Re: Jordan Cove Energy Project Land Use Applications
Coos County File Nos. HBCU-19-003/FP19-003
Applicant's Second Open Record Period Submittal

Dear Mr. Stamp:

This office represents Jordan Cove Energy Project L.P. ("JCEP"), the applicant requesting approval of concurrent land use applications to construct various components of a larger project to process, liquefy, and export natural gas from the North Spit ("Project") in Coos County ("County") File Nos. HBCU-19-003/FP-19-003 ("Applications"). This letter and its enclosures constitute JCEP's second open record period submittal for the Applications. Please consider these materials before completing your recommended order for this matter.

Enclosed please find the following materials (exhibit numbering picks up with the next sequential exhibit number following JCEP's previous exhibits for the Applications):

- Exhibit 27 - Draft Environmental Impact Statement ("DEIS") issued by the Federal Energy Regulatory Commission ("FERC") dated March 2019: This report assesses the potential environmental effects of the construction and operation of the Project in accordance with the requirements of the National Environmental Policy Act. It also proposes avoidance, minimization, and mitigation measures.

- Exhibit 28 - Supplemental Response to Comments on DEIS dated September 3, 2019: This letter includes JCEP's responses filed with FERC to comments regarding the DEIS for the Project and the Pacific Connector Gas Pipeline. Some of JCEP's responses are relevant to issues raised in the County land use proceedings.

- Exhibit 29 - Consents to Applications by Oregon Department of State Lands ("DSL"): This exhibit consists of the DSL Director's signed consents to the filing of the Applications for Project components affecting submerged and submersible non-trust lands in Coos Bay owned by the State of Oregon and managed by DSL.

- Exhibit 30 - Response to FERC Environmental Information Request dated October 4, 2019: This submittal from JCEP to FERC addresses the Bureau of Land Management's questions regarding the Project's industrial wastewater pipeline.

- Exhibit 31 - Excerpts of Resource Report No. 1 (General Project Description): This report was submitted by JCEP to FERC to describe the Project. The excerpts of this report in this exhibit include Section 1.2.3 (Current LNG Terminal Proposal), which explains the new power source (direct combustion-turbine liquefaction-drive) for the gas liquefaction aspect of the Project.

- Exhibit 32 - Letter of Withdrawal dated April 12, 2019: This letter was submitted by JCEP to the Oregon Department of Energy to withdraw the application for an exemption from a site certificate for a high-efficiency cogeneration energy facility for the Project.

- Exhibit 33 - Letter from Black & Veatch dated January 11, 2016: This letter, which is from a Black & Veatch engineer, explains how the Project industrial emissions will not adversely affect airport approach surfaces.

- Exhibit 34 - Resource Report No. 9 (Air and Noise Quality): This report was submitted by JCEP to FERC to evaluate air and noise impacts caused by construction and operation of the Project and to propose measures to mitigate such impacts.

- Exhibit 35 - Letter Addressing Concrete Batch Plant dated October 28, 2019: This letter, which was prepared by the joint venture team of Kiewit, Black & Veatch, and JGC, describes and depicts the proposed concrete batch plant, its potential impacts, and measures designed to minimize and mitigate those impacts to existing surrounding uses.

- Exhibit 36 - Biological Assessment and Essential Fish Habitat Assessment revised September 2018: This report identifies the extent of effects on endangered or threatened species (including species regulated under a federal fisheries management plan) and their critical habitat and recommends measures that would avoid, reduce, or mitigate such impacts.

- Exhibit 37 - Thermal Plume Study: This exhibit consists of the study referred to as Exhibit 27 in Mr. Himes' letter.

- Exhibit 38 - Airport Imaginary Surfaces Diagram: This graphic consists of Figure 15 referenced in Mr. Himes' letter.

JCEP will offer additional argument based upon this evidence before the close of the local record. Based upon the enclosed evidence and the additional evidence and argument in the whole record, the Hearings Officer should enter an order recommending that the County Board of Commissioners approve the Applications.

I have asked County Planning staff to place a copy of this submittal into the official record for this file and to place a copy before you. JCEP reserves the right to submit additional argument and evidence in this matter consistent with the open record schedule established by the Hearings Officer and ORS 197.763.

Thank you for your careful review of this information.

Very truly yours,

Seth J. King

Federal Energy Regulatory Commission

Office of Energy Projects
Washington, DC 20426

DRAFT
ENVIRONMENTAL IMPACT STATEMENT
FOR THE
JORDAN COVE ENERGY PROJECT

Docket Nos. CP17-494-000 and CP17-495-000

FERC/DEIS-0292D

March 2019

Cooperating Agencies:

FEDERAL ENERGY REGULATORY COMMISSION
WASHINGTON, D.C. 20426

OFFICE OF ENERGY PROJECTS

In Reply Refer To:
OEP/DG2E/Gas Branch 3
Jordan Cove Energy Project, L.P.
Docket No. CP17-495-000
Pacific Connector Gas Pipeline, LP
Docket No. CP17-494-000
FERC/EIS-0292D

TO THE INTERESTED PARTIES:

The staff of the Federal Energy Regulatory Commission (FERC or Commission) with the participation of the cooperating agencies listed below, has prepared a draft environmental impact statement (EIS) for the Jordan Cove Liquefied Natural Gas Project proposed by Jordan Cove Energy Project L.P. (Jordan Cove) and the Pacific Connector Gas Pipeline Project proposed by Pacific Connector Gas Pipeline LP (Pacific Connector) (collectively referred to as the Jordan Cove Energy Project or Project). Under Section 3 of the Natural Gas Act (NGA), Jordan Cove requests authorization to liquefy at a terminal in Coos Bay, Oregon up to 1.04 billion cubic feet of natural gas per day for export for to overseas markets. Pacific Connector seeks a Certificate of Public Convenience and Necessity under Section 7 of the NGA to construct and operate an interstate natural gas transmission pipeline providing about 1.2 billion cubic feet per day of natural gas from the Malin hub to the Jordan Cove terminal, crossing portions of Klamath, Jackson, Douglas, and Coos Counties, Oregon.

The draft EIS assesses the potential environmental effects of the construction and operation of the Project in accordance with the requirements of the National Environmental Policy Act (NEPA). As described in the draft EIS, the FERC staff concludes that approval of the Project would result in a number of significant environmental impacts; however, the majority of impacts would be less than significant because of the impact avoidance, minimization, and mitigation measures proposed by Jordan Cove and Pacific Connector and those recommended by staff in the draft EIS.

The United States Department of the Interior Bureau of Land Management (BLM); U.S. Department of Agriculture Forest Service (Forest Service); Bureau of Reclamation (Reclamation); U.S. Department of Energy; U.S. Army Corps of Engineers; U.S. Environmental Protection Agency; U.S. Department of the Interior Fish and Wildlife Service; U.S. Department of Commerce National Oceanic and Atmospheric Administration's National Marine Fisheries Service; U.S. Department of Homeland

Security Coast Guard; the Coquille Indian Tribe; and the Pipeline and Hazardous Materials Safety Administration within the U.S. Department of Transportation participated as cooperating agencies in preparation of this EIS. Cooperating agencies have jurisdiction by law or special expertise with respect to resources potentially affected by the proposal and participate in the NEPA analysis. The cooperating agencies provided input into the conclusions and recommendations presented in the draft EIS. Following issuance of the final EIS, the cooperating agencies will issue subsequent decisions, determinations, permits or authorizations for the Project in accordance with each individual agency's regulatory requirements.

The BLM, with the concurrence of the Forest Service and Reclamation, would adopt and use the EIS to consider issuing a right-of-way grant for the portion of the Project on federal lands. Other cooperating agencies would use this EIS in their regulatory process, and to satisfy compliance with NEPA and other related federal environmental laws (e.g., the National Historic Preservation Act).

The BLM and the Forest Service would also use this EIS to evaluate proposed amendments to their District or National Forest land management plans that would make provision for the Pacific Connector pipeline. In order to consider the Pacific Connector right-of-way grant, the BLM must amend the affected Resource Management Plans (RMPs). The BLM therefore proposes to amend the RMPs to re-allocate all lands within the proposed temporary use area and right-of-way to a District-Designated Reserve, with management direction to manage the lands for the purposes of the Pacific Connector right-of-way. Approximately 885 acres would be re-allocated. District-Designated Reserve allocations establish specific management for a specific use or to protect specific values and resources. In accordance with Code of Federal Regulations (CFR) part 36 CFR 219.16, the Forest Service gives notice of its intent to consider amendments of Land and Resource Management Plans (LRMP) for the Umpqua, Rogue River and Winema National Forests. Proposed amendments of LRMPs include reallocation of matrix lands to Late Successional Reserves and site-specific exemptions from standards and guidelines and other LRMP requirements to allow construction of the Pacific Connector pipeline. Exemptions from standards and guidelines include requirements to protect known sites of Survey and Manage species, changes in visual quality objectives at specific locations, limitations on detrimental soil conditions, removal of effective shade at perennial stream crossings and the construction of utility corridors in riparian areas. Further information on Forest Service LRMP amendments is included below.

The Commission mailed a copy of the Notice of Availability of the draft EIS to federal, state, and local government representatives and agencies; elected officials; environmental and public interest groups; Indian Tribes; potentially affected landowners and other interested individuals and groups; and newspapers and libraries in the Project area. The draft EIS is only available in electronic format. It may be viewed and downloaded from the FERC's website (www.ferc.gov), on the Environmental Documents page (https://www.ferc.gov/industries/gas/enviro/eis.asp). In addition, the draft EIS may be accessed by using the eLibrary link on the FERC's website. Click on the eLibrary link (https://www.ferc.gov/docs-filing/elibrary.asp), click on General Search, and enter the docket number in the "Docket Number" field, excluding the last three digits (i.e., CP17-494 or CP17-495). Be sure you have selected an appropriate date range. For assistance, please contact FERC Online Support at FercOnlineSupport@ferc.gov or toll free at (866) 208-3676, or for TTY, contact (202) 502-8659.

Any person wishing to comment on the draft EIS may do so. Your comments should focus on the draft EIS's disclosure and discussion of potential environmental effects, reasonable alternatives, and measures to avoid or lessen environmental impacts. To ensure consideration of your comments on the proposal in the final EIS, it is important that the Commission receive your comments on or before 5:00 p.m. Eastern Time on **July 5, 2019.**

For your convenience, there are four methods you can use to submit your comments to the Commission.[1] The Commission will provide equal consideration to all comments received, whether filed in written form or provided verbally. The Commission encourages electronic filing of comments and has staff available to assist you at (866) 208-3676 or FercOnlineSupport@ferc.gov. Please carefully follow these instructions so that your comments are properly recorded.

1) You can file your comments electronically using the eComment feature on the Commission's website (www.ferc.gov) under the link to Documents and Filings. This is an easy method for submitting brief, text-only comments on a project;

2) You can file your comments electronically by using the eFiling feature on the Commission's website (www.ferc.gov) under the link to Documents and Filings. With eFiling, you can provide comments in a variety of formats by attaching them as a file with your submission. New eFiling users must first create an account by clicking on "eRegister." If you are filing a comment on a particular project, please select "Comment on a Filing" as the filing type; or

---

[1] The contents of your comment including your address, phone number, e-mail address, or other personal identifying information may be made available to the public. While you may request that your personal identifying information be withheld from public view, we cannot guarantee that we will be able to do so.

3) You can file a paper copy of your comments by mailing them to the following address. Be sure to reference the Project docket numbers (CP17-494-000 and CP17-495-000) with your submission: Kimberly D. Bose, Secretary, Federal Energy Regulatory Commission, 888 First Street NE, Room 1A, Washington, DC 20426

4) In lieu of sending written or electronic comments, the Commission invites you to attend a public comment session that will be held in the Project area to receive comments on the draft EIS. The dates, locations, and times of these sessions will be provided in a supplemental notice.

Any person seeking to become a party to the proceeding must file a motion to intervene pursuant to Rule 214 of the Commission's Rules of Practice and Procedures (18 CFR 385.214). Motions to intervene are more fully described at http://www.ferc.gov/resources/guides/how-to/intervene.asp. Only intervenors have the right to seek rehearing or judicial review of the Commission's decision. The Commission grants affected landowners and others with environmental concerns intervenor status upon showing good cause by stating that they have a clear and direct interest in this proceeding which no other party can adequately represent. **Simply filing environmental comments will not give you intervenor status, but you do not need intervenor status to have your comments considered.** Subsequent decisions, determination, permits, and authorization by the cooperating agencies are subject to the administrative procedures of each respective agency.

Questions?

Additional information about the Project is available from the Commission's Office of External Affairs, at **(866) 208-FERC**, or on the FERC website (www.ferc.gov) using the eLibrary link. The eLibrary link also provides access to the texts of all formal documents issued by the Commission, such as orders, notices, and rulemakings.

In addition, the Commission offers a free service called eSubscription that allows you to keep track of all formal issuances and submittals in specific dockets. This can reduce the amount of time you spend researching proceedings by automatically providing you with notification of these filings, document summaries, and direct links to the documents. Go to www.ferc.gov/docs-filing/esubscription.asp.

EXECUTIVE SUMMARY

The staff of the Federal Energy Regulatory Commission (FERC or Commission) has prepared this draft environmental impact statement (EIS) to assess the impacts of constructing and operating the Jordan Cove Liquefied Natural Gas (LNG) Project proposed by Jordan Cove Energy Project LP (Jordan Cove) and the Pacific Connector Gas Pipeline Project proposed by Pacific Connector Gas Pipeline L.P. (Pacific Connector). The purpose and need of the Jordan Cove LNG Project is to export natural gas supplies derived from existing interstate natural gas transmission systems to overseas markets. The purpose and need of the Pacific Connector Gas Pipeline Project is to connect the existing interstate natural gas transmission systems of Gas Transmission Northwest, LLC and Ruby Pipeline, LLC with the proposed LNG export terminal. Collectively, Jordan Cove and Pacific Connector are referred to as the applicants, and the projects are referred to collectively as the Project.

The purpose of this draft EIS is to inform the FERC decision-makers, the public, and the permitting agencies about the potential adverse and beneficial environmental impacts of the proposed Project and recommend mitigation measures that would reduce adverse impacts to the extent practicable. We[1] prepared this analysis based on information provided by the applicants; our independent review of this information; in consultation with federal cooperating agencies (see below); and in consideration of comments provided by state and local agencies, Indian Tribes, and individual members of the public. This draft EIS was prepared in accordance with the requirements of the National Environmental Policy Act of 1969 (NEPA) and the Commission's implementing regulations under Title 18 of the Code of Federal Regulations, Part 380 (18 CFR 380).

The FERC is the federal agency responsible for authorizing onshore LNG facilities, and is responsible for regulating the siting and construction of interstate natural gas transmission pipelines. FERC is the lead federal agency responsible for the preparation of this draft EIS. The U.S. Department of the Interior Bureau of Land Management (BLM); U.S. Department of Agriculture Forest Service (Forest Service); Bureau of Reclamation; U.S. Department of Energy; U.S. Army Corps of Engineers (COE); U.S. Environmental Protection Agency; U.S. Department of the Interior Fish and Wildlife Service; U.S. Department of Commerce National Oceanic and Atmospheric Administration's National Marine Fisheries Service; U.S. Department of Homeland Security Coast Guard (Coast Guard); the Coquille Indian Tribe; and the Pipeline and Hazardous Materials Safety Administration within the U.S. Department of Transportation are cooperating agencies for the development of this draft EIS consistent with 40 CFR 1501.6(b). A cooperating agency has jurisdiction by law or has special expertise with respect to the environment potentially affected by the Project. The cooperating agencies provided input to the conclusions and recommendations presented in the draft EIS. Following issuance of the final EIS, the cooperating agencies will issue subsequent decisions, determinations, permits or authorizations for the Project in accordance with each individual agency's regulatory requirements.

PROPOSED ACTION

On September 21, 2017, the applicants, in Docket Nos. CP17-494-000 and CP17-495-000, filed applications with the FERC pursuant to Sections 3 and 7 of the Natural Gas Act (NGA) seeking an Authorization and a Certificate of Public Convenience and Necessity to construct and operate

[1] "We," "us," and "our" refer to the environmental and engineering staff of the FERC's Office of Energy Projects.

an LNG export terminal and an interstate natural gas transmission pipeline. The LNG terminal would be located in Coos County, Oregon on the North Spit of Coos Bay and would be capable of liquefying up to 1.04 billion cubic feet of natural gas per day for export. The 200-acre LNG terminal site would include:

- an access channel from the existing Coos Bay Federal Navigation Channel to the LNG terminal;
- modifications to the existing Federal Navigation Channel;
- a marine slip containing two berths (one Production Loading Berth and one Emergency Lay Berth), a dock for tug and escort boats, and a material offloading facility (MOF);
- LNG loading platform and transfer line;
- two full-containment LNG storage tanks and associated equipment;
- five natural gas liquefaction trains;
- a pipeline gas conditioning facility;
- a temporary workforce housing facility;
- the non-jurisdictional Southwest Oregon Regional Security Center and Fire Department building; and
- other security and control facilities, administrative buildings, and other support structures.

As proposed, the LNG terminal would be called upon by about 120 LNG carriers per year.

The pipeline would originate at interconnections with existing pipeline systems in Klamath County, Oregon, and would span parts of Klamath, Jackson, Douglas, and Coos Counties, Oregon, before connecting with the LNG terminal. The approximately 229-mile-long, 36-inch-diameter pipeline would be capable of transporting up to 1.2 billion cubic feet of natural gas per day. Operating the pipeline would require the use of one compressor station (i.e., the Klamath Compressor Station) and other associated facilities including mainline block valves, pig[2] launchers and receivers, communication systems, and meter stations.

PUBLIC INVOLVEMENT

The applicants began participating in the Commission's Pre-filing Process in early 2017 (Docket No. PF17-4-000). The FERC's Pre-filing Process encourages the early involvement of interested stakeholders and responsible regulatory agencies to identify and resolve environmental issues before an application is filed with the FERC. During the Pre-filing Process, the applicants held Open Houses in Coos Bay and along the pipeline route in March of 2017 to provide the public with information about the Project and to solicit its concerns about the Project.

In June 2017, the FERC issued a *Notice of Intent to Prepare an Environmental Impact Statement for the Planned Jordan Cove LNG Terminal and Pacific Connector Pipeline Projects, Request for Comments on Environmental Issues, and Notice of Public Scoping Sessions* (NOI). The NOI was sent to affected landowners; federal, state, and local government agencies; elected officials; environmental and public interest groups; interested Indian tribes; and local libraries and newspapers. The NOI also began a 30-day scoping period. During the scoping period, the FERC along with the BLM and Forest Service, held joint public scoping sessions in Coos Bay and along the pipeline route to receive comments about the Project. Each session was attended by at least

[2] A pig is a remotely operated pipe inspection and cleaning tool.

150 people, and some sessions were attended by substantially more. During scoping, we also met with several federally recognized Indian Tribes in person and via teleconference meeting to discuss their concerns about the Project.

To date, we have received more than 9,000 comments on the Project. Most comments concern property rights, land use, purpose and need, safety and security, potential geological hazards (tsunamis and mountainous terrain), and the FERC's approach to the NEPA process. Comments from Indian Tribes expressed concern about meaningful consultation, cultural resources, environmental resources including fish (salmon) and vegetation, impacts on traditional use(s) of the land, environmental justice, cumulative impacts, and documentation of concerns in the EIS. All comments received prior to the issuance of this EIS were considered and addressed as appropriate in our analysis. Additionally, many comments raised concerns that are outside the scope of this EIS. Examples include comments concerning the public benefit or need to export LNG, unconventional natural gas production ("fracking"), induced production of natural gas, "life-cycle" cumulative environmental impacts associated with the LNG export process, and downstream greenhouse gas emissions resulting from the combustion of exported natural gas.

PROJECT IMPACTS

Constructing and operating the Project would impact geological resources, soils and sediments, water resources, wetlands, vegetation, wildlife, aquatic resources, threatened and endangered species, and other species of concern, land use, recreation, visual resources, socioeconomics, transportation, cultural resources, air quality, and noise. Our analysis also evaluates the potential for cumulative impacts on these resources.

Constructing and operating the LNG terminal would permanently impact about 200 acres of land, resulting in the loss of about 22 acres of wetlands. Coos Bay would temporarily experience increased turbidity and sedimentation due to the construction of the marine facilities. Wildlife in the vicinity of the LNG terminal, especially those species who are sensitive to noise and light would experience increased rates of stress, injury, and mortality. Areas adjacent to the Coos Bay Federal Navigation Channel would be modified, but it is suitable to support the LNG carriers that would call on the terminal. LNG carriers transiting the Federal Navigation Channel would likely cause minor delays for other marine traffic in the waterway. Vehicle traffic and associated commute times near the LNG terminal site would also increase. Permanent and temporary structures at the LNG terminal as well as LNG carrier operations in the Federal Navigation Channel would exceed FAA obstruction standards and there is a potential significant impact to the safe air operations of the Southwest Oregon Regional Airport if a resolution cannot be settled between Jordan Cove and FAA. Constructing the LNG terminal would temporarily impact the Coos Bay area short-term housing market. The LNG terminal would permanently impact the visual character of Coos Bay. The LNG terminal design accounts for possible tsunamis and includes safeguards and protections to ensure facility integrity and public safety.

Constructing the pipeline would require the temporary use of more than 4,000 acres of land. Operating the pipeline would permanently impact about 1,400 acres of land; however, many land uses including livestock grazing would not be permanently affected. The pipeline would be located across steep terrain through the Cascade Mountains, but Pacific Connector has planned accordingly for potential landslides and erosion. The pipeline would also cross over 300 waterbodies including the Coos, Rogue, and Klamath Rivers. These larger rivers would be crossed using horizontal directional drills to minimize impacts. The pipeline would also impact over 2,000 acres of forest including over 750 acres of late stage old-growth forest that provides habitat to marbled murrelet, northern spotted owl, and other federally-listed threatened and endangered species. Recreation areas crossed by the pipeline would be temporarily disturbed and use of these areas would likely find construction to be an annoyance and an inconvenience. Vehicle traffic on area roads would increase as well as demand for local services and business, but these increases would be temporary. Following construction, the primary impact of the Project would be the visible nature of the permanent pipeline easement. The visual impact of the easement would be similar to that of other utilities and roadways in the region.

ALTERNATIVES CONSIDERED

As required by NEPA and in consultation with the cooperating agencies, we identified and considered reasonable alternatives to the Project to determine if the implementation of an alternative would be preferable to the proposed action. An alternative is considered reasonable if it meets the stated purpose of the Project and is technically and economically feasible and practical. A preferable alternative would offer a significant environmental advantage over the proposed action.

In our alternatives analysis we considered the no action alternative, system alternatives, LNG terminal site alternatives, and pipeline route alternatives. The EIS evaluates all alternatives developed by staff, developed by the applicants, or suggested by stakeholders that were able to meet the Project's purpose and were feasible or practical.

Under the No Action alternative, the environmental impacts associated with constructing and operating the Project would not occur; however, equal or greater impacts could occur at other location(s) in the region as a result of another LNG export project seeking to meet the demand identified by the applicants.

The systems alternatives we considered include existing and proposed LNG terminals in Alaska, Canada, and Mexico; an LNG project currently under construction in Tacoma, Washington; an existing interstate natural gas transmission pipeline system in Oregon; and a non-jurisdictional intrastate pipeline in Coos County. Existing and proposed LNG terminals in Alaska, Canada, and Mexico are too far removed (700 to 3,000 miles) from the interconnections in Klamath County to offer a significant environmental advantage over the proposed action. The Tacoma LNG Project is designed to serve local customers and provide marine vessel fuel; it would not meet the Project's stated purpose for export. Additionally, the Tacoma LNG Project is being built on a 30-acre site and there is insufficient land available for expansion. The Northwest Pipeline interstate system and the intrastate Coos County Pipeline have insufficient capacities to replace the capacity that would be provided by the proposed pipeline. Modifications to these systems to create such capacity would result in equal or greater environmental impacts and would not offer a significant environmental advantage over the proposed action.

The LNG terminal site alternatives we considered include a site in Humboldt Bay, California; sites in Oregon and Washington; another site in Coos Bay; and an inland site east of Coos Bay. The impacts of constructing an LNG terminal and pipeline to Humboldt Bay would be comparable to that of the proposed Project. Alternative sites in Oregon and Washington would result in greater impacts on the environment. Therefore, alternative LNG terminal sites in California, Oregon, and

Washington would not offer a significant environmental advantage over the proposed action. The Coos Bay site alternative would also not offer a significant environmental advantage over the proposed action. The inland site alternative would be located at least 5 miles east of Coos Bay and would require the construction of an LNG cryogenic pipeline to the proposed marine loading facilities. Our analysis indicates that the relocation of the terminal site would reduce, but not eliminate impacts on wetlands; it would also still result in impacts on Coos Bay, and would likely increase overall impacts on the environment due to the need for an LNG cryogenic pipeline. Therefore, an inland alternative would not offer a significant environmental advantage over the proposed action.

Pipeline route alternatives considered include three major route alternatives and nine pipeline route variations. Based on our analysis as described in the draft EIS, we conclude that four route variations would be preferable to the corresponding proposed action. We are recommending that Pacific Connector incorporate the Blue Ridge Variation, the Survey and Manage Species Variation, the East Fork Cow Creek Variation, and the Pacific Crest Trail Variation into its proposed route for the Project. We have concluded that these variations would offer a significant environmental advantage over the proposed action.

CONCLUSIONS

We conclude that constructing and operating the Project would result in temporary, long-term, and permanent impacts on the environment. Many of these impacts would not be significant or would be reduced to less than significant levels with the implementation of proposed and/or recommended impact avoidance, minimization, and mitigation measures. However, some of these impacts would be adverse and significant. Specifically, we conclude that constructing the Project would temporarily but significantly impact housing in Coos Bay and that constructing and operating the Project would permanently and significantly impact the visual character of Coos Bay. Furthermore, constructing and operating the Project is likely to adversely affect 13 federally-listed threatened and endangered species including the marbled murrelet, northern spotted owl, and coho salmon. Our conclusions are based wholly or in part on the following factors:

- the Project would be constructed in compliance with all applicable federal laws, regulations, permits, and authorizations;
- the applicants would implement all best management practices, the measures described in their *Erosion Control and Revegetation Plan, Wetland and Waterbody Construction and Mitigation Procedures* and *Upland Erosion Control, Revegetation, and Maintenance Plans*, and other impact avoidance, minimization, and mitigation measures;
- the applicants' *Compensatory Wetland Mitigation Plan* would satisfy the COE's regulatory requirements to mitigate unavoidable impacts on wetlands and waters of the U.S.;
- the BLM and Forest Service's plan amendments would provide for the crossing of federal lands;
- compliance with the Endangered Species Act and the National Historic Preservation Act would be complete prior to construction;
- the LNG terminal was designed consistent with maximum tsunami run-up elevations and considered tsunami wave heights and inundation elevations;

- the LNG terminal would include protections and safeguards that ensure facility integrity and public safety;
- the Coast Guard issued a Letter of Recommendation indicating the Coos Bay Federal Navigation Channel would be considered suitable for the LNG marine traffic associated with the Project; and
- FERC's environmental and LNG engineering construction inspection programs would ensure compliance with the applicants' commitments, and the conditions of any FERC Authorization and Certificate.

