9	65.2	65.2	0.0	54.9
NSA 3	43.0	42.4	41.9	48.4	56.3	57.0	0.7	59.5
REC 1	51.7	51.1	50.6	57.1	55.2	59.3	4.1	69.3

The potential extents of underwater noise above the marine mammal interim behavioral disturbance thresholds during vibratory piling (Deveau and MacGillivray 2017) and during impact piling (O'Neill and MacGillivray 2017) have been identified in two studies. Sheet piles are expected to be installed "in the dry," behind a soil berm to be installed between the water and the sheet pile location. The modeling in the studies indicates that the highest underwater noise levels from piling would be found where the sound is able to propagate away from the source in deeper water for the furthest distance, before being attenuated by bottom loss in shallower water. The maximum modeled distance to the interim marine mammal behavioral disturbance threshold is less than 2 km from the noise source.

On the basis of the noise levels predicted during the studies (Deveau and MacGillivray 2017; O'Neill and MacGillivray 2017), and with reference to Popper, et al. (2014), there is a high likelihood of behavioral responses for fish in the vicinity of vibratory piling. More severe impacts (mortality or injury) to fish due to underwater noise from vibratory piling behind the soil berm are not expected. When piling in water using an impact hammer, there is potential for fish mortality or injury if fish are present within about 100 feet of the largest marine pipe piles (36 inch diameter) during pile driving. The areas with potential piling noise physical impacts to fish would be within the excavated and dredged area required to construct the marine facility.

Additional evaluation and quantification of noise impacts from sound pressure waves generated within the water due to pile driving are provided in the Underwater Noise Impact Assessment, included as **Appendix I.9**, to this RR9 report.

9.4.1.3 Open Water Dredging Operations

Dredging is scheduled to take place during the first three years of the project. Two different dredge types are anticipated to be used during construction and operate on a 24-hour basis. A portion of the initial dredging will be undertaken using a clamshell dredge. Other portions will utilize a hydraulic cutter-head suction dredge. Clamshell dredging operations are performed with a standard mechanical crane and are expected to blend into the general construction sound levels discussed earlier in this Resource Report.

A noise model was developed to predict the sound levels due to the hydraulic open water dredging operations. Dredging sound power levels were based on sound level measurements of a typical diesel driven dredge during channel maintenance activities at a Corps of Engineers channel. This dredge produced sound levels of 59 dBA at 500 feet during standard dredging operations.

Open water dredging activities will occur in five separate work areas, with four work areas along the Federal Navigation Channel and one in the slip area of the Project. Once it commences, dredging will take place 24 hours per day, 7 days per week until it is complete or the work window closes. Generally, due to the large distances between the dredging activities and the nearest NSAs, airborne sound level contributions at the NSAs from dredging will be minimal. To simplify the noise model calculation and data presentation, the noise model includes a dredging noise source at each of the five separate work areas, all operating simultaneously. This is an extremely conservative approach as it will overestimate the levels at the NSAs.

The modeled sound pressure levels at the NSAs are shown in **Table 9.4-5**. Because the Federal Navigation Channel extends south through a large distance of Coos Bay, NSA 1 is not the closest residential receptor to the dredging operations. An additional NSA, labeled NSA D1, has been included in the dredging evaluation, located at the closest residential area to the Federal Navigation Channel dredging area. This NSA location is shown along with the predicted sound level contours in **Figure 9.4-3**. As shown in **Table 9.4-5**, dredging noise levels will be quite low at the NSAs and are not expected to result in a substantial increase in sound level over the ambient levels.

Dredging will take place over 24-hours; therefore the dredging contribution during activity is equivalent to the daytime average and the nighttime average.

Table 9.4-5 Predicted Dredging Noise Levels at Receptors

Receptor	Predicted Sound Level, dBA L_{eq} (1)	Predicted Sound Level, dBA L_{dn}(1)	Existing Ambient Level, dBA L_{dn}	Future Combined Level, dBA L_{dn}	Increase Over Existing Ambient, dB
NSA 1	35.8	42.2	52.7	53.1	0.4
NSA 2	24.6	31.0	65.2	65.2	0.0
NSA 3	22.0	28.4	56.3	56.3	0.0
REC 1	28.0	34.4	55.2	55.2	0.0
NSA D1	44.7	51.1	52.7	55.0	2.3

(1) For simplicity, the sound levels shown include sound level contributions from simultaneous dredging activities at five areas, even though only one dredge will be used.

(2) Ambient sound levels at NSA D1 are assumed to be the same as at NSA 1, a residence in the same neighborhood, and the same distance from the bay and ocean as NSA D1.

As for underwater noise impacts, most of the dredging will be conducted in isolation from Coos Bay. Only the dredging of the access channel and the berm (which isolates the slip construction area from Coos Bay) will be dredged with a connection to Coos Bay. The noise associated with dredging is largely related to ship traffic. It is not anticipated that dredging noise would have any potential to cause more severe effects to marine mammals or fish than behavioral disturbance. This is discussed in more detail in the Marine Mammal Noise Impact Assessment included in **Appendix H.9**

Major dredging operations can generate underwater sound levels of up to 185 dB re 1 μPa at one meter (CEDA 2011) if using a large trailing suction hopper dredger to excavate rock. For the LNG Terminal, the material to be removed is expected to be soil or relatively soft sediment. Underwater noise emissions are expected to be greater from the hydraulic dredge than from the clamshell dredge, since this type of equipment adds sounds generated by the rotating cutterhead, slurry intake, suction pumps and sediment moving through pipes to the ship and machinery sounds generated by a clamshell dredge. Reine and Dickerson (2014) measured noise from a hydraulic dredge during maintenance dredging in a deepwater shipping channel in California. They identified rms source noise levels of up to 157 dB re 1μPa at one meter from the source for a dredge with overall length approximately 100 ft., a total power of 1000 hp operating the main pumps, and with dredged material moving through a 16-in. pipeline. Use of a similar dredge is anticipated for JCEP dredging.

Underwater noise levels attenuate with distance. The NMFS (2012) suggests that underwater noise transmission loss with distance can be estimated using a practical spreading loss model. The algorithm utilized is provided below:

$$R1 = 10^{(TL/15)} * R2$$

Where:

R1 = distance (meters) to the required sound level;

R2 = reference distance (meters) from the source of the sound; and

TL = required reduction in sound level (dB).

The NMFS interim underwater threshold for marine mammal behavioral effects for continuous noise sources such as dredging is 120 dB (rms) re 1 μPa. Utilizing the above algorithm, hydraulic dredging noise would be reduced to below the 120 dB marine mammal behavioral disturbance threshold level at a distance of approximately 300 meters or 1,000 feet from the dredging.

Similarly for fish, behavioral reactions such as avoidance behavior are possible but there is a low probability of more severe effects due to underwater dredging noise (Popper et al., 2014).

Additional evaluation and quantification of noise impacts from sound pressure waves generated within the water due to dredging both in the berth pocket and along the Coos Bay navigation channel are provided in the attached Underwater Noise Impact Assessment in **Appendix I.9**.

9.4.1.4 Cumulative Construction Noise Impacts

Sound levels from general construction, dredging, and pile driving have been evaluated in separate sections of this Resource Report. With the current construction schedule, these activities will overlap, and there will be cumulative noise impacts due to the combined construction sound levels. However, the cumulative noise impact will not be the direct summation of the individual contributions, as the period of maximum general construction sound levels are unlikely to overlap with the periods of maximum pile driving sound levels. Jordan Cove construction personnel have estimated the worst-case combination of pile driving and construction activities. With the equipment operating during this combined case, the construction, pile driving, and dredging noise models have been used to calculate the expected cumulative sound levels at the closest NSAs.

As shown in **Table 9.4-6**, cumulative construction noise levels are just slightly higher than the pile driving noise levels alone, indicating that pile driving noise is the dominant noise source.

Table 9.4-6 Predicted Cumulative Construction Noise Levels at Receptors

Receptor	Predicted Sound Level, dBA (Weighted to account for duration of each activity)			Existing Ambient Level, dBA	Future Combined Level, dBA	Increase Over Existing Ambient, dB
	Day, L_d	Night, L_n	L_{dn}	L_{dn}	L_{dn}	
NSA 1	54.8	53.6	60.2	52.7	60.9	8.2
NSA 2	41.8	39.9	46.6	65.2	65.3	0.1
NSA 3	45.2	43.3	50.0	56.3	57.2	0.9
REC 1	53.2	51.6	58.3	55.2	60.0	4.8
NSA D1	44.7	44.7	51.1	52.7(1)	55.0	2.3

(1) Ambient sound levels at NSA D1 are assumed to the same as at NSA 1, a residence in the same neighborhood, and the same distance from the bay and ocean as NSA D1.

9.4.2 Facility Operation Noise and Mitigation

9.4.2.1 General Operation

The following major noise-producing equipment will normally be in operation at the LNG Terminal:

- Five refrigerant compressors, combustion turbines, heat recovery steam generators (HRSGs), and associated piping;
- Refrigerant compressor interstage and discharge aerial coolers;
- Three steam turbines and their associated air-cooled condensers;
- Two BOG compressors with interstage and discharge aerial coolers; and
- Various other smaller condensers, coolers, pumps and valves.

The above equipment packages will be specified to meet sound level requirements appropriate to support an overall far-field sound level that does not exceed the applicable FERC regulatory limits.

Facility operational noise levels have been evaluated using a CadnaA noise model. Noise associated with an idling tanker and ground flares were also included in the model. The results of the analysis are presented in **Table 9.4-7**. The calculated LNG Terminal L_{dn} levels, the existing ambient L_{dn} levels, and the projected increases in future noise at each NSA are also shown. The predicted L_{dn} levels at all NSAs are below the FERC criterion of 55 dBA and the predicted increase over ambient is well below 10 dB at all NSAs.

The predicted sound level due to operations at REC 1, the receptor representative of the closest areas of the nearby Oregon Dunes Recreational Area, is 54 dBA L_{dn}, or just below the FERC criteria for NSAs.

Table 9.4-7 Predicted Operational Noise Levels at Receptors

Receptor	Predicted Sound Level, dBA L_{eq}	Predicted Sound Level, dBA L_{dn}	Existing Ambient Level, dBA L_{dn} (1)	Future Combined Level, dBA L_{dn}	Increase Over Existing Ambient, dB
NSA 1	45	51	52.7	54.9	2.2
NSA 2	37	43	65.2	65.2	0.0
NSA 3	43	49	56.3	57.0	0.7
REC 1(1)	49	55	55.2	58.1	2.9

(1) Predicted levels at REC 1 were estimated based on Figure 7-1 in the Acoustical Modeling Report in Appendix G.9.

The complete Computer Noise Modeling and Mitigation Report is attached as **Appendix G.9**. The report provides details of the noise modeling methodology, inputs, and results, including the octave band sound power levels of noise sources and the data sources.

Mitigation

Mitigation is discussed in **Appendix G.9**. No supplemental mitigation measures such as acoustical enclosures, acoustical barriers, or custom silencers were included in the LNG Terminal design. Rather, the LNG Terminal equipment will be specified to meet the sound power level specifications noted in Appendix G.9, and will be inherently quiet enough to produce the sound levels shown in Table 9.4-7.

Vibration

Ground borne vibrations are typically not significant outside of the facility boundary. Facility equipment is designed and balanced in order to minimize extraneous vibration as a means to preserve and extend the service life of the equipment. Ground borne vibration resulting from the LNG Terminal equipment is not expected at the NSAs.

Low frequency airborne sound has the potential to induce rattling of residential building structures. ANSI S12.2-2008 publishes criteria for sound pressure levels that should not be exceeded in order to avoid moderately perceptible vibration and rattle inside a room. These criteria are 65 dB and 70 dB in the 31.5 Hz and 63 Hz octave bands, respectively. The predicted LNG Terminal (only) sound levels in the 31.5 and 63 Hz bands at the NSA receptors are expected to all be below 65 dB, thus satisfying these criteria. The LNG Terminal site is not expected to cause a perceptible increase in vibration at any noise-sensitive area.

9.4.2.2 Flaring

Flaring is not expected to occur as part of normal operations. Flaring noise levels were therefore evaluated separately from general facility operations. Cold process flaring is expected to occur five times a year and last for approximately 30 minutes and warm process flaring is expected to take place once every three years and last for approximately two hours. The marine flare is expected to be used four times a year and could last approximately 14 hours per event.

The process flare is a multi-point ground flare with 324 burners surrounded by a 60 to 85 foot radiation wall. The marine flare is a totally enclosed ground flare with 55 burners in a 120 foot enclosure.

Modeled process flare noise levels were based on vendor estimated noise levels and the flare noise spectrum was based on measurements taken of another flare system. There is no expected noise level difference between hot and cold process flaring. The process flare was modeled as a 259 foot by 227 foot area source with a height of 12 feet. The sound power spectrum was adjusted to produce a total sound pressure level of 100 dBA at 3 feet outside of the radiation wall at a height of 5 feet. The radiation wall was assumed to have the transmission loss of a standard metal louver.

The marine flare was modeled as a 45 foot diameter source at a height of 120 feet, with an additional source around the perimeter at a height of approximately 15 feet to simulate the burner noise. The marine flare was modeled as producing a sound pressure level of 85 dBA at three feet.

The results of process and marine flaring are shown in **Table 9.4-8**. Because flaring lasts for fewer than 24-hours, nighttime flaring was conservatively assumed to take place before daytime flaring in the L_{dn} calculations. For example, the marine flare is expected to last for 14 hours. These hours were allocated to the 9 nighttime hours between 10:00 pm and 7:00 am first, and the remaining 5 hours were allocated to daytime use. Process flaring was assumed to consist of the warm flare operating for 2 hours during the night and not at all during the day and the cold flare operating for 30 minutes during the night and not at all during the day.

Though process and marine flaring are not expected to take place simultaneously, they were also modeled together to be conservative. Process flaring is significantly louder than marine flaring and therefore dominates the combined case. Noise contours for simultaneous process and marine flaring are shown in **Figure 9.4-4**.

Table 9.4-8 Predicted Process and Marine Flare Noise Levels at NSAs

Receptor	Predicted Sound Level Contribution During Activity dBA L_{eq}	Predicted Sound Level dBA L_{dn} (Adjusted for event duration)	Existing Ambient Level, dBA L_{dn}	Future Combined Level, dBA L_{dn}	Increase Over Existing Ambient, dB
Process Flare					
NSA 1	47.0	44.1	52.7	53.3	0.6
NSA 2	39.7	36.8	65.2	65.2	0.0
NSA 3	45.9	43.1	56.3	56.5	0.2
REC 1	60.0	57.1	55.2	59.3	4.1
Marine Flare					
NSA 1	25.2	31.2	52.7	52.7	0.0
NSA 2	15.5	21.5	65.2	65.2	0.0
NSA 3	11.6	17.6	56.3	56.3	0.0
REC 1	28.2	34.2	55.2	55.2	0.0
Combined Process and Marine Flares					
NSA 1	47.0	44.3	52.7	53.3	0.6
NSA 2	39.7	36.9	65.2	65.2	0.0
NSA 3	45.9	43.1	56.3	56.5	0.2
REC 1	59.9	57.1	55.2	59.3	4.1

9.4.2.3 Ship Traffic

Underwater noise levels from large commercial ships are fairly consistent, ranging from about 177 dB to 188 dB re 1µPa at one meter (McKenna 2011). The Coos Bay area has therefore historically, and currently, experienced elevated underwater noise levels due to shipping. LNG carriers travelling at half speed generate underwater noise levels of about 175 dB re 1µPa at one meter. Considering both peak noise levels and cumulative sound exposure, vessel noise is not expected to exceed the NMFS guideline thresholds for the onset of PTS for cetaceans and pinnipeds.

Marine animals in close proximity to the transiting carriers would be exposed to elevated noise levels for approximately 20 to 25 minutes (LGL 2005). Marine life in the bay has historically, and currently, experienced similar sound level from transiting commercials ships.

The addition of approximately 110-120 additional LNG carriers on an annual basis will add some noise to the existing environment specifically within the 0.3 mile zone. The addition of approximately 110-120 LNG carriers to the existing average deep-draft traffic (50 ships per year) and existing commercial and recreational vessel traffic will increase the average ambient in-water sound level (Coos Bay Pilots' Association 2017). An estimate of the increase is derived based on the assumption that noise levels from all large ships that traverse the waterway generate essentially the same underwater sound levels, which is supported by research conducted by McKenna (2011). The increase in the average annual noise level due to shipping is subsequently conservatively based on the increase in large ship traffic. A doubling of ship traffic would result in a 3 dB increase in noise. The increase in average sound levels is based on the following formula:

$$Increase\ dB = 10*\log_{10}(total\ ship\ traffic/existing\ ship\ traffic)$$

Accordingly then, the projected addition of up to 120 LNG carriers annually to the existing volume of 50 deep draft ships results in a 5.3 dB increase in the annual average underwater noise level due to shipping. Since the additional LNG carrier traffic, when combined with the existing ship traffic, will still be less than the number of ships that once called on the Port, the effect of the slight increase in noise is predicted to be insignificant.

Additional evaluation and quantification of noise impacts from sound pressure waves generated within the water due to tugs and LNG vessels are provided in the Underwater Noise Impact Assessment in **Appendix I.9**.

9.4.2.4 Cumulative Noise Impacts

Resource Report 1, Attachment A.1 lists "Recent, Current, or Proposed Actions that may Cumulatively Affect Resources." Of the many Proposed Actions in the list, the vast majority are not likely to cause any significant cumulative noise impact with the Project. Proposed Actions that have been eliminated from potential cumulative noise impacts include those that meet any of the following criteria:

- All timber-related Actions – timber tracks are too far away from the NSAs to be significant cumulative noise contributors
- Actions in other counties – due to distance
- Residential developments – no significant operational noise contribution
- Hotel / casino developments – remote from the NSAs

There are three Proposed Actions that are not eliminated from consideration using the above criteria. Two of these Actions are dredging and channel maintenance associated with Coos Bay: Port – Maintenance Dredging and USACE Coos Bay Navigation Channel Maintenance Dredging. As discussed in **Section 9.4.1.3** of this Resource Report, the distances between the Federal Navigation Channel and the closest NSAs are large enough that noise due to dredging in the channel is not a significant impact at the closest residences. It is likely that any channel dredging will be performed using similar equipment to that proposed for the Project with similar sound level impacts.

The third Proposed Action that might have some cumulative impact is the Coos County Airport District's plan to expand the Southwest Oregon Regional Airport. The plan is to extend Runway 4-22 by an additional 400 feet. A review of the Coos County Airport District master plan for the Southwest Oregon Regional Airport indicates that there has been a significant decrease in passenger traffic from the airport due to the departure of Horizon Air in October of 2008 (Reynolds et al., 2013). Air traffic at the airport, even with the expansion of the runway, is not expected to approach 2008 levels until 2030. As such, the runway extension project is not expected to have a cumulative impact for noise as there will not be a commensurate dramatic increase in air traffic at the airport.

1. INTRODUCTION

Jordan Cove Energy Project, L.P. (JCEP) is submitting a Type B State New Source Review (NSR) application for approval to construct and operate the Jordan Cove liquefied natural gas (LNG) Terminal (JCLNG) near Coos Bay, Oregon. JCEP obtained approval for construction and operation of the terminal under Standard Air Contaminant Discharge Permit (ACDP) No. 06-0118-ST-01 on June 16, 2015. Since that approval, several changes were made to the facility design to optimize energy use and lower the environmental impacts. This permit application is being submitted to obtain a Standard ACDP to reflect the final facility equipment and emissions.

JCLNG will be a LNG export terminal and will consist of facilities to receive, liquefy, store, and load the refrigerated fuel onto LNG carriers (LNGC). JCEP has designed the LNG Terminal to receive a maximum of 1,200,000 dekatherms per day (dth/d) of natural gas and produce a maximum of 7.8 million tonnes per annum (mtpa) of LNG for export.

The project site is 199 acres located on the bay side of the North Spit of Coos Bay, between Coos Bay Navigation Channel Miles 7.0 and 8.0. The site consists of two areas located on either side of Roseburg Forest Products and connected by a utility corridor. The liquefaction facility, LNG storage tanks, and berth will be located at Ingram Yard to the west of Roseburg Forest Products. The South Dunes part of the site will contain administrative buildings and temporary workforce housing. JCLNG will include five turbine-driven refrigeration compressors, gas conditioning equipment, a thermal oxidizer, an auxiliary boiler, emergency fire water pumps, black start engine generators, backup engine generators, a marine flare, a warm flare, and a cold flare.

The LNG Terminal site is located in Coos County, Oregon, which is in attainment or unclassified for all pollutants. The proposed Jordan Cove LNG Project has the potential to emit nitrogen oxides (NO_X), volatile organic compounds (VOC), carbon monoxide (CO), sulfur dioxide (SO_2), particulate matter (PM), particulate matter less than 10 micrometers (PM_{10}), particulate matter less than 2.5 micrometers ($PM_{2.5}$), and sulfuric acid mist (H_2SO_4) above Oregon Significant Emission Rates (SERs) but below the Prevention of Significant Deterioration (PSD) threshold of 250 tons per year (tpy).[1] JCEP is submitting an application for approval in accordance with Oregon Administrative Rule (OAR) 340-224-0270 for these pollutants, which includes a Type B State NSR air quality impact analysis for CO, SO_2, PM_{10}, $PM_{2.5}$, and NO_X. This report provides a description of the proposed facility, emission calculations, regulatory applicability, and the air quality impact analysis.

[1] 340-224-0010(2)(b)(A)

2. PROJECT DESCRIPTION

Jordan Cove Energy Project, L.P. is proposing to construct and operate an LNG export terminal in Coos Bay, Oregon. The LNG Terminal will turn natural gas into its liquid form via refrigeration to approximately -260 degrees Fahrenheit (°F). The Jordan Cove terminal includes an access channel from the Coos Bay navigation channel, a marine slip with one LNG carrier berth, an emergency lay berth, four tug boat berths, a loading platform and transfer piping, two LNG storage tanks, five liquefaction trains, one gas conditioning train, several support buildings, and the Southwest Oregon Regional Security Center (SORSC).

In coordination with federal and state agencies and in consultation with the public, plans for both the terminal and natural gas pipeline route have been optimized to avoid or minimize potential impacts and increase efficiency.

The project will include the following emitting equipment:

- Five aero-derivative gas turbines (with waste heat recovery);
- Thermal oxidizer;
- Auxiliary boiler;
- Fire-water pumps;
- Black start generators;
- Backup generators;
- A multi-point ground flare (warm and cold flares); and
- A totally enclosed ground flare (marine flare).

The general location of the proposed LNG Terminal is shown on Figure 1. Also, Figure 1 includes a general layout of the surrounding area and identifies the names of various geographic areas related to the project.

The LNG Terminal will receive natural gas from the Pacific Connector Gas Pipeline (PCGP), process the gas, liquefy the gas into LNG, store the LNG, and load the LNG onto ocean-going LNG carriers at its marine berth. The main operational components of the LNG Terminal are shown on Figure 2 (Plot Plan of the LNG Terminal) and include a connection to the Pipeline metering station, gas inlet facilities, a gas conditioning plant, an access and utility corridor, liquefaction facilities (including five liquefaction trains), two full-containment LNG storage tanks, an LNG loading line, LNG loading facilities, a marine slip, and an access channel for LNG carriers.

JCEP currently anticipates that construction for the Project would begin in the first half of 2019, with a target in-service date in the first half of 2024. Planned construction milestones are:

- Q1 2019 - Q4 2019 – Purchasing combustion equipment
- Q3 2019 - Q4 2019 – Release combustion equipment for manufacturing
- Q3 2019 – Mobilize to site and break ground
- Q3 2021 - Q2 2023 – Pre-Commissioning
- Q4 2022 – Introduce natural gas to site

- Q3 2022 - Q4 2023 – Commissioning
- Q2 2023 – LNG Tank Cooldown
- Q4 2023 – Plant Completion/Operations Begin

2.1 PROPOSED PROJECT

2.1.1 PROCESS DESCRIPTION

2.1.1.1 Gas Inlet and Conditioning

Pipeline quality feed gas will be supplied to the LNG Terminal via the 36-inch-diameter PCGP natural gas transmission pipeline routed from Malin, Oregon to a metering skid located on the South Dunes Site. Inlet pipeline metering facilities consist of a pipeline pig receiver, inlet filter/separator, and a flow meter. Additionally, a feed inlet heater will provide heating of the high pressure feed gas on cold days to prevent formation of natural gas hydrates resulting from Joule-Thomson cooling when gas pressure is let down by the pressure reduction unit. The feed inlet heater uses low pressure steam to warm the gas.

The feed gas from the pipeline will be treated before the gas enters the liquefaction trains. A Gas Conditioning train, in a 1 x 100 percent configuration, will include a system for mercury removal via sulfur impregnated activated carbon, carbon dioxide (CO_2) and acid gas removal via an amine system, and dehydration via a molecular sieve adsorbent system.

Mercury is removed via adsorption onto sulfur-impregnated activated carbon beds, in a 3 x 33 percent configuration, in order to prevent cold box corrosion during gas liquefaction and to minimize the exposure of other equipment and vent streams to mercury contamination. The mercury removal beds will reduce the amount of mercury in the treated pipeline gas down to less than 0.01 micrograms per Normal cubic meter ($\mu g/Nm^3$). Spent catalyst from the mercury removal vessels will be removed periodically and sent off-site for disposal at a licensed hazardous waste management contractor.

Acid gas removal involves a closed-loop system that circulates a promoted methyldiethanolamine solution to absorb CO_2 and sulfur species from the feed gas. The process reduces the feed gas CO_2 concentration from a maximum of 2 percent on a molar basis to less than 50 parts per million on a volumetric basis (ppmv). The CO_2 removed from the feed gas is to be vented to the atmosphere, but the vent stream must first be treated for co-absorbed contaminants. To limit emissions, absorbed hydrogen sulfide (H_2S) and other sulfur species in the vent stream will be thermally oxidized after passing through the sulfur scavenger unit. Co-absorbed hydrocarbons, including benzene, toluene, ethylbenzene, and xylenes, will also be combusted and destroyed in the thermal oxidizer at greater than 99.9 percent destruction efficiency.