In addition, we recommend that the Project-specific impact avoidance, minimization, and mitigation measures that we have developed (included in this EIS as recommendations) be attached as conditions to any Authorization and Certificate of Public Convenience and Necessity issued by the Commission for the Project.

1.0 INTRODUCTION

1.1 PROJECT SUMMARY

The staff of the Federal Energy Regulatory Commission (FERC or Commission) prepared this draft Environmental Impact Statement (EIS) to describe our assessment of the potential environmental impacts that may occur from constructing and operating the Jordan Cove Liquefied Natural Gas (LNG) Project and Pacific Connector Gas Pipeline Project.

On September 21, 2017 Jordan Cove Energy Project, L.P. (Jordan Cove) and Pacific Connector Gas Pipeline, L.P. (Pacific Connector)1 filed applications with the FERC pursuant to Sections 3 and 7 of the Natural Gas Act (NGA) to construct and operate an LNG terminal and associated pipeline facilities. A Notice of Application for the Jordan Cove and Pacific Connector Projects2 was issued by the FERC on October 5, 2017.

In FERC Docket No. CP17-495-000, Jordan Cove seeks an NGA Section 3 Authorization (Authorization) to construct and operate an LNG export terminal in Coos County, Oregon. The terminal would be capable of receiving, processing, and liquefying natural gas3 into LNG, then storing and loading the LNG onto LNG carriers. The Jordan Cove facilities could receive a maximum of 1.2 billion cubic feet per day (Bcf/d) of natural gas from the Pacific Connector pipeline and produce a maximum of 7.8 million metric tons per annum (MMTPA) of LNG.

In FERC Docket No. CP17-494-000, Pacific Connector seeks a Certificate of Public Convenience and Necessity (Certificate), under NGA Section 7, to construct and operate an approximately 229-mile-long, 36-inch-diameter natural gas transmission pipeline, crossing through Klamath, Jackson, Douglas, and Coos Counties, Oregon.4 The pipeline would transport about 1.2 Bcf/d of natural gas from interconnections with the existing Ruby Pipeline LLC (Ruby) and Gas Transmission Northwest LLC (GTN) systems5 near Malin, Oregon to the Jordan Cove terminal.

---

[1] Jordan Cove and Pacific Connector are both subsidiaries of Pembina Pipeline Corporation (Pembina) of Calgary, Alberta, Canada. They are also referred to in this EIS as the applicants.

[2] Individually, the Jordan Cove proposal may be referred to in this EIS as the Jordan Cove Liquefaction Project, Jordan Cove LNG Project, LNG Project, Jordan Cove facilities, or the JCEP Project; the Pacific Connector proposal may be referenced similarly, as the Pacific Connector Pipeline Project, Pacific Connector pipeline, pipeline Project, or PCGP Project. Both proposals combined are often called the Project.

[3] Natural gas is a fossil fuel, consisting primarily of methane (CH_4), that is used for a variety of purposes, including electrical generation, home heating and cooking, fuel for motor vehicles, and other industrial/commercial applications. Natural gas is obtained from underground wells and transported from places of production to consumers mainly by way of pipelines. LNG is natural gas that has been cooled to about -260 degrees Fahrenheit (°F). As a liquid, LNG is about 600 times more dense than natural gas in a vapor state and can be stored and transported much more efficiently than the equivalent amount of gas. There are specially designed vessels (referred to as LNG carriers) that can transport LNG overseas from points of origin to customers. Exported LNG can be vaporized at receipt terminals, returned to natural gas, and then transported by pipelines to end-users.

[4] Pacific Connector also requested a blanket certificate to allow for future construction, operation, and abandonment activities under Subpart F of Title 18 Code of Federal Regulations (CFR) Part 157 of the Commission's regulations and requested a blanket certificate to provide open-access transportation services under its tariff in accordance with Subpart G of Part 284.

[5] GTN is owned by TransCanada, while Ruby is owned by Pembina.

As specified by the NGA and the Energy Policy Act of 2005 (EPAct), the FERC is responsible for authorizing onshore LNG terminals and interstate natural gas transmission facilities. EPAct also establishes the FERC as the lead federal agency responsible for coordinating applicable federal authorizations and complying with the requirements of the National Environmental Policy Act (NEPA). The FERC's regulations for implementing the elements of NEPA are at Title 18 Code of Federal Regulations (CFR) Part 380.

Consistent with federal regulations, applicable guidance, and other agreements,6 the United States (U.S.) Department of the Interior Bureau of Land Management (BLM) Oregon State Office; U.S. Department of Agriculture Forest Service (Forest Service) Pacific Northwest Region; Bureau of Reclamation (Reclamation) Klamath Basin Area Office; U.S. Department of Energy (DOE); U.S. Army Corps of Engineers (COE) Portland District; U.S. Environmental Protection Agency (EPA) Region 10; U.S. Department of the Interior Fish and Wildlife Service (FWS) Oregon Fish and Wildlife Office; U.S. Department of Commerce National Oceanic and Atmospheric Administration's (NOAA) National Marine Fisheries Service (NMFS) Oregon Coast Branch; U.S. Department of Homeland Security Coast Guard (Coast Guard) Portland (Sector Columbia River); the Coquille Indian Tribe7; and the Pipeline and Hazardous Materials Safety Administration (PHMSA) within the U.S. Department of Transportation (USDOT) are cooperating agencies in the development of this EIS. Cooperating agencies have jurisdiction by law or special expertise with respect to any environmental impacts involved in a proposal. The responsibilities of cooperating agencies are summarized in 40 CFR 1501.6, the Council of Environmental Quality (CEQ) regulations for implementing NEPA.

1.1.1 Previous Proposals

Beginning in 2006, Jordan Cove and Pacific Connector sought to import LNG into a terminal at Coos Bay, Oregon, and transport natural gas through a sendout pipeline to interconnections with existing pipeline systems at the Malin hub.8 The import terminal and associated sendout pipeline

---

[6] May 2002 "*Interagency Agreement on Early Coordination of Required Environmental and Historic Preservation Reviews Conducted in Conjunction With the Issuance of Authorizations to Construct and Operate Interstate Natural Gas Pipelines Certificated by the Federal Energy Regulatory Commission*", signed by the FERC, Advisory Council on Historic Preservation, CEQ, EPA, Department of the Army, Department of Agriculture, Department of Commerce, DOE, Department of the Interior, and USDOT. February 2004 "*Interagency Agreement Among the Federal Energy Regulatory Commission, United States Coast Guard, and Research and Special Programs Administration for the Safety and Security Review of Waterfront Import/Export Liquefied Natural Gas Facilities*." June 2005 "*Memorandum of Understanding Between the United States Army Corps of Engineers and the Federal Energy Regulatory Commission Supplementing the Interagency Agreement on Early Coordination of Required Environmental and Historic Preservation Reviews Conducted in Conjunction with the Issuance of Authorizations to Construct and Operate Interstate Natural Gas Pipelines Certificated by the Federal Energy Regulatory Commission*," executed 30 June 2005.

[7] The Project would be located across ancestral territory of the Coquille Indian Tribe (CIT). Due to their continued presence in the area, their modern and historic interest throughout their five-county fee-to-trust / service area, their concern for the land, and their special expertise regarding the natural environment, the CIT are participating as a cooperating agency. The CIT manages over 10,000 acres of land, primarily as sustainable forest; and provides education assistance, health care, elder services, and housing assistance to its members. The CIT have provided a unique and invaluable perspective to the development of this EIS.

[8] The originally proposed Pacific Connector sendout pipeline (in Docket No. CP07-441-000) would have connected with the existing GTN, Pacific Gas and Electric Company, and Tuscarora pipelines near Malin, Oregon. The original Jordan Cove LNG import project was authorized by the Commission in an "Order Granting Authorizations Under Section 3 and Issuing Certificates" issued on December 17, 2009 in Docket No. CP07-444-000.

applications were authorized by the Commission with conditions; however, due to changes in the natural gas industry, the facilities were never constructed, and the Commission withdrew its previous approval for the Project.9 Although the facilities required for the import of LNG are different than those required to export LNG, the original terminal location and footprint and the pipeline route are similar to the current Project proposed in Docket Nos. CP17-494-000 and CP17-495-000.

In 2012, Jordan Cove and Pacific Connector sought to export LNG from a terminal at Coos Bay, Oregon, with an associated feeder pipeline proposed to transport natural gas from existing pipeline systems near Malin.10 In response to those applications, the Commission issued an Order Denying Applications for Certificate and Section 3 Authorization on March 11, 2016 for Docket Nos. CP13-483-000 and CP13-492-000, and upheld its decision in its Order Denying Rehearing issued December 9, 2016. However, because the denial was without prejudice, Jordan Cove and Pacific Connector were able to file new applications in Docket Nos. CP17-494-000 and CP17-495-000.

1.1.2 Proposed Action

The facilities addressed in this EIS and described further in chapter 2 are the proposed LNG and pipeline facilities identified by Jordan Cove and Pacific Connector in their respective applications, and are summarized as follows:

LNG Project Facilities:

- an access channel from the existing Coos Bay Federal Navigation Channel to the LNG terminal;
- Modifications to the marine waterway, including four dredge locations located adjacent to the Federal Navigation Channel;
- a terminal marine slip containing two berths (one Production Loading Berth and one Emergency Lay Berth), and a dock for tug and escort boats, and a material offloading facility (MOF);
- LNG loading platform and transfer line;
- LNG storage system, consisting of two full-containment storage tanks;
- five natural gas liquefaction trains;
- a pipeline gas conditioning facility;
- the workforce housing facility located at the South Dunes Site;
- Southwest Oregon Regional Security Center (SORSC); and Fire Department building; and
- other security and control facilities, administrative buildings, meteorological station, and other support structures associated with the terminal.

Pipeline Project Facilities:

- a 229-mile-long, 36-inch-diameter welded steel underground pipeline, extending between interconnections near Malin in Klamath County and the Jordan Cove LNG terminal in Coos County, Oregon;
- the Klamath Compressor Station, at the eastern end of the pipeline; and

[9] On April 16, 2012, the Commission issued an “Order Granting Rehearing in Part, Dismissing Request for Stay, and Vacating Certificate and Section 3 Authorizations” in Docket Nos. CP07-441-000 and CP07-444-000.
[10] Like the current Project, the first LNG export and feeder pipeline proposal had the Pacific Connector pipeline connecting with the existing GTN and Ruby pipelines near Malin, Oregon.

- other associated facilities (e.g., meters stations, mainline block valves, pig launchers, and communication systems).

The general location of LNG terminal and pipeline facilities are depicted in figure 1.1-1 and chapter 2.

The primary differences between the previously proposed LNG terminal facilities (in Docket No. CP13-483-000) from the currently proposed Project are as follows:

- The South Dunes Power Plant has been eliminated from the current proposal.
- The locations of the workforce housing facility, the SORSC, and the project related Fire Department have been relocated.
- New staging areas have been added at Oregon International Port of Coos Bay (Port) Laydown and Boxcar Hill sites.
- The Al Pierce Company (APCO) sites (APCO 1 and 2) would be used for some Project related dredge disposal.
- The number of LNG carriers that would visit the terminal has increased to 110 to 120 vessels per year.
- The proposal now includes the excavation of four submerged areas (removing about 700,000 cubic yards of material) lying adjacent to the existing federally-authorized Federal Navigation Channel, and dredge slurry pipelines in Coos Bay; and
- The habitat mitigation areas at West Jordan Cove and West Bridge locations have been eliminated.

The primary differences between the previously proposed pipeline Project (Docket No. CP13-492-000) from the currently proposed project are as follows:

- Multiple horizontal directional drill (HDD) crossings have been newly proposed, including an approximately 5,200-foot-long HDD crossing under Coos Bay from about mileposts (MP) 0.12[11] to 1.11.
- Multiple route modifications have been made based on detailed civil survey, project design enhancements, and landowner or land-management agency input.
- Increased compression at the Klamath Compressor Station from 41,000 horsepower (hp) to 93,300 hp.
- Elimination of the Clark's Branch Meter Station.

[11] Notice that the MPs for the current version of the Pacific Connector pipeline in Docket No. CP17-494-000 are reversed from the actual direction of natural gas. Although the natural gas would flow east (from Malin) to west (to Coos Bay) in the current Project, the MPs are numbered from west (0.0. at the Jordan Cove Meter Station) to east (MP 228.8 at the Klamath Compressor Station). The letter "R" is used with some MPs to denote re-routes adopted after the original 2007 proposed pipeline route design.

1.2 APPLICANTS' PURPOSE AND NEED

The FERC does not plan, design, build, or operate natural gas infrastructure. As an independent regulatory commission, the FERC reviews proposals developed by other entities. Accordingly, the project proponent is the source for identifying the purpose for developing and constructing a project.

In its application, Jordan Cove states the purpose of its project is to export natural gas supplies derived from existing interstate natural gas transmission systems (linked to the Rocky Mountain region and Western Canada) to overseas markets, particularly Asia.12 According to Jordan Cove, the project is a market-driven response to increasing natural gas supplies in the U.S. Rocky Mountain and Western Canada production areas, and the growth of international demand, particularly in Asia.

In its application, Pacific Connector states that the purpose of its project is to connect the existing interstate natural gas transmission systems of GTN and Ruby with the proposed Jordan Cove LNG terminal.

1.3 FEDERAL AGENCY ROLES AND RESPONSIBILITIES

NEPA requires all federal agencies to consider the environmental consequences of federal actions or undertakings. The Commission's environmental staff, in partnership with the aforementioned cooperating agencies, has prepared this EIS to comply with the requirements of NEPA. This EIS discloses and assesses the potential environmental effects that are likely to result from the construction and operation of the Project. In addition to complying with NEPA, our purposes for preparing this EIS include:

- identify and assess potential impacts on the human environment that would result from the implementation of the proposed action;
- identify and assess reasonable alternatives to the proposed action that would avoid or minimize adverse impacts on the human environment;
- identify and recommend specific mitigation measures to minimize environmental impacts; and
- facilitate public involvement in identifying significant environmental impacts on specific resources.

The information and analyses presented in this EIS are intended to support subsequent conclusions and decisions made by the Commission and the cooperating agencies. For example, the BLM would use this EIS in its assessments of amendments to the Resource Management Plan (RMP) for the Coos Bay, Roseburg, Medford, and Lakeview Districts, and the Forest Service would use this EIS in its assessments of amendments to the Land and Resource Management Plan (LRMP) for the Umpqua, Rogue River, and Winema National Forests (see figure 1.1-1). In addition, the BLM would use this EIS when considering the issuance of a Right-of-Way (ROW) Grant to Pacific Connector for a pipeline easement over federal lands, with concurrence from the Forest Service and Reclamation (as further discussed below in sections 1.3.2, 1.3.3, and 4.7). The NMFS would

[12] Note that the Commission will consider as part of its decision whether or not to authorize natural gas facilities, all factors bearing on the public interest, including the project's purpose and need. Additional information regarding the Commission's process and considerations in regard to the project's purpose and need are provided in section 1.3.1.

use this EIS when considering the issuance of an authorization pursuant to the Marine Mammal Protection Act of 1972, as amended (MMPA) section 101(a)(5) for the take of marine mammals incidental to the proposed action (as further discussed in section 1.5.1.3).

1.3.1 Federal Energy Regulatory Commission

Sections 3 and 7 of the NGA provide the Commission with the authority to regulate the siting, construction, and operation of onshore LNG terminals, and pipelines engaged in the interstate transportation of natural gas. The Commission would consider the findings in this EIS during its review of Jordan Cove's and Pacific Connector's applications. The identification of environmental impacts related to Project construction and operation, and the mitigation of those impacts, as disclosed in this EIS, would be components of the Commission's decision-making process. The Commission would issue its decision in an Order. The Commission may accept the application in whole or in part, and can attach engineering and environmental conditions to the Order that would be enforceable actions to assure that the proper mitigation measures are implemented.

Specifically, regarding whether to authorize the siting of an LNG terminal under NGA Section 3, the Commission would approve the proposal unless it finds the proposed facilities would not be consistent with the public interest. In considering whether or not to issue a Certificate to a natural gas pipeline under NGA Section 7, the Commission would balance public benefits against potential adverse consequences,13 as documented in the Order. The Commission bases its decision on technical competence, financing, rates, market demand, gas supply, environmental effects, long-term feasibility, and other issues concerning a proposed project.

1.3.2 U.S. Department of the Interior Bureau of Land Management

The Pacific Connector pipeline would cross portions of four BLM Districts: Coos Bay District (of which about 17 miles would be crossed), Roseburg District (crossing about 13 miles), Medford District (crossing about 15 miles), and Lakeview District (Klamath Falls Resource Area; crossing about 1 mile). The BLM anticipates adopting this EIS pursuant to 40 CFR 1506.3(c). The EIS will address potential impacts resulting from the pipeline route crossing BLM land, and potential impacts resulting from BLM District Plan amendment that allow the pipeline.

BLM land use planning requirements were established in Sections 201 and 202 of the Federal Land Policy and Management Act of 1976 (FLPMA, 43 United States Code [U.S.C.] 1711-1712) and the regulations in 43 CFR 1600. These laws and regulations require a unit-specific Land Management Plan (LMP) for each BLM administrative management unit (also known as Resource Management Plan [RMP]). All projects or activities on BLM land must be consistent with the governing RMP.

Representatives of the BLM have worked cooperatively with the FERC staff and Pacific Connector during pipeline route selection over BLM lands and incorporation of best management practices (BMP) to minimize environmental consequences. The BLM has determined that the Pacific Connector Pipeline Project would not be consistent with certain requirements of the RMPs of the

[13] The Commission developed a "Certificate Policy Statement" (see *Certification of New Interstate Natural Gas Pipeline Facilities*, 88 FERC ¶ 61,227 (1999), clarified in 90 FERC ¶ 61,128, and further clarified in 92 ¶ 61,094 (2000)), that established criteria for determining whether there is a need for a proposed project.

BLM Districts crossed. To address these inconsistencies, the BLM proposes to amend the RMPs of the respective BLM Districts to make provision for the Project.

For the BLM, the primary purpose of this EIS is to consider and disclose the environmental consequences of construction and operation of the Pacific Connector pipeline on BLM lands and to evaluate proposed RMP amendments. The need for this EIS arises from the BLM's obligation to respond to the application for a ROW Grant submitted by Pacific Connector. The BLM will utilize this EIS to consider Pacific Connector's ROW application and decide, with concurrence from the Forest Service and Reclamation, to grant, grant with conditions, or deny the Temporary Use Permit and the ROW Grant. The BLM is also using this EIS process to identify specific stipulations (including project design features and mitigation measures) related to resources within its respective jurisdiction for inclusion in the ROW Grant.

The BLM has identified suites of "Project Design Features" or "Project Requirements" that are deemed necessary to accomplish the management objectives and direction in the respective RMPs.14 The project design features or requirements specific to the pipeline crossing of BLM lands are included as attachments to Pacific Connector's Plan of Development (POD). There are 28 attachments to the POD; these include draft monitoring elements as needed to ensure that the wide array of actions are implemented and to assess the effectiveness of the actions relative to the management objectives and direction in the respective RMPs. Collectively, the POD is incorporated into the Project's description.

In the 2015 EIS that evaluated the Pacific Connector Project, the BLM had required a compensatory mitigation plan to offset the unavoidable adverse impacts of the Project. This offsite mitigation plan would have been included in the ROW Grant, had the grant been approved. The BLM issued new policy and agency guidance regarding the imposition of offsite compensatory mitigation on July 24, 2018 in Instruction Memorandum (IM) No. 2018-093. The policy states; "Except where the law specifically requires, the BLM must not require compensatory mitigation from public land users. While the BLM, under limited circumstances, will consider voluntary proposals for compensatory mitigation, the BLM will not accept any monetary payment to mitigate the impacts of a proposed action." The policy does not affect compensatory mitigation required under federal laws other than the FLPMA, or the ability of any state government, or other non-federal party, to require and enforce mandatory compensatory mitigation as authorized under state law. This new policy addresses compensatory mitigation and does not affect the project design features and project requirements that are contained in the POD.

The BLM will continue to coordinate with the applicant on any voluntary compensatory mitigation they may propose, and with other federal and state agencies that identify compensatory mitigation as a matter of law on lands managed by the BLM. Any compensatory mitigation that is developed as a result of this coordination would be attached to the POD and included in the ROW Grant if the grant is approved.

[14] The BLM, Forest Service, and Reclamation use the term "Project Design Features" or "Project Requirements" rather than "mitigation" to describe elements of a plan that occur within a project area and are standard requirements of a project. The BLM and Forest Service reserve the term "mitigation" to describe measures taken to reduce or compensate for otherwise unavoidable impacts. The term "mitigation" as used elsewhere in this EIS refers to the full range of activities designed to reduce adverse effects of the Project.

The BLM Oregon State Director is the authorized officer for decisions related to amendments of the respective BLM RMPs, issuance of the Temporary Use Permit, and issuance of a ROW Grant, if authorized.

1.3.3 U.S. Department of Agriculture Forest Service

The Pacific Connector pipeline route would cross portions of the Umpqua, Rogue River, and Winema National Forests (see figure 1.1-1). As a cooperating agency, the Forest Service anticipates adopting this EIS pursuant to 40 CFR 1506.3(c).

Forest Service land use planning requirements were established by the National Forest Management Act (NFMA) and the regulations in 36 CFR 219. These laws and regulations require a unit-specific LMP for each National Forest (LRMPs). All projects or activities within a National Forest must be consistent with the governing LRMP.

On December 15, 2016, the Department of Agriculture Under Secretary for Natural Resources and Environment issued a final rule that amended the 36 CFR 219 regulations pertaining to National Forest System Land Management Planning (the planning rule) (81 Federal Register [FR] 90723, 90737). The amendment to the 219 planning rule clarified the Department's direction for amending LRMPs. The Department of Agriculture Under Secretary of Natural Resources and Environment also added a requirement for amending a plan for the responsible official to consider "which substantive requirements of §§ 219.8 through 219.11 are likely to be directly related to the amendment" (36 CFR 219.13(b)(2), 81 FR at 90738). Whether a rule provision is directly related to an amendment is determined by any one of the following: the purpose for the amendment, a beneficial effect of the amendment, a substantial adverse effect of the amendment, or a lessening of plan protections by the amendment.

Representatives of the Forest Service have worked cooperatively with the FERC staff and Pacific Connector during pipeline route selection over Forest Service lands and incorporation of BMPs to minimize environmental consequences. The Forest Service has determined that the linear nature of the Pacific Connector Pipeline Project would not be consistent with certain requirements of the LRMPs of the National Forests crossed. To address these inconsistencies, the Forest Service proposes to amend the LRMPs of the respective National Forests to make provision for the Project.

For the Forest Service, the primary purpose of this EIS is to consider and disclose the environmental consequences of construction and operation of the Pacific Connector pipeline on National Forest System (NFS) lands and to evaluate proposed LRMP amendments. The Forest Service will use this EIS to assess which, if any, substantive requirements of the planning rule are likely to be directly related to the amendment. The Forest Service is also using this EIS process to identify specific stipulations (including project design features and mitigation measures) related to resources within their jurisdiction for inclusion in the ROW Grant.

The Forest Service has identified suites of "Project Design Features" or "Project Requirements" that are deemed necessary to accomplish goals and objectives of the respective LRMPs. The project design features or requirements specific to the pipeline crossing Forest Service lands are included as attachments to Pacific Connector's POD. There are 28 attachments to the POD; each of these includes draft monitoring elements to ensure that the wide array of actions are implemented and assess the effectiveness of the actions relative to the goals and objectives of the respective LRMPs. Collectively, the POD is incorporated into the project's description. The

Forest Service would require a Compensatory Mitigation Plan (CMP) be developed for implementation on lands they manage and would require that this CMP be attached to the POD. This CMP would focus on off-site actions such as reallocation of land from the Matrix land allocation to the Late Successional Reserve (LSR) land allocation, placement of large woody debris (LWD), snag creation, stand density/fuels reduction, road resurfacing and decommissioning, culvert replacement, stream crossing repairs, invasive weed control, pre-commercial thinning, fire suppression facilities development, and meadow restoration.

Although these compensatory mitigation actions required by the Forest Service (which are summarized in section 2.1.5 of this EIS and described in appendix F of this EIS) are specific in terms of activity and location, this EIS addresses them in a programmatic fashion. Many of these mitigation actions may require additional analyses and surveys to comply with NEPA and ensure consistency with LRMPs. The Forest Service anticipates that this EIS would provide the basis for tiering subsequent site-specific NEPA analyses, in accordance with the CEQ regulations at 40 CFR 1508.28(b). The Forest Service would conduct any needed supplemental environmental analysis and consultation efforts with various federal, state, and local entities, as well as tribal governments, prior to authorizing future site-specific mitigation actions described in the CMP. Environmental compliance for these mitigation actions could be concurrent with authorized project actions.

The Forest Supervisor for the Umpqua National Forest is the authorized officer for decisions related to amendments of Forest Service LRMPs and issuance of a concurrence letter for a ROW grant to BLM, if warranted.

1.3.4 U.S. Department of the Interior Bureau of Reclamation

The Pacific Connector pipeline route would cross a portion of Reclamation's Klamath Basin Project area (see figure 1.1-1). As a cooperating agency, Reclamation anticipates adopting this EIS pursuant to 40 CFR 1506.3(c). Although Reclamation's Klamath Basin Area is not subject to an LMP, the agency has also worked closely with the FERC staff and Pacific Connector to address issues related to the siting, construction, and operation of the pipeline where it would cross Reclamation lands and facilities that are part of Reclamation's Klamath Irrigation Project. These procedures are outlined in the POD, including Pacific Connector's *Klamath Project Facilities Crossing Plan* (Attachment O of the POD) and its *Winter Construction Plan for the Klamath Basin* (Appendix E.1 attached to Resource Report 1 of Pacific Connector's application to the FERC).

Reclamation and Pacific Connector have not identified specific mitigation projects at this time; therefore, Reclamation may conduct additional environmental compliance activities to meet their responsibilities under NEPA and other federal laws and regulations prior to implementation of any mitigation requirements specific to Reclamation jurisdiction. The Responsible Official for Reclamation regarding issuance of a concurrence letter for a ROW grant to the BLM, if warranted, is the Area Manager of Reclamation's Mid-Pacific Region Klamath Basin Area Office.

1.3.5 U.S. Department of Energy

The DOE's Office of Fossil Energy (DOE/FE) may adopt this EIS to consider the environmental effects associated with its decision whether to authorize the export of LNG, as proposed by Jordan Cove, to countries with which the United States does not have a free trade agreement (FTA) requiring national treatment for trade in natural gas. The purpose and need for the DOE/FE action is to respond to the application filed by Jordan Cove with the DOE/FE to export LNG to non-FTA countries. The DOE/FE must meet its obligations under Section 3 of the NGA, to authorize the import and export of natural gas, including LNG, unless it finds that the proposed import or export would not be consistent with the public interest. The DOE/FE's authority to regulate the export of the natural gas commodity arises from Section 3 of the NGA. By law, under Section 3(c) of the NGA, applications to export natural gas to countries with which the United States has FTAs that require national treatment for trade in natural gas are deemed to be consistent with the public interest and the Secretary of the DOE must grant authorization without modification or delay. In the case of applications to export LNG to non-FTA nations, NGA Section 3(a) requires the DOE/FE to conduct a public interest review and to grant the applications unless the DOE/FE finds that the proposed exports will not be consistent with the public interest. Additionally, DOE/FE must consider the environmental effects of its decisions regarding applications to export natural gas to non-FTA nations.

On September 22, 2011, Jordan Cove filed an application with the DOE/FE seeking authorization to export up to 1.2 Bcf/d of natural gas converted to LNG from its proposed terminal at Coos Bay, Oregon to FTA nations. The DOE/FE issued its *Order Granting Long-Term Multi-Contract Authorization to Export Liquefied Natural Gas by Vessel from the Jordan Cove LNG Terminal to Free Trade Agreement Nations* on December 7, 2011, in DOE/FE Docket No. 11-127-LNG (DOE/FE Order No. 3041).

On March 23, 2012, Jordan Cove filed an application with the DOE/FE, in DOE/FE Docket No. 12-32-LNG, seeking authorization to export LNG to non-FTA nations. The DOE/FE issued its *Order Conditionally Granting Long-Term Multi-Contract Authorization to Export Liquefied Natural Gas by Vessel from the Jordan Cove LNG Terminal in Coos Bay, Oregon to Non-Free Trade Agreement Nations* (DOE/FE Order No. 3413) on March 24, 2014. This Order would allow Jordan Cove to export up to the equivalent of 438 Bcf/year of natural gas, in the form of LNG, for 30 years after either the first shipment or 10 years after the date of the Order. The LNG may be exported to any country with which the United States does not have an FTA, which currently has or in the future could develop the capacity to import LNG, and with whom trade is not prohibited by United States law or policy. The authorization was conditioned on the satisfactory completion of the environmental review process in FERC Docket Nos. CP13-483-000 and CP13-492-000, to comply with NEPA, and on issuance by DOE/FE of findings of no significant impact or a record of decision pursuant to NEPA. Jordan Cove would have to also comply with all preventive and mitigation measures required by federal and state agencies for the Project. Under that conditional authorization, Jordan Cove must also file with the DOE/FE copies of executed long-term contracts for both natural gas supply and the export of LNG.

Jordan Cove submitted an amendment to its FTA application and non-FTA application on February 6, 2018 to reflect the new export capacity of the LNG terminal under the current proposal. The DOE/FE authorized Jordan Cove's amended request for export to FTA countries on July 20, 2018, reflecting a new authorized export volume of approximately 395 Bcf/year over a 30-year term, beginning on the earlier of the date of first export or 10 years from the date of the amended authorization. The DOE/FE is currently reviewing this amendment in regard to exports to non-FTA countries. If export to non-FTA countries is approved, this authorization would be considered a new authorization that supersedes the previous conditional authorization.

Because the Project may involve actions in floodplains, in accordance with 10 CFR Part 1022, *Compliance with Floodplain and Wetland Environmental Review Requirements*, this EIS includes a floodplain assessment. A floodplain statement of findings would be included in any DOE/FE determinations. Section 4.3 of this EIS discusses elements of the Project that may be within floodplains, so that the FERC, as lead federal agency, can document compliance with Executive Order (EO) 11988.[15]

1.3.6 U.S. Army Corps of Engineers

The COE exerts regulatory authorities over waters of the United States pursuant to Sections 9, 10, and 14 (i.e., Section 408) of the Rivers and Harbors Act of 1899 (RHA), Sections 404 of the Clean Water Act (CWA), and Section 103 of the Marine Protection Research and Sanctuaries Act of 1972 (MPRSA). The laws and regulations underpinning the COE's actions are further discussed below in section 1.5 and table 1.5.1-1. The agency's purpose for participating in the development of the EIS is to streamline the COE's review of the applicant's Regulatory and Section 408 application evaluation processes by working with the FERC to eliminate duplication of efforts. The EIS can reduce duplications of efforts in COE permit and permission reviews for the Project by allowing the FERC to be the lead federal agency and fulfill obligations for compliance with a variety of federal environmental laws. The COE may adopt the EIS for the purposes of exercising its regulatory authorities.

Approval from the COE is required for alterations to, or to temporarily or permanently occupy or use, any COE federally authorized civil works project pursuant to Section 408 of the RHA. Proposed alterations must not be injurious to the public interest or affect the COE project's ability to meet its authorized purpose. The Project as currently proposed may affect multiple COE civil works projects including the Coos Bay Federal Navigation Channel or other designated navigation channels (e.g., the Coos River where a proposed HDD would occur), the federal pike structure west of the proposed slip (where a rock apron is currently proposed to minimize impacts to this structure), and a 40-acre multi-use COE real estate easement located partially within the proposed LNG terminal tank site. The COE is currently reviewing the current applicant proposal to determine if these Project-related effects to the civil works projects would constitute an injury to the public interest or affect the COE project's ability to meet its authorized purpose or impair its usefulness.

The COE is currently evaluating a permit application from Jordan Cove and Pacific Connector to conduct work and/or construct structures in navigable waters of the U.S. pursuant to Section 10 of the RHA and to discharge dredged and fill material into waters of the U.S. pursuant to Section 404 of the CWA. The COE's involvement in the EIS process may assist the COE in complying with NEPA, informing the COE's public interest determination, and informing the COE's evaluation of the applicant's proposal pursuant to the CWA 404(b)(1) Guidelines.

1.3.7 U.S. Environmental Protection Agency

The EPA has responsibilities under the Clean Air Act (CAA), CWA, and MPRSA (see section 1.5.1 of this EIS for more details). The EPA shares responsibility for administering and enforcing Section 404 of the CWA with the COE and has authority to veto COE permit decisions.

[15] EO 11988, *Floodplain Management*, requires federal agencies to avoid adverse impacts associated with the occupancy and modification of floodplains, and to avoid floodplain development wherever there is a practicable alternative. The objectives of the EO include the minimization of impacts from floods resulting from agency actions, and the preservation of floodplains where possible. While the FERC, as an independent commission, is not subject to EOs, the other federal permitting agencies must confirm compliance.

In addition, Section 309 of the CAA directs the EPA to review and comment in writing on the environmental effects associated with all major federal actions. This obligation is independent of its role as a cooperating agency under NEPA regulations. Consistent with this direction, the EPA evaluates all federally issued EISs for adequacy in meeting the procedural and public disclosure requirements of NEPA.

1.3.8 U.S. Fish and Wildlife Service and National Marine Fisheries Service Review

The FWS and NMFS are charged with the protection of federally-listed threatened and endangered species as described in the Endangered Species Act (ESA) of 1973, as amended. As requested, the FWS and NMFS will consult with the lead federal agency (i.e., the FERC) for actions that may affect ESA-listed species and/or critical habitats. The FWS and NMFS also have the authority under the Fish and Wildlife Coordination Act of 1934, as amended (FWCA) to review applications for CWA Section 404 and Section 401 permits. The FWS has authority under the Bald and Golden Eagle Protection Act of 1940, as amended (Eagle Act), to protect bald and golden eagles, and to issue permits for actions that would negatively affect eagles or their nests. The FWS also has authority under the Migratory Bird Treaty Act of 1918, as amended (MBTA) to conserve migratory birds; EO 13186 encourages federal agencies to consider conservation actions for birds in the course of their operations, documented in Memoranda of Understanding (MOU). The NMFS has the authority under the Magnuson-Stevens Fishery Conservation and Management Act of 1976, as amended (MSA) and MMPA to review a project's effects on essential fish habitats (EFH) and to protect marine mammals, respectively. The process for review and potential subsequent authorizations under each law are described further in section 1.5.1.

1.3.9 U.S. Department of Homeland Security Coast Guard

The Coast Guard serves as a subject matter expert for and providing recommendations on the maritime safety and security aspects of the Project. The Coast Guard does not issue a permit, license, order, or record of decision in this context, but is responsible for assessing the suitability of the waterway and issuing a Letter of Recommendation (LOR).

The Coast Guard exercises regulatory authority over LNG facilities that affect the safety and security of port areas and navigable waterways under EO 10173; the Magnuson Act; the Ports and Waterways Safety Act of 1972, as amended; and the Maritime Transportation Security Act of 2002. The Coast Guard is responsible for matters related to navigation safety, vessel engineering and safety standards, and all matters pertaining to the safety of the facilities or equipment located in or adjacent to navigable waters up to the last valve immediately before the LNG storage tanks. The Coast Guard also has authority for LNG facility security plan review, approval, and compliance verification, and siting as it pertains to the management of vessel traffic in and around the LNG facility. As required by its regulations, the Coast Guard is responsible for issuing an LOR as to the suitability of the waterway for LNG marine traffic.

On June 14, 2005, the Coast Guard issued a Navigation and Vessel Inspection Circular (NVIC), *Guidance on Assessing the Suitability of a Waterway for Liquefied Natural Gas (LNG) Marine Traffic* (NVIC 05-05). The purpose of the NVIC 05-05 is to provide Coast Guard Captains of the Port (COTPs)/Federal Maritime Security Coordinators, members of the LNG industry, and port stakeholders with guidance on assessing the suitability of a waterway for LNG marine traffic that takes into account conventional navigation safety/waterway management issues contemplated by the existing Letter of Intent (LOI)/LOR process. In addition, maritime security implications were also considered. In accordance with this guidance, each LNG project applicant is to submit a Waterway Suitability Assessment (WSA) to the cognizant COTP. On December 22, 2008, the Coast Guard published a second NVIC, *Guidance Related to Waterfront Liquefied Natural Gas (LNG) Facilities* (NVIC 05-08; Coast Guard 2008). The purpose of NVIC 05-08 was to revise the format of the LOR to conform to its intended effect of being a recommendation of the waterway suitability to the FERC. NVIC 05-08 is further discussed in section 4.13. On January 24, 2011, the Coast Guard published a third NVIC: *Guidance Related to Waterfront Liquefied Natural Gas (LNG) Facilities* (NVIC 01-2011). The purpose of NVIC 01-2011 was to revise the format of the LOR to conform to its intended effect of being a recommendation to the FERC as to the suitability of the waterway. In this NVIC, the Coast Guard has added guidance on release of the LOR and message management and provided an updated template for the LOR analysis.

The WSR for the Jordan Cove LNG Project was issued pursuant to NVIC 05-05. The final review and LOR were issued pursuant to NVIC 05-08, which replaced NVIC 05-05. NVIC 05-08 eliminated the term WSR and replaced it with "Letter of Recommendation (LOR) Analysis." For the purpose of clarity, the WSR is equivalent to the LOR Analysis. Section 813 of the Coast Guard Authorization Act of 2010 requires the Coast Guard to consider recommendations made by the States prior to making a recommendation to the FERC on the suitability of the waterway for marine traffic associated with an LNG facility. Although this law was effective after the WSR and LOR were issued, the Oregon Department of Energy (ODE) (as lead State agency) was an active participant in the WSA validation committee and concurred with the verbiage of the WSR and LOR.

On January 13, 2014, Jordan Cove forwarded its most recent annual review of the WSA to the Coast Guard, who responded on February 14, 2014, with the following statement: "we have no objection to your conclusion that the minor changes do not change the risk associated with the waterway or the facility as originally evaluated in your 2007 WSA." On February 27, 2014, the Coast Guard accepted the annual review of the WSA for the Jordan Cove LNG Project. On January 23, 2017, the Coast Guard accepted the Project's existing WSA as it relates to the new proposed project and stated that a new "Follow-On" WSA is not required.[16] On May 10, 2018, a revised LOR was issued, in which the Coast Guard stated that "the Coos Bay Channel be considered suitable for accommodating the type and frequency of LNG marine traffic associated with this project."

1.3.10 U.S. Department of Transportation

The USDOT has prescribed the minimum federal safety standards for LNG facilities in compliance with 49 U.S.C. 60101. Those standards are codified in 49 CFR 193 and apply to the siting, design, construction, operation, maintenance, and security of LNG facilities. The National Fire Protection Association (NFPA) Standard 59A, Standard for the Production, Storage, and Handling of Liquefied Natural Gas (2001 ed.), is incorporated into these requirements by reference, with regulatory preemption in the event of conflict. In accordance with the 2004 Interagency Agreement, the USDOT participates as a cooperating agency on the safety and security review of waterfront import/export LNG facilities. The USDOT does not issue a permit or license but, as a cooperating agency, assists FERC staff in evaluating whether an applicant's proposed siting criteria meets the USDOT requirements in Part 193, Subpart B. On August 31, 2018, the USDOT

[16] The WSA is considered Sensitive Security Information and is therefore not publicly releasable. Public documents related to the Coast Guard's determination can be found in appendix B of this EIS.

and FERC signed a new MOU to improve coordination throughout the LNG permit application process for FERC jurisdictional LNG facilities. Under the 2018 MOU, the USDOT will issue a Letter of Determination (LOD), determining whether a proposed LNG facility will be capable of complying with Part 193, Subpart B, Siting (see section 4.13 of this EIS). The LOD is provided to the Commission for consideration in its decision on the Project application. The USDOT also has the authority to enforce safety regulations and standards related to the design, construction and operation of natural gas pipelines, under the Natural Gas Pipeline Safety Act. The USDOT would also monitor the construction and operation of the natural gas facilities to determine compliance with its design and safety standards.

1.3.11 Federal Aviation Administration (FAA)

The FAA is a federal agency under the USDOT, which has the authority to regulate all aspects of civil aviation. The FAA is responsible for enforcing the elements of 14 CFR 77 (i.e., Objects Affecting Navigable Airspace), which would include an assessment of whether the proposed project could represent a hazard to aircraft at the Southwest Oregon Regional Airport.

1.4 PUBLIC REVIEW AND COMMENTS

On January 23, 2017 Jordan Cove and Pacific Connector filed a request to implement the Commission's Pre-filing Process for the Jordan Cove liquefaction and LNG export proposal, and the associated Pacific Connector supply pipeline. The FERC established the Pre-filing Process to encourage early involvement of interested stakeholders, facilitate interagency cooperation, and identify and resolve environmental issues before an application is filed with the FERC and facility locations are formally proposed. The FERC granted this request to use the Pre-filing Process on February 10, 2017 and established pre-filing Docket Nos. PF17-4-000 for the Projects.

Prior to and during the Pre-filing Process, Jordan Cove and Pacific Connector (Applicants) contacted federal, state, and local agencies to inform them about their respective projects and discuss project-specific issues and concerns. The applicants initiated contact with potentially affected landowners prior to entering the FERC Pre-filing Process. These initial contacts were in the form of a letter describing each applicant's project and seeking permission to conduct environmental and cultural resource surveys on landowner property. Jordan Cove held an Open House meeting in North Bend on March 21, 2017. Pacific Connector held additional Open House meetings in Canyonville, Medford, and Klamath Falls during the week of March 22, 2017. These Open House meetings were advertised to the public through notices published in local newspapers. The FERC staff attended these Open House meetings and were available to answer questions from the public regarding the FERC and NEPA process.

On June 9, 2017, the FERC issued a *Notice of Intent to Prepare an Environmental Impact Statement for the Planned Jordan Cove LNG Terminal and Pacific Connector Pipeline Projects, Request for Comments on Environmental Issues, and Notice of Public Scoping Sessions* (Notice of Intent, or NOI). The NOI was sent to affected landowners; federal, state, and local government agencies; elected officials; environmental and public interest groups; interested Indian tribes; and local libraries and newspapers. The NOI described the Project; listed currently identified environmental issues; outlined the proposed actions of the DOE, BLM, and Forest Service; discussed the scoping and environmental review process; announced the date, location, and time of four public scoping meetings; and explained how the public could participate and comment.

During the week of June 27, 2017, the FERC, BLM, and Forest Service held joint public scoping sessions in Coos Bay, Roseburg, and Klamath Falls to receive comments about the Project, which were recorded by a court reporter.[17]

Throughout the Pre-filing Review Process, we received comments on a wide variety of environmental issues. Between February 10, 2017 (when pre-filing was initiated) and July 10, 2017 (i.e., the end of the announced scoping period), we received more than 5,100 comments. These comments were provided via 1,174 discrete comment letters/documents; this included 1,028 letters from individuals, 55 letters from non-governmental organizations, 1 letter from a federal agency, 16 letters from state and local agencies, 64 letters from private companies, 2 letters from members of the U.S. Congress, and 8 letters from federally recognized Tribes. We also received 462 form letters during this time. In addition, between July 10, 2017, and issuance of this EIS, the FERC received more than 3,700 additional comments contained within over 700 discrete documents, and an additional 14 form letters. All comments received prior to the writing of this EIS were considered. The analysis in this EIS addresses all relevant environmental topics raised during scoping.

Table 1.4-1 categorizes the relevant environmental issues raised in letters to the FERC and considered in this EIS. The table does not account for the out-of-scope issues (as discussed below) and general environmental concerns or non-specific comments. The most frequently expressed comments concerned property rights, land use, purpose and need, safety and security; potential geological/topographical hazards, and the FERC's approach to the NEPA process (e.g., length of scoping periods, number of public meetings, etc.).

TABLE 1.4-1

Environmental Issues Identified During the Pre-filing Public Scoping Process for the Jordan Cove and Pacific Connector Projects

Specific Issue/Comment	EIS Section Where Comments are Addressed
Purpose and Need, and FERC Process/NEPA Process/State Process .	1.0
Comments about scoping period and meeting locations.	
Project Description	**2.0**
Life of Project, decommissioning	
Concerns over temporary work areas (TEWAs), uncleared storage areas	
BLM, Forest Service, and FERC process	
Alternatives	**3.0**
Comments urging that investments be redirected towards renewable, domestic energy sources such as wind, solar and wave power.	
Request rigorous analysis of pipeline route alternatives (evaluate more than action/no-action)	
Geologic Hazards	**4.1**
Regional seismic activity (earthquake and/or tsunami) on the export terminal or pipeline.	
Soils and Minerals	**4.2**
Concerns over erosion of sensitive soils.	
Sedimentation of streams as a result of soil disruption	
Soil and slope stability along the pipeline route.	

[17] Transcripts of all of the public scoping meetings for this Project were placed into the FERC public record for the proceedings.

TABLE 1.4-1 (continued)

Environmental Issues Identified During the Pre-filing Public Scoping Process for the Jordan Cove and Pacific Connector Projects

Specific Issue/Comment	EIS Section Where Comments are Addressed
Water Resources	**4.3**
Effects of construction and operation of the project elements, including export terminal facilities and pipeline crossings, on surface water and groundwater, including drinking water and salmon spawning habitat, and especially that of the Rogue River.	
Concerns over horizontal directional drilling under streams and rivers along the pipeline route.	
Concerns over hydrostatic testing of the pipeline.	
Wetlands and Riparian Areas	**4.3**
Effects on sensitive wetlands in the vicinity of the export terminal and pipeline.	
Biological Resources	**4.4, 4.5, and 4.6**
Effects on threatened and endangered species.	
Effects on fisheries and EFH.	
Effects on wildlife habitat, including connectivity.	
Effects on pipeline construction on forestlands, including sensitive forest types.	
Introduction and propagation of noxious weeds in the pipeline ROW.	
Land Use and Recreation	**4.7 and 4.8**
Location of access roads, hydrostatic test locations, uncleared storage areas, cleared areas.	
Effects on recreational opportunities, recreation-based tourism.	
Comments supporting and opposing the use of federal lands for the pipeline corridor.	
Comments making specific pipeline alignment adjustments (generally to avoid private properties, also to avoid resources.	
Concerns over BLM and Forest Service LMP revisions.	
BLM and Forest Service Plan Revisions, and associated mitigation/restoration requirements	
Visual Resources	**4.8**
Concerns over specific views, typically from private properties.	
Socioeconomics	**4.9**
Opposition to use of eminent domain to acquire pipeline easements, especially when some land uses would not be allowed or practicable once the pipeline is installed.	
Comments supporting and opposing the creation of local jobs; reconcile with environmental effects and safety risks involved.	
Effects on the local economy, including anticipated drop in tourism (fishing, birding).	
Concerns over application of eminent domain.	
Concerns over decreased property values.	
Transportation	**4.10**
Effects and risks of proximity to the Southwest Oregon Regional Airport.	
Cultural Resources	**4.11**
Effects on tribal lands and lands traditionally used by tribal members, especially fishing.	
Request outreach to the tribes.	
Air Quality and Noise	**4.12**
Effects on climate change.	
Concerns over operations emissions of the LNG carriers and terminal on local communities (respiratory health).	
Safety and Security/Public Health/Monitoring and Accountability/Siting	**4.13**
Risk of catastrophic events, either accidental, intentional (terrorism) or as a result of a natural disaster on the export terminal, LNG carriers or the pipeline.	

TABLE 1.4-1 (continued) **Environmental Issues Identified During the Pre-filing Public Scoping Process for the Jordan Cove and Pacific Connector Projects**	
Specific Issue/Comment	**EIS Section Where Comments are Addressed**
Availability and readiness of emergency response personnel in the event of a catastrophic incident, especially in remote areas.	
Concerns over the health effects of spilled or leaked gas on nearby communities.	
Emergency response planning (tsunami, earthquake).	
Concerns over pipeline weakness, potential for leak or explosion leading to wildfire.	
Concerns over rural pipeline safety, including non-odorized gas and construction standards.	
Monitoring and mitigation; accountability and responsibility.	
Cumulative Impacts	**4.14**
Effects of increased marine traffic.	
Effects from other energy projects.	

The BLM and Forest Service also reviewed the results of scoping to identify any concerns specific to their proposed plan amendments and mitigation actions. Comments were received that addressed concerns about the Forest Service planning regulations that govern amending LRMPs as well as the need for further detail on proposed BLM plan amendments. Comments were also received that identified concerns regarding the proposed mitigation actions of the BLM and Forest Service and the need for additional alternatives that would avoid impacts to areas such as LSRs and riparian areas. These issues are addressed in more detail in a scoping report prepared by the BLM and Forest Service in appendix F.8 (Federal Lands Review) of this EIS.

Numerous citizens and organizations raised issues that are outside the scope of this EIS. Examples of out-of-scope issues include comments regarding the public benefit or need to export LNG; horizontal hydraulic drilling through shale formations during exploration for natural gas (often referred to as "fracking"); induced production of natural gas; "life-cycle" cumulative environmental impacts associated with the entire LNG export process; downstream greenhouse gas emissions resulting from the combustion of exported gas; the concept of a "programmatic" EIS to cover LNG export terminals throughout the United States; and administrative information technology system operations at the FERC. These issues are not addressed in this EIS.

1.5 PERMITS, APPROVALS, AND CONSULTATIONS

1.5.1 Federal Environmental Laws, Regulations, Permits, Approvals, and Consultations

In addition to the NGA, EPAct, and NEPA, the FERC and cooperating agencies are required to comply with other federal laws and regulations that involve consideration of the Project's potential effect on a range of environmental resources (see table 1.5.1-1). This includes, but is not limited to, compliance with the CAA, CWA, Coastal Zone Management Act (CZMA), ESA, MSA, MMPA, MBTA, and the National Historic Preservation Act (NHPA).

As the lead federal agency for the Project, the FERC has taken on the lead role for consultation under these statutes for itself and in collaboration with the cooperating agencies. The BLM will make its determinations in accordance with the FLPMA, NFMA, and Mineral Leasing Act (MLA), as it relates to the Pacific Connector's ROW Grant application to cross federal lands, with concurrence necessary from the Forest Service and Reclamation (see section 1.3). Some federal permits or approvals, such as Section 401 of the CWA, the CAA, and the CZMA, have been delegated to state agencies, as discussed below.

In accordance with Section 313(d) of the EPAct, the FERC is required to keep a complete consolidated record of all actions or decisions made by agencies undertaking federal authorizations. On October 19, 2006, in Order No. 687, the FERC issued implementing regulations regarding the maintenance of a consolidated record.

Table 1.5.1-1 lists the major federal, state, and local permits, approvals, and consultations identified for the Project.

TABLE 1.5.1-1

Major Permits, Approvals, and Consultations for the Jordan Cove & Pacific Connector Project

Agency	Authority/Regulation/ Permit	Agency Action	Initiation of Consultations and Permit Status
FEDERAL			
FERC	Sections 3 and 7 of the NGA Section 311 of the EPAct	Order Granting Section 3 Authorization and Issuing Certificate of Public Convenience and Necessity.	Jordan Cove and Pacific Connector filed applications with the FERC on September 21, 2017. In September 2017, Pacific Connector filed an application with the FERC under Section 7 of the NGA. The FERC's decision is pending.
Forest Service	MLA	Concur with ROW Grant.	Pending. The Forest Service letter on concurrence of the ROW grant is pending until after issuance of the FEIS and preparation of a Record of Decision (ROD).
	36 CFR 219 Subpart B 36 CFR 218 Subpart A and B	Amend Land and Resource Management Plans (LRMP).	Pending. The Forest Service proposed decision(s) on plan level amendments of LRMPs are subject to Administrative Review Regulations at 36 CFR 219 Subpart B. Decisions by the Forest Service to approve project-specific plan amendments are subject to the Administrative Review Process of 36 CFR 218 Subpart A and B. A final decision will follow consideration and resolution of any administrative reviews.
BLM	Section 28 of MLA	Issue ROW Grant for crossing federal lands.	Pending. The BLM decision on the ROW grant will follow BLM and Forest Service decisions on LRMP amendments and receipt of Letters of Concurrence from the Forest Service and Reclamation.

TABLE 1.5.1-1 (continued)

Major Permits, Approvals, and Consultations for the Jordan Cove & Pacific Connector Project

Agency	**Authority/Regulation/ Permit**	**Agency Action**	**Initiation of Consultations and Permit Status**
	Federal Land Policy and Management Act of 1976, as amended	Resource Management Plan (RMP) Amendments.	Pending. BLM's proposed decision(s) on amendments of RMPs are subject to Protest following completion of the FEIS. A final decision will follow consideration and resolution of any Protests.
Bureau of Reclamation	MLA	Concur with issuance of the ROW Grant	Pending.
DOE	Section 3 of the NGA	Long-Term authority to export LNG to Free Trade Agreement (FTA) Nations	FTA authorization granted December 7, 2011 (DOE/FE Order No. 3041). DOE authorized amendment to FTA authorization on July 20, 2018 (DOE/FE Order No. 3041-A).
	Section 3 of the NGA	Long-Term conditional authority to export LNG to Non-FTA Nations.	Conditional non-FTA authorization issued on March 24, 2014; subject to satisfactory completion of NEPA review and related conditions. DOE is currently reviewing the amendment request with respect to the non-FTA application.
COE	Section 10 and 408 of the RHA	Process permit applications for structures or work in or affecting navigable waters of the United States. Approval of requests to alter COE civil works projects.	Pending. The applicants requested COE initiate the project's review per the RHA and have submitted both regulatory and Section 408 applications to the COE. The applicants are continuing to work with the COE to provide supplemental information regarding the RHA review.
	Section 404 of the CWA	Process permit application for the discharge of dredged or fill material into waters of the United States.	Pending. The applicants requested the COE initiate the Project's review per the CWA and have submitted a regulatory application to the COE. The applicants are continuing to work with the COE to provide supplemental information regarding the CWA review
EPA	Section 404 of the CWA	Co-administers CWA 404 program with the COE. EPA retains veto authority for wetland permits issued by the COE.	Pending.
	Section 309 of the CAA	Reviews and evaluates EIS for adequacy in meeting the procedural and public disclosure requirements of NEPA.	Pending.
FWS	Section 7 of the ESA		Pending. The FERC is preparing a biological assessment (BA) that will be submitted to the FWS and NMFS.
	FWCA	Provide comments to prevent loss of and damage to wildlife resources.	Pending. FWS generally addresses FWCA issues via comments on the FERC NEPA and COE 404 permit processes.