The dehydration system is located immediately downstream of the acid gas removal system and employs four molecular sieve adsorption beds. The water removal system will reduce water in the treated feed gas to less than 0.1 ppmv. At any time, two beds will be in adsorption mode, one bed will be in regeneration/cooling mode, and the remaining bed will be on stand-by. Regeneration of a bed involves passing dehydrated heated feed gas through it, in an up-flow direction, which drives the adsorbed water out of the bed. This water-saturated regeneration gas is then cooled to condense and remove the water, which is collected and recycled back into the acid gas removal system. This regeneration gas is then compressed and recycled upstream of the dehydration units. The regenerated bed will then be cooled by non-heated dehydrated feed gas until a low enough temperature is achieved to place it back into adsorption service.

2.1.1.2 Natural Gas Liquefaction

Liquefaction Trains

The LNG Terminal includes five liquefaction trains utilizing the Black & Veatch proprietary PRICO® LNG technology to produce a maximum of 7.8 mtpa (1,077 MMscf/d [million standard cubic feet per day]) of LNG production net, after deduction for Boil-Off Gas (BOG) generation. Each liquefaction train will have an anticipated maximum annual capacity of 1.56 mtpa (215.5 MMscf/d). The nominal annual capacity may be less than this value due to annual ambient temperature variation, planned non-major facility maintenance outages, unplanned facility outages, and the expected degradation of the combustion gas turbines. The PRICO® LNG technology utilizes a single mixed refrigerant (SMR) circuit with a two-stage compressor and a brazed aluminum refrigerant exchanger.

The dry treated gas from the gas conditioning train is divided equally among the five liquefaction trains. In each liquefaction train, the dry treated gas stream flows into a refrigerant exchanger where it is pre-cooled and condensed into liquid by cooling it to approximately -260 °F via heat transfer with the mixed refrigerant. The refrigeration cycle is a closed-loop process that utilizes a single-body, two-stage refrigerant compressor. For each liquefaction train, an aero-derivative combustion turbine directly provides the power to drive the refrigerant compressor. Turbine exhaust-gas waste heat recovery steam generators (HRSGs) maximize the overall thermal efficiency of the LNG Terminal.

Heavies Removal

Heavy hydrocarbons, or “heavies” (generally referred to as C5+ components), will be removed from the feed gas before the final liquefaction step in order to meet the LNG specification and prevent possible freezing in the brazed aluminum refrigerant exchanger at subcooled temperatures. The system will be designed to remove the most likely-to-freeze components—benzene and octane—to less than 1 ppmv while recovering as much of the C4 and lighter molecules as economically as possible into the gas going to the final liquefaction step. The total volume of heavies removed across the range of feed compositions is not enough to produce economically viable natural gas liquids product for sale or export; however, it will be blended into the fuel gas stream, so no tankage or disposal logistics need to be considered.

Refrigerant Makeup

For many technologies, refrigerant losses occur from the closed-loop refrigeration loops primarily due to normal compressor seal leakage. However, the Black & Veatch patented seal gas recovery system will be utilized to minimize the refrigerant losses to flare by returning the normal leakage to the refrigerant compressor suction. Even with seal gas recovery, the refrigeration loop components must be replenished periodically to normal operation inventory levels. The hydrocarbons that provide make-up to the SMR circuit used in the liquefaction trains cannot be generated on-site (with the exception of methane, which comes from the treated feed gas) and will be delivered to the LNG Terminal and stored in pressurized vessels for intermittent makeup to the SMR circuit.

LNG Storage and Containment

The LNG will be stored in two full-containment insulated LNG storage tanks, each of which is designed for a working capacity of 160,000 cubic meters (m^3) (42,232,000 gallons) of LNG. Each tank will have a primary 9 percent nickel inner tank and a secondary concrete outer containment wall with a steel vapor barrier. The LNG storage tanks will have top connections only with piping that will permit top and bottom loading. Top loading operation will be done via a spray device/splash plate in order to obtain flashing and mixing of the LNG as it combines with LNG inventory. The bottom loading operation will be achieved via a standpipe to ensure effective mixing. The separated flash vapor combines with vapors from tank displacement and heat leak and flows to the boil-off gas compressors for use as fuel.

LNG is pumped to the marine berth and into an LNG carrier at a normal loading rate of 12,000 m^3/hr. An LNG transfer line will connect the shore-based storage system with the LNG loading system. A smaller recirculation, “keep cool” line is provided from the LNG storage tank area to the marine berth in order to maintain the LNG transfer piping at cryogenic temperatures to avoid excessive boil-off losses and potential damage from thermal cycling between carrier arrivals.

Marine Facilities

The LNG Terminal will include a single-use marine slip dedicated to supporting LNG exports. The east side of the slip will be utilized for the LNG carrier loading berth and LNG loading facilities. Berths for tugboats and security vessels will be located on the north side of the slip. An emergency lay berth will be provided on the west side of the slip to allow for berthing a temporarily disabled LNG carrier in an emergency. This berth will have no product loading facility, but it will comply with and be designed to meet all of the safety and security standards of the Oil Companies International Marine Forum (OCIMF) and the United States Coast Guard (USCG).

The LNG carrier loading berth will be capable of accommodating LNG carriers with a cargo capacity range of 89,000 m^3 to 217,000 m^3.

Vessel Transit

LNG carriers would access the LNG Terminal through a waterway for LNG marine traffic, which is defined by the USCG for the Project as extending from the outer limits of the U.S. territorial waters 12 nautical miles off the coast of Oregon, and up the existing Federal Navigation Channel about 7.5 miles to the LNG Terminal.

The total average LNG carrier port time is estimated to be approximately 36 hours, assuming there are no delays caused by natural environmental conditions. This estimate includes the transit time from the Pilot boarding to arrival at the LNG loading berth to the Pilot drop-off at departure, time of mooring, unmooring and cast off, the bulk LNG loading time of approximately 15 hours (using the 12,000 m^3/hr loading rate), and the 8 hours of time waiting for the next available high tide cycle needed for safe departure transit of the Federal Navigation Channel.

Vapor Handling System

BOG is primarily generated from the LNG storage and loading system and consists of flash gas from the LNG product stream entering the LNG flash drum, vapors from the heat leak into the LNG storage tanks, piping and pump systems, vapor displaced as the LNG storage tanks are filled, and vapor return from the LNG carrier during LNG loading. The BOG will be consumed as fuel. Two BOG compressor trains are included to compress the vapor from LNG storage tank pressure to fuel gas pressure. The centrifugal compressors have electric motors and dry gas seals.

The mode of operation of the liquefaction plant when not loading an LNG carrier is known as "holding mode." The mode of operation during LNG carrier loading is known as "loading mode." One BOG compression train will be operating continuously to handle holding mode BOG volumes; the second will be needed only during loading mode or during an off-design condition that results in increased BOG generation.

During normal operation, fuel gas will be supplied from BOG and vaporized heavy hydrocarbon streams and supplemented with gas from the inlet pipeline upstream of the gas conditioning train. After mixture in the high-pressure fuel gas mixing drum, this high-pressure fuel gas stream primarily feeds the combustion gas turbines to drive the refrigerant compressors. Some high-pressure fuel gas is let down from the high-pressure fuel gas header to the low-pressure fuel gas knockout drum before going to other smaller consumers, such as the thermal oxidizer, duct burners, and flare pilots. Normally, a small amount of makeup to the high-pressure fuel from the pipeline feed gas is required to meet demands; if the BOG/heavies mixture results in excess fuel for the demand, it can be recycled upstream of the amine unit and re-liquefied.

Instrument Air

Instrument air will be provided through compression and drying packages. Air will be compressed in 1 x 100 percent centrifugal compressors. There will be one additional compressor with the ability to provide essential instrument air duty. Air will be dried in 2 x 100 percent air dryer packages, with each package containing four air dryers designed for full, continuous operation. During operations, one dryer will be in adsorption mode while the other dryer regenerates. Instrument air will be used for pneumatic control of automated instrumentation, utility air, and supply for nitrogen generation.

Flare, Relief, and Blowdown System

Flare systems are a necessary safety feature of all LNG export facilities. The LNG Terminal will have three separate flare systems for pressure relief plant-protection conditions: one for warm (wet) reliefs; one for cold, cryogenic (dry) reliefs; and one for low-pressure cryogenic reliefs from the LNG storage tanks and marine loading system. The “warm” relief loads are separated to ensure that wet fluids cannot freeze in the header if there was a cryogenic relieving event. The “cold” and “marine” relief loads are separated to ensure that the relief of near-atmospheric pressure vapors is not affected by back-pressure in the header if an unrelated release were to occur. The warm and cold flares will both be within a multi-point ground flare field surrounded by radiation fencing, while the marine flare will be a cylindrical totally enclosed ground flare. Small pilots with electronic ignition are provided on each flare.

The flare system will be used only during plant-protection situations, maintenance activities, cases of purging and gassing-up an LNG carrier, and initial commissioning/start-up.

Electrical Systems

JCEP plans to obtain limited power from the regional electric grid for the SORSC and temporary construction activities. With the exception of the SORSC, the LNG Terminal facilities will be islanded (with black-start capability) and will not have the means, infrastructure, or need to import or export power during operations. The total power requirements for the LNG Terminal are 39.2 MW (holding mode) and 49.5 MW (loading mode).

Electrical power will be via two 30 MW steam turbine generators (STGs) and one spare 30 MW STG. The steam is efficiently generated by HRSGs using exhaust from the refrigerant compressor combustion turbine drivers. A black-start auxiliary boiler will be used to generate steam for power when gas turbines are not in operation. In addition, there are 2 x 100 percent standby diesel generators for the LNG facility and one for the SORSC. The facility will not be connected to the local grid and will not import or export power.

2.1.2 PROPOSED EQUIPMENT

Final vendors have not been selected for the LNG Terminal equipment. Equipment parameters and specifications presented in this application are based on design needs of the project and preliminary quotes obtained from vendors, where available.

The proposed project will include five combustion turbine-driven refrigeration compressors with duct burners operating in combined-cycle mode with a HRSG. Steam will be used to generate power for the facility in STGs. All power produced by the STGs will be used on site. Steam from the HRSGs will be used as a heat transfer fluid for process heating.

The project will also involve installation of combustion and post-combustion emission controls. The aero-derivative turbines will use dry low NO_X burners (LNBs) and selective catalytic reduction (SCR) systems with aqueous ammonia injection to control NO_X emissions and oxidation catalysts to control emissions of CO and VOC.

The operating parameters for the turbines and duct burners are presented in Table 2-1. During startup of the facility, the turbines will be fueled by pipeline natural gas. During routine facility operations the turbines will be fueled by BOG from the LNG vapor system, supplemented by pipeline natural gas. Fuel specifications for pipeline gas and BOG differ slightly but do not affect emissions substantially.

The turbines are expected to operate full time with the exception of maintenance downtime. One startup and shutdown per month per turbine is expected. Duct burner firing is dependent on the power needs of the facility given the ambient temperature. Per year, 4,000 hours of duct burner firing per turbine is anticipated. The turbines have inlet air preheating to 42 °F during cold weather. A chiller provides inlet air cooling for the turbines during warmer weather.

Table 2-1. Combined Cycle Turbine Model Parameters for JCEP

Parameter(1)	Aero-derivative Turbine
Mechanical Power Output (MW)	55.6
Maximum CT Heat Input – HHV (MMBtu/hr)	504.4
Maximum Duct Burner Heat Input – HHV (MMBtu/hr)	19.7
Maximum Total Heat Input – HHV (MMBtu/hr)	524.1

(1) 100 percent load at 42 degrees Fahrenheit ambient dry bulb temperature

In addition, the JCLNG will include a 296.2 MMBtu/hr natural gas-fired auxiliary boiler for startup of the liquefaction trains. The boiler may also be used to provide supplemental steam if more than two liquefaction turbines are offline. The auxiliary boiler will be equipped with SCR for NO_X control and an oxidation catalyst for CO and VOC control. The boiler will be used extensively during facility commissioning but is expected to operate only 10 percent of the year after facility startup. The operating parameters for the auxiliary boiler are presented in Table 2-2.

Table 2-2. Description of Auxiliary Boiler

Parameter	Auxiliary Boiler
Manufacturer/Model	TBD
Fuel	Natural Gas
Sulfur Content	1 gr/100 scf
Maximum Fuel Consumption	296.2 MMBtu/hr HHV
Operating Hours	876 hrs/yr

A thermal oxidizer will combust the gases exhausted from the acid gas removal system to destroy reduced sulfurs and co-absorbed hydrocarbons. The oxidizer will also combust flash gases and supplemental fuel gas. The single oxidizer will operate full time. Acid gas removal exhaust will be vented during any maintenance downtime. The operating parameters for the thermal oxidizer are presented in Table 2-3.