TABLE 1.5.1-1 (continued)

Major Permits, Approvals, and Consultations for the Jordan Cove & Pacific Connector Project

Agency	Authority/Regulation/ Permit	Agency Action	Initiation of Consultations and Permit Status
	MBTA Executive Order 13186	Consultation regarding compliance with the MBTA.	Pending. The applicants are currently consulting with the FWS regarding the projects requirements under the MBTA.
	Eagle Act	Coordination regarding compliance with the Eagle Act	Pending. The applicants will consult with the FWS regarding the project's requirements under the Eagle Act. Jordan Cove and Pacific Connector would apply for an Eagle Act permit if needed.
NMFS	Section 7 of the ESA	Provide a BO if the Project is likely to adversely affect federally listed threatened or endangered aquatic species or their habitat.	Pending. The FERC is preparing a BA that will be submitted to the FWS and NMFS.
	MMPA	Authorize, upon request, take of marine mammals incidental to otherwise lawful activities, subject to mitigation monitoring and reporting requirements.	Pending. The applicants have indicated that a MMPA Incidental Take Authorization (ITA) request will be filed with the NMFS.
	MSA	Provide conservation recommendations if the Project would adversely impact EFH.	Pending. EFH will be addressed in the FERC BA.
Coast Guard	Ports and Waterway Safety Act	Captain of the Port (COTP) issues a Letter of Recommendation (LOR) recommending the suitability of the waterway for LNG marine traffic.	Jordan Cove submitted LOI on January 9, 2017. Coast Guard issued LOR on May 10, 2018.
		Review Emergency Manual.	Pending. Must be completed prior to receiving first LNG carrier.
		Review Operations Manual.	Pending. Must be completed prior to receiving first LNG carrier.
		Establish safety and security zones for LNG vessels in transit and while docked.	Pending.
	Maritime Transportation Security Act	Review and Approve Facility Security Plan.	Pending. Must be completed 60 days prior to receiving first LNG carrier at the facility
	Navigation and Vessel Inspection Circular – Guidance related to Waterfront LNG Facilities	Develop LNG Vessel Transit Management Plan.	Pending. Must be completed prior to receiving first LNG carrier.
		Validate WSA and produce LOR and LOR Analysis.	Issued LOR and LOR Analysis on May 10, 2018.
USDOT; PHMSA	Natural Gas Pipeline Safety Act	Administer national regulatory program to ensure the safe transportation of natural gas and issue LOD on the project's compliance with the siting requirements of 49 CFR 193.	Pending. Applicants met with PHMSA in November 2017 to review their technical design package. In June 2018, PHSMA determined that the Project's design spill determination methodology meets the requirements of 49 CFR 193. LOD is pending. Anticipated prior to FEIS.

TABLE 1.5.1-1 (continued)

Major Permits, Approvals, and Consultations for the Jordan Cove & Pacific Connector Project

Agency	Authority/Regulation/ Permit	Agency Action	Initiation of Consultations and Permit Status
U.S. Department of Defense (DOD)	Section 311(f) of the EPAct and Section 3 of the NGA Memorandum of Understanding (MOU) between the FERC and DOD	Consult with the Secretary of Defense to determine whether an LNG facility would affect the training or activities of an active military installation.	In November 2012, the DOD indicated that the previously proposed project would have minimal impacts on military operations in the area. In December 2017, the DOD indicated that because it had previously reviewed the last proposal, it has “no issues” concerning the current Project.
DOE, Bonneville Power Administration (BPA)	Land Use Agreement for electric transmission line crossings	Permit review.	Pending.
USDOT, FAA	18 CFR Subchapter E Federal Aviation Regulations (FAR) Part 77 IAW FAA Order 7400.2G, 6-1-6	Aeronautical Study of Objects Affecting Navigable Airspace. Feasibility Study for Hazard Determination.	Pending. The FAA has issues a Notice of Presumed Hazard. Jordan Cove is currently consulting with the FAA regarding the potential for aeronautical operations to be impacted by the LNG terminal.
ACHP	Section 106 of the NHPA	Opportunity to comment on the undertaking.	Pending.
Federal Communication Commission	License for fixed microwave stations and service	Review proposals for new or additions to existing communication towers.	Pending.
U.S. Department of Agriculture (USDA), Natural Resources Conservation Service (NRCS)	Farmland Protection Policy Act	Determine if the Project would result in the permanent conversion of prime farmland.	Pending.
U.S. Department of the Treasury, Bureau of Alcohol, Tobacco, and Firearms	Explosives User Permit	Issue permit to purchase, store, and use explosives during project construction.	Pending. Permits to be obtained by Jordan Cove and Pacific Connector, as necessary, before construction.
STATE – OREGON			
Oregon Department of Geology and Mineral Industries (DOGAMI)	Building Code Section 1802.1 Oregon Revised Statute (ORS) 455.446	Review of structural designs in tsunami zones. Review of geotechnical investigations for geological hazards.	Pending.
Oregon Department of Agriculture (ODA)	Oregon Endangered Species Act Oregon Senate Bill 533 and ORS 564	Consult on Oregon listed plant species, and ODA would review botanical survey reports covering non-federal public lands prior to ground-disturbing activities where state listed botanical species are likely to occur.	Pending.
Oregon Department of Consumer and Business Services – Building Code Division	ORS 455.446	Site-specific exemption approval under the state building code,	Pending.

TABLE 1.5.1-1 (continued)

Major Permits, Approvals, and Consultations for the Jordan Cove & Pacific Connector Project

Agency	**Authority/Regulation/ Permit**	**Agency Action**	**Initiation of Consultations and Permit Status**
ODE	State Authorities under Section 311 of the EPAct	Furnish an advisory report on state safety and security issues to the FERC regarding the Jordan Cove LNG terminal proposal and conduct operational safety inspections if the facility is approved and built.	Pending.
Oregon Department of Environmental Quality (ODEQ)	Water Quality Certification Section 401 of the CWA	Issue a license or permit to achieve compliance with state water quality standards.	Applicants submitted their CWA Section 401 application package to the ODEQ on April 6, 2018. On September 25, 2018, the applicants requested that the 401 application be withdrawn and resubmitted to allow ODEQ additional time to consider the request. Processing of the permit is pending.
	Section 402 of CWA	Issue National Pollutant Discharge Elimination System (NPDES) permits for discharge of stormwater.	NPDES permit for storm water issued in July 2015 and expires in June 2020
	Ballast Water Management	Review liabilities and offences connected to shipping and navigation.	Pending.
	CAA – Title V	Issue Title V Air Quality Operating permit. Issue Title V Acid Rain permit. Enforce Greenhouse Gas (GHG) Reporting Requirements.	Permit application to be filed by Pacific Connector one year after beginning operations of the Klamath Compressor Station.
	Prevention of Significant Deterioration CAA	Review Best Available Control Technologies to minimize discharges from new major sources, and review air quality analyses to ensure compliance with National Ambient Air Quality Standards.	Pending.
	Hazardous Waste Activity ORS 466 Oregon Administrative Rule (OAR) 340-102	Review plans for storage and management of hazardous waste	Pending.
Oregon Department of Fish and Wildlife (ODFW)	Fish and Wildlife Coordination Act and the Oregon Endangered Species Act under ORS 496, 506, and 509 OAR 635	Consult on sensitive species and habitats that may be affected by the Project and, in general, regarding conservation of fish and wildlife resources.	Pending.
	Fish and Wildlife OAR 345-22 & 60	Consult on and approve fish and wildlife mitigation plan.	Pending.
	Oregon Fish Passage Law ORS 509.-585 OAR 635-412-5 to 40	Review stream crossing plans for consistency with Oregon Fish Passage Law and screening criteria.	Pending.
	In-Water Blasting ORS 509-140, et al. OAR 635-425 to 50	Consider issuance of in-water blasting permits.	Pending.

TABLE 1.5.1-1 (continued)

Major Permits, Approvals, and Consultations for the Jordan Cove & Pacific Connector Project

Agency	Authority/Regulation/ Permit	Agency Action	Initiation of Consultations and Permit Status
Oregon Department of Forestry (ODF)	Easement on State lands Oregon Forest Practices Act OAR 629 ORS 477 ORS 527	Management of State Forest lands for Greatest Permanent Value, develops Forest Management Plans, stewardship under State's Land Management Classification System, monitors harvests of timber on private lands, and protects non-federal public and private lands from wildfires.	Pending.
Oregon Department of Land Conservation and Development (ODLCD)	CZMA 15 CFR Part 930 ORS 196.435	Determine consistency with CZMA program policies.	Pending.
Oregon Department of Transportation (ODOT)	Section 303(c) DOT Act 49 CFR 303 OAR 734-030(4) OAR 734-051-4020	Review and approve traffic management plans	Pending. A draft traffic impact analysis was provided to ODOT, Coos County, and City of North Bend on December 4, 2017 by the applicants. ODOT and North Bend provided comments on December 21, 2017. The applicants continue to work with ODOT.
	State Highway ROW ORS 374-305 OAR 734- 55	Permits to be issued from each ODOT District Office to allow construction within State Highway ROW and use of State Highways for Project access, and where utilities would cross over, under, or run parallel to ODOT ROWs.	Pending. Applications for ODOT Approach and Utility Permits to be submitted with enough advance notice (which could be up to 12 months or more depending on individual District requirements) prior to construction activities to ensure adequate time to review the specific proposals.
Oregon Department of State Lands (ODSL)	Submerged and Submersible Land Easement OAR 141-122	Grant submerged land easements.	Pending.
	Lease and Registrations OAR 141-082	Issue wharf registrations	Pending.
	Sand and Gravel Lease/License OAR 141-014	Issue licenses or leases for removal of state-owned materials.	Pending.
	Joint Removal-Fill Law ORS 196-795-990 OAR 141-85	Approve removal or fill of material in waters of the state.	Pending.
	Special Use Permits OSAR 141-125	Allow work within state-owned lands	Pending.
	Compensatory Wetland Mitigation Rules OAR 141-85-121	Review and approve wetland mitigation plans.	Pending.
Oregon Water Resources Department (OWRD)	New Water Rights ORS 537 OAR 690-310	Issue permits to appropriate surface water and groundwater.	Pending.
	Temporary Water Use ORS 537 OAR 690-340	Issue limited licenses for temporary use of surface waters.	Pending.

TABLE 1.5.1-1 (continued)

Major Permits, Approvals, and Consultations for the Jordan Cove & Pacific Connector Project

Agency	Authority/Regulation/ Permit	Agency Action	Initiation of Consultations and Permit Status
Oregon Public Utilities Commission (OPUC)	OAR 860-031	Authorize intrastate electric transmission lines. Inspect the natural gas facilities for safety.	Pending Pacific Connector's submittal of appropriate applications to OPUC.
State Historic Preservation Office (SHPO)	Section 106 of the NHPA 36 CFR 800 ORS 338-920	Review cultural resources reports and comments on recommendations for National Register of Historic Places eligibility and project effects. Issue permits for excavation of archaeological sites on non-federal lands.	Pending. SHPO wrote letters to the FERC on June 21, 2017, January 18 and September 24, 2018, commenting on reports submitted by the applicants.
LOCAL – COUNTIES and CITIES			
Various County Permits	Coos County Zoning and Land Development Ordinance, Coos County Comprehensive Plan, and Coos Bay Estuary Management Plan (CBEMP) Douglas County Comprehensive Plan and Douglas County Land Use and Development Ordinance Jackson County Comprehensive Plan and Jackson County Land Development Ordinance Jackson County Comprehensive Plan and Jackson County Land Development Ordinance Klamath County Land Development Code Various Road Crossing; Grading; and Solid Waste Disposal North Bend Comprehensive Plan North Bend City Code	Issue Conditional Use Permits. Zoning Changes and Verifications. Issue Land Use Compatibility Statement under Statewide Planning Goals.	Pending.

1.5.1.1 Endangered Species Act

Section 7 of the ESA, as amended, states that "Federal agencies shall, in consultation with and with the assistance of the Secretary, utilize their authorities in furtherance of the purposes of this Act by carrying out programs for the conservation of endangered species and threatened species listed pursuant to Section 4 of this Act," and any project authorized, funded, or conducted by a federal agency should not "jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species which is determined...to be critical". The lead federal agency, or the applicant as a non-federal party, is required to consult with the FWS and the NMFS to determine whether any federally listed or proposed endangered or threatened species or their designated critical habitat occur in the vicinity of the Project. If, upon review of existing data, or data provided by the applicant, one (or both) of the Services find that any federally listed species or critical habitats may be affected by the Project, the FERC is required to prepare a biological assessment (BA) to identify the nature and extent of adverse effects, and to recommend measures that would avoid, reduce, or mitigate effects on habitats and/or species. The FERC's request for consultation with the BA begins the consultation process. The consultation process concludes with the issuance of a biological opinion(s) as to whether or not the proposed action may result in jeopardy to the species or adverse modification to critical habitat. If the determination is no jeopardy/adverse modification, an incidental take statement is included when needed. An incidental take statement would contain reasonable and prudent measures necessary or appropriate to minimize the proposed action's impact and terms and conditions that must be complied with by the federal agency(s) and applicants. See section 4.6 of this EIS, as well as the pending BA, for further information regarding the Project's effects on federally listed species and protected habitats.

1.5.1.2 Magnuson-Stevens Fishery Conservation and Management Act

The MSA, as amended by the Sustainable Fisheries Act of 1996, established procedures designed to identify, conserve, and enhance EFH for those species regulated under a federal fisheries management plan. The MSA requires federal agencies to consult with the NMFS on all actions or proposed actions authorized, funded, or undertaken by the agency that may adversely affect EFH. Although absolute criteria have not been established for conducting EFH consultations, the NMFS recommends consolidated EFH consultations with interagency coordination procedures required by other statutes, such as NEPA, the Fish and Wildlife Coordination Act, or the ESA to reduce duplication and improve efficiency.

See sections 4.5 and 4.6 of this EIS for further information regarding the Project's effects on EFH.

1.5.1.3 Marine Mammal Protection Act

All marine mammals are protected under the MMPA. This act was amended by the U.S. Congress in 1994. Sections 101(a)(5)(A) and (D) of the MMPA (16 U.S.C. 1361 et seq.) direct the Secretary of Commerce (as delegated to the NMFS) to allow, upon request, the incidental, but not intentional, taking of small numbers of marine mammals by U.S. citizens who engage in a specified activity (other than commercial fishing) within a specified geographical region if certain findings are made and either regulations are issued or, if the taking is limited to harassment, a notice of a proposed authorization is provided to the public for review (note that the FWS has jurisdiction over some species of marine mammals, but none within Oregon).

An authorization for incidental takings shall be granted if the NMFS finds that the taking will have a negligible impact on the species or stock(s), will not have an unmitigable adverse impact on the availability of the species or stock(s) for subsistence uses (where relevant), and if the permissible methods of taking and requirements pertaining to the mitigation, monitoring and reporting of such takings are set forth. The NMFS has defined "negligible impact" in 50 CFR 216.103 as an impact resulting from the specified activity that cannot be reasonably expected to, and is not reasonably likely to, adversely affect the species or stock through effects on annual rates of recruitment or survival.

The MMPA states that the term "take" means to harass, hunt, capture, or kill, or attempt to harass, hunt, capture, or kill any marine mammal. Except with respect to certain activities not pertinent here, the MMPA defines "harassment" as: any act of pursuit, torment, or annoyance which has the potential to injure a marine mammal or marine mammal stock in the wild (Level A harassment); or has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering (Level B harassment).

The NMFS may use relevant portions of this EIS during its review and may adopt measures to protect marine mammals outlined in this EIS. It may also require additional mitigation, monitoring, and reporting measures to ensure that the taking results in the least practicable adverse impact on affected marine mammal species or stocks. The public would have an opportunity to comment to the NMFS in response to its publication of a notice of proposed Incidental Take Authorization (ITA), or in response to its publication of a notice of proposed rule.

See sections 4.5 and 4.6 of this EIS for further information regarding the Project's effects on marine mammals.

1.5.1.4 National Historic Preservation Act

Section 101(d)(6) of the NHPA states that properties of traditional religious and cultural importance to Indian tribes[18] may be determined eligible for the National Register of Historic Places (NRHP). In carrying out our responsibilities under Section 106 of the NHPA, the FERC consulted on a government-to-government basis with Indian tribes that may attach religious and cultural importance to properties in the area of potential effect (APE), in accordance with the implementing regulations at 36 CFR 800.2(c)(2)(ii). Those consultations with tribes are detailed in section 4.11.1.2 of this EIS. The BLM and Forest Service are proposing to amend their respective LMPs to make provision for the pipeline, Reclamation must concur with the BLM ROW Grant to allow the pipeline to cross lands and facilities related to the Klamath Project, and the COE is considering issuing permits under the RHA and CWA, and these other federal agencies may consult separately, under their responsibilities, with affected Indian tribes on those actions.

Section 106 of the NHPA requires that federal agencies take into account the effects of their undertakings on historic properties and afford the Advisory Council on Historic Preservation (ACHP) an opportunity to comment. Historic properties include prehistoric or historic sites, districts, buildings, structures, objects, landscapes, or properties of traditional religious or cultural importance listed on or eligible for listing on the National Register of Historic Places (NRHP). Jordan Cove and Pacific Connector, as non-federal parties, can provide cultural resources data, analyses, and recommendations to the FERC, as allowed by the regulations for implementing Section 106. However, the FERC remains responsible for all findings and determinations.

The FERC is responsible under Section 106 and its implementing regulations, to consult with the Oregon State Historic Preservation Office (SHPO), identify historic properties within the APE, and make determinations of NRHP eligibility and project effects, on behalf of all the federal

[18] Indian tribes are defined in 36 CFR 800.16(m) as: "an Indian tribe, band, nation, or other organized group or community, including a Native village, Regional Corporation, or Village Corporation, as those terms are defined in Section 3 of the Alaska Native Claims Settlement Act (43 U.S.C. 1602), which is recognized as eligible for the special programs and services provided by the United States to Indians because of their special status as Indians."

cooperating agencies. Section 4.11 of this EIS summarizes the status of our compliance with the NHPA.

1.5.1.5 Rivers and Harbors Act

Section 10 of the RHA prohibits the unauthorized obstruction or alteration of any navigable water of the United States. This section provides that the construction of any structure in or over any navigable water of the United States, or the accomplishment of any other work affecting the course, location, condition, or physical capacity of such waters is unlawful unless the work has been authorized by the COE.

1.5.1.6 Clean Water Act

The CWA establishes the basic structure for regulating discharges of pollutants into the waters of the United States and regulating quality standards for surface waters. Section 404 of the CWA outlines procedures by which the COE can issue permits (after notice and opportunity for public hearings) for the discharge of dredged or fill material into waters of the United States at specified disposal sites.[19] The EPA has the authority to review and veto COE decisions on Section 404 permits. The FWS and NMFS use their Fish and Wildlife Coordination Act authorities to review and comment during the 404 permitting process. The authority to issue Water Quality Certifications pursuant to Section 401 of the CWA and National Pollutant Discharge Elimination System (NPDES) permits pursuant to Section 402 of the CWA has been delegated to the ODEQ (see section 1.5.2.4).

See section 4.3 of this EIS for further information regarding water quality issues.

1.5.1.7 Clean Air Act

The primary objective of the CAA as amended, is to establish federal standards for various pollutants from both stationary and mobile sources, and to provide for the regulation of polluting emissions via state implementation plans. In addition, the CAA was established to prevent significant deterioration in certain areas where air pollutants exceed national standards and to provide for improved air quality in areas that do not meet federal standards (non-attainment areas).

The EPA has regulatory authority under the CAA. Section 309 of the CAA directs the EPA to review and comment in writing on environmental effects associated with all major federal actions. The EPA has delegated permitting authority under the CAA to the ODEQ. Emissions from all phases of construction and operation of the proposed LNG terminal and pipeline would be subject to applicable federal and state air regulations.

See section 4.12.1 of this EIS for further information regarding air quality issues.

[19] For activities involving CWA Section 404 discharges, a permit will be denied by the COE if the associated discharge does not comply with the EPA's 404(b) (1) Guidelines. The Guidelines are binding regulations and provide substantive environmental standards by which all Section 404 permit applications are evaluated. The Guidelines specifically require that "no discharge of dredged or fill material shall be permitted if there is a practicable alternative to the proposed discharge which would have less adverse impact on the aquatic ecosystem, so long as the alternative does not have other significant adverse effects." The burden of proving no practicable alternative exists is the sole responsibility of the applicant.

1.5.1.8 Coastal Zone Management Act

In 1972, Congress passed the CZMA to "preserve, protect, develop, and where possible, to restore or enhance, the resources of the nation's coastal zone for this and succeeding generations" and to "encourage and assist the states to exercise effectively their responsibilities in the coastal zone through the development and implementation of management programs to achieve wise use of the land and water resources of the coastal zone".

Section 307 (c)(3)(A) of the CZMA states that "any applicant for a required federal license or permit to conduct an activity, in or outside the coastal zone, affecting any land or water use or natural resource of the coastal zone of that state shall provide a certification that the proposed activity complies with the enforceable policies of the state's approved program and that such activity will be conducted in a manner consistent with the program." In order to participate in the coastal zone management program, a state is required to prepare a program management plan for approval by the NOAA Office of Coast and Ocean Resource Management (OCRM). Once the OCRM has approved a plan and its enforceable program policies, a state program gains "federal consistency" jurisdiction. This means that any action requiring a federally issued licenses or permits that takes place within a state's coastal zone must be found to be consistent with state coastal policies before the action authorized by the federal license or permit can occur.

All components of the Project from MP 0.0 to approximately MP 53.2 are within the designated Oregon coastal zone and are subject to federal CZMA review. The ODLCD is the state's designated coastal management agency and has established the Oregon Coastal Management Program (OCMP). The program's mission is to work in partnership with coastal local governments, state and federal agencies, and other stakeholders to ensure that Oregon's coastal and ocean resources are managed, conserved, and developed consistent with statewide planning goals. To accomplish this mission, the program combines various state statutes for managing coastal lands and waters into a single, coordinated package. These include: (1) the 19 Statewide Planning Goals, which are Oregon's standards for comprehensive land use planning; (2) city and county comprehensive land use plans; and (3) state agencies and natural resource laws such as the Oregon Beach Bill and the Removal-Fill Law. Under the provisions of the CZMA, Jordan Cove and Pacific Connector must provide a certification to the FERC, COE, and the ODLCD that their projects comply with and would be conducted in a manner consistent with the state's approved management program (15 CFR 930.50 Subpart D).

See section 4.7 of this EIS for further information regarding the FERC's compliance with the CZMA.

1.5.1.10 Migratory Bird Treaty Act

The MBTA protects 1,027 species (50 CFR §10.13). Intentional destruction or disturbance of active migratory bird nests, or any eggs or young contained within it, without authorization, is a violation of the MBTA.

EO 13186 encourages federal agencies to find ways to conserve birds protected under MBTA, especially those of greatest conservation concern, in the course of conducting agency activities. On March 30, 2011 the FERC and FWS entered into an MOU that focuses on migratory birds and strengthening conservation through enhanced collaboration between the agencies. This voluntary MOU does not waive legal requirements under the MBTA, Eagle Act, ESA, or any other statutes, and does not authorize the take of migratory birds. Under the MOU, the FERC would promote the applicants' use of BMPs to avoid and minimize impacts on birds to the extent practicable during project implementation.

See sections 4.5 and 4.6 of this EIS for further information regarding the migratory bird species that inhabit the Project area, as well as measures the applicants would implement to avoid, reduce, or mitigate effects on migratory birds.

1.5.1.11 Bald and Golden Eagle Protection Act (Eagle Act)

The Eagle Act prohibits the "take" of bald and golden eagles, including their parts, nests, or eggs, without a permit. "Take" is defined as "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest or disturb."

Activities that may affect an eagle's ability to forage, nest, roost, breed, or raise young, constitute 'disturbance' and require a permit; habitat manipulation in this project might result in disturbance and require a permit. The FWS can issue permits for non-purposeful take under the Eagle Act and encourages applicants to coordinate early to avoid and minimize impacts to bald and golden eagles that may be in the vicinity of the project.

See section 4.6 of this EIS for further information regarding bald and golden eagles that inhabit the Project area, as well as measures the applicants would implement to avoid, reduce, or mitigate effects on bald and golden eagles as required by the Eagle Act.

1.5.2 State Agency Permits and Approvals

In addition to the federal permitting authorities that have been delegated to the states, as discussed above, various Oregon laws pertain to the Project. Permits, authorizations, and consultations with state agencies relevant to the Project are listed in table 1.5.1-1.

The FERC encourages cooperation between applicants and state and local authorities, but this does not mean that state and local agencies (through application of state and local laws) may prohibit or unreasonably delay the construction or operation of facilities approved by the FERC. Any state or local permits issued with respect to FERC regulated facilities must be consistent with the conditions of any Certificate the FERC may issue.[20]

1.5.2.1 Oregon Department of Geology and Mineral Industries (DOGAMI)

The mission of the DOGAMI is to provide earth science information for the citizens of Oregon. DOGAMI identifies and quantifies natural hazards, and works to minimize potential effects of earthquakes, landslides, and tsunamis. Its administrative rule at OAR 632 includes the identification of Tsunami Inundation Zones under Division 5. The agency is also the steward of Oregon's mineral resources, and it regulates mining activities, and oil and gas exploration and production on non-federal lands.

[20] *See* 15 U.S.C. § 717r(d) (state or federal agency's failure to act on a permit considered to be inconsistent with Federal law); *see also Schneidewind v. ANR Pipeline Co*., 485 U.S. 293, 310 (1988) (state regulation that interferes with FERC's regulatory authority over the transportation of natural gas is preempted) and *Dominion Transmission, Inc. v. Summers,* 723 F.3d 238, 245 (D.C. Cir. 2013) (noting that state and local regulation is preempted by the NGA to the extent it conflicts with federal regulation, or would delay the construction and operation of facilities approved by the Commission).

1.5.2.2 Oregon Department of Agriculture (ODA)

The ODA maintains the state list of endangered and threatened plant species, in accordance with Oregon Administrative Rule (OAR) Chapter 603, Division 73, and reviews reports of botanical surveys under Oregon Senate Bill 533 and its corresponding Oregon Revised Statute (ORS) 564. These state laws and regulations require surveys for state listed species on non-federal public lands prior to ground-disturbing activities, unless habitat for the species does not exist in the Project area. Furthermore, the ODA Noxious Weed Control Program and the Oregon State Weed Board maintain the State Noxious Weed List for the State of Oregon.