Table 2-3. Description of Thermal Oxidizer

Parameter	Thermal Oxidizer
Manufacturer/Model	TBD
Process Feeds	Acid Gas, Flash Gas, Natural Gas assist
Maximum Process Mass Input	238,142 lb/hr
Maximum Process Heat Input	110 MMBtu/hr

JCLNG will include three 700 hp diesel-fired fire water pump engines and two 1,073 hp diesel-fired backup generators to provide emergency back-up power for the SORSC and two 4,376 hp diesel-fired black-start generators for the LNG Terminal. Operation of the fire water pumps and backup generators, other than for emergency purposes, will be limited to reliability testing and maintenance. The two diesel-fired black-start generators will be used to power the auxiliary boiler; the backup air compressor; control building essential loads; miscellaneous electrical loads for enclosures and buildings; and miscellaneous process loads during initial startup of the facility and in the event of a facility-wide power outage. A summary of the operating parameters for the diesel-fired engines is provided in Table 2-4 below.

Table 2-4. Description of Diesel-Fired Engines

Parameter	Fire Water Booster Pumps	Backup Generators	Black-Start Generators
Manufacturer/Model	Caterpillar/C18	Caterpillar/C27	Caterpillar/C175
Number of Units	3	2	2
Engine Tier	Tier 3	Tier 2	Tier 2
Fuel	Diesel	Diesel	Diesel
Fuel Sulfur Content	15 ppm	15 ppm	15 ppm
Maximum Fuel Consumption	35.9 gal/hr	57.3 gal/hr	219 gal/hr

There will be three separate flare systems: one for warm (wet) reliefs; one for cold, cryogenic (dry) reliefs; and one marine flare for low-pressure cryogenic relief. The low-pressure cryogenic relief totally enclosed ground flare (TEGF) will be located at the southwest side of the LNG tank area. The warm and cold flare systems have been combined into one multi-point ground flare which will be located in the northwest corner of the facility. A summary of the operating parameters for the flares is provided in Table 2-5 below.

Table 2-5. Description of Flares

Parameter	MPGF	TEGF
Manufacturer/Model	TBD	TBD
Description	Warm and cold flares	Marine flare
Fuel Sulfur Content	1 grain/100 scf	1 grain/100 scf
Number of Pilots	28 pilots	6 pilots
Pilot Fuel Consumption – LHV	1.82 MMBtu/hr	0.39 MMBtu/hr
Purge Gas Fuel Consumption – LHV	0.31 MMBtu/hr	0.35 MMBtu/hr

2.1.3 APPLICATION FORMS

The ODEQ application forms for the project and equipment described above are included in Appendix A. Specification sheets (or pertinent portions of vendor quotes) and equipment performance data have been included as attachments to each form where available.

2.2 SITE LOCATION

The proposed site of the LNG Terminal is located in the coastal, western region of the State (Section 5, Township (T.) 25 South (S.), Range (R.) 13 West (W.), shown on Coos County Assessor's map as tax lots 100/200/300) on the bay side of the North Spit, about 7.5 miles up the existing Federal Navigation Channel, approximately 1,000 feet north of the city limit of North Bend, in Coos County, Oregon. An area map indicating the location of the proposed terminal is shown in Figure 3. The area map shows the site property relative to predominant geographical features such as the bay, roads, and surrounding dunes. Typically, and due to the functional requirements of the facility, the facility will be at or above 46 feet above sea level. Exceptions include the LNG tanks and water-dependent facilities such as the marine terminal and Material Offloading Facility (MOF).

2.3 EMISSIONS

Emissions attributable to the LNG Terminal are generated from natural gas combustion in the combustion turbines (CTs), natural gas combustion in the HRSG duct burners, natural gas combustion in the auxiliary boiler, combustion of the gas conditioning train acid gas stream in the thermal oxidizer, and diesel combustion in the fire water pumps, backup generator, and black start generators. Routine pilot and purge gas combustion will result in emissions from the MPGF and the TEGF; both of those units will also have emissions during upset or other condition flaring events. Fugitive emissions of natural gas (or BOG) and refrigerants will result from components and fittings throughout the LNG Terminal.

Emissions from the five CTs are exhausted via the HRSG stacks. The heating value of the turbine fuel gas is assumed to be 952 Btu/scf (standard cubic feet) HHV, based on a fuel specification provided by the terminal design engineering firm (a Kiewit, Black & Veatch, and JGC joint venture, "KBJ"), incorporating a mix of pipeline natural gas with BOG.

Emission factors for the CTs were provided by KBJ for several operation loads and ambient temperatures. Annual potential emissions for each CT are estimated from maximum hourly emissions at 100% load with 4,000 hours per year of duct burner firing and an ambient temperature of 42 °F. The turbines will have inlet air pre-heating to a minimum of 42 °F, and the highest emissions occur at the lowest inlet temperature.

Emissions are based on the proposed emission limits with control using SCR for NO_X, oxidation catalysts for CO and VOC, and good combustion practices for particulate matter species. A maximum fuel sulfur content of 1 grain per 100 standard cubic feet (gr/100 scf) of natural gas is used to estimate emissions of SO_2 and oxidation rates. H_2SO_4 emissions are based on oxidation rates provided by KBJ (SO_2 to SO_3 based on the turbine type, post-combustion configuration and control, and 100% conversion of SO_3 to H_2SO_4). SO_2 emission rates do not take oxidation into account and are conservative. A two percent by volume oxidation rate of SO_2 in the CT is assumed, with zero oxidation in the duct burner. A 20 percent oxidation rate is expected to occur in the CO catalyst and a three percent oxidation rate is expected for the SCR. Ammonia slip is calculated at 5 ppmvd for a maximum emission rate of 3.47 lb/hr at 42 °F.

Turbine startup and shutdown emissions are calculated for 12 startups and 12 shutdowns for each turbine per year. The liquefaction trains will operate continuously with the exception of maintenance downtime. Low load turbine operations are not expected except during short startup and shutdown periods.

Emission estimates for PM_{10} and $PM_{2.5}$ include the ammonium sulfates created downstream of the SCR (again assuming all SO_3 is converted to H_2SO_4). Hazardous air pollutant (HAP) emissions are based on AP-42 Section 1.4 (September 1999) for duct burner and Section 3.1 (April 2000) for combustion turbine emission factors.

Criteria pollutant emissions from the auxiliary boiler are calculated using manufacturer's emission factors and information from KBJ. SO_2 emissions are based on natural gas sulfur content of 1 gr/100 scf. 44 percent by volume conversion of SO_3 to H_2SO_4 is assumed. PM and HAP emissions are calculated using factors from AP-42 Section 1.4, July 1998. The boiler will have SCR and an oxidation catalyst to control NO_X and CO/VOC, respectively.

The gas conditioning unit produces an acid gas process stream which is routed to the thermal oxidizer for destruction. Emissions are calculated using manufacturer's emission rate information. The VOC and greenhouse gas (GHG) emission estimates also include 350 hours per year of venting to account for maintenance downtime. HAP emissions are calculated using factors from AP-42 Section 1.4, July 1998.

For the fire water pump engines, the backup generators, and the black start generators, PM/PM_{10}/$PM_{2.5}$, CO, NO_X, and VOC emission factors are based on the emission rates provided by the manufacturer. Mass balance with a diesel fuel sulfur content of 0.0015 percent by weight (15 ppm) is used to estimate SO_2 emissions for all diesel engines. AP-42 Section 3.1 and Section 3.4, October 1996, emission factors are used to estimate HAP emissions for all diesel engines.

For the MPGF and the TEGF, emissions are calculated for full time firing of pilot gas and purge gas.

The flare events which will occur are unplanned and have unknown gas volumes, with one exception. When an LNGC arrives following a dry dock overhaul period, the hull will be too warm to load LNG, and the carrier must be 'conditioned' prior to loading. The conditioning process is typically called "Gas-up" and "Cool Down." During "Gas Up," the ship vapor within the hull is replaced by vaporized LNG (methane), and the inert gases are displaced. At this stage the tanks are full of methane at ambient temperature. During "Cool Down" LNG is sprayed into the tanks by spray heads which vaporizes and cools the tank. When tank temperatures reach -220 °F, the tanks are ready for bulk loading.

At the LNG Terminal, the "Gas Up" displaced hull vapors will be routed to the TEGF for combustion. When the gas contains less than 50 ppmv CO_2 it will be routed to the fuel gas system. The emission calculations include up to 3 ships a year requiring "Gas Up." During the "Cool Down" procedure, all vapors will be sent to the fuel gas system.

Fugitive emissions of natural gas, BOG, and refrigerants will result from the components and fittings throughout the facility. Fugitive emission estimates of VOC, GHGs, and HAPs have been estimated for equipment leaks using component counts and emission factors from the EPA Protocol for Equipment Leak Emission Estimates, November 1995. LNG Tank fugitive emissions were provided in the May 2013 PSD Air Permit Application for the JCEP; those emission estimates have been included.

One ton per year of aggregate insignificant emissions is included for each criteria pollutant, and 0.7 tons per year of aggregate insignificant emissions of H_2SO_4 is included.

The potential emissions are summarized in Table 2-6 below. Detailed emission rate calculations are provided in Appendix B.

Table 2-6. JCLNG Potential Emission Rates (tons/yr)

Unit	NO_X	CO	SO_2	VOC	$PM/PM_{10}/PM_{2.5}$	H_2SO_4	NH_3	Lead	CO_2(e)	HAPs(1)
Turbines	81.99	97.82	35.19	32.72	112.26	23.61	75.4	--	1,292,706	5.06

Total Emissions	**156.8**	**153.9**	**56.6**	**69.5**	**120.2**	**24.6**	**76.3**	**4.8E-04**	**1,951,406**	**8.1**

Note: '--' = not applicable.
(1) Maximum single HAP is n-hexane at 3.29 tpy.

2.4 PROPOSED PLANT SITE EMISSION LIMITS

Based on the proposed installation of the equipment described in this application, the Plant Site Emission Limits (PSELs) presented in Table 2-7 are requested.

Table 2-7. Proposed PSELs for JCLNG (tons/yr)

Pollutant	Proposed PSELs
PM	121
PM_{10}	121
$PM_{2.5}$	121
SO_2	57
NO_X	157
CO	154
VOC	70
H_2SO_4	25
GHG	1,951,410

3. REGULATORY APPLICABILITY

This section describes the applicable regulations triggered by the proposed project. The applicability determination conducted in this analysis is pursuant to the Oregon NSR regulations, National Emissions Standards for Hazardous Air Pollutants (NESHAP), and New Source Performance Standards (NSPS).

3.1 NEW SOURCE REVIEW APPLICABILITY

The JCLNG must be evaluated in relation to Oregon's NSR program. The Coos Bay area is designated as "attainment" or is unclassified for all criteria pollutants. JCLNG was permitted as a Prevention of Significant Deterioration (PSD) source under ACDP No. 06-0118-ST-01 in 2015. The facility has not yet been constructed and the design has changed. The planned facility and equipment must then be re-evaluated under the NSR and PSD requirements of OAR 340, Division 224 to determine whether it will be a federal major source in order to determine whether Oregon's PSD program has been triggered and, if so, for what pollutants.[2]

A "federal major source" is a source with the potential to emit 100 tons per year or more of any individual regulated pollutant (excluding greenhouse gases and hazardous air pollutants) if that source is in one of the designated source categories or 250 tons per year or more if it is not.[3] The JCLNG (i.e., the source) is no longer within one of the designated source categories which have a PSD threshold of 100 tons per year. The design no longer includes a power plant. The fossil fuel fired auxiliary boiler does have a capacity in excess of 250 MMBtu/hr heat input. The auxiliary boiler potential to emit will not, however, exceed 100 tons per year, meaning the boiler is not a federal major source.[4]

Because LNG terminals are not within any of the 28 listed source categories in OAR 340-200-0020(66), the JCLNG emissions must be compared to the 250-tpy threshold to determine whether the project constitutes a federal major source. The potential to emit is compared to the PSD threshold for each regulated pollutant except GHG and HAPs in Table 3-1.

Table 3-1. Oregon PSD Applicability (tons/yr)

Pollutant	Potential to Emit	PSD Federal Major Source Threshold	PSEL Requested in Excess of PSD Threshold?
PM	120	250	No
PM_{10}	120	250	No
$PM_{2.5}$	120	250	No
SO_2	57	250	No
NO_X	157	250	No
CO	154	250	No
VOC	70	250	No

[2] OAR 340-224-0070. It is important to note that the term "federal major source" should not be taken to imply that the federal PSD rules apply to the JCEP. Rather "federal major source" is a defined term of art under the Oregon New Source Review program.
[3] OAR 340-200-0020(66)
[4] Refer to the Dispersion Modeling Protocol included in Appendix D for additional analysis of the boiler applicability.

As shown in Table 3-1, the potential to emit of the plant as a whole will be less than 250 tpy for each for each regulated pollutant. As neither the facility as a whole nor the fossil fuel fired boiler qualifies as a federal major source, the JCLNG is not subject to Major NSR/PSD program requirements.

The project must then be assessed for applicability under State NSR requirements per OAR 340-224-0010(2)(b)(A). The requested PSELs are compared to the significant emission rates for each regulated pollutant in Table 3-2.

Table 3-2. Oregon State NSR Applicability (tons/yr)

Pollutant	Requested PSEL	Significant Emission Rate	PSEL Requested in Excess of SER?
PM	120	25	**Yes**
PM_{10}	120	15	**Yes**
$PM_{2.5}$	120	10	**Yes**
SO_2	57	40	**Yes**
NO_X	157	40	**Yes**
CO	154	100	**Yes**
VOC	70	40	**Yes**
H_2SO_4	25	7	**Yes**
Lead	0	0.6	No
GHG	1,951,406	75,000	NA

The project is subject to State NSR requirements because emissions of PM, PM_{10}, $PM_{2.5}$, NO_X, CO, SO_2, VOC, and H_2SO_4 will each exceed the significant emission rates, as identified in Table 3-2. GHG emissions will exceed the SER, but GHGs are not subject to State NSR.

State NSR projects are categorized as Type A or Type B actions. Construction of projects located in attainment areas are categorized as Type B State NSR actions. JCLNG will be located in an attainment area and construction of the LNG Terminal will be a Type B State NSR action.

As a result, this application is prepared in accordance with OAR 340-224-0270, "State New Source Review Requirements for Sources in Attainment or Unclassified Areas" for the proposed emissions of PM, PM_{10}, $PM_{2.5}$, SO_2, NO_X, CO, VOC, and H_2SO_4.

3.2 AMBIENT AIR QUALITY ANALYSIS

JCEP must provide an air quality impacts analysis for the proposed project in accordance with OAR 340-225-0050(1) and (2) and 340-225-0060 for each pollutant other than GHGs for which emissions will exceed the SER.[5] The JCLNG potential emissions of CO, SO_2, VOC, PM_{10}, $PM_{2.5}$, PM, NO_X, and H_2SO_4 exceed the netting basis of zero by more than the SERs; therefore, an air quality impact analysis is required for CO, SO_2, PM_{10}, $PM_{2.5}$, and NO_X. No air quality impact analysis is required for H_2SO_4 as no

[5] OAR 340-224-0270(1)(a)

National Ambient Air Quality Standard (NAAQS) or PSD Increment has been established in relation to this pollutant.

A dispersion modeling analysis is conducted to demonstrate that impacts from PM_{10}, $PM_{2.5}$, NO_X, SO_2, and CO emissions from the JCLNG comply with the NAAQS and PSD Increments as they apply to Class I and Class II areas. The analyses are provided in Section 4 and Section 5 of this report.

In addition, for increases of direct $PM_{2.5}$ or $PM_{2.5}$ precursors greater than the SER, an analysis of $PM_{2.5}$ air quality impacts based on the emission increases must be performed.[6]

Draft EPA guidance on addressing secondary formation of ozone was used to develop a project-specific evaluation of the potential impacts from project VOC and NO_X emissions. Following this guidance, it was determined that significant ozone concentrations will not be generated from the project. Further discussion of the ozone precursor analysis may be found in Section 4.7.3.

3.2.1 AIR QUALITY MAINTENANCE AREAS

The owner or operator of any source subject to OAR 340-224-0270 that significantly affects air quality in a designated nonattainment or maintenance area must meet the requirements of net air quality benefit in OAR 340-224-510 and 340-224-0520 for ozone areas and OAR 340-224-510 and 340-224-0540 for other designated areas.[7] The JCLNG is located greater than 100 km from all designated nonattainment and maintenance areas, including the Grants Pass particulate and CO maintenance area, the Eugene-Springfield CO area, and the Salem ozone and CO maintenance area.

3.3 NEW SOURCE PERFORMANCE STANDARDS

NSPS are established under 40 CFR Part 60 and adopted by reference in OAR 340-238-0060. The following NSPS are applicable to the proposed project.

3.3.1 NSPS SUBPART KKKK

The combustion turbines are subject to 40 CFR 60 Subpart KKKK, *Standards of Performance for Stationary Combustion Turbines*, because they are stationary combustion turbines with a heat input capacity greater than 10 MMBtu/hr and will commence construction after February 18, 2005. Pursuant to 40 CFR 60.4305, the turbines, HRSGs, and duct burners are exempt from the requirements of Subparts GG, Da, Db, and Dc.

Subpart KKKK regulates emissions of SO_2 and NO_X. Based on the source type and heat input, the NO_X emission limit for the JCEP turbines is 25 ppm at 15% O_2 or 1.2 lb/MW-hr of useful output. The heat content of the natural gas/BOG mixture meets the definition of 'natural gas' in Subpart KKKK. JCLNG will use a continuous emission monitoring system (CEMS) in accordance with §60.4335(b) and 60.4345 to demonstrate continuous compliance with the NO_X emissions limit for each unit.

[6] OAR 340-224-0270(1)(b)
[7] OAR 340-224-0070(4)

The SO_2 emission limit of 0.90 pounds per megawatt-hour (lb/MWh) gross output is based on an emission factor of 0.06 lb/MMBtu-heat input (or 20 gr/100 scf). JCLNG will maintain a natural gas tariff sheet to demonstrate that the fuel burned by each affected facility contains a total sulfur content of 20 gr/100 scf, or less, in accordance with §60.4365(a). The fuel gas fired in the turbines will often have a lower sulfur content than the incoming pipeline natural gas because the BOG has had sulfur compounds removed.

3.3.2 NSPS SUBPART Db

The proposed 296 MMBtu/hr auxiliary boiler is subject to 40 CFR 60 Subpart Db, *Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units*, because it is a steam generating unit with a design capacity greater than 100 MMBtu/hr heat input that will commence construction after June 19, 1984. Units firing only gaseous fuel with a potential SO_2 emission rate of 140 ng/J (0.32 lb/MMBtu) heat input or less are exempt from the SO_2 emissions limit in §60.42b(k)(1). In addition, PM standards do not apply to units combusting only natural gas. Per §60.44b(l)(1), the auxiliary boiler will be subject to the emission standard of 0.20 lb/MMBtu heat input determined on a 30-day rolling average basis.

The projected boiler operating hours result in a 10 percent annual capacity factor estimate. The annual capacity factor is calculated on annual actual operating hours. Because there may be years when auxiliary boiler operations exceed 876 hours per year, JCEP does not want to take a federally enforceable limit on the annual capacity factor. A NO_X CEMS will be required to monitor NO_X emissions.

Refer to Table 3-3 for a summary of NSPS Subpart Db emission limits applicable to the auxiliary boiler. Refer to Appendix C for a more detailed compliance summary and the supporting calculations.

Table 3-3. Emission Standards for Auxiliary Boilers

Boiler Category	Annual Capacity Factor	NO_X lb/MMBtu	PM lb/MMBtu	SO_2 lb/MMBtu
Natural gas-fired, > 250 MMBtu/hr	10%	0.20	Exempt	Exempt

3.3.3 NSPS SUBPART IIII

NSPS Subpart IIII, *Standards of Performance for Stationary Compression Ignition Internal Combustion Engines*, applies to all of the proposed diesel-fired engines. The 700 hp fire pump engines are subject to the emission limits of Table 4 in Subpart IIII, and JCLNG must comply with the emission standards shown in Table 3-4. The proposed engines are rated to meet Tier 3 standards.

Table 3-4. Emission Standards for Stationary Fire Pump Diesel Engines

Maximum Engine Power	Model Year	NMHC + NO_X g/kW-hr (g/hp-hr)	PM g/kW-hr (g/hp-hr)
450≤KW≤560 (600≤HP≤750)	2009 +	4.0 (3.0)	0.20 (0.15)

The 1,214 hp emergency backup generator engines have a displacement of 2.25 liters per cylinder and must comply with the certification emission standards for new non-road compression ignition engines for the same model year and maximum engine power in 40 CFR 89.112 and 40 CFR 89.113 for all pollutants because the engines will be newer than the 2007 model year. The engines must be certified for Tier 2 standards and operation will be limited according to 40 CFR 60.4211(f). The engines must comply with the emission standards shown in Table 3-5.

Table 3-5. Emission Standards for Stationary Emergency Diesel Engines

Maximum Engine Power	Model Year	NMHC + NO_X g/kW-hr (g/hp-hr)	CO g/kW-hr (g/hp-hr)	PM g/kW-hr (g/hp-hr)
kW ≥ 560 (hp ≥ 750)	2007 +	6.4 (4.8))	3.5 (2.6)	0.2 (0.15)

The 4,376 hp black start engines will serve the dual function of providing power for turbine startup and providing power to supply the plant's critical essential services during loss of on-site generation, resulting from turbine trips offline. The facility, including instrument air and safety mechanisms, is islanded from the power grid and the black start generators serve an emergency response function. The engines have a displacement of 5.29 liters per cylinder and must comply with the certification emission standards for new non-road compression ignition engines for the same model year and maximum engine power in 40 CFR 89.112 and 40 CFR 89.113 for all pollutants because the engines will be newer than the 2007 model year. The engines must be certified for Tier 2 standards and operation will be limited according to 40 CFR 60.4211(f). The applicable emission standards are shown in Table 3-6.

Table 3-6. Emission Standards for Stationary Emergency Diesel Engines

Maximum Engine Power	Model Year	NMHC + NO_X g/kW-hr (g/hp-hr)	CO g/kW-hr (g/hp-hr)	PM g/kW-hr (g/hp-hr)
kW ≥ 560 (hp ≥ 750)	2007 +	6.4 (4.8))	3.5 (2.6)	0.2 (0.15)

In order to demonstrate compliance with the NSPS, JCEP will purchase engines certified by the manufacturer and operate and maintain all diesel engines according to the manufacturer's instructions. Pursuant to §60.4207, JCEP will only burn ultra-low-sulfur fuel (15 ppm sulfur) in the diesel-fired engines. A non-resettable hour meter will also be installed for the fire pump engines, emergency backup generator units, and black start units. Initial notification is not required by this subpart.

3.3.4 NSPS SUBPART Kb

40 CFR 60, Subpart Kb, *Standards of Performance for Volatile Organic Liquid Storage Vessels (Including Petroleum Liquid Storage Vessels) for which Construction, Reconstruction, or Modification Commenced after July 23, 1984*, applies to storage vessels greater than 75 cubic meters that are used to store volatile organic liquids (VOL), which is an organic liquid that can emit VOC into the atmosphere. Methane is not considered a VOC due to its limited photochemical reactivity. LNG typically includes more than just methane, specifically propane and butane, which are considered VOCs. However, Subpart Kb does not apply to storage vessels with a capacity greater than or equal to 151 cubic meters, storing a liquid with a maximum true vapor pressure less than 3.5 kilopascals (kPa). The maximum true vapor pressure is the

equilibrium partial pressure exerted by the VOCs in the stored VOL. The vapor pressure of propane (and butane) is below 3.5 kPa at the storage temperature. As such, 40 CFR 60 Subpart Kb is not applicable to the LNG storage tanks at JCLNG.

3.3.5 NSPS SUBPART OOOOa

40 CFR 60, Subpart OOOOa, *Standards of Performance for Crude Oil and Natural Gas Production Facilities for which Construction, Modification or Reconstruction Commenced After September 18, 2015*, applies to certain equipment within the crude oil and natural gas source category that are constructed, modified, or reconstructed after September 18, 2015. Subpart OOOOa has superceded, in date, the NSPS, Subpart OOOO, which was found to be applicable to certain operations at JCLNG in ACDP 06-0118.

Subpart OOOOa must be examined for applicability. Each affected facility equipment type must be considered. The applicability findings are as follows.

- JCLNG will not include any well affected facilities.
- JCLNG will not include any centrifugal or reciprocating compressor affected facilities. Centrifugal compressors will be used to move BOG through the fuel gas system, but the compressors will have dry seals.
- JCLNG does not meet the definition of natural gas processing plant (gas plant) in Subpart OOOOa. Consequently, pneumatic controllers will not be affected sources. In addition, the process unit equipment associated with the liquefied natural gas unit is exempt from the provisions of §§60.5400a, 60.5401a, 60.5402a, 60.5421a, and 60.5422a because it is not located at an onshore natural gas processing plant site.
- JCLNG will not operate a sweetening unit because the pipeline natural gas being treated in the gas conditioning unit is not sour gas.
- JCLNG will not include any affected source VOC storage tanks. The LNG storage tanks will not contain an accumulation of crude oil, condensate, intermediate hydrocarbon liquids, or produced water, and fugitive VOC emissions will be less than 6 tons per year.
- JCLNG will not include any pneumatic pumps.
- JCLNG does meet the definition of compressor station in Subpart OOOOa. Consequently, JCLNG will not have a fugitive component affected source.

JCLNG will not be subject to any NSPS Subpart OOOOa requirements.

3.4 NATIONAL EMISSIONS STANDARDS FOR HAZARDOUS AIR POLLUTANTS

NESHAPs have been established in 40 CFR Parts 61 and 63 to control the emissions of HAPs. NESHAP regulations establish emission standards or work practices for specific types of equipment located at a HAP major source. A HAP major source is a facility with a potential to emit 10 tpy or more of a single HAP or 25 tpy or more of a combination of HAPs. The JCLNG will not be a Major Source of HAPs. Potential emissions are below the 10 tpy single HAP and 25 tpy total HAPs thresholds. Thus, JCLNG qualifies as an “area source” under the following NESHAP rules.