1.5.2.3 Oregon Department of Energy (ODE)

According to the EPAct, the Governor of a state in which an LNG terminal is proposed is to designate an appropriate state agency to consult with the Commission. That state agency should provide the FERC with an advisory report on state and local safety concerns, within 30 days of the FERC's notice of an application for an LNG terminal, for the Commission to consider prior to making a decision. The ODE has been designated by the Governor of Oregon as the state agency to coordinate the review of proposed LNG projects by other state agencies and consult with the FERC.

1.5.2.4 Oregon Department of Environmental Quality (ODEQ)

The ODEQ is responsible for protecting and enhancing Oregon's water and air quality, managing the proper disposal of hazardous and solid waste, overseeing clean-ups of spills or releases of hazardous materials, and enforcing Oregon's environmental laws and regulations. The agency's duties to regulate sewage treatment and disposal systems are found in ORS Chapter 454, for solid waste management in Chapter 459, hazardous materials in Chapters 465 and 466, air and water quality in Chapter 468, and ballast water in Chapter 783. The EPA has delegated authority to the ODEQ under both the CWA and CAA.

Under its delegated responsibilities required by the CAA, the ODEQ administers the Title V Air Permit program and the acid rain program, and issues air contaminant discharge permits (ACDP). The agency is also responsible for enforcing greenhouse gas (GHG) reporting requirements, and collecting data on GHG emissions for certain facilities that hold Title V or ACDP operating permits. In addition, ODEQ makes determinations about the Prevention of Significant Deterioration (PSD) of air quality from new major sources or major modifications at existing sources, and reviews air quality analyses completed to comply with National Ambient Air Quality Standards (NAAQS).

1.5.2.5 Oregon Department of Fish and Wildlife (ODFW)

The OODFW is responsible for keeping the state sensitive fish and wildlife list and developing the state's Wildlife Diversity Plan. The purpose of the Fish and Wildlife Habitat Mitigation Policy (OAR 345-22-60) developed by the ODFW is to apply consistent goals and standards to mitigate effects on fish and wildlife habitat caused by land and water development actions. The policy provides goals and standards for general application to individual development actions, and for the development of more detailed policies for specific classes of development actions or habitat types. In implementing this policy, the ODFW will recommend or require mitigation for losses of fish and wildlife habitat resulting from development actions; priority is given to native species.

ORS 509.585 (Oregon Fish Passage Law) applies to all project components that cross waters of the state where native migratory fish species are or were historically present. The ODFW would also review fish screening at water intakes under ORS 498-306. Under ORS 509 and OAR 635, the ODFW has responsibilities for review of stream crossing plans to provide for passage of native migratory fish.

OAR 635-425-000 through 635-425-0050 requires in-water blasting permits to be issued by ODFW for locations where explosives may be used to cross streams. While, in general, in-water blasting is discouraged, unless it is the only practicable method for accomplishing project goals, the ODFW may issue a permit if it contains conditions for preventing injury to fish and wildlife and their habitats.

1.5.2.6 Oregon Department of Forestry (ODF)

The ODF manages State Forests for the Greatest Permanent Value. The ODF has created a Forest Management Plan to provide strategic direction and guide management activities. Part of the plan is to identify multi-purpose objectives, and protect sensitive resources according to the state's Land Management Classification System. The ODF also monitors the commercial harvest of forest products from private timber lands, according to the Oregon Forest Practices Act. The ODF is responsible for protection of non-federal and private forest lands from wildfires.

Pacific Connector would be required to submit a Notification to the ODF. The Notification serves three purposes: notification of a forest operation, a request for a Permit to Use Fire or Power Driven Machinery, and notice to the Department of Revenue of timber harvest. A separate notification should be filed for each county and timber owner affected by the Project. All notifications require a 15-day waiting period before activity may begin unless a waiver is requested. Also, any action that would result in the conversion of forestland to other land uses or practices not in statute or rule would require the submission of a Plan for Alternate Practice and written approval from the State Forester.

1.5.2.7 Oregon Department of Land, Conservation, and Development (ODLCD)

The ODLCD assists communities and citizens in improving the built and natural environment. Under Oregon's statewide land use planning program, the ODLCD provides protection for farm and forest lands, conservation of natural resources, plans for orderly development, and coordinates among local governments. Comprehensive land use planning coordination is required under ORS 197. All cities and counties in Oregon have adopted plans that meet state standards and adhere to 19 Statewide Planning Goals and Guidelines.

In addition, NOAA has delegated to the state of Oregon the finding of consistency with the CZMA. In accordance with ORS 196.435, the ODLCD's Ocean and Coastal Services Division has been designated the state's coastal zone management agency and administers the CZMA federal consistency review program. Applicants for certification of CZMA consistency are encouraged by the ODLCD to obtain state and local permits and other authorizations required by enforceable policies. The requirements of the CZMA are applicable to NPDES permits and must be included in the NPDES permit for the Jordan Cove industrial wastewater treatment facility.

1.5.2.7 Oregon Department of Transportation (ODOT)

The ODOT has the responsibility to preserve the operational safety, integrity, and function of the state's highway facilities. The ODOT must also ensure that improvements to the highway system can be accomplished without undue effects or damage to utilities within the highway ROW. Construction that may affect the state ROW is subject to ORS 374.305, under which no person, firm, or corporation may place, build, or construct on any state highway ROW, approach road, structure, pipeline, ditch, cable or wire, or any other facility, thing, or appurtenance without first obtaining written permission from the ODOT. A permit from the ODOT is required for any work on a highway that is part of the state highway system, including but not limited to interstate highways, other highways on the National Highway System, and routes on the federal-aid highway system.

1.5.2.8 Oregon Department of State Lands (ODSL)

Under Oregon's Removal-Fill Law, permits are issued by the ODSL for projects requiring the removal or fill of 50 cubic yards or more of material in waters of the state; the removal or fill of any material regardless of the number of cubic yards affected in a stream designated as essential salmon habitat; and the removal or fill of any material from the bed and banks of scenic waterways regardless of the number of cubic yards affected.

An application to the ODSL should demonstrate independent utility, identify best use of waters, and outline measures to minimize effects on water resources. To meet the requirements of OAR Division 85, compensatory mitigation should be offered to replace all lost functions and values of wetlands and waterbodies effected by a project.

1.5.2.9 Oregon Water Resources Department (OWRD)

The mission of the OWRD is to address the state's water supply needs through the restoration and protection of stream flows and watersheds. The OWRD is charged with administering state laws and regulations governing surface and groundwater resources, such as the Ground Water Act under ORS 537-505. Its core functions include collecting water resources data and enforcing water rights, under OAR Chapter 690. All water is publicly owned in Oregon, and users must obtain a permit or water right from OWRD, including water withdrawals from underground wells, streams, or lakes. OWRD also maintains a database of water well locations, and a database for stream flows and lake levels. The applicants utilized the OWRD database for their application to the FERC.

1.5.2.8 Oregon State Historic Preservation Office (SHPO)

The FERC, as the lead federal agency, on behalf of the federal cooperating agencies, is consulting with the Oregon SHPO regarding the identification of historic properties and determination of Project-related effects, in accordance with 36 CFR 800, in order to comply with Section 106 of the NHPA. The SHPO also has authorities under ORS 358-920 to issue permits for cultural resources surveys on non-federal public land, and for the excavation of archaeological sites on non-federal lands. Jordan Cove and Pacific Connector would obtain applicable permits from the SHPO prior to conducting other archaeological work related to the Project.

2.0 DESCRIPTION OF THE PROPOSED ACTION

As described herein, Jordan Cove proposes to construct and operate an LNG production, storage, and export facility in Coos County, Oregon. Pacific Connector also proposes to construct and operate an interstate natural gas transmission pipeline and associated facilities in Coos, Douglas, Jackson, and Klamath Counties, Oregon. The proposed action also includes amendments to BLM and Forest Service LMPs. The proposed amendments and associated mitigation actions are described in sections 2.1.3, 2.1.4, and 2.1.5 below.

2.1 PROJECT OPERATIONAL COMPONENTS

2.1.1 Jordan Cove LNG Project

The Jordan Cove LNG export terminal would be located on the bay side of the North Spit of Coos Bay, Oregon. The general location of the terminal and associated temporary construction work areas including marine facilities and mitigation sites is shown on figure 2.1-1. The primary components of the LNG terminal include five liquefaction trains[21], two full-containment LNG storage tanks, vessel loading facilities, a vessel slip, and a marine access channel. The terminal site would also include a connection to the Pacific Connector pipeline and a gas conditioning facility. Jordan Cove is proposing five mitigation sites (i.e., the Kentuck project; the Eelgrass Mitigation site; and the Lagoon, Panhandle, and North Bank upland wildlife habitat mitigation sites). As shown on figure 2.1-2, portions of the terminal site are referred to as Ingram Yard which would contain the main terminal facilities; South Dunes, which would contain the SORSC, administration building, and temporary workforce housing and laydown areas; and an access and utility corridor between the Ingram Yard and South Dunes. Components that make up the proposed LNG terminal are described below, and the location of specific components are shown on figure 2.1-3.

The proposed LNG terminal site is within a potential tsunami inundation zone, and Jordan Cove has incorporated measures into the proposed facility design to account for potential tsunami inundation. Measures include elevating some site components and protecting some site components with berms or wall. Details are discussed as appropriate within this EIS.

2.1.1.1 Gas Conditioning

Natural gas would require conditioning prior to liquefaction to remove components that could freeze out and clog the liquefaction equipment or would otherwise be incompatible with the liquefaction process such as mercury, hydrogen sulfide, carbon dioxide (CO_2), water, and heavy hydrocarbons that would freeze during the liquefaction process. Heavy hydrocarbons removed would be blended into the fuel gas stream, so no on-site storage or disposal would be required.

[21] A liquefaction train consists of all components of the liquefaction process arranged in a linear relationship.

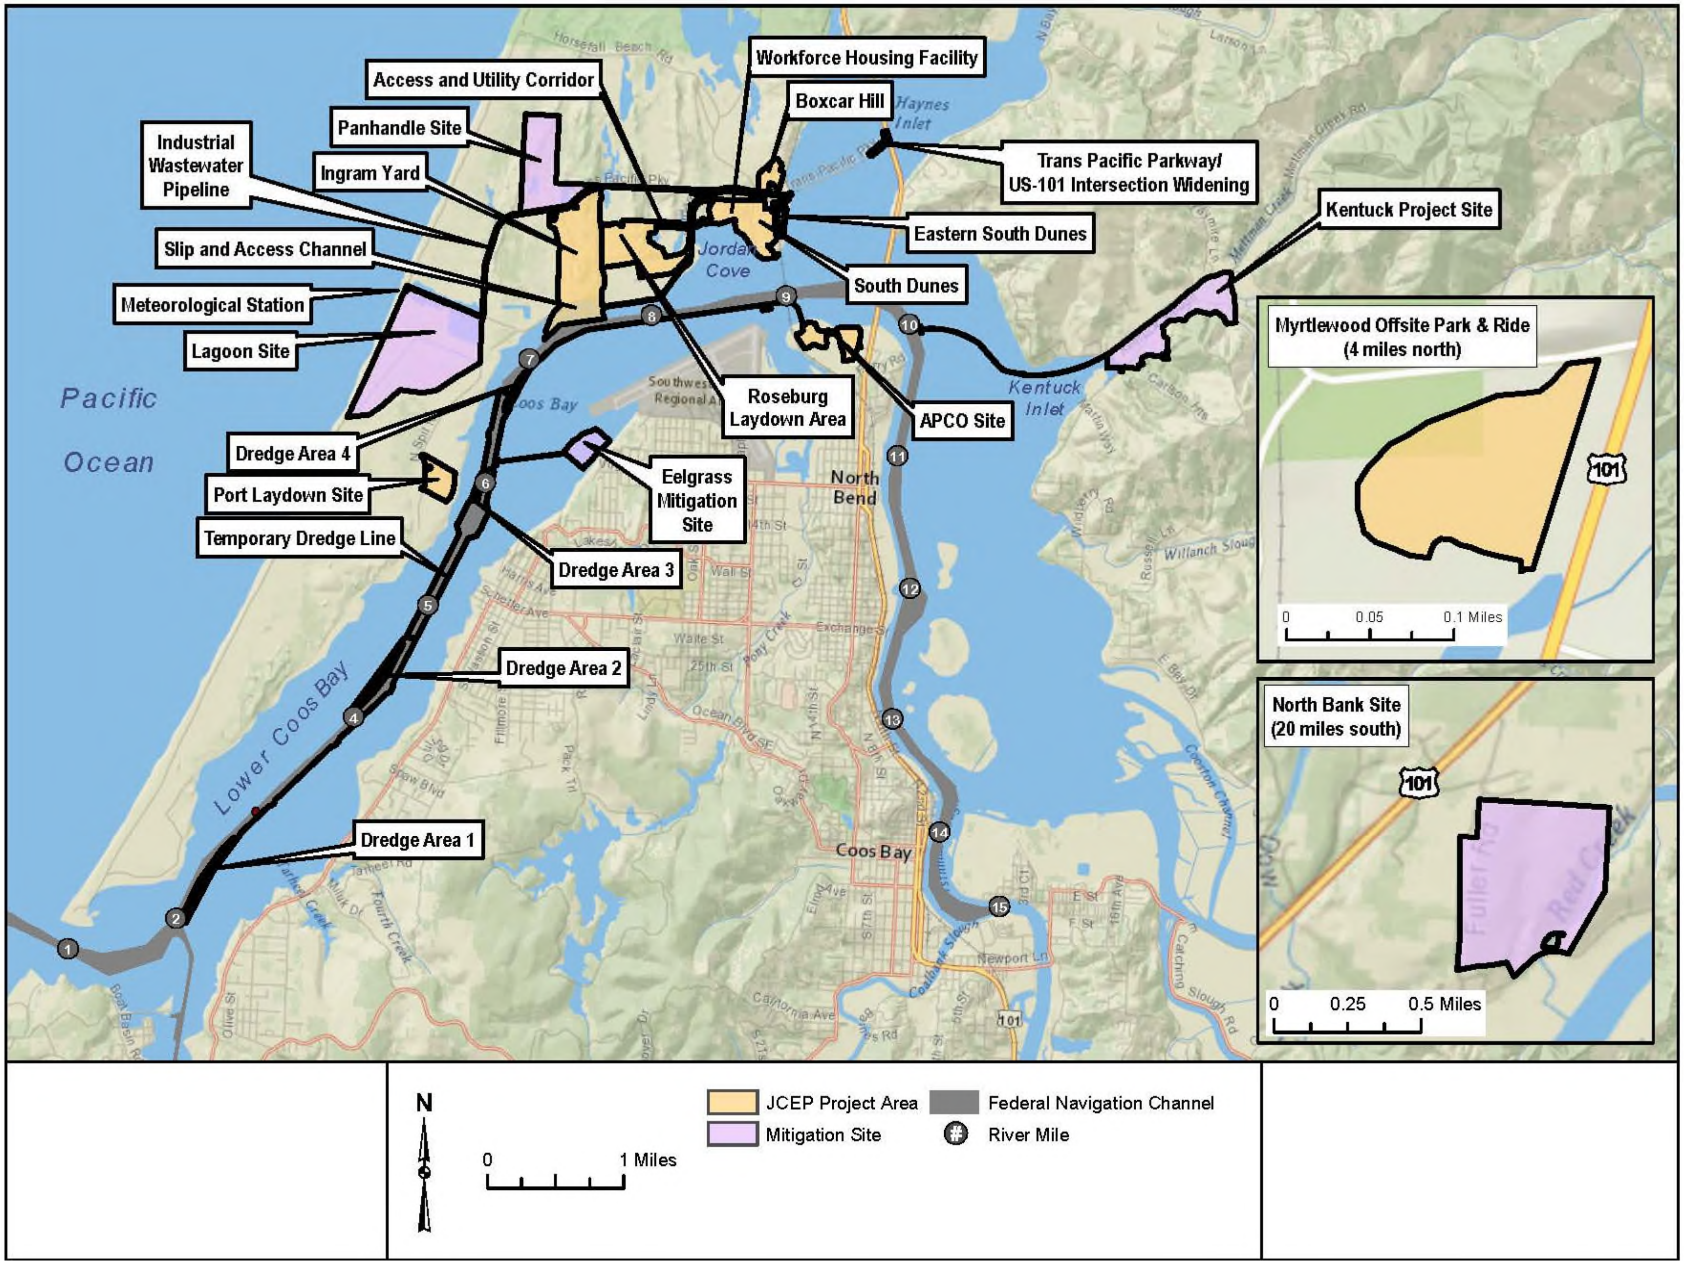

Figure 2.1-1
Jordan Cove LNG Project General Location

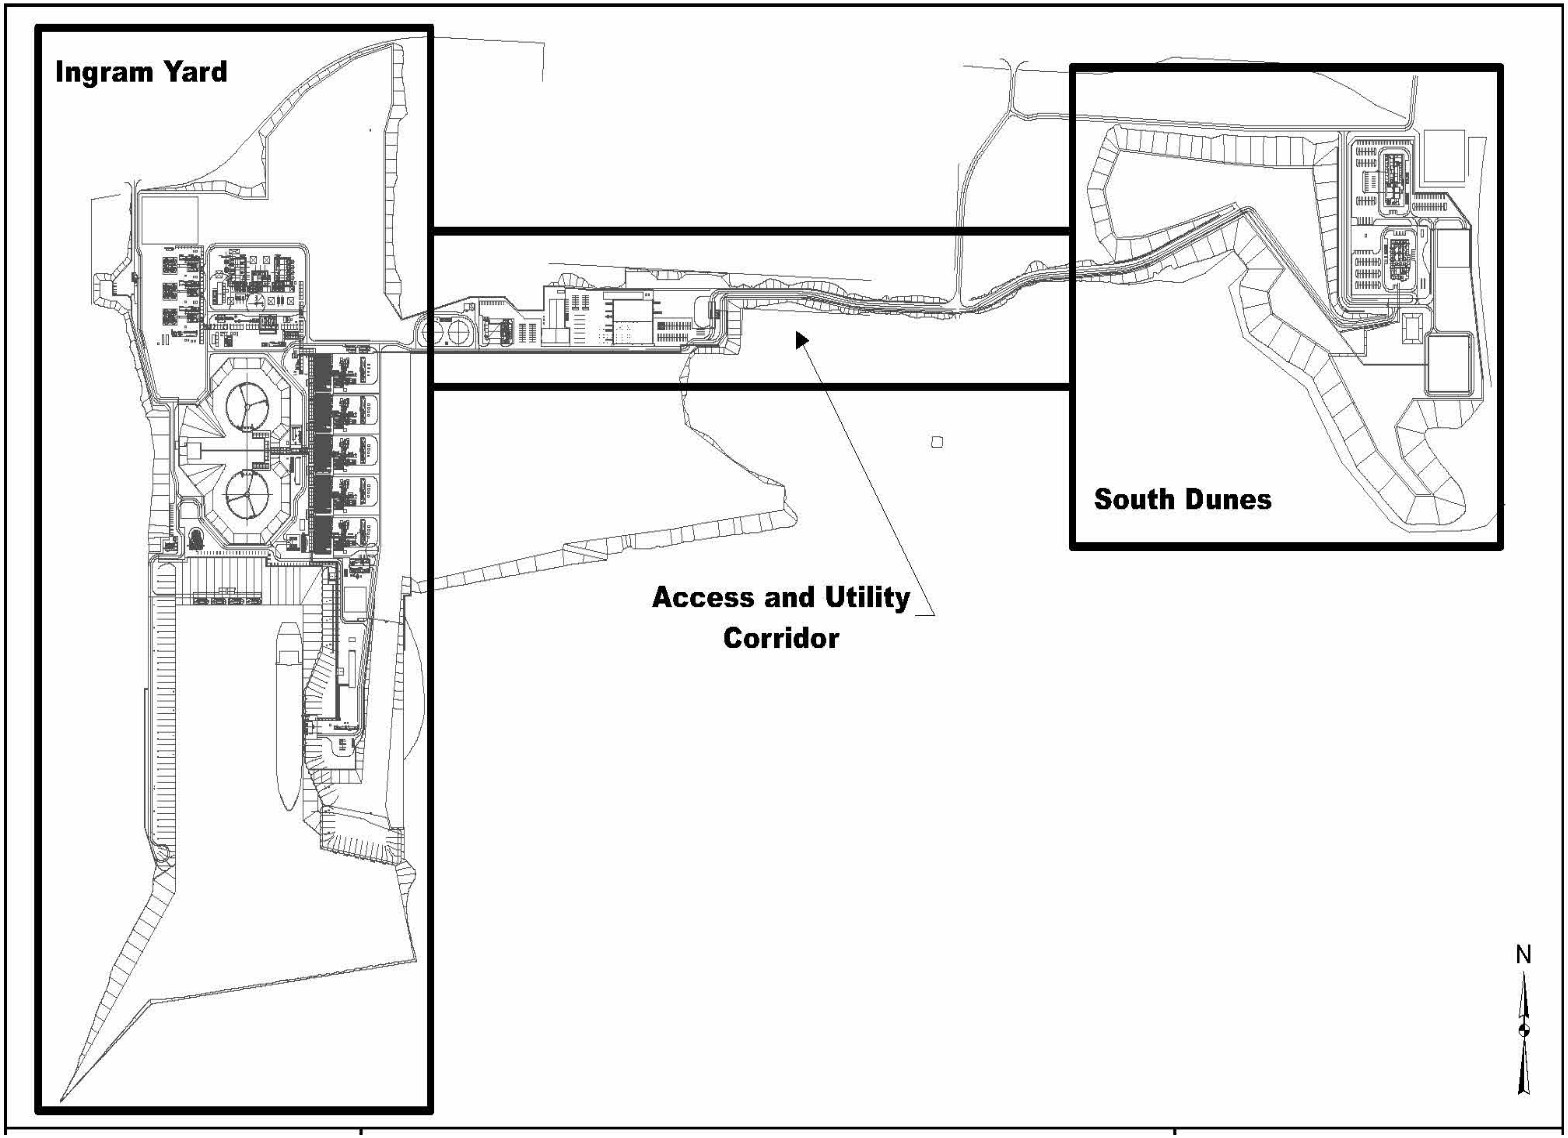

Figure 2.1-2
LNG Terminal Facilities

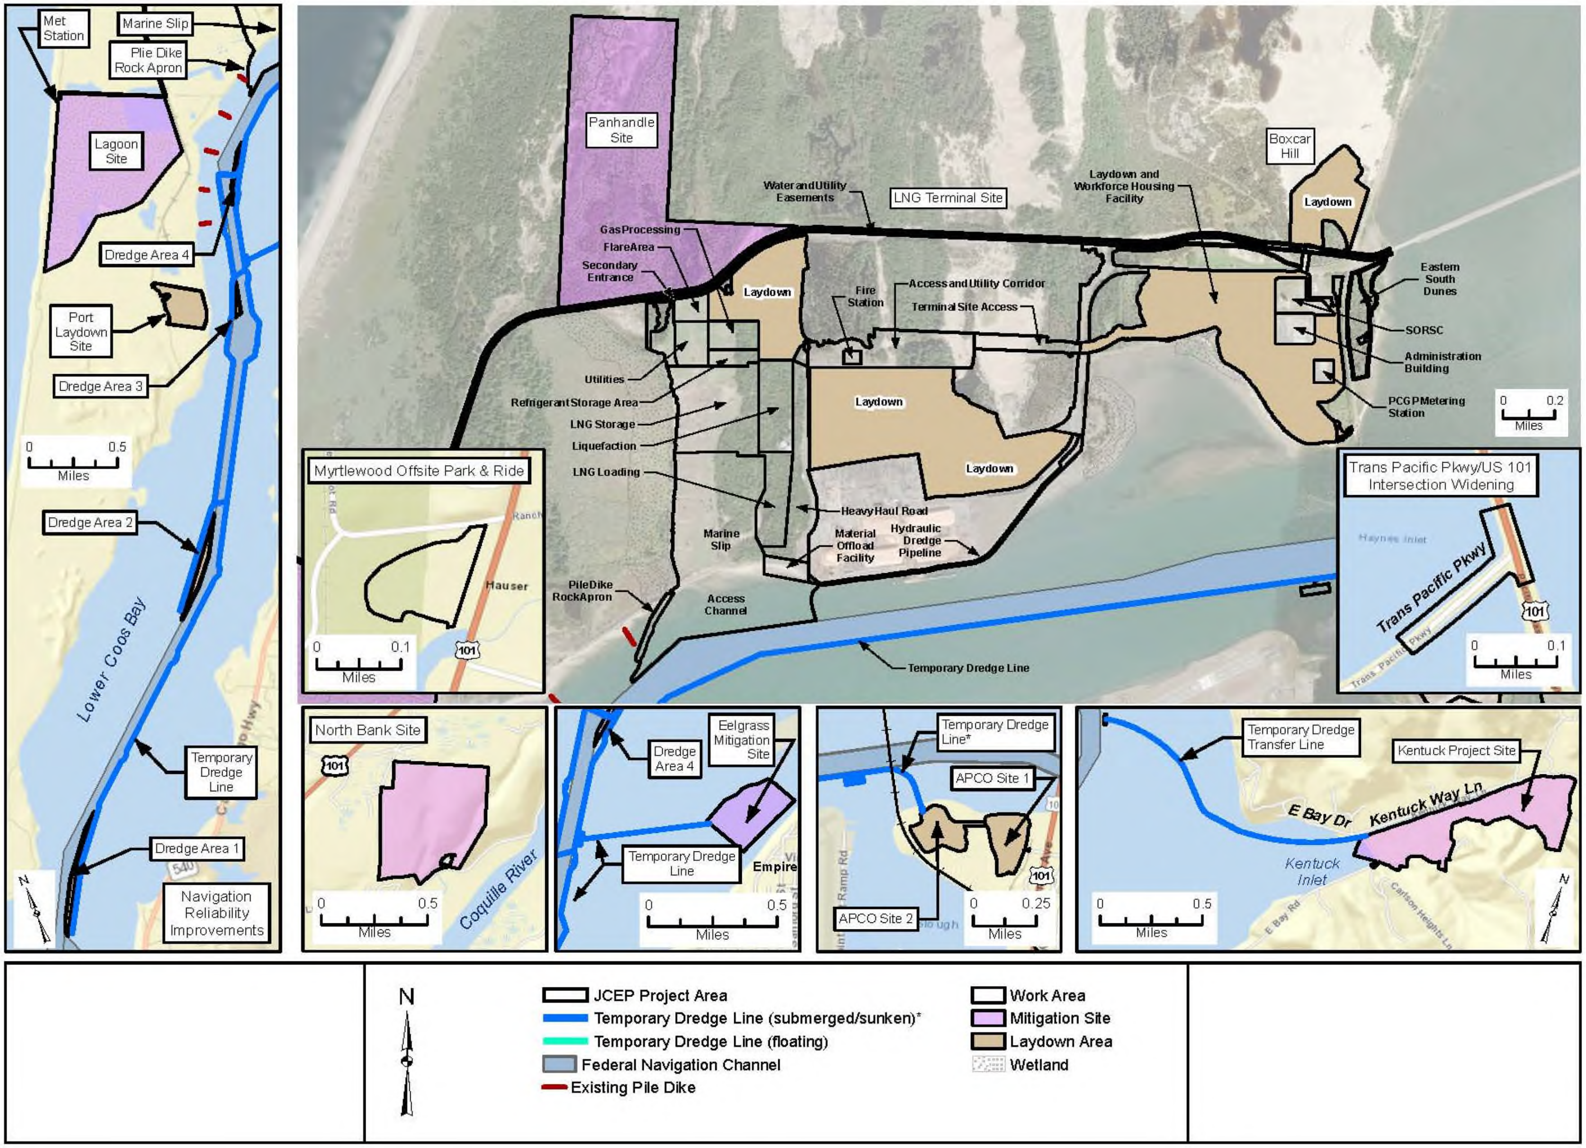

Figure 2.1-3
Jordan Cove LNG Project Detail

2.1.1.2 Liquefaction

The liquefaction trains would use Black & Veatch proprietary Poly Refrigerant Integrated Cycle Operation (PRICO®) LNG technology, each with a maximum annual capacity of 1.56 metric tonnes per annum (mtpa), for a total annual capacity of 7.8 mtpa for export. Gas delivered from the conditioning units would be divided equally among the five liquefaction trains where it would be turned into liquid by cooling to approximately -260°F. Upon leaving the LNG trains the produced LNG would be conveyed to the LNG storage tanks.