The following NESHAPs were reviewed for applicability to the proposed project.

3.4.1 40 CFR 63, SUBPART JJJJJJ

The proposed 296.2 MMBtu/hr auxiliary boiler is exempt from 40 CFR 63 Subpart JJJJJJ, *National Emission Standards for Hazardous Air Pollutants for Industrial, Commercial, and Institutional Boilers Area Sources,* because it is a gas-fired boiler.

3.4.2 40 CFR 63, SUBPART ZZZZ

Subpart ZZZZ, *National Emissions Standards for Hazardous Air Pollutants for Stationary Reciprocating Internal Combustion Engines* (RICE), applies to all of the proposed diesel-fired engines. However, a new diesel engine meeting the criteria in paragraphs 40 CFR 63.6590 (c)(1) through (7) of Subpart ZZZZ meets the requirements of the subpart by meeting the requirements of 40 CFR 60 Subpart IIII for compression ignition engines. Each of the proposed diesel engines will meet the criteria of 40 CFR 63.6590(c)(1), so no further requirements apply for any of the engines under the NESHAP.

3.5 TITLE V

JCLNG will be a major source of air pollutants because the facility will have the potential to emit over 100 tpy or more of NO_X, CO, and $PM/PM_{10}/PM_{2.5}$. JCEP will be required by OAR 340, Division 218 to obtain a Title V Operating Permit from ODEQ. The complete application to obtain the Oregon Title V Operating Permit must be submitted within 12 months after commencing operation (initial startup).[8]

3.6 CONTINUOUS EMISSIONS MONITORING

JCEP will install CEMS to record the exhaust concentration of NO_X and CO from all five combustion turbines. These CEMS will be used to demonstrate compliance with the NSPS standards and to provide accurate measurement of actual emissions from each turbine for PSEL compliance demonstration on a rolling 12-month basis. Because the turbines are subject to NSPS Subpart KKKK, the CEMS will comply with the performance evaluations for the monitoring systems detailed in 40 CFR 60. Although Subpart KKKK provides alternative provisions for use of Part 75 CEMS methods, JCEP is not subject to Acid Rain requirements and use of the Part 75 alternative methods is not proposed.

JCEP will also install a NO_X CEMS on the auxiliary boiler to meet the monitoring requirements of NSPS Subpart Db. The auxiliary boiler CEMS will also be installed and operated following Part 60 methods.

[8] 340-218-0040(1)(a)(B)

4. CLASS II AMBIENT AIR QUALITY ANALYSIS

This section summarizes the dispersion modeling used to demonstrate compliance with the applicable NAAQS and Class II PSD Increments. A dispersion modeling analysis was conducted to demonstrate compliance with the applicable air quality standards for all criteria pollutants subject to State NSR review. The results of the analysis, summarized below, indicate that the project will be in compliance with all applicable Class II air quality standards.

The modeling analysis summarized herein is based on the approved modeling protocol[9], except for the following clarifications or revisions:

- Clarification - the meteorological data were not processed with the adjust_u* option;
- Clarification - the moisture selection by month was based on data collected at the Southwest Oregon Regional Airport following EPA guidance; and
- Revision - the receptor grid was extended out to 50 km in the north, east, and south directions to capture all potential significant impacts (to the west lies the Pacific Ocean).

A full discussion of the modeling methodology, including model versions, meteorology, land use, receptor grid setup, and downwash analyses, is provided in the approved modeling protocol (the Protocol), attached as Appendix D. Summaries of model inputs are provided in Appendix E. All modeling files used in support of this analysis are provided in Appendix F.

4.1 EQUIPMENT LIST

JCLNG emission units include the following equipment:

- Five (5) combined-cycle natural gas turbines with duct burners;
- One (1) auxiliary boiler;
- Three (3) liquefaction area fire pumps;
- Four (4) emergency generators;
- One (1) thermal oxidizer;
- One (1) multipoint (warm and cold) ground flares; and
- One (1) totally enclosed (marine) ground flare.

LNG carrier emissions are not part of the stationary source, but LNGC emissions and downwash are included in the cumulative source analysis as competing sources.

4.2 SITE LAYOUT

The effect of plume downwash due to airflow around project-related buildings and structures was considered for all stationary point sources.[10] As shown in Figure 4, large buildings and structures near

[9] The modeling protocol was approved, with edits, by ODEQ on July 15, 2017. Email from Phil Allen (ODEQ) to Jason Reed (SLR).

[10] For the totally enclosed (marine) ground flare, downwash effects were considered from other surrounding structures, but not the flare enclosure itself.

the stationary sources were entered in to the current version of the EPA-approved Building Profile Input Program (BPIPPRM Version 04274). BPIPPRM produced direction-specific downwash parameters for direct input into AERMOD and also the Good Engineering Practice (GEP) stack height for each stack. All stacks are below their calculated GEP-stack height.

The facility design also includes the use of vapor dispersion walls along the fenceline of the LNG Terminal for safety purposes. The vapor dispersion walls will range from 20 feet to 80 feet above grade. Although BPIPRM was not designed or tested for a structure with these height-to-width ratios, a sensitivity analysis was conducted to quantify the potential impact of these features on air quality concentrations. Based on the site layout and the height of the vapor dispersion walls, only the fire-water pumps would be affected by the inclusion of the walls in the development of downwash coefficients using BPIPRM. When input into AERMOD, the design-value air quality concentrations for all averaging periods are virtually identical when the vapor dispersion walls are included.

4.3 SOURCE PARAMETERS

All emissions from the combined-cycle turbines, auxiliary boiler, fire pumps, emergency generators, and thermal oxidizer will be released from vertical, unobstructed stacks. One of the three flares, the total enclosed ground flare, is also treated as a vertical stack. The other two flares are warm and cold flare lines in a combined multi-point ground flare, which were modeled as an area source. The source locations and elevations are shown in Table 4-1.

Table 4-1. Source Locations

GFlare	MPGF	85.0	259	227	39.5

(1) The parameters were input into the model using the metric units. English units are shown here for ease of comparison with the supplied vendor data in Appendix A.

4.4 OPERATING SCENARIOS

The potential operating scenarios for the turbines include normal operation and startup and shutdown (SU/SD). The support equipment is held constant for both turbine scenarios. The scenarios will include the following:

- Normal operation – where the turbine operates in normal mode for the entire period (short-term).
- SU/SD mode – where the turbine undergoes a startup or shutdown for a portion of the period (i.e., 9-10 minutes) and operates in normal mode for the remainder of the period (short-term).

The annual emissions scenario includes the total emissions from the expected number of startups and shutdowns plus normal operation for the remainder of the year.

4.5 BACKGROUND CONCENTRATIONS

The use of ambient background concentrations is an important aspect to air quality analyses as they represent the effects from existing sources, which directly influences the attainment status with respect to ambient standards. For the NAAQS analysis, background concentrations represent non-modeled sources and are added to the modeled impacts of the proposed project and any nearby industrial sources to assess the potential cumulative impacts.

Ambient background concentrations for this project were obtained from the Northwest AIRQUEST database hosted by Washington State University. Northwest AIRQUEST maintains a database of criteria pollutant design values based on monitoring data and archived CMAQ modeling runs for the 2009-2011 period. The database of design values exists for 12 km by 12 km grid cells covering the states of Idaho, Oregon, and Washington. For the modeling demonstration, the values were obtained from the grid cell representative of the proposed facility location (latitude 43.434°, longitude -124.524°).

Background concentrations can also be used to assess the available headroom between existing conditions and the ambient standards in order to justify the use the SILs.[11] If that headroom is less than the SIL, then project contributions less than the SIL may not be sufficient to demonstrate that the standards will be protected. A list of background concentrations, NAAQS, the difference between the background and NAAQS (i.e. "headroom"), and SILs are shown in Table 4-4. In all cases, the difference between the NAAQS and background concentration is at least 10 times the level of the SIL. This table demonstrates that the difference between the background concentrations and NAAQS is adequate to demonstrate that use of the SIL will not threaten compliance with the NAAQS in the project area.

Table 4-4. Analysis of Headroom Between NAAQS and Background Air Quality (µg/m^3)

Pollutant/ Averaging Period	Background Concentration	NAAQS	Difference	SIL
NO_2 1-hr	16	188	172	8
NO_2 Annual	1.9	100	98.1	1
CO 1-hr	755	40,000	39,245	2,000
CO 8-hr	591	10,000	9,409	500
$PM_{2.5}$ 24-hr	9.9	35	25.1	1.2
$PM_{2.5}$ Annual	6.7	12	5.3	0.3
PM_{10} 24-hr	35.0	150	115.0	1.0
PM_{10} Annual	N/A(1)	N/A(1)	N/A(1)	0.2(1)
SO_2 1-hr	3.1	196	192.9	8
SO_2 3-hr	2.9	1,300	1,297.1	25
SO_2 24-hr	2.9	260	259.1	5
SO_2 Annual	1.1	52	50.9	1

(1) There is no current Oregon standard or NAAQS for PM_{10} at the annual averaging period; however, there is still a SIL per OAR 340-200-0010(163).

4.6 SIGNIFICANCE ANALYSIS

Using the source inputs summarized in previous sections and inputs and methodology described in the approved modeling protocol (Appendix D), the maximum project impacts from either operating scenario are shown in Table 4-5 and maximum concentration contour plots are provided in Figures 5 through 16. Table 4-5 also lists SILs and monitoring *de minimis* levels for comparison to the project modeled concentrations.

The maximum predicted 1-hr CO concentration and the maximum predicted 8-hr CO concentration both occur on the western facility fenceline. As shown in Figures 5 and 6 and Table 4-5 below, predicted concentrations of CO do not exceed the SIL for either the 1-hr averaging period or the 8-hr averaging period. Therefore, no further analysis is required of CO for either averaging period.

For the SIL analysis, the NO to NO_2 conversion ratio has been conservatively assumed to be 100 percent. The maximum predicted 1-hr NO_2 concentration is located on the western facility fenceline, while the

11 OAR 340-225-0050(1)(b)(A)

maximum predicted annual NO_2 concentration is located on the South Dunes fenceline. As shown in Figures 7 and 8 and Table 4-5 below, predicted concentrations of NO_2 exceed the SIL for the 1-hr averaging period and the annual averaging period. Therefore, full impact analysis for NO_2 is required for the 1-hr averaging period and annual averaging period.

The maximum predicted 1-hr SO_2 concentration is located in hilly terrain approximately 8 km south of the facility. The maximum predicted 3-hr SO_2 concentration is located on the southern facility fenceline. The maximum predicted 24-hr concentration is located about 1 km northwest of the facility. The maximum predicted annual concentration is located on the western facility fenceline. As shown in Figures 9 to 12 and Table 4-5 below, predicted concentrations of SO_2 exceed the SIL for the 1-hr averaging period but do not exceed the SIL for the 3-hr, 24-hr, and annual averaging periods. Therefore full impact analysis for SO_2 is required for the 1-hr averaging period, but no further analysis is required for the 3-hr, 24-hr, and annual averaging periods.

The maximum predicted concentrations for $PM_{2.5}$ and PM_{10} for the 24-hr averaging period occurs just west of the facility. The maximum predicted concentrations for $PM_{2.5}$ and PM_{10} for the annual averaging period occur on the western facility fenceline. As shown in Figures 13 to 16 and Table 4-5 below, for both species of particulate matter and both the 24-hr and annual averaging periods, the predicted concentrations of particulate matter exceed the SILs. Therefore, full impact analysis of both $PM_{2.5}$ and PM_{10} for the 24-hr and annual averaging periods will be required. [12]

Table 4-5. Significance Analysis Results

Pollutant	Averaging Period	Maximum Modeled Concentration (μg/m^3)	SIL (μg/m^3)
NO_2(1)	Annual	3.4	1
	1-hr	50.5	8
$PM_{2.5}$	Annual	1.1	0.3
	24-hr	8.1	1.2
PM_{10}	Annual	1.1	0.2
	24-hr	8.1	1
SO_2	Annual	0.3	1
	24-hr	2.5	5
	3-hr	5.7	25
	1-hr	11.5	8
CO	8-hr	16.2	500
	1-hr	108.0	2,000

(1) Assumes 100% NO_X to NO_2 conversion.

[12] It is noted that there are currently no state or federal ambient air quality standards for annual PM_{10}; however, an annual Class II increment is still present.

4.7 FULL IMPACT ANALYSIS

The proposed project emissions are shown to have maximum ambient concentrations that exceed the SILs for PM_{10} at the 24-hr and annual averaging periods, $PM_{2.5}$ at the 24-hr and annual averaging periods, SO_2 at the 1-hr averaging period, and NO_2 at the 1-hr and annual averaging periods. Therefore, a Full Impact Analysis is conducted for these seven combinations of pollutants and averaging periods. The same project emission and operating scenarios from the significance analysis are combined with LNG carrier emissions and nearby, competing sources that were provided by ODEQ. Only receptors where the predicted concentration, for each pollutant and averaging time, was greater than the SIL are considered in the Full Impact Analysis.[13]

4.7.1 COMPETING SOURCES

ODEQ provided a list of competing sources on August 5, 2017 for NO_2, $PM_{2.5}$, PM_{10}, and SO_2.[14] All provided sources are included in the full impact analysis as provided by ODEQ. A list of those sources and emission rates are included in Appendix E. The information provided by ODEQ includes the actual emissions for calendar year 2016, as well as the allowable, potential to emit for each source. The allowable, potential to emit values are used in the competing source analysis. Tons per year emission rates provided by ODEQ were converted to grams per second rates for input into AERMOD[15], and stack parameters provided in English units were converted to metric units before AERMOD input.