2.1.1.3 LNG Storage Tanks

The terminal would include two full-containment storage tanks, each designed to store 160,000 cubic meters (m^3) (1,006,000 barrels) of LNG at an approximate temperature of -260 degrees Fahrenheit (°F) at atmospheric pressure. Each storage tank would consist of a nine percent nickel inner steel container and a secondary concrete outer container wall with a steel vapor barrier, and would be designed so that both the primary inner container and the secondary outer concrete shell are capable of independently containing the entire volume of stored LNG.

The base elevation of the LNG storage tanks would be at about +27 feet above mean sea level (MSL). The top of the tanks (dome) would be about 180 feet above grade, and the diameter of the outer tank would be about 267 feet wide. Jordan Cove proposes to enclose the LNG storage tanks within an earthen berm that would be about +46 feet high. The berm would be designed to contain the contents of one 160,000 m^3 storage tank.

Each LNG storage tank would be built on a shallow mat foundation. Cellular glass insulation would be incorporated into the foundation and a glass wool blanket would be installed on the inner tank. The remainder of the annular space between the outer tank and inner tank would be filled with expanded perlite to keep the stored LNG at a temperature of approximately -260°F while maintaining the outer container at near ambient temperature. The LNG storage tanks would have top connections only with piping that would allow top and bottom filling. Top filling would be done via a spray device or a splash plate while bottom loading would be achieved via a standpipe to allow mixing of incoming LNG as it combines with the LNG inventory within the LNG storage tanks. A conceptual design drawing of a typical full containment LNG storage tank is illustrated in figure 2.1-4.

2.1.1.4 Terminal Access, Utility Corridor, and Parking

The feed gas supply pipeline and other utilities including power, water supply, and communications would be located in an approximately one-mile-long corridor connecting the South Dunes and Ingram Yard. The corridor would also provide temporary and permanent access to the LNG terminal site. Paved access between the South Dunes portion of the site and the western portion of the access and utility corridor would be via the existing Jordan Cove Road. A two-lane access road would be installed to the northwest of Ingram Yard to provide emergency, marine terminal, and occasional maintenance access from the Trans-Pacific Parkway.

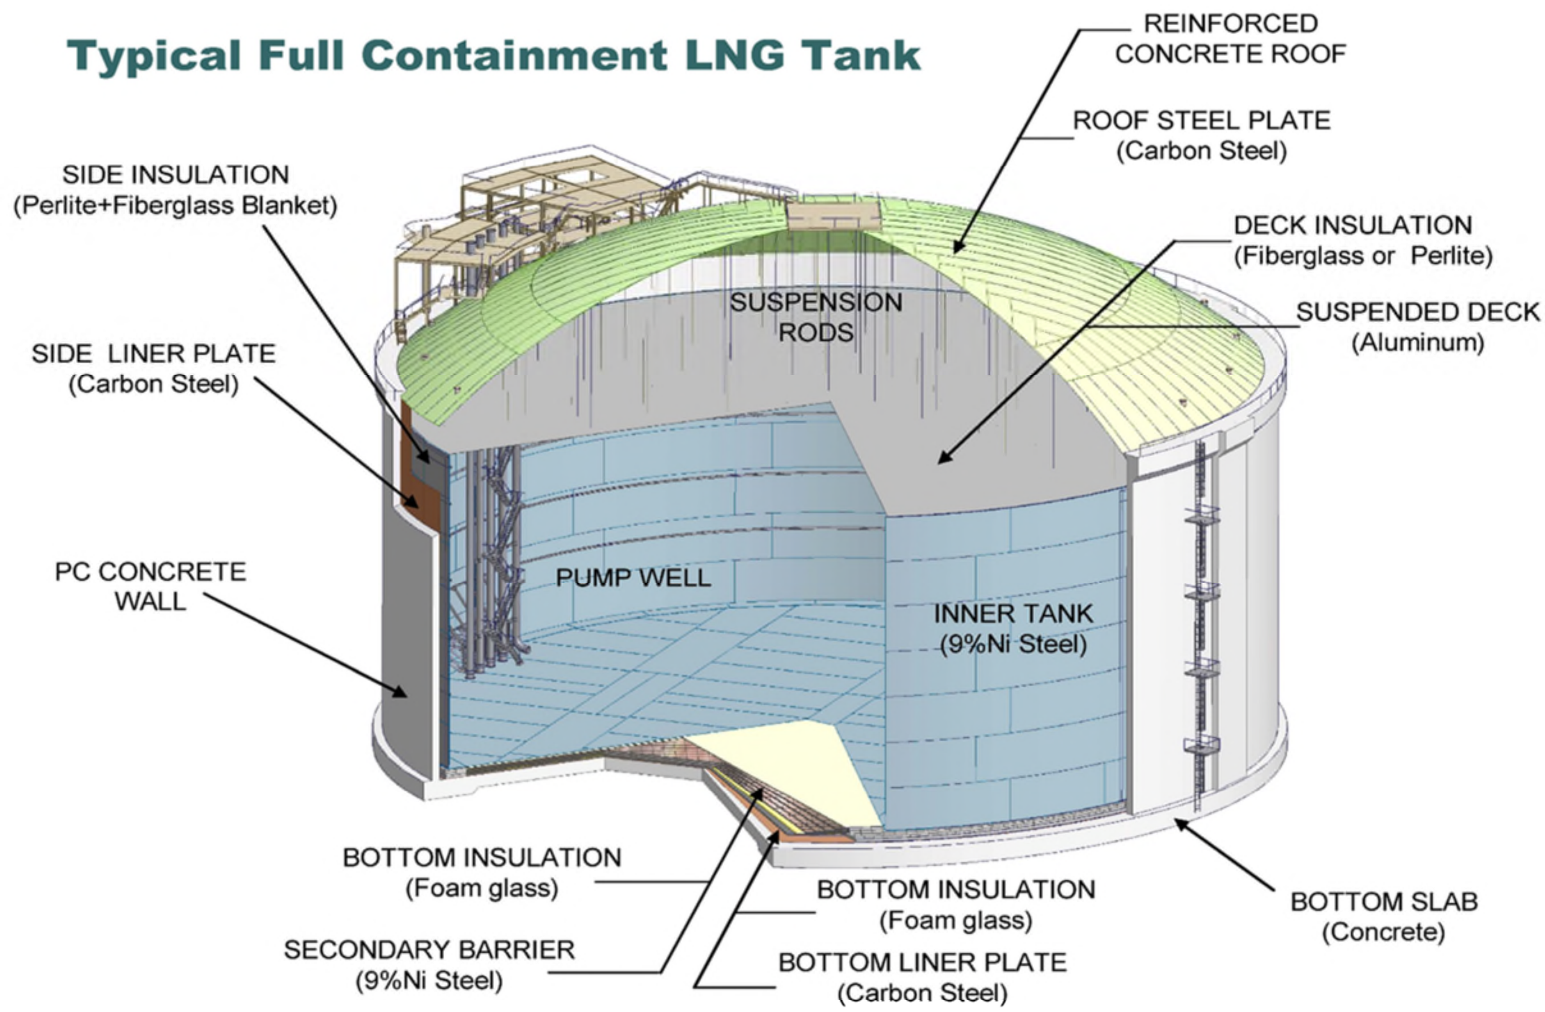

Figure 2.1-4

Typical Full Containment LNG Storage Tank

2.1.1.5 Other Terminal Support Systems

The LNG terminal operation would require installation of several other systems within the LNG terminal site, as described below.

Vapor Handling System

The liquefaction and vessel loading processes would result in the creation of miscellaneous LNG vapors, which would be recovered and directed into a vapor handling system and recycled into the liquefaction process.

Ground Flares

The LNG terminal would have three separate flare systems for occasional pressure relief or plant protection conditions: one flare system for warm (or wet) reliefs, one for cold cryogenic (or dry) reliefs, and one for low-pressure cryogenic reliefs from the marine loading system. The warm and cold flares would both be combined within a shared multi-point ground flare, while the marine flare would be within an enclosed cylindrical ground flare. The multi-point ground flare systems would be located at the northern end of the LNG terminal site and the enclosed ground flare would be located north of the marine vessel slip. The flare systems would only be used during plant-protection situations, maintenance activities, cases of purging and gassing-up an LNG carrier, and initial commissioning/start-up.

During initial commissioning and startup flaring would occur for approximately 1 week, at 10 to 20 percent of the flare design capacity. For dryout and cooldown, flaring would occur for approximately 2 weeks at less than about 20 percent of the flare design capacity. When each subsequent liquefaction train is started, flaring may occur for approximately 2 hours, and each train would be staggered by about 1 month between startups. Flaring during other commissioning activities would occur intermittently but would consist of individual pieces of equipment being isolated with very small volumes flared compared to the flare design capacity until the system is depressurized.

Instrumentation and Process Control System

The facility would be operated through a distributed control system (DCS) that would include control panels and numerous field-mounted instruments connected to remote input/output cabinets that would interface with the central control room. In addition, independent Safety Instrumented Systems (SIS) and Fire and Gas Systems (FGS) would monitor hazardous conditions and provide emergency shutdown capability.

Electrical Systems

Electrical power to the LNG terminal would be supplied via two 30-megawatt (MW) steam turbine generators and one spare 30 MW steam turbine generator, with the steam generated by heat recovery from gas turbine operation. A black-start auxiliary boiler would be used to generate steam for power when gas turbines are not in operation. The system would also include two standby diesel generators for the LNG facility and two for the SORSC.

Lighting System

Twenty-four-hour facility lighting would be required for security and personnel safety during operation of the LNG terminal. A final lighting plan, including lighting of the LNG storage tanks, would be developed during detailed LNG terminal design; however, Jordan Cove states that only lighting required for operation and maintenance, safety, security, and meeting FAA requirements would be used on the LNG storage tanks.

Water Systems

Jordan Cove would design and construct a stormwater management system to gather runoff from impervious surfaces within the terminal and direct the flow to designated areas for disposal. Stormwater collected in areas that are potentially contaminated with oil or grease would be pumped or would flow to oily water collection sumps before discharging to the industrial wastewater pipeline. No untreated stormwater would be allowed to enter federal or state waters.

Sanitary waste would either be directed to a holding tank and disposed of by a sanitary waste contractor as necessary or would be treated by a packaged treatment system and directed to an existing industrial wastewater pipeline (IWWP).

During construction of the Jordan Cove LNG Project, an existing industrial wastewater pipeline would be abandoned, replaced, and relocated. The new replacement pipeline would consist of 16-inch-diameter slip joint polyvinyl chloride (PVC). It would run for about two miles from the South Dunes portion of the site along the shoulder of the Trans-Pacific Parkway within an easement owned by the Port to connect with the existing outfall pipe west of the Weyerhaeuser lagoon on the North Spit (see figure 2.1-5).

Jordan Cove proposes to use raw water from the existing Coos Bay North Bend Water Board (CBNBWB) raw water pipeline for construction water needs, including hydrostatic testing of the LNG storage tanks. Following testing and ODEQ approval, the water would be locally discharged to the stormwater system for infiltration or discharged into the IWWP according to the applicable NPDES permit requirements.

An interconnect to the CBNBWB potable water pipeline would be used for all normal operational water needs in the LNG terminal, which includes fire water makeup, utility water used for such items as equipment and area cleaning, and potable water required to supply buildings and eyewash/safety shower stations. In addition, the raw water pipeline tap at the LNG terminal site would remain connected after construction, but there are no normal operational uses anticipated for this raw water supply. The water pipelines and proposed taps are shown on figure 2.1-5.

During construction of the terminal, Jordan Cove would use approximately 595.5 million gallons of water for various activities, including hydrostatic testing. During terminal operations, about 71.5 million gallons of water would be consumed annually. Water usage and impacts are more fully discussed in section 4.3 of this EIS.

The LNG terminal would include a fire suppression system with the main fire water supply for the system provided by two aboveground firewater storage tanks located in the access and utility corridor. Water supply for the two tanks would be potable water obtained from CBNBWB. Each tank would hold a minimum usable capacity of 3,240,000 gallons. This would supply approximately 4 hours of firefighting water. The fire water systems would also include stationary fire water pumps, fire hydrant mains, fixed water spray systems, automatic sprinkler extinguishing systems, high expansion foam system, and remotely controlled monitored spray systems. The fire water supply would also be used to provide water for on-site firefighting trucks.

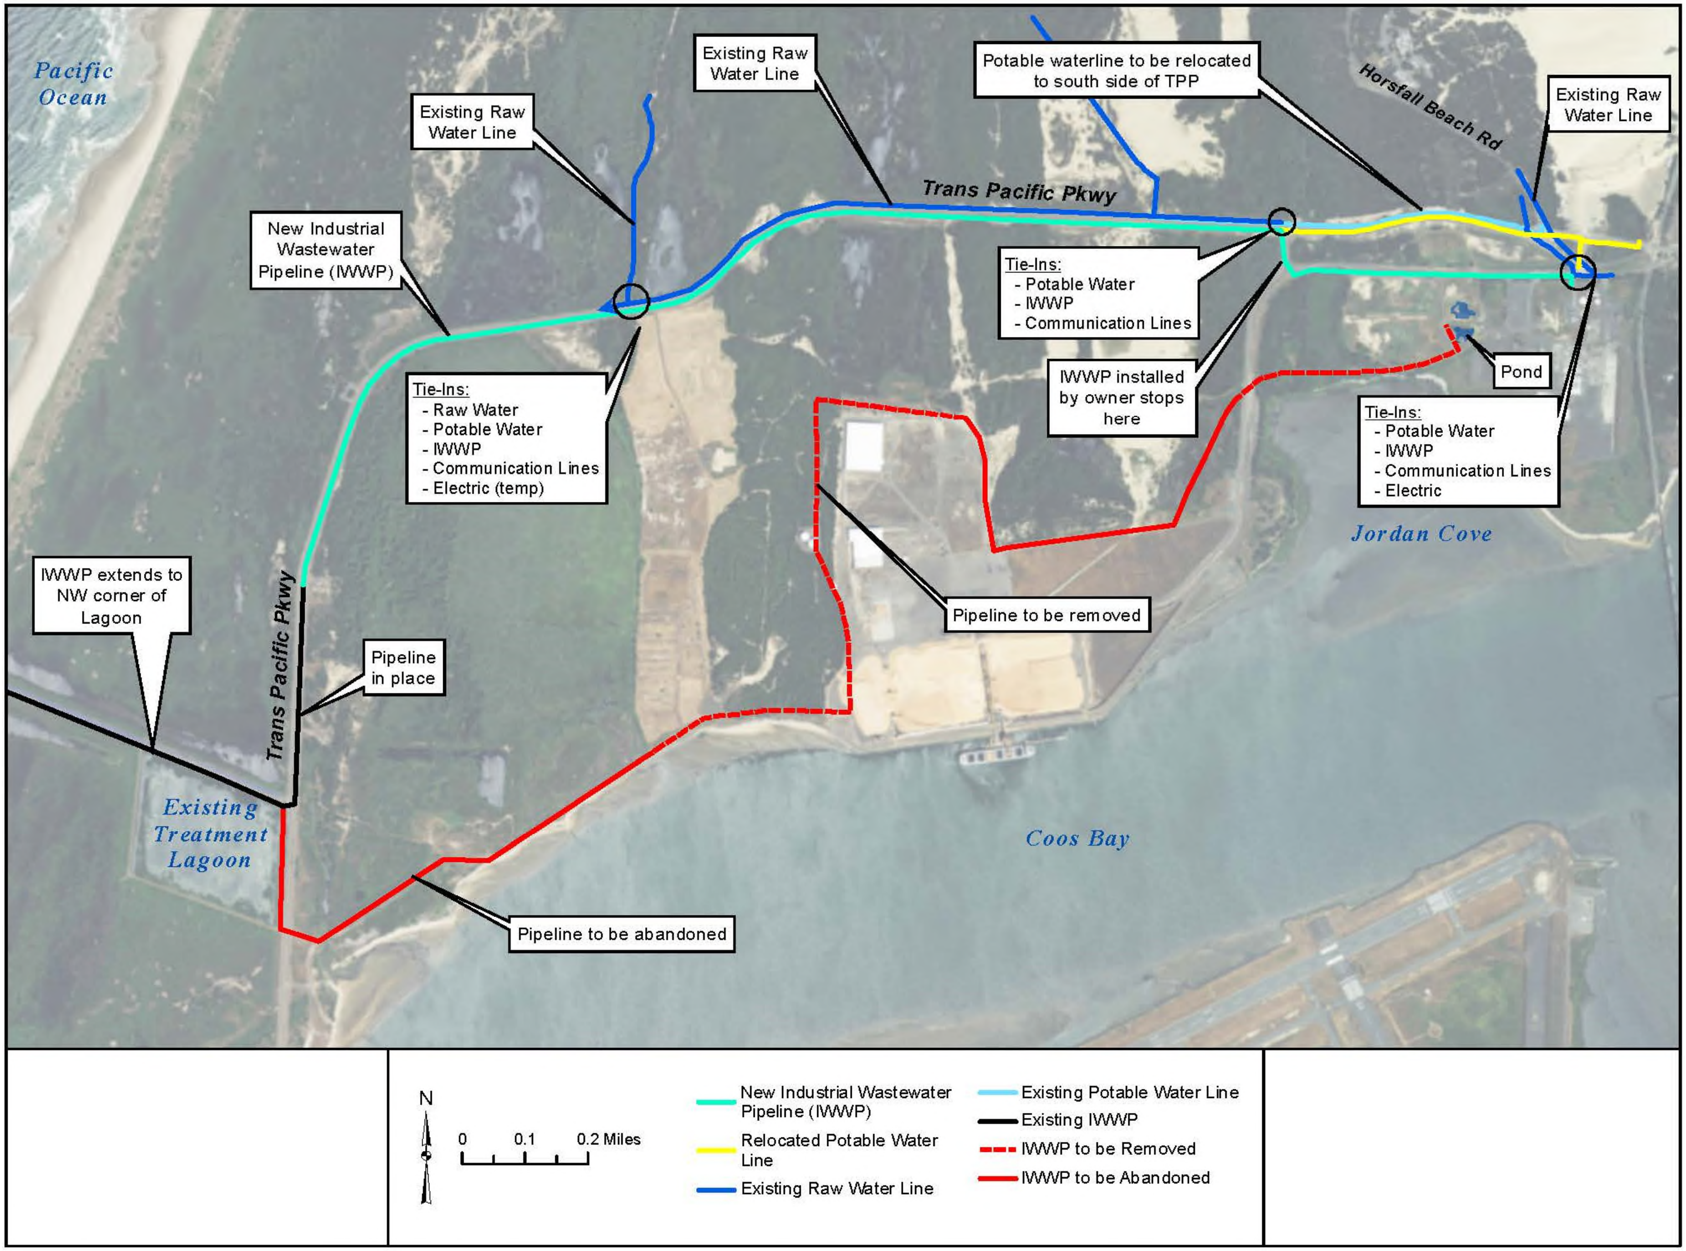

Figure 2.1-5
Industrial Wastewater Pipeline, Water Pipelines Relocation, and Utility Tie-Ins

Support Buildings

The LNG terminal would include buildings to house LNG process equipment, administration and office space, warehouse and receiving, guard houses and security, tugboat storage, and chemical and material storage. Support buildings would also include the non-jurisdictional SORSC and fire department building (see section 2.2). The SORSC would be located adjacent to the LNG terminal administration building on the South Dunes portion of the site. The fire department building would be located in the access and utility corridor.

2.1.1.6 Marine Waterway including Proposed Modifications to the Marine Waterway[23]

The Coast Guard defines the waterway for LNG marine traffic as extending from the outer limits of the United States territorial waters 12 nautical miles off the coast of Oregon, and 7.5 nautical miles up the Federal Navigation Channel to the LNG terminal site (figure 2.1-6). The Federal Navigation Channel extends from the mouth of Coos Bay to the city of Coos Bay Docks at about river mile (RM) 15.1. Jordan Cove would dredge four areas abutting the current boundary of the navigation channel between RM 2 to RM 7 (figure 2.1-1). Dredging could potentially modify the physical morphology of the channel, by widening four turns along the channel, to allow for more efficient transit of LNG carriers. These proposed dredging actions would not result in a change in the overall depth of the Federal Navigation Channel (only a widening of four turns along the channel). The COE is currently evaluating if the dredging of these four turns would alter the Federal Navigation Channel. The four dredging actions are summarized below.

- **Enhancement #1 – Coos Bay Inside Range channel and right turn to Coos Bay Range:** To reduce constriction to vessel passage at the inbound entrance to Coos Bay Inside Range. Widen channel from the current 300 feet to 450 feet, and lengthen the total corner cutoff on the Coos Bay Range side from the current 850 feet to about 1,400 feet.
- **Enhancement #2 – Turn from Coos Bay Range to Empire Range channels:** Widen the turn area from the Coos Bay Range to the Empire Range from current 400 feet to 600 feet and lengthen the total corner cutoff area from the current 1,000 feet to about 3,500 feet.
- **Enhancement #3 – Turn from the Empire Range to Lower Jarvis Range channels:** Add a corner cut on the west side in this area that would be about 1,150 feet wide to provide additional room for vessels to make this turn.
- **Enhancement #4 – Turn from Lower Jarvis Range to Jarvis Turn Range channels:** Widen turn area from current 500 feet to 600 feet and lengthen total corner cutoff area from the current 1,125 feet to about 1,750 feet, to allow vessels to begin a turn in this area earlier.

In addition, Jordan Cove would install five meteorological ocean data collection buoys to aid navigation within the waterway, by measuring wind speed and direction, current speed and direction, as well as tide height. Jordan Cove intends to replace three existing buoys with the new buoys (one located in the Pacific Ocean near the bay entrance, and one within Coos Bay along the LNG carrier route), and two new buoys located near the access channel.

[23] The proposed modifications to the marine waterway (i.e., dredging at four points along the Federal Navigation Channel) are referred to as "marine waterway modifications" or "navigation channel modifications" in this EIS.

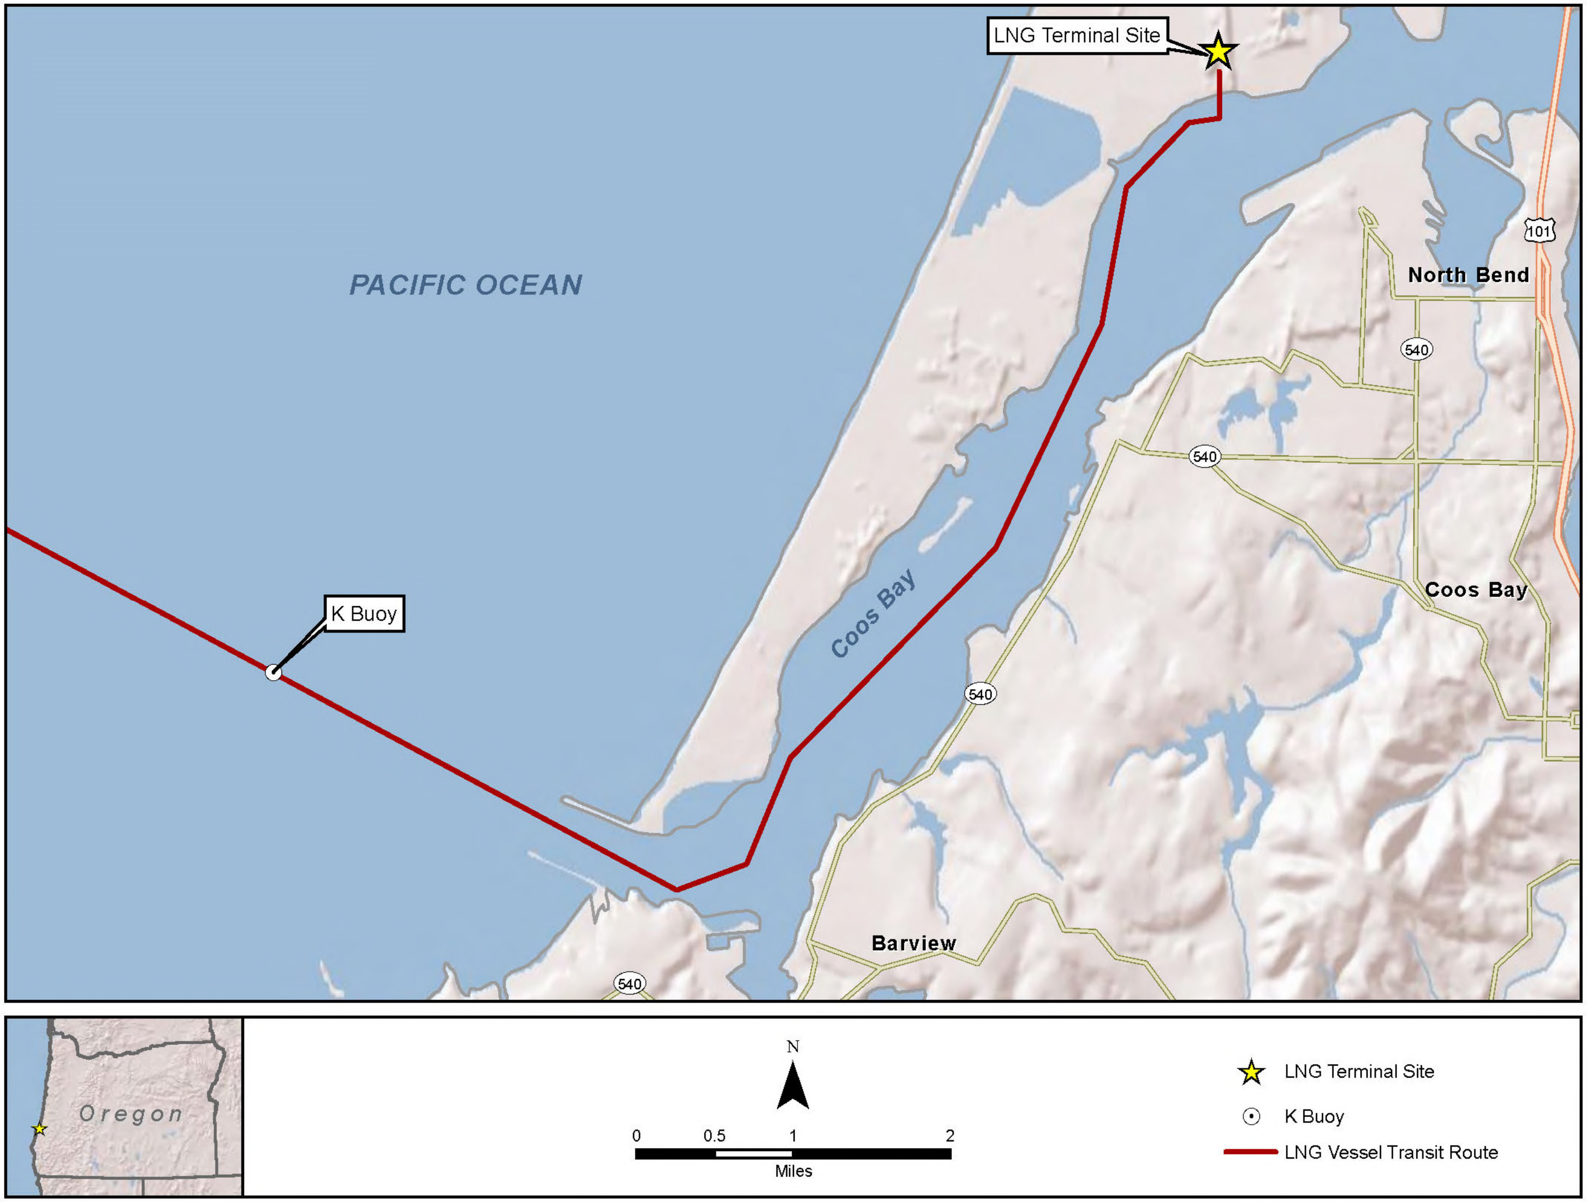

Figure 2.1-6
Proposed LNG Carrier Transit Route

2.1.1.7 Marine Access and Facilities

Access Channel

Jordan Cove would construct an access channel to connect the terminal to the Federal Navigation Channel (figure 2.1-7).[24] The access channel would begin at the confluence between the Jarvis Turn and the Upper Jarvis Range at about navigation channel mile (NCM) 7.5, and would be about 2,200 feet wide at the navigation channel and about 780 feet wide at the terminal. The distance from the north edge of the navigation channel to the mouth of the terminal would be about 700 feet. The walls of the access channel would be sloped to meet the existing bottom contours at an angle of 3 feet horizontal to one foot vertical (3:1). The access channel would be approximately 45 feet deep and would cover about 22 acres below the highest measured tide elevation of 10.3 feet (North American Vertical Datum of 1988 [NAVD88]).

Terminal Slip

Jordan Cove would construct a marine slip to support vessel operations at the north end of the access channel. This would be a single use slip that would be sized to provide flexibility to safely maneuver an LNG carrier from the access channel into the slip when another LNG carrier is already berthed on the east or west sides. The slip would also be sized to allow for tugs to move a temporarily disabled LNG carrier away from the loading berth on the east side of the slip to the emergency lay berth on the west side of the slip if necessary. The slip would be bounded on the east and west sides by sheet pile walls, creating a vertical face to support mooring structures. The northern side of the slip would be sloped to meet the existing bottom contours at an angle of 3 feet horizontal to one foot vertical (3:1). The minimum water depth within the slip would be -45 feet (NAVD88) in order to maintain at least 10 percent under-keel clearance when the ships are in dock. A berm/tsunami wall would also be constructed between the western edge of the slip and Henderson Marsh to approximate elevation +34.5 feet to increase tsunami resistance (figure 2.1-7).

Material Offloading Facility

The material offloading facility (MOF) would be constructed to receive components of the LNG terminal that are too large or heavy to be delivered by road or rail. The MOF would cover about 3 acres on the southeast side of the slip (see figure 2.1-7). The MOF would be constructed using the same sheet pile wall system as the LNG loading berth to an elevation approximately +13.0 feet (NAVD88). Following construction, the MOF would be retained as a permanent feature of the LNG terminal to support maintenance and replacement of large equipment components.

---

[24] The access channel and a portion of the marine slip would be within state waters managed by the ODSL. Jordan Cove would construct the access channel and would transfer responsibility for maintenance to the Oregon International Port of Coos Bay (Port) following construction. The Port has already obtained an easement from ODSL for operation and maintenance of the access channel and the in-water portion of the slip. Jordan Cove would reimburse the Port for costs associated with its operation and maintenance of the access channel and slip.

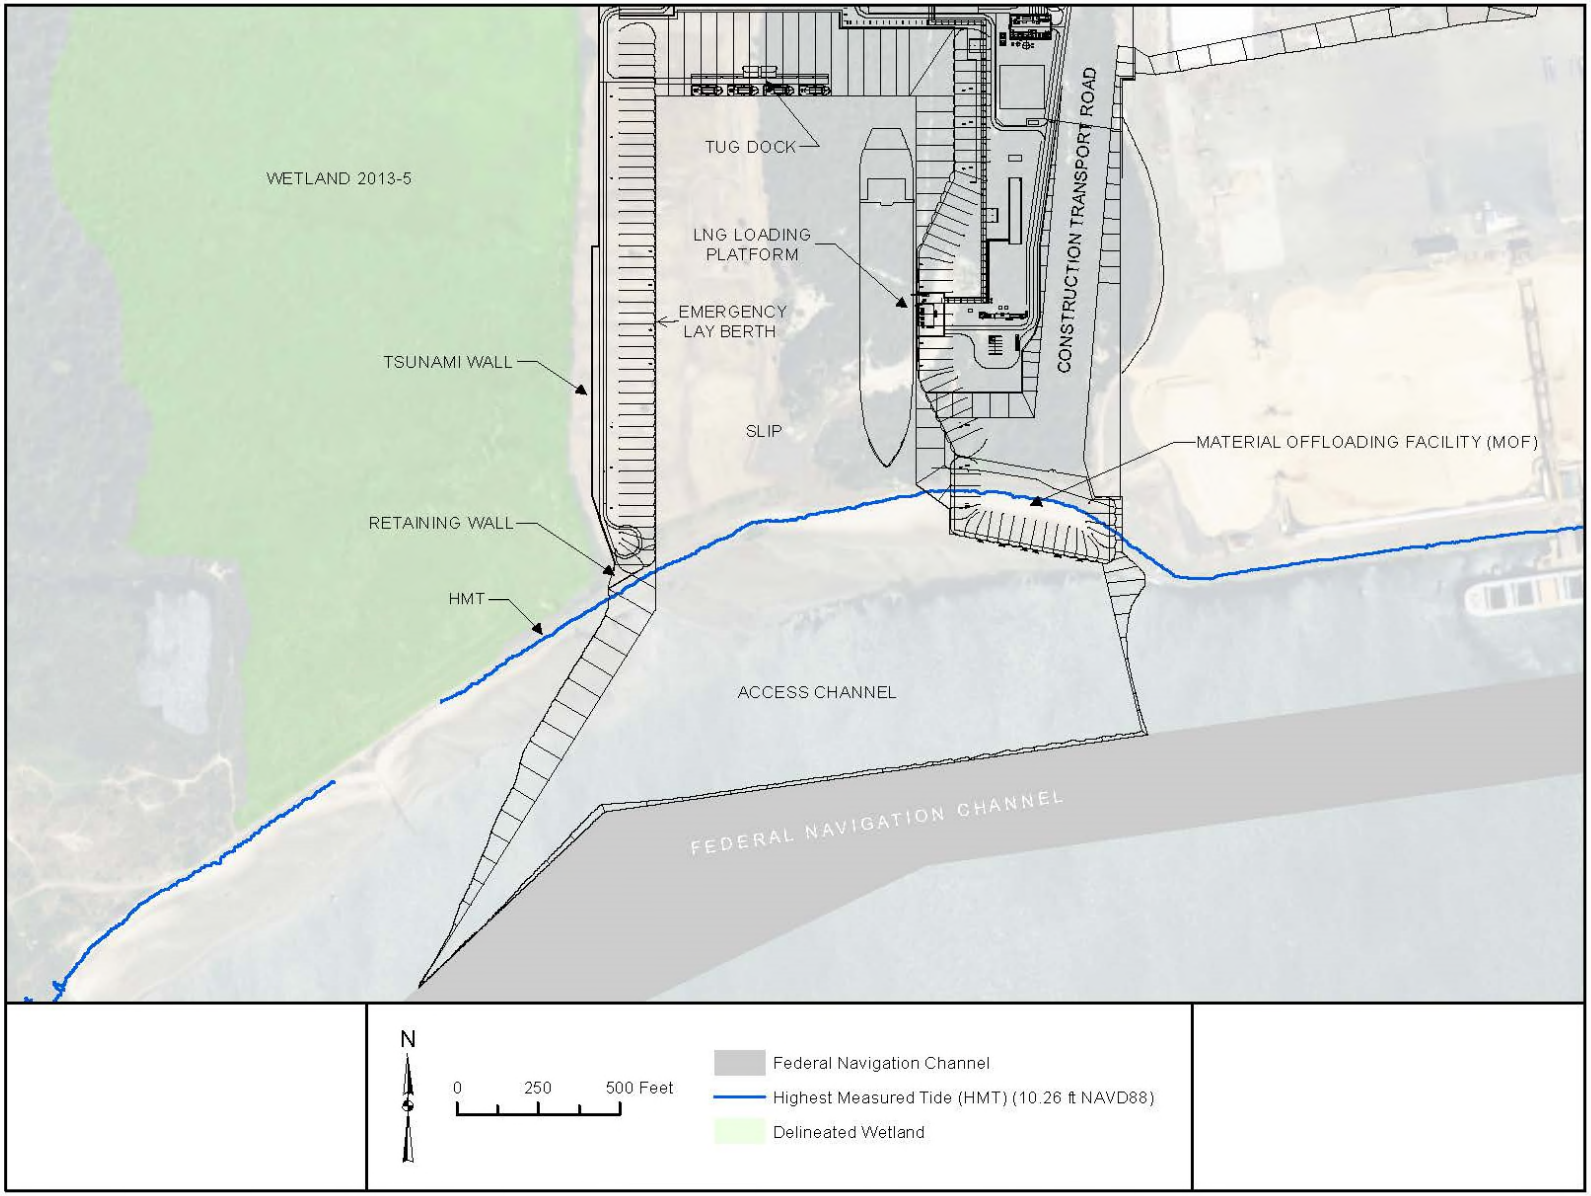

Figure 2.1-7
Plot Plan of the Marine Facilities

LNG Carrier Loading Berth and Product Loading Facility

An LNG carrier loading berth would occupy the eastern side of the slip. A profile of the loading berth is provided in figure 2.1-8. The loading berth would be constructed of steel sheet piles that support surface structures (the loading area) and provide the foundation for the breasting and mooring structures. The berth support wall would extend from the bottom of the slip (elevation approximately -45 feet) to approximate elevation +34.5 feet (NAVD88).[25]

The product loading facility (PLF), or LNG loading platform, would be a pile-supported concrete slab that provides structural support to the marine loading arms, terminal gangway, and other ancillary equipment at the berth. The PLF would be constructed on top of the sheet pile wall at approximate elevation +34.5 feet (NAVD88), with a foundation of reinforced concrete supported by steel pilings.

Emergency Lay Berth

An emergency vessel lay berth on the west side of the slip would be constructed to safely moor a temporarily non-operational LNG carrier (figure 2.1-7). This berthing facility would be supported by the west side sheet pile wall with a top-of-wall elevation of approximately +20 feet (NAVD 88). Support infrastructure would include an access road from the tug berth area, duct bank with cabling for powering the mooring hooks and capstans, and lighting of the ship access area.

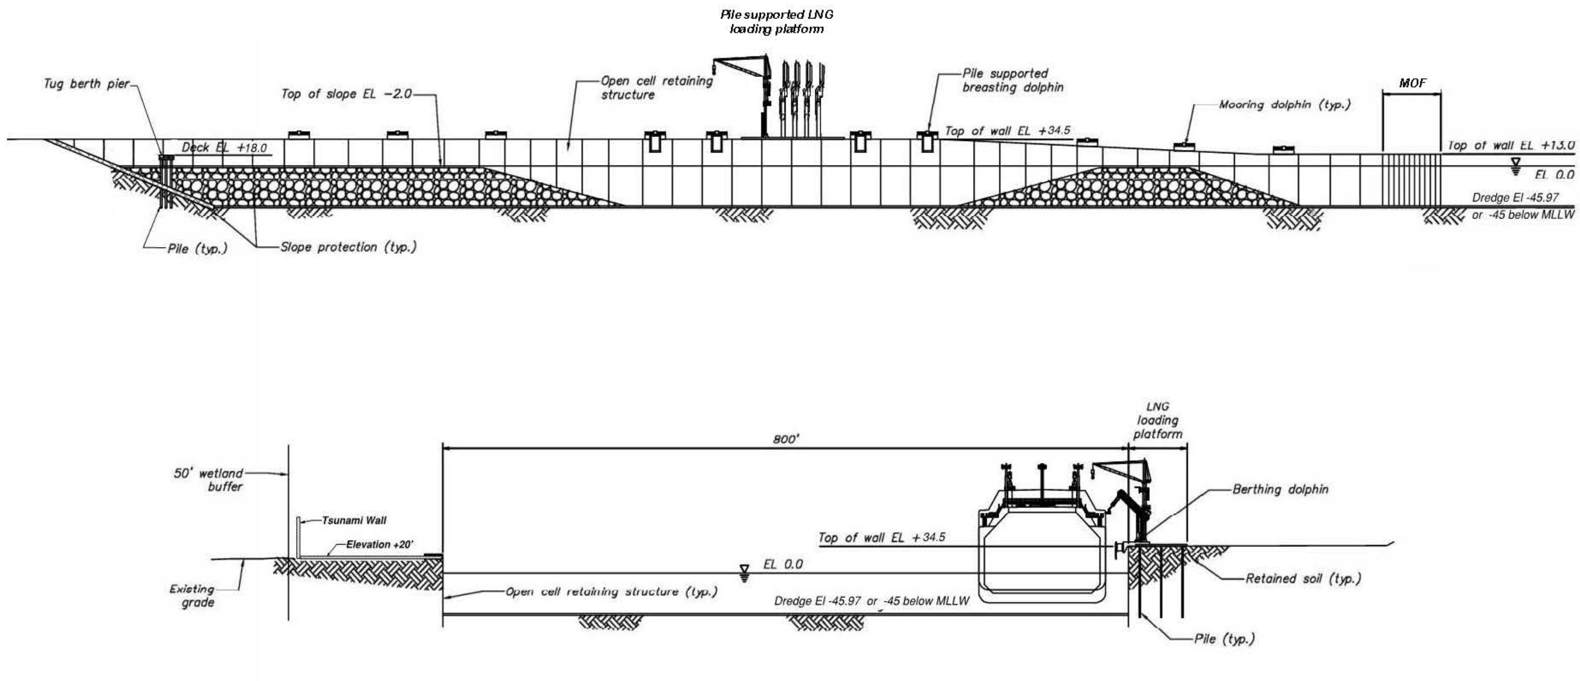
Tug and Escort Boat Berth

A berth, also referred to as a tug dock, would be constructed on the north side of the marine slip (figure 2.1-7) to accommodate up to four tugboats, two sheriff's escort boats, and six other visitor boats with similar characteristics as the sheriff's boats. This dock would be about 470 feet long and 18 feet wide and would be precast concrete supported by steel piles. The tug dock would be accessible from land by a pile-founded trestle. Included as part of the dock would be two boat houses. North of the dock would be a tug operator building.

LNG Marine Traffic

Section 2.1.1.6 defines the extent of the marine waterway. For the analysis in this EIS, and the corresponding BA and EFH Assessment specific to species covered by the ESA and MSA, we also considered impacts from LNG carrier marine traffic extending out to the edge of the Outer Continental Shelf. Jordan Cove estimated that it would take an LNG carrier between 1.5 hours (at 6 knots) and 2 hours (at 4 knots) to travel through the waterway from Buoy "K" to the terminal (a description of the LNG carriers is provided in section 2.2.1.). An additional 90 minutes would be necessary for the LNG carrier to be turned in the access channel and parked at the terminal berth, with the assistance of tug boats. The entire round-trip transit time for a single LNG carrier to travel from Buoy K through the waterway, turn and dock at the berth, take on a full cargo of LNG, and then exit the terminal slip and travel through the waterway back out to the open ocean past Buoy K would be about 22 hours.

[25] The slip and berth would be designed to accommodate LNG carriers as large as 217,000 m^3 in capacity.



All elevations are to the NAVD88 datum

NOT TO SALE

Figure 2.1-8
Profile of Marine Berth

Rock Apron

The COE expressed concern that erosion resulting from the Jordan Cove LNG Project's operation could result in impacts on Pile Dike 7.3 (located immediately west of the access channel) as well as the Project's slip. As a result, Jordan Cove would construct a rock apron west of the access channel to arrest slope migration, or equilibration, before it can progress to a condition that could potentially negatively impact Pile Dike 7.3 or the proposed slip. The design involves a 50-foot-wide by 3-foot-thick by approximately 1,100-foot long rock apron set back approximately 20 feet from the top (slope catch point) of the access channel side slope. The size of rock to be used is well graded 6-inch to 22-inch angular stone with a median size of 14 inches. The rock apron design also includes an approximately 100-foot-long extension of the slip's sheetpile bulkhead at the northwest corner of the access channel to minimize slope cut-back at this location. Total required rock volume is approximately 6,500 cy.

2.1.1.8 Dredged and Excavated Material Disposal

Dredging for the Marine Facilities

Dredging for the marine facilities, including the marine waterway modifications, would generate about 6.32 million cubic yards (mcy) of dredged and excavated material (see table 2.1.1.8-1). Of this, about 3.6 mcy would be dry excavated and then dredged in the fresh water pocket in the slip area and access channel behind an earthen berm that would remain in place to separate work prior to dredging activities in the bay. The remainder of the dredge material would be removed during open water dredging while exposed to the bay and Federal Navigation Channel.

TABLE 2.1.1.8-1

Materials Excavated and Dredged During Construction of LNG Terminal Marine Facilities

Area	Construction Phase	Volume (mcy)	Disposal Location
Slip	Excavation and Dredge Behind Berm	3.6	Ingram Yard, Corridor, South Dunes, Roseburg site
Slip	Salt Water Dredge	0.2	Ingram Yard, Corridor, South Dunes, Roseburg site
Protective Berm	Upland Excavation	0.03	Ingram Yard, Corridor, South Dunes
Protective Berm	Salt Water Dredge	0.5	Ingram Yard, Corridor, South Dunes, Kentuck Project
Access Channel	Upland Excavation	0.004	Ingram Yard, Corridor, South Dunes, Roseburg site
Access Channel	Salt Water Dredge	1.4	Ingram Yard, Corridor, South Dunes, Roseburg site
Marine Waterway Modifications	Salt Water Dredge	0.59	APCO Sites 1 and 2
	Total:	**6.32**	

Most of the material excavated and dredged during construction of the marine facilities would be used to raise the elevation of the terminal facilities above the tsunami inundation zone. Ingram Yard, the access and utility corridor, and the South Dunes portions of the site, including temporary use areas (see section 2.1.1.10), would receive material to raise their respective site elevations. Some material would also be deposited at the adjacent Roseburg Forest Products property, and at the Kentuck project mitigation site. Material dredged for the marine waterway modifications would be deposited at Al Pierce Company (APCO) Sites 1 and 2.

Dredging for the Marine Waterway Modifications

Approximately 590,000 cy of material would be excavated/dredged to complete the marine waterway modifications. Storage of the dredge material would be distributed between the APCO 1 and APCO 2 upland disposal sites (see figure 2.1-1), or placed entirely at APCO Site 2 if shown to be feasible.

Operational Maintenance Dredging

Jordan Cove proposes to conduct maintenance dredging about every 3 years with about 115,000 cy of material removed per dredging interval for the first 12 years of operation, and after that maintenance dredging could be done about every 5 years with up to 160,000 cy of materials removed during each dredging event.[26] For the marine waterway modification projects within the channel, maintenance dredging would also be conducted about every 3 years with about 27,900 cy of materials removed during each dredging event. Jordan Cove proposes to distribute maintenance dredge material between the upland APCO Sites 1 and 2 (see figure 2.1-3). Jordan Cove would be required to acquire a new permit from the COE if future dredge materials could not be distributed at the upland APCO Sites 1 and 2, due to unforeseen future conditions.

2.1.1.9 Mitigation Areas

Jordan Cove and Pacific Connector have identified several mitigation areas that are directly related to the proposed Project. These areas and associated mitigation actions are not under the jurisdiction of the Commission; however, because they are directly related to the proposed Project, we include them in this EIS where appropriate. Jordan Cove and Pacific Connector propose to mitigate the loss of wetlands that would result from both the Jordan Cove LNG and Pacific Connector Pipeline Projects through the Kentuck project (i.e., wetland impacts include permanent and temporary impacts and loss of aquatic resource types, functions and values; see section 4.3). The Kentuck project would cover about 140 acres on the eastern shore of Coos Bay at the mouth of Kentuck Slough (see figures 2.1-1 and 2.1-3). Formerly, this property was the Kentuck Golf Course, but it is currently owned by Jordan Cove. On August 30, 2016, the Coos County Board of County Commissioners granted Jordan Cove's request for a conditional use permit to allow for mitigation and restoration within this property.

Jordan Cove proposes to mitigate for the loss of aquatic vegetation via an eelgrass restoration program in Coos Bay, near the Southwest Oregon Regional Airport in North Bend, including establishing new eelgrass beds (see figures 2.1-1 and 2.1-3). Additional information about wetland impacts and mitigation is presented in section 4.3.3.

Jordan Cove developed three upland mitigation sites per recommendations from the ODFW in response to the mitigation policy set forth in OAR 635-415-0000 through 0025. The proposed upland habitat mitigation sites include the Panhandle site, the Lagoon site, and the North Bank site. The Panhandle site is approximately 133 acres and is located north of Trans-Pacific Parkway. The Lagoon site is approximately 320 acres and is located adjacent to the meteorological station. The North Bank site is approximately 156 acres and is located on the north bank of the Coquille River adjacent to the Bandon Marsh National Wildlife Refuge (NWR).

[26] Proposed maintenance dredge frequency and volume is based on a sedimentation study conducted by Jordan Cove and summarized in Jordan Cove's *Dredged Material Management Plan* filed as Appendix N.7 in Resource Report 7 as part of its September 2017 application to FERC.

2.1.1.10 Temporary Construction Use Areas

During construction of the LNG terminal, temporary use areas outside of the footprint of the permanent LNG terminal, would be required for equipment and material staging, dredge material disposal and transport, workforce housing, workforce parking, and road improvement. These facilities and their locations are shown on figures 2.1-1 and 2.1-3, and summarized below.

Laydown Yards

Jordan Cove would use several construction laydown areas immediately adjacent to the LNG terminal site, including at the north side of the Ingram Yard, within the Roseburg Forest Products property east of marine terminal facilities, and within the South Dunes portion of the site (figure 2.1-3). Jordan Cove would also use one laydown yard (Boxcar Hill) on the north side of the Trans-Pacific Parkway just north of the South Dunes portion of the site, one laydown yard (Port Laydown Site) within Port property about 2 miles south of the LNG terminal site, and two laydown yards across Coos Bay on North Point in North Bend (APCO Sites 1 and 2) (figures 2.1-1 and 2.1-3). The laydown yards would be used during construction to house construction offices, workforce lunchrooms, warehousing, equipment maintenance, and laydown of materials after delivery to the site.

Dredge Pipelines

During construction of the marine slip and access channel, a slurry pipeline and return water pipeline would be laid across the Roseburg Forest Products tract to the South Dunes portion of the site. A temporary dredge pipeline would also be laid adjacent to the Federal Navigation Channel (via a floating or submerged pipe) to transport dredge material from the four marine waterway modification sites to the APCO Sites 1 and 2, and a temporary dredge line would be laid between the Federal Navigation Channel and the Kentuck project site to transfer dredge material from marine transport barges to the disposal sites.

Workforce Housing

Jordan Cove proposes to construct a temporary workforce housing facility within the South Dunes portion of the LNG terminal site that could accommodate common facilities and 200 to 700 beds. Parking would be provided on-site, and shuttle buses would be provided to and from local communities to reduce traffic on the road network after working hours. After completion of construction and commissioning activities the entire facility would be decommissioned and removed from the site.

Off-Site Parking

To reduce construction traffic along U.S. Highway 101, Jordan Cove would establish a park-and-ride facility at the vacated Myrtlewood RV park near the community of Hauser, north of the U.S. Highway 101 McCullough Bridge (figures 2.1-1 and 2.1-3).[27] Jordan Cove would also provide dedicated buses to and from private RV parks, subject to demand, where those parks could house a large number of construction personnel. After construction of the terminal is completed, the off-site parking lot would be restored to pre-construction condition and use.

[27] Jordan Cove has indicated that they are working with local developers to identify a second park-and-ride that would be used for the Project. However, at this time the only park-and-ride that has been identified and filed with the FERC is the Myrtlewood RV park-and-ride.

2.1.2 Pacific Connector Pipeline and Associated Aboveground Facilities

The 36-inch-diameter, Pacific Connector natural gas pipeline would extend for about 229 miles across Klamath, Jackson, Douglas, and Coos Counties, Oregon and terminate at the proposed LNG export facility in Coos County (figure 1.1-1 in chapter 1). As identified in table D-1 in appendix D, the pipeline would be located adjacent to, but separated from, existing rights-of-way including powerlines, roads, and other pipelines for about 97.7 miles (43 percent).

The pipeline would have a design capacity of 1.2 Bcf/d of natural gas, with a maximum allowable operating pressure (MAOP) of 1,600 pounds per square inch gauge (psig).[28] The pipeline (and aboveground facilities) would be designed, constructed, tested, operated, and maintained to conform with USDOT requirements found in 49 CFR Part 192, *Transportation of Natural and Other Gas by Pipeline: Minimum Safety Standards*; the FERC requirements at 18 CFR 380.15, *Site and Maintenance Requirements*; and other applicable federal and state regulations. The location of the proposed pipeline Project facilities is shown on detailed maps included in appendix C and described below.

2.1.2.1 Aboveground Pipeline Facilities

New aboveground facilities would include one compressor station, 3 meter stations, 5 pig launcher/receiver assemblies, 17 mainline valves (MLV), and 15 communication towers (table 2.1.2.1-1).