The fleet of LNG vessels expected to call at the JCEP terminal consists of both vessels that have boiler/steam turbine-driven (ST) propulsion systems, as well as vessels powered by duel-fuel diesel-electric (DFDE) propulsion. Further, each type of vessel may be operated on either natural gas or fuel oil. For the DFDE ships, however, operation on oil versus operation on natural gas was confined to different activities during the ship's call. Therefore, three vessel emissions scenarios were created in order to determine worst-case air emissions calculations and associated air quality impacts:

- ST carriers operating on oil;
- ST carriers operating on natural gas; and
- DFDE carriers.

JCEP expects up to 120 LNG vessel calls per year. For the purposes of the modeling, in each of the three scenarios, it is assumed that all of the 120 vessel calls will be of ships of the same propulsion and fuel type.

The LNG vessel call activities can be divided into several scenarios and operating periods per visit. These activity times are not dependent on the ship or fuel type. Emission rates for different activities during the carrier's call were developed from the emission factors shown in Appendix G and the amount of power expected to be consumed during that particular activity. As the emission factors are in a g/kW-hr basis, and the power will vary depending on activity, the emission rates (on a mass per unit time basis) will vary depending on the activity in which the ship is engaged.

[13] OAR 340-225-0050(1)(a) and (b).
[14] Further discussions between ODEQ and SLR on August 30, 2017 about larger significant impact areas confirmed no additional offsite sources needed to be included.
[15] Assuming 8,760 hours of operation.

If a ship is engaged in a particular activity for the full averaging period, than the full mass per unit time rate was used for modeling of that activity. If a ship is engaged for the activity for a portion of the averaging period, then the mass per unit time emission factor was weighted by the proportion of the activity time to the time of the averaging period. For example, for an activity that takes four hours, the full mass per unit time emission rate calculated was used for 1-hour averaging periods (as the activity time is longer than that averaging period), but one-sixth of the full mass per unit time emission rate was used for 24-hour averaging periods (as the four hours of activity time is one-sixth of the averaging period).

In addition to the activities at, and in, the immediate vicinity of the terminal, the emissions of the carrier's transit of the channel and near-shore open water were considered by setting up 68 surrogate sources[16] along the geographic track of arriving and departing ships. The transit emission rates were used for these surrogate sources, with the emissions divided equally over the 68 surrogate sources.

In addition to the 120 LNG vessels, three tugboats will also be deployed in operation at the JCEP LNG Terminal. The worst-case scenario resulting in the highest emissions involves use of one tugboat while the carrier is berthed. Because the tugboat will be maneuvering around the ship during the worst case scenario, the tugboat is represented as a series of four surrogate sources in the channel adjacent to the ship dock, with one-quarter of the total tugboat emissions assigned to each surrogate source. The tugboat emissions, location of surrogate sources, and stack parameters are shown in Appendix G. The effects of plume downwash were also considered for the marine carriers and support vessels in the multisource modeling.

4.7.2 NO_2 FORMATION

The modeling analysis used the first two tiers in the approach described in the latest EPA guidance:

1. The first Tier will assume a full, 100% conversion of NO_X to NO_2.
2. If needed, the second tier will utilize the ambient ratio method (ARM2) method implemented and documented per EPA guidance.
3. If needed, the third tier will utilize the Ozone Limiting Method (OLM) or Plume Volume Molar Ratio Method (PVMRM) implemented and documented per EPA guidance.

The significant impact analysis utilized the first tier and the NAAQS and increment analysis utilized the second tier, ARM2.

4.7.3 OZONE AND $PM_{2.5}$ SECONDARY FORMATION

The draft EPA guidance on addressing secondary formation of $PM_{2.5}$ and ozone was used to develop a project-specific evaluation of the potential impacts from project VOC, SO_2, and NO_X emissions.[17,18] The

[16] The surrogate sources are the discrete locations where the carrier emissions are modeled to represent the movement of the ship along the channel.

[17] Guidance on the Development of Modeled Emission Rates for Precursors (MERPs) as a Tier 1 Demonstration Tool for Ozone and $PM_{2.5}$ under the PSD Permitting Program, December 2016.

project emissions were compared to the information provided in the EPA guidance for Modeled Emission Rates for Precursors (MERPs). This EPA guidance is based on a suite of photochemical modeling runs across the continental U.S. designed to assess secondary ozone and $PM_{2.5}$ formation from various, hypothetical sources. These runs were used to establish modeled responses to precursor emissions, which can be used to determine:

- Emission thresholds below which insignificant secondary formation is expected to occur
- Secondarily-formed downwind concentrations of ammonium sulfate, ammonium nitrate, or ozone from emitted precursors.

The first step of the guidance is to compare Project emissions to the emission thresholds. Since the Project emits more than one precursor pollutant, an additional calculation is needed to account for the combined effect of the precursors. This is accomplished by adding ratios (project emissions divided by an emission threshold) for each precursor together. If the combined ratios of the precursors are greater than one, then significant secondary formation is possible and needs to be quantified.

The second use of the guidance allows for quantification of the secondary formation. Because the EPA modeling was for a limited number of sources, several inputs were varied by EPA to obtain more robust model responses. The inputs that were varied include stack height and parameters, precursor emission levels, and inherently based on the source's location, regional emissions, and geophysical characteristics (i.e., climate, terrain, proximity to other large sources or cities). For the pollutants in which the quantification of secondary effects is required, Appendix A of the EPA guidance was reviewed to find a source-impact relationship that is representative of the Project. Representativeness was determined by stack parameters, emission levels, local/regional emissions, and geophysical environment.

Table 4-6 compares the lowest (most conservative) ozone emission threshold values for NO_X and VOCs in the Western U.S to Project emissions. Because both NO_X and VOC are emitted, the combined effect is accounted for, as shown in Table 4-6. Following the draft EPA guidance, since the sum of the combined ratios (project emissions/emission threshold value) for each precursor is less than a value of 1, significant ozone concentrations will not be generated from the Project.

Table 4-6. Summary of MERPs Analysis for Ozone

Precursor	Project Emissions (tpy)	8-hr O3 MERP (tpy)[(1)]	Ratio of Project Emissions to Daily Ozone MERP	Sum of Ratios
NO_X	155.0	184	0.84	0.91
VOC	72.5	1,049	0.07	

(1) These are the most conservative (lowest) MERP values for ozone in the Western U.S. as summarized in the February 23, 2017 memorandum.

[18]Distribution of the EPA's modeling data used to develop illustrative examples in the draft Guidance on the Development of Modeled Emission Rates for Precursors (MERPs) as a Tier 1 Demonstration Tool for Ozone and $PM_{2.5}$ under the PSD Permitting Program, February, 2017.

A similar analysis for daily and annual $PM_{2.5}$ is shown in Tables 4-7 and 4-8, respectively. The approach for secondary $PM_{2.5}$ formation from NO_X and SO_2 emissions is the same as ozone, but $PM_{2.5}$ also needs to include direct $PM_{2.5}$ impacts as modeled in AERMOD.[19] As shown in Tables 4-7 and 4-8, insignificant secondary formation is expected to occur for both daily and annual $PM_{2.5}$. However, because Project direct $PM_{2.5}$ impacts (i.e., modeled in AERMOD) are above the significant impact level (see Table 4-5), then the reported $PM_{2.5}$ will include the expected secondary formation using representative modeled responses in Appendix A of the EPA guidance as discussed further below.

While the lowest (most conservative) emission thresholds are useful for screening project emissions, they are not necessarily representative of potential secondary formation due to project emissions. For instance, the sources with the lowest (most conservative) SO_2 and NO_X emission thresholds are in interior California, which is not representative of the climatology or source environment of the proposed project. Furthermore, both of these sources were modeled with 'low' source heights (release height of 1 m), which is not representative of Project sources.

The summarized modeling results for 24-hour average concentrations of secondary formation for precursor SO_2 and NO_X in Appendix A of the MERP guidance was further reviewed. The data were sorted to only include:

- Sources located in Oregon or Washington (considered to be more representative of climate at the Project site);
- Precursor emissions of 500 tpy (similar in magnitude to Project emissions, yet conservative); and
- And 'high' stack heights (similar to Project sources).

The results of this analysis are summarized in Table 4-9. Taking the two highest modeled responses, 0.15 $\mu g/m^3$ and 0.24 $\mu g/m^3$ for NO_X and SO_2, respectively, the combined potential secondary formation from Project emissions is 0.39 $\mu g/m^3$. This concentration is added to the modeled result for direct $PM_{2.5}$ on a 24-hour basis to represent the additional concentration from $PM_{2.5}$ formation. For conservatism, this 24-hour secondary formation will also be added to annual $PM_{2.5}$ impacts.

Table 4-7. Summary of MERPs Analysis for Daily $PM_{2.5}$

Precursor	Project Emissions (tpy)	Daily $PM_{2.5}$ MERP (tpy)(1)	Ratio of Project Emissions to Daily $PM_{2.5}$ MERP	Sum of Ratios
Direct $PM_{2.5}$	AERMOD results > SIL			0.34
NO_X	155.0	1,075	0.14	
SO_2	40.2	210	0.19	

(1) These are the most conservative (lowest) MERP values for ozone in the Western U.S. as summarized in the February 23, 2017 memorandum.

[19] Total $PM_{2.5}$ is the sum of direct $PM_{2.5}$ plus secondary $PM_{2.5}$. Direct $PM_{2.5}$ emissions and downwind impacts are modeled in AERMOD. The secondary formation of Project NO_X and SO_2 emissions into $PM_{2.5}$ is crux of the MERPs guidance.

Table 4-8. Summary of MERPs Analysis for Annual $PM_{2.5}$

Precursor	Project Emissions (tpy)	Annual $PM_{2.5}$ MERP (tpy)(1)	Ratio of Project Emissions to Annual $PM_{2.5}$ MERP	Sum of Ratios
Direct $PM_{2.5}$	AERMOD results > SIL			0.07
NO_X	155.0	2,289	0.05	
SO_2	40.2	3,184	0.02	

(1) These are the most conservative (lowest) MERP values for ozone in the Western U.S. as summarized in the February 23, 2017 memorandum.

Table 4-9. Summary of Modeled Responses for Representative Sources

Precursor	Area	Emissions (tpy)	Height	Source	FIPs	State	County	Modeled Response (μg/m^3)
NO_X	**WUS**	**500**	**H**	**18**	**41049**	**Oregon**	**Morrow**	**0.15**
NO_X	WUS	500	H	22	53057	Washington	Skagit	0.05
NO_X	WUS	500	H	23	53039	Washington	Klickitat	0.03
SO_2	**WUS**	**500**	**H**	**23**	**53039**	**Washington**	**Klickitat**	**0.24**
SO_2	WUS	500	H	18	41049	Oregon	Morrow	0.19
SO_2	WUS	500	H	22	53057	Washington	Skagit	0.08

4.7.4 NAAQS ANALYSIS

The NAAQS analysis takes into consideration a representative background concentration in addition to emissions from competing sources and the proposed project to determine compliance. Results of the NAAQS analysis for the seven pollutants and averaging periods that were above their respective SILs are shown in Figures 17 through 22 and Table 4-10 below. As shown, the total predicted concentration from the proposed and competing sources plus background concentration is below the NAAQS for all pollutants and averaging periods.

Table 4-10. NAAQS Analysis Results

Pollutant	Averaging Period	Modeled Concentration(1) (μg/m^3)	Secondary Formation (μg/m^3)	Background (μg/m^3)	Total Impact (μg/m^3)	NAAQS (μg/m^3)
NO_2(2)	1-hour	132.3	--	16.0	148.3	188.0
	Annual	4.1	--	1.9	6.0	100.0
PM_{10}(3)	24-hour	9.3	--	35.0	44.3	150.0
	Annual	1.4	--	n/a	1.4	n/a
$PM_{2.5}$(4)	24-hour	6.9	0.4	9.9	17.2	35.0
	Annual	1.3	0.4	6.7	8.4	12.0
SO_2	1-hour	30.1	--	3.1	33.2	196.0

(1) Modeled concentrations are as follows. These are in some cases conservative as compared to the NAAQS, as several NAAQS standards allow use of three-year average values, while the presented results are based on results from the single worst year.
   a. The modeled 1-hour NO_2 concentration is the highest result for the 98th percentile of 1-hour daily maximum concentrations for any of the five given years.
   b. The modeled annual NO_2 is the maximum concentration at any receptor.
   c. The modeled 24-hour PM_{10} concentration is the highest second high result for any of the five given years.
   d. The modeled 24-hour $PM_{2.5}$ concentration is the highest result for the 98th percentile of 1-hour daily maximum concentrations for any of the five given years.
   e. The modeled annual $PM_{2.5}$ concentration is the maximum concentration at any receptor.
   f. The modeled 1-hour SO_2 concentration is the the highest result for the 99th percentile of 1-hour daily maximum concentrations for any of the five given years.

(2) The reported NO_2 modeled concentration is based on the ARM2 method in AERMOD.
(3) PM_{10} has a Class II SIL defined in OAR 340, but no associated NAAQS.
(4) As described in Section 4.7.3.

4.7.5 CLASS II PSD INCREMENT ANALYSIS

Results of the Class II PSD Increment analysis for NO_2, PM_{10}, and $PM_{2.5}$ are provided in Figures 23 through 27 and Table 4-11 below. The 1-hr NO_2 and SO_2 pollutants/averaging periods do not have an applicable increment, so an increment analysis was not performed for those pollutants. As shown, the total predicted concentration is below the Class II PSD Increment standard for all pollutants and both averaging periods.

Table 4-11. Class II PSD Increment Results (µg/m^3)

Pollutant	Averaging Period	Modeled Concentration(1) (µg/m^3)	Secondary Formation (µg/m^3)	Total Impact (µg/m^3)	Class II Increment (µg/m^3)
NO_2	Annual	4.1	--	4.1	25.0
PM_{10}	24-hour	9.3	--	9.3	30.0
	Annual	1.4	--	1.4	17.0
$PM_{2.5}$(2)	24-hour	7.9	0.4	8.3	9.0
	Annual	1.3	0.4	1.7	4.0

(1) Maximum second highest 24-hour concentration in the modeled year. Maximum annual average concentration.
(2) As described in Section 4.7.3.

5. CLASS I AMBIENT AIR QUALITY ANALYSIS

In addition to the Class II air quality analysis discussed in Section 4 above, a Class I screening air quality and regional haze analysis was also performed for relevant areas within 200 km of the project site. There are five federal Class I areas within that radius, managed by either the National Park Service or the Forest Service. The modeling analysis summarized herein is based on the approved modeling protocol and the project inputs detailed in Section 4.

5.1 CLASS I PSD SIGNIFICANCE ANALYSIS

An assessment of project impacts in comparison to the Class I significant impact level for the Class I PSD increments was run using with the same model and inputs as described in Section 4. If results for all years at these 50 km receptors for a particular Class I area were below the SIL for a particular pollutant and averaging period, then it was presumed the concentrations would be below the SIL for that pollutant and averaging period at the more distant Class I area (110 km to 178 km) as well, and no further analysis was conducted in these cases.

Receptors were placed at a distance of 50 km from the project (the farthest distance for which AERMOD is approved) in arcs that were located to capture plume impacts in the direction of each Class I area. The elevations of the receptors were based on the actual elevation of each receptor location as determined by AERMAP and standard NED data. Receptors were also placed at the potential plume height to ensure the maximum potential impacts were captured. Results from the screening modeling are compared to the Class I SILs defined in the OAR, which are listed in Table 5-1, below. For Project impacts that are above the Class I SILs, a screening analysis was conducted to determine the impacts on the Class I areas within 200 km of the proposed facility.

Further analysis was conducted if results at 50 km associated with a particular pollutant, averaging period, and Class I area were above the SIL. In these cases, the concentrations from each year and receptor were averaged over the five years, and the receptor on the 50 km ring with the highest five-year average concentration was chosen. A receptor was then placed at the 1 km distance along the ray ranging from the center of the proposed facility to the 50 km receptor with the highest average concentration. AERMOD was run at this 1 km receptor for each of the five years, and the average of the five years was taken. As such, five-year averages at both 1 km and 50 km were obtained. Use of the five-year average at 50 km was chosen based on an assumption that steady-state, deterministic results at that distance are conservative, particularly for longer time periods. The use of the five-year average at 1 km, rather than the single highest value obtained from any year, was a conservative choice so as not to allow a particularly high value to create a sharp and rapid decay function and corresponding lower result at the farther Class 1 areas.

An exponential decay function was then calculated to fit the results at 1 km and 50 km. The exponential decay function was used as the concentrations will decrease faster than they would under a linear relationship as distance increases from the facility, and the concentrations cannot go below zero (a limit for development of a mathematical extrapolation of concentration versus distance). The faster-than-linear decrease occurs because rather than existing in one dimension, air may move in three different dimensions as distance increases from the facility. In addition, sinks such as deposition would reduce the ambient air concentrations of the pollutant as well. The rate of decay depends on the relative difference between the 1 and 50 km values; higher values at 1 km and lower values at 50 km produce a more rapid rate of decay. Hence the use of the average value rather than the highest value at 1 km is conservative because it lowers the rate of modeled decay, resulting in a higher pollutant concentration at the Class I area distances (110 to 178 km away).

Curve parameters were determined for each pollutant, averaging period, and Class I area for which there was a modeled result at 50 km measured above the SIL, and the parameters were used to determine a concentration at the distance to the boundary of the Class I areas. It is shown that for all cases, the concentrations obtained through the curve fitting and extrapolation analysis are below the Class I SILs at the distance to the Class I areas. Class I analysis results for each area are summarized in Appendix H. Table 5-1 shows the results of the highest concentrations from all Class I areas. The results demonstrate the LNG Terminal emissions will below the Class I SILs and the project is not expected to contribute to Increment or NAAQS impacts in those locations.

Table 5-1. Class I Results and Significant Impact Levels (μg/m^3)

Pollutant	Averaging Period	Maximum Concentration at 50 km	Maximum Concentration at Class I Area Boundary	Class I SILs[(1)]
SO_2	3-hr	1.33	0.24	1.0
	24-hr	0.35	0.023	0.2
	Annual	0.012	N/A	0.1
NO_2	Annual	0.032	N/A	0.1
PM_{10}	24-hr	0.854	0.061	0.3
	Annual	0.026	N/A	0.2
$PM_{2.5}$	24-hr	0.854	0.061	0.07
	Annual	0.026	N/A	0.06

(1) OAR 340-200-0020(163). All SILs are based on the first highest concentration at any one location.

5.2 CLASS I AQRV ANALYSIS

An air quality related values (AQRV) analysis is not required for a Type B State NSR project but is part of other regulatory requirements for the Project.[20] Therefore, for consistency and informational purposes, a Q/D calculation for regional haze and deposition was used to screen for AQRVs.[21] The screening analysis was based on distance from the source to the Class I area and the annualized daily emissions of AQRV-impacting pollutants. If the Q/D analysis results are less than or equal to the screening factor of 10, then FLM agencies do not require any further Class I AQRV impact analyses from those sources.

[20] The 2017 FERC guidance recommends Class I analyses for those projects within 100 km of a Class I area, subject to PSD permitting requirements, or for projects in which comments are expected.

[21] U.S. Forest Service – Air Quality Program, National Park Service – Air Resources Division, U.S. Fish and Wildlife Service – Air Quality Branch, *Phase I Report of the Federal Land Managers' Air Quality Related Values Workgroup (FLAG)- Revised*, Section 3.2. October 2010.

A detailed calculation of the Q value along with the resultant Q/D values (all less than 10) is provided in Appendix H. Also provided are concurrences from the National Park Service and US Forest Service that no additional AQRV analyses are warranted.

Facility Name: JCEP LNG Terminal Project Permit Number: ______________

1. Description of facility and processes:

Jordan Cove Energy Project, L.P. (JCEP) is proposing to construct and operate a natural gas liquefaction and export facility (LNG Terminal or Project), located on the bay side of the North Spit of Coos Bay, Oregon. Natural gas will be delivered to the LNG Terminal via the proposed Pacific Connector Gas Pipeline (PCGP), which will connect the Project with existing interstate natural gas pipeline systems.

Natural gas received at the LNG Terminal will be cooled into liquid form at - 260 degrees F and stored in two 160,000 cubic meter full-containment LNG storage tanks. The Project facilities would have the capability to export up to 7.8 million tonnes per annum (MTPA) via LNG carriers.

The Project will consistent of the following facilities:
- A pipeline gas conditioning facility consisting of one feed gas cleaning and dehydration train with a combined natural gas throughput of approximately 1.19 billion standard cubic feet per day (Bscf/d);
- A thermal oxidizer to combust the acid gases produced by the gas conditioning unit;
- Five natural gas liquefaction trains, each with the export capacity of 1.56 MTPA;
- Five turbine-driven compressors with waste heat recovery;
- A refrigerant storage and resupply system;
- An Aerial Cooling System (Fin-Fan);
- An LNG storage system consisting of two full-containment LNG storage tanks, each with a net capacity of 160,000 m3 (42,232,000 gallons), and each equipped with three fully submerged LNG in-tank pumps sized for approximately 11,600 gallons per minute (gpm) each;
- An LNG transfer line consisting of one approximately 2,500-foot-long, 36-inch-diameter line that would connect the shore based storage system with the LNG loading system;
- An LNG carrier cargo loading system designed to load LNG at a rate of 10,000 m3 per hour (m3/hr) with a peak capacity of 12,000 m3/hr, consisting of three 16-inch loading arms and one 16-inch vapor return arm;
- A protected LNG carrier loading berth constructed on an Open Cell® technology sheet pile slip wall and capable of accommodating LNG carriers with a range of capacities;
- A boil off gas (BOG) recovery system used to control the pressure in the LNG storage tanks;
- Electrical, nitrogen, fuel gas, lighting, instrument/plant air and service water facility systems;
- An emergency relief system (a marine flare and warm and cold ground flares);
- An LNG spill containment system, a fire water system and various other hazard detection, control, and prevention systems; and
- Utilities, buildings and support facilities.

2. Attach plot plan. Please see Figures 1, 2, and 3 as well as attached plot plans.

3. Attach process flow diagram. Please see attached Figures A-1, A-2, and A-3.

4. Attach a city map or drawing showing the facility location. Please see Figure 1.

NOTES:

Engine Information

1.	Device ID Number	EUs 1.CT through 5.CT (Turbines)
2.	Existing or future?	Future
3.	Date construction commenced	January 2019
4.	Date installed/completed	April 2022 (1.CT) - July 2022 (5.CT)
5.	Special controls (if applicable)	No
6.	Manufacturer	General Electric
7.	Date manufactured	
8.	Maximum rating (MMbtu/hr for turbines, Hp for others)	504.4 turbine, 19.7 duct burner
9.	Control device(s) (yes/no)	Yes
	If yes, enter the identification number(s)	CD.SCR1-5, CD.OC1-5
10.	Description of device:	

Natural gas/ boil off gas- fired, combined cycle General Electric LM6000PF+ turbines to drive refrigeration compressors for five liquefaction trains. Each turbine is equipped with a duct burner and operates in combined cycle mode with a heat recovery steam generator.

Operating Schedule

11.	Projected maximum hours/day	24
12.	Projected maximum hours/year	8,760

Fuel Information

13. Fuel usage:	a. Type	b. Hourly usage	c. Annual usage
Primary	Natural Gas/ BOG	0.530 MMscf/hr	4,641 MMscf
Back-up			
Other			

Stack Information

14.	Exit height (ft)	119
15.	Exit diameter (ft)	10
16.	Design flowrate (dscf/min)	

Monitoring Information

17. Monitoring equipment			
fuel flow (y/n)	Yes	recorder? (y/n)	Yes
engine load (y/n)	Yes	recorder? (y/n)	Yes
other (specify)	CEMS	recorder? (y/n)	Yes

State of Oregon Department of Environmental Quality

Facility Name: JCEP LNG Terminal Project

Permit Number:

1.	Control Device ID	CD.SCR1 through CD.SCR5 (Selective Catalytic Reduction)
2.	Process/Device(s) Controlled	EUs 1.CT through 5.CT (combined-cycle turbines)
3.	Year installed	2022
4.	Manufacturer/Model No.	
5.	Control Efficiency (%)	NOx reduction- 92.0 %wt
6.	Design inlet gas flow rate (acfm)	790,170 acfm
7.	Design parameter(s)	Exhaust gas flow rate and NOx concentration
8.	Inlet gas pretreatment? (yes/no) If yes, list control device ID and complete a separate control device form	No
9.	Describe the control device	

Each combined cycle liquefaction turbine has an SCR system on the HRSG exhaust to reduce emissions of NOx.

MISCELLANEOUS **FORM AQ307**
CONTROL DEVICE INFORMATION **ANSWER SHEET**

State of Oregon Department of Environmental Quality

Facility Name: JCEP LNG Terminal Project Permit Number:

1.	Control Device ID	CD.OC1 through CD.OC5 (Oxidation Catalyst)
2.	Process/Device(s) Controlled	EUs 1.CT through 5.CT (combined-cycle turbines)
3.	Year installed	2022
4.	Manufacturer/Model No.	
5.	Control Efficiency (%)	CO reduction- 84.6%wt VOC reduction- 30.0%wt
6.	Design inlet gas flow rate (acfm)	790,170 acfm (CTG exhaust gas flow)
7.	Design parameter(s)	Exhaust flow rate and CO concentration
8.	Inlet gas pretreatment? (yes/no) If yes, list control device ID and complete a separate control device form	No
9.	Describe the control device	

Each combined cycle liquefaction turbine has an oxidation catalyst on the HRSG exhaust to reduce emissions of CO and VOC.