TABLE 2.1.2.1-1

Pacific Connector Aboveground Facilities

Facility	MP	Operational Acres a/	County	Ownership/ Jurisdiction
Jordan Cove Meter Station, MLV #1, Pig Receiver, and Communication Tower	0.0	1.7	Coos	Private
MLV #2 (Boone Creek Road)	15.1	0.1	Coos	Private
MLV #3 (Myrtle Point Stikum Road)	29.5	0.1	Coos	Private
MLV #4 and Communication Tower (Deep Creek Spur)	48.6	0.1	Douglas	BLM
MLV #5 (South of Olalla Creek)	59.6	0.1	Douglas	Private
MLV #6 and Launcher/Receiver (Myrtle Creek)	71.5	0.5	Douglas	Private
MLV #7 (Pack Saddle Road)	80.0	0.1	Douglas	BLM
MLV #8 (Highway 227)	94.7	0.1	Douglas	Private
MLV #9 (BLM Road 33-2-12)	113.7	0.1	Jackson	Private
MLV #10 and Communication Tower (Shady Cove)	122.2	0.1	Jackson	Private
MLV #11, Communication Tower, and Launcher/Receiver (Butte Falls)	132.5	0.3	Jackson	Private
MLV #12 (Heppsie Mountain Quarry Spur)	150.7	0.1	Jackson	BLM
MLV #13 (Clover Creek Road)	169.5	0.1	Klamath	Private
MLV #14 and Launcher/Receiver (Keno)	187.4	0.4	Klamath	Private
MLV #15 and Communication Tower	196.5	0.1	Klamath	Private
MLV #16 and Communication Tower	211.6	0.1	Klamath	Private
Klamath Compressor Station, Klamath-Beaver and Klamath-Eagle Meter Stations, MLV #17, Pig Launcher, and Communications Tower	228.8	21.4	Klamath	Private
Blue Ridge Communication Tower	Approx. 20	0.2	Coos	BLM
Signal Tree Communication Tower	Approx. 45	0.2	Coos	BLM

[28] On October 5, 2018, Pacific Connector notified the Commission that it would use thicker pipe than initially proposed in order to increase the design pressure from 1,600 psig to 1,950 psig and allow for possible increased volume in the future, however the proposed MAOP remains at 1,600 psig. Any addition or change to the proposed psig would require additional review and approval from the FERC, and is not covered within the scope of the EIS.

TABLE 2.1.2.1-1 (continued)

Pacific Connector Aboveground Facilities

Facility	MP	Operational Acres a/	County	Ownership/ Jurisdiction
Sheep Hill Communication Tower	Approx. 70	0.2	Douglas	Private
Harness Mountain Communication Tower	Approx. 75	0.0	Douglas	Private
Starveout Communication Tower	Approx. 115	0.2	Douglas	Private
Flounce Rock Communication Tower	Approx. 123	0.2	Jackson	BLM
Robinson Butte Communication Tower	Approx. 159	0.2	Jackson	Forest Service
Stukel Mountain Communication Tower b/	Approx. 209	0.2	Klamath	BLM

a/ Values are rounded to the nearest tenth of an acre.
b/ Assumes that existing BLM communication Site Plan is sufficient. If not, supplemental environmental compliance may be required.

Meter Stations

The Jordan Cove Meter Station would be located within the South Dunes portion of the terminal. The meter station would be comprised of one building which would house gas chromatographs, moister analyzer, communication equipment, and flow computer. A canopy would also be installed to cover the control valves and ultrasonic meters. The Jordan Cove Meter Station would also include an MLV, a pig launcher/receiver, and a 140-foot-high steel communication tower. The station would be enclosed by a 7-foot-high chain-link fence, and the interior of the yard would be graveled.

The Klamath-Beaver and the Klamath-Eagle Meter Stations would be co-located within the fenced boundaries of the Klamath Compressor Station at about MP 228.8. The Klamath-Beaver Meter Station would include an interconnection with the existing GTN pipeline system; while the Klamath-Eagle Meter Station would serve as the interconnect with the existing Ruby pipeline system.

Klamath Compressor Station

The Klamath Compressor Station would be located approximately 1.8 miles northeast of the town of Malin, at the eastern terminus of the Pacific Connector pipeline, and would be accessible from Malin Loop and Morelock Roads. The station would include the Klamath-Eagle and Klamath-Beaver Meter Stations and would be located adjacent to the existing GTN Malin/Tuscarora Gas Transmission Company (Tuscarora) Meter Station and the Ruby Turquoise Flats facility.

The compressor station would include 62,200 International Organization for Standardization (ISO) hp of new compression and a 31,100 ISO hp standby compressor unit, consisting of turbine-driven, natural gas fired centrifugal compressor units. Other facilities would include an inlet filter/separator, lube oil cooler, inlet air silencer/cleaner, exhaust system, and gas coolers. The compressor building would include skid-mounted fuel gas conditioning, measuring, and regulation equipment. Related suction and discharge headers and piping would be installed between the pipeline and the compressor units. Other buildings inside the station would include a control room/ancillary equipment building and unit valve skid buildings. The ancillary equipment building would include an air compressor system, hot water boiler, and back-up generator. A high-pressure vent system with a silencer would be installed to allow the compressor to be blown down. There would also be a small office in one of the buildings and the station would contain aboveground pig launcher/receiver equipment, an MLV, and a 140-foot-high communication tower. The compressor station would be secured by a 7-foot-high chain-link fence.

The Klamath Compressor Station would be utilized as a maintenance base for operation of the pipeline facilities. The station would not be manned 24 hours per day, but would have emergency pipe, spare parts, and equipment and tools stored on site.

Mainline Block Valves

Pacific Connector would install 17 MLVs along its pipeline in compliance with USDOT requirements (CFR 192.179) (see table 2.1.2.1-1). The MLVs would be within the construction and operational right-of-way for the pipeline, except for the MLVs at meter stations, the compressor station, and that include pig launchers and receivers. Five of the MLVs would be automated to allow remote operation, which would require a 40-foot communication tower to be installed within the facility's fenced footprint.

Pig Launchers/Receivers

Pig launchers and receivers would allow Pacific Connector to maintain the interior of its pipeline using remotely operated pipe inspection and cleaning tools (known as "pigs"). A pig launcher would be located within the proposed Klamath Compressor Station, and a pig receiver would be installed at the proposed Jordan Cove Meter Station. There would also be pig launcher and receivers at MLVs #6, #11, and #14. The pig launcher and receiver facilities would be fenced at all locations.

Gas Control Communications

The meter stations and compressor station would require a communications link with the gas control monitoring system. New radio towers are proposed at the Jordan Cove Meter Station, the Klamath Falls Compressor Station, and at five MLVs. Pacific Connector has conducted initial communications studies and determined that leased space on eight existing communication towers would also be needed for gas control communications (see table 2.1.2.1-2 and figure 1.1-1). For the five locations on federal lands, Pacific Connector prepared a *Communication Facilities Plan* (dated January 2013) as part of its POD.

TABLE 2.1.2.1-2

Proposed and Existing Gas Control Communication Towers

Facility	County	Landowner	Tower Height (ft)	Operational Acres a/
Proposed New Towers Within Proposed Aboveground Facility Sites				
Jordan Cove Meter Station b/	Coos	Private (Pacific Connector)	140	1.7 c/
MLV #4	Douglas	BLM	40	0.1
MLV #10	Jackson	Private	40	0.1
MLV #11, Launcher/Receiver (Butte Falls)	Jackson	Private	40	0.3
MLV #15 (Klamath River)	Klamath	Private	40	0.1
MLV #16 (Hill Road)	Klamath	Private	40	0.1
Klamath Compressor Station	Klamath	Private (Pacific Connector)	140	17
Existing Communication Tower Sites d/				
Blue Ridge	Coos	BLM (Coos District)	170	0.2
Signal Tree (Kenyon Mt.)	Coos	BLM (Coos District)	120	0.2
Sheep Hill	Douglas	Private	125	0.2
Harness Mountain e/	Douglas	Private (Northwest Pipeline)	150	0.0
Starveout Communication	Jackson	Private	115	0.2
Flounce Rock	Jackson	BLM (Medford District)	120	0.2

TABLE 2.1.2.1-2 (continued)

Proposed and Existing Gas Control Communication Towers

Facility	County	Landowner	Tower Height (ft)	Operational Acres a/
Robinson Butte	Jackson	Forest Service (Rogue River National Forest)	125	0.2
Stukel Mountain	Klamath	BLM (Lakeview District)	100	0.2

a/ Acreages are rounded to the nearest 0.1 acre.
b/ A tower at this site would only be necessary if Pacific Connector is unable to mount an antenna on one of the structures within the LNG terminal site.
c/ The towers at meter or compressor stations and MLVs would be within the fenced operational area of the facilities.
d/ Space would be leased on an existing tower, or a new tower and equipment building installed if lease space is not available. Operational acres column assumes worst case.
e/ Communication equipment would be installed on an existing tower.

2.1.3 BLM and Forest Service Land Management Plan Amendment Actions

2.1.3.1 Proposed Amendments of the BLM Districts RMPs

Approximately 46.9 miles of the proposed Pacific Connector pipeline route would cross federal land administered by BLM Coos Bay, Roseburg, and Medford Districts and the Klamath Falls Field Office of the Lakeview District.

Similar to a county zoning ordinance, projects or activities that occur on BLM lands must be consistent with the respective RMP where the project or activity occurs. The proposed Right-of-Way for the Project on BLM-managed lands would not conform to the Southwestern Oregon RMP and the Northwestern and Coastal RMP (RMPs for Western Oregon). The RMPs for Western Oregon allow for the construction of linear rights-of-way within the LSR "as long as northern Spotted Owl (NSO) nesting-roosting habitat continues to support nesting and roosting at the stand level, and NSO dispersal habitat continues to support movement and survival at the landscape level," and construction of linear rights-of-way "as long as the occupied stand continues to support marbled murrelet nesting" (BLM 2016b: 71; BLM 2016a: 65). BLM staff initially evaluated that the proposed right-of-way would cross approximately 268 acres of LSR and approximately 116 acres of known or presumed occupied marbled murrelet (MAMU) habitat and/or NSO nesting-roosting habitat within LSR. Additional analysis concluded that the clearing and removal of vegetation required within the LSR for the proposed Project would likely result in some NSO habitat no longer continuing to support nesting and roosting at the stand level, and some MAMU habitat no longer continuing to support nesting at the stand level.

BLM management direction in the RMPs for Western Oregon specific to wildlife prohibits activities that "*disrupt marbled murrelet nesting at occupied sites ... within all land use allocations within 35 miles of the Pacific Coast and... within reserved land use allocation between 35-50 miles of the Pacific Coast*" (BLM 2016b:118; BLM 2016a: 98). BLM staff concluded that construction of the Project would likely result in disruption of MAMU nesting at some occupied sites within these two discrete geographic ranges.

In order to consider the Right-of-Way Grant, the BLM must address these inconsistencies by amending the affected RMPs to make provisions for the Project. BLM therefore proposes to amend the RMPs to re-allocate all lands within the proposed temporary use area and right-of-way to a District-Designated Reserve, with management direction to manage the lands for the purposes of the Pacific Connector Gas Pipeline Right-of-Way. Approximately 885 acres would be re-allocated. District-Designated Reserve allocations establish specific management for a specific use or to protect specific values and resources. Other uses that are compatible with the purpose of the District-Designated Reserve may be authorized.

District-Designated Reserve is an existing land use allocation in both the Northwestern and Coastal Oregon RMP and the Southwestern Oregon RMP. Under these RMPs, District-Designated Reserves encompass a wide variety of lands, including constructed facilities, infrastructure, roads, communication sites, seed orchards, quarries, lands biologically or physically unsuitable for timber production, Areas of Critical Environmental Concern (ACEC), and lands managed for their wilderness characteristics. District-Designated Reserves are reserved from sustained-yield timber production in order to manage them for another set of specific values and resources. Within the District-Designated Reserve, the BLM would maintain the values and resources necessary for construction, operation, maintenance, and decommissioning of the proposed Project.

Specifically, BLM proposes to add the following text to the RMPs for Western Oregon (BLM 2016a:59; BLM 2016b: 57):

<u>District-Designated Reserve – Pacific Connector Gas Pipeline</u>

Management Objectives

- See *District-Designated Reserves* management objectives.
- Maintain the values and resources for which the BLM has granted the right-of-way for the Pacific Connector Gas Pipeline Project.

Management Direction

- Allow the construction, operation, maintenance, and decommissioning of the Pacific Gas Connector Pipeline, notwithstanding the restrictions and requirements of management direction described for resource programs.

The Project-specific amendment would not change RMP requirements for other projects or authorize any other actions. Therefore, resource impacts of the proposed plan amendments are those associated with construction, operation, maintenance and decommissioning of the proposed pipeline. With this amendment, the granting of a ROW on BLM-managed lands for the Pacific Connector Project would conform to the Southwestern Oregon Record of Decision and Resource Management Plan (BLM 2016b) and the Northwestern and Coastal Oregon ROD and RMP (BLM 2016a).

Amendment Approaches Considered

Four different approaches were considered to address the identified plan conformance issues. Three were evaluated and determined to have resource and management impacts beyond those associated with the direct, indirect, induced and cumulative effects of construction, operation, maintenance, and decommissioning the proposed Project.

<u>Change Management Direction for LSR, NSO, and MAMU to Accommodate Rights-of-Way</u>

The BLM considered eliminating the requirement that rights-of way maintain NSO nesting-roosting habitat function and continue to support MAMU nesting in occupied stands within LSR at the stand level and removing the prohibition on activities that disrupt MAMU nesting at occupied sites within 35 miles of the Pacific coast. Similar rights-of-way that may be proposed in the future would conform with plan direction for LSR, NSO, and MAMU.

No projects of a similar nature have been proposed. However, this approach would reduce protections for LSR, NSO, and MAMU provided by the RMPs for Western Oregon throughout the LSR land use allocation and in all allocations within 35 miles of the Pacific coast, and could substantially alter the effects analysis conducted by the BLM for NSO and MAMU in the two RMPs for western Oregon. This alternative could trigger re-initiation of ESA consultation on BLM RMPs for western Oregon.

This amendment approach would generate environmental effects beyond those associated with the construction, operation, maintenance, and decommissioning of the proposed Project pipeline and is beyond the scope of the application submitted by the proponent and currently under consideration by the BLM. For these reasons, the BLM determined that this amendment approach would not meet the BLM's purpose and need. This amendment approach was not analyzed in further detail.

<u>Change Management Direction for LSR, NSO, and MAMU at Specific Locations</u>

The BLM considered amendments to the RMPs for Western Oregon to specifically exempt the proposed Project from management direction for LSR, NSO, and MAMU in with known conformance problems (known MAMU occupied stands, existing MAMU nesting habitat, and existing NSO nesting-roosting habitat). This amendment approach would not create environmental effects beyond those associated with construction, operation, maintenance, and decommissioning of the proposed Project. However, unanticipated or currently unknown conformance problems, such as newly identified MAMU occupied stands, could arise which would require additional amendments and supplemental analysis following completion of the FERC-prepared EIS.

This amendment approach presents a risk that could require additional amendments and supplemental analysis, and would result in identical environmental effects if the proposed Project right-of-way is granted. For these reasons, the BLM determined that this amendment approach is substantially similar to the proposed action and would not fulfill the BLM's commitment as a cooperating agency in the preparation of the EIS should supplemental analysis be required. This amendment approach was not analyzed in further detail.

<u>Designate All Lands within the Proposed Right-of-Way as a Right-of-Way Corridor</u>

Designation of a Right-of-Way Corridor under 43 CFR 2806 would be for the purpose of construction, operation, maintenance, and decommissioning of the proposed Project. Designated Rights-of-Way Corridors are typically 1,000 to 2,000 feet in width and designed to encourage co-location of additional facilities in the future. Designating a Right-of-Way Corridor would require an analysis of reasonably foreseeable projects that could be co-located in the future and could substantially alter the effects analysis conducted by the BLM for NSO and MAMU in the two RMPs for western Oregon. This amendment approach could trigger re-initiation of ESA consultation on BLM RMPs for Western Oregon.

This amendment approach would generate environmental effects beyond those associated with the construction, operation, maintenance, and decommissioning of the proposed Project pipeline and is beyond the scope of the application submitted by the proponent and currently under consideration by the BLM. For these reasons, the BLM determined that this amendment approach would not meet the BLM's purpose and need. This amendment approach was not analyzed in further detail.

2.1.3.2 Proposed Amendments of National Forest LRMPs

Approximately 30.6 miles of the Pacific Connector pipeline route would cross NFS lands administered by the Umpqua, Rogue River, and Winema National Forests (see figure 1.1-2). NFS lands are managed according to current LRMPs. Similar to a county zoning ordinance, projects or activities that occur on NFS lands must be consistent with the respective LRMP where the project or activity occurs. As proposed, the Pacific Connector Pipeline Project would not be consistent with certain provisions of the affected Forest Service LRMPs. Before the Forest Service can consent to the BLM Right-of-Way Grant application, the Forest Service must amend the affected LRMPs to make provisions for the Pacific Connector Project. With the exception of amendments to reallocate Matrix lands to LSR, the LRMP amendments described below are specific to the Pacific Connector Pipeline Project. The project-specific amendments would not change LRMP requirements for other projects or authorize any other actions. With these amendments, the Pacific Connector Pipeline Project would be a conforming use of the affected National Forests.

In addition to the proposed amendments specific for each National Forest described in the sections below, table 2.1.3.2-1 describes the proposed amendments that would apply to all three National Forests.

TABLE 2.1.3.2-1

Forest Service LRMP Amendments Associated with the Pacific Connector Pipeline Project that Apply to the Umpqua, Rogue River, and Winema National Forests

Amendment #	Amendment	Description
FS-1	Project-Specific Amendment to Exempt Management Recommendations for Survey and Manage Species on the Umpqua, Rogue River and Winema National Forests:	These National Forest LRMPs would be amended to exempt certain known sites within the area of the proposed Pacific Connector right-of-way grant from the Management Recommendations required by the 2001 "Record of Decision and Standards and Guidelines for Amendments to the Survey and Manage, Protection Buffer, and other Mitigation Measures Standards and Guidelines. For known sites within the proposed right-of-way that cannot be avoided, the 2001 Management Recommendations for protection of known sites of Survey and Manage species would not apply. For known sites located outside the proposed right-of-way but with an overlapping protection buffer only that portion of the buffer within the right-of-way would be exempt from the protection requirements of the Management Recommendations. Those Management Recommendations would remain in effect for that portion of the protection buffer that is outside of the right of way. The proposed amendment would not exempt the Forest Service from the requirements of the 2001 Survey and Manage Record of Decision, as modified, to maintain species persistence for affected Survey and Manage species within the range of the northern spotted owl. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The amendment would provide an exception from these standards for the Pacific Connector Project and include specific mitigation measures and project design requirements for the project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.9(a)(2)(ii) – [the plan must include plan components to maintain or restore] "Rare aquatic and terrestrial plant and animal communities." § 219.9(b)(1) – "The responsible official shall determine whether or not the plan components required by paragraph (a) provide ecological conditions necessary to: …maintain viable populations of each species of conservation concern within the plan area."

2.1.3.3 Proposed Amendments Specific to the Umpqua National Forest LRMP

The Forest Service proposes to amend the Umpqua National Forest LRMP. The proposed amendments are described in table 2.1.3.3-1.

TABLE 2.1.3.3-1

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Umpqua National Forest

Amendment #	Amendment	Description
UNF-1	Project-Specific Amendment to Allow Removal of Effective Shade on Perennial Streams:	The Umpqua National Forest LRMP would be amended to exempt the Standards and Guidelines for Fisheries (Umpqua National Forest LRMP, page IV-33, Forest-Wide) to allow the removal of effective shading vegetation where perennial streams are crossed by the Pacific Connector right-of-way. This change would potentially affect an estimated total of three acres of effective shading vegetation at approximately five perennial stream crossings in the East Fork of Cow Creek subwatershed from pipeline mileposts (MP) 109 to 110 in Sections 16 and 21, T.32S., R.2W., W.M., OR. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(3)(i) – The plan must include plan components "to maintain or restore the ecological integrity of riparian areas in the plan area, including plan components to maintain or restore structure, function, composition, and connectivity."
UNF-2	Project-Specific Amendment to Allow the Pacific Connector Pipeline Project in Riparian Areas	The Umpqua National Forest LRMP would be amended to change prescriptions C2-II (LRMP IV-173) and C2-IV (LRMP IV-177) to allow the Pacific Connector pipeline route to run parallel to the East Fork of Cow Creek for approximately 0.1 mile between about pipeline MPs 109.5 and 109.6 in Section 21, T.32S., R.2W., W. M., OR. This change would potentially affect approximately one acre of riparian vegetation along the East Fork of Cow Creek. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(3)(i) – The plan must include plan components "to maintain or restore the ecological integrity of riparian areas in the plan area, including plan components to maintain or restore structure, function, composition, and connectivity"
UNF-3	Project-Specific Amendment to Exempt Limitations on Detrimental Soil Conditions within the Pacific Connector Right-of-Way in All Management Areas:	The Umpqua National Forest LRMP would be amended to exempt limitations on the area affected by detrimental soil conditions from displacement and compaction within the Pacific Connector right-of-way. Standards and Guidelines for Soils (LRMP page IV-67) requires that not more than 20 percent of the project area have detrimental compaction, displacement, or puddling after completion of a project. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(2)(ii) – [The plan must include plan components to maintain or restore] "soils and soil productivity, including guidance to reduce soil erosion and sedimentation."

TABLE 2.1.3.3-1 (continued)

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Umpqua National Forest

Amendment #	Amendment	Description
UNF-4	Reallocation of Matrix Lands to LSR	The Umpqua National Forest LRMP would be amended to change the designation of approximately 585 acres from Matrix land allocations to the LSR land allocation in Sections 7, 18, and 19, T.32S., R.2W.; and Sections 13 and 24, T.32S., R.3W., W.M., OR. This change in land allocation is proposed to partially mitigate the potential adverse impact of the Pacific Connector Pipeline Project on LSR 223 on the Umpqua National Forest. This is a plan level amendment that would change future management direction for the lands reallocated from Matrix to LSR. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(1)(i) – [the plan must include plan components to maintain or restore] "Interdependence of terrestrial and aquatic ecosystems in the plan area." § 219.8(b)(1) – [the plan must include plan components to guide the plan area's contribution to social and economic sustainability] "Social, cultural and economic conditions relevant to the area influenced by the plan." § 219.9(b)(1) "The responsible official shall determine whether or not the plan components required by paragraph (a) of this section provide the ecological conditions necessary to: contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and maintain a viable population of each species of conservation concern within the plan area," and § 219.9(a)(2)(ii) – [the plan must include plan components to maintain or restore] "Rare aquatic and terrestrial plant and animal communities."

If any of the proposed amendments to the Umpqua National Forest LRMP described above are determined to be "directly related" to a substantive rule requirement, the Responsible Official must apply that requirement within the scope and scale of the proposed amendment and, if necessary, make adjustments to the proposed amendment to meet the rule requirement (36 CFR 219.13 (b)(5) and (6)).

2.1.3.4 Proposed Amendments Specific to the Rogue River National Forest LRMP

The Forest Service proposes to amend the Rogue River National Forest LRMP. The proposed amendments are described in table 2.1.3.4-1.

TABLE 2.1.3.4-1

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Rogue River National Forest

Amendment #	Amendment	Description
RRNF-2	Project Specific Amendment of Visual Quality Objectives (VQO) on the Big Elk Road:	The Rogue River National Forest LRMP would be amended to change the VQO where the Pacific Connector pipeline route crosses the Big Elk Road at about pipeline MP 161.4 in Section 16, T.37S., R.4E., W.M., OR, from Foreground Retention (Management Strategy 6, LRMP page 4-72) to Foreground Partial Retention (Management Strategy 7, LRMP page 4-86) and allow 10-15 years for the amended VQO to be attained. The existing Standards and Guidelines for VQO in Foreground Retention where the Pacific Connector pipeline route crosses the Big Elk Road require that VQOs be met within one year of completion of the project and that management activities not be visually evident. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment that would apply only to the Pacific Connector Pipeline Project in the vicinity of Big Elk Road and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.10(a)(1) – […the responsible official shall consider: …] "(1) Aesthetic values,… scenery,... viewsheds...". § 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities,…and scenic character…"
RRNF-3	Project-Specific Amendment of VQO on the Pacific Crest Trail:	The Rogue River National Forest LRMP would be amended to change the VQO where the Pacific Connector pipeline route crosses the Pacific Crest Trail at about pipeline MP 168 in Section 32, T.37S., R.5E., W.M., OR, from Foreground Partial Retention (Management Strategy 7, LRMP page 4-86) to Modification (USDA Forest Service Agricultural Handbook 478) and to allow 15-20 years for amended VQOs to be attained. The existing Standards and Guidelines for VQOs in Foreground Partial Retention in the area where the Pacific Connector pipeline route crosses the Pacific Crest Trail require that visual mitigation measures meet the stated VQO within three years of the completion of the project and that management activities be visually subordinate to the landscape. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment that would apply only to the Pacific Connector Pipeline Project in the vicinity of the Pacific Crest Trail and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.10(a)(1) – […the responsible official shall consider: …] "(1) Aesthetic values,… scenery,... viewsheds...". § 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities,…and scenic character…"

TABLE 2.1.3.4-1 (continued)

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Rogue River National Forest

Amendment #	Amendment	Description
RRNF-4	Project-Specific Amendment of Visual Quality Objectives Adjacent to Highway 140:	The Rogue River National Forest LRMP would be amended to allow 10-15 years to meet the VQO of Middleground Partial Retention between Pacific Connector pipeline MPs 156.3 to 156.8 and 157.2 to 157.5 in Sections 11 and 12, T.37S., R.3E., W.M., OR. Standards and Guidelines for Middleground Partial Retention (Management Strategy 9, LRMP Page 4-112) require that VQOs for a given location be achieved within three years of completion of the project. Approximately 0.8 miles or 9 acres of the Pacific Connector right-of-way in the Middleground Partial Retention VQO visible at distances of 0.75 to 5 miles from State Highway 140 would be affected by this amendment. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment that would apply only to the Pacific Connector Pipeline Project in Sections 11 and 12, T.37S., R.3E., W.M., OR, and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.10(a)(1) – […the responsible official shall consider: …] "(1)Aesthetic values,… scenery,... viewsheds...". § 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities, . . . and scenic character...".
RRNF-5	Project-Specific Amendment to Allow the Pacific Connector Pipeline Project in Management Strategy 26, Restricted Riparian Areas:	The Rogue River National Forest LRMP would be amended to allow the Pacific Connector right-of-way to cross the Restricted Riparian land allocation. This would potentially affect approximately 2.5 acres of the Restricted Riparian Management Strategy at one perennial stream crossing on the South Fork of Little Butte Creek at about pipeline MP 162.45 in Section 15, T.37S., R.4E., W.M., OR. Standards and Guidelines for the Restricted Riparian land allocation prescribe locating transmission corridors outside of this land allocation (Management Strategy 26, LRMP page 4-308,). The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a site-specific amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(3)(i) – The plan must include plan components "to maintain or restore the ecological integrity of riparian areas in the plan area, including plan components to maintain or restore structure, function, composition, and connectivity"
RRNF-6	Site-Specific Amendment to Exempt Limitations on Detrimental Soil Conditions within the Pacific Connector Right-of-Way in All Management Areas:	The Rogue River National Forest LRMP would be amended to exempt limitations on areas affected by detrimental soil conditions from displacement and compaction within the Pacific Connector right-of-way in all affected Management Strategies. Standards and Guidelines for detrimental soil impacts in affected Management Strategies require that no more than 10 percent of an activity area should be compacted, puddled or displaced upon completion of project (not including permanent roads or landings). No more than 20 percent of the area should be displaced or compacted under circumstances resulting from previous management practices including roads and landings. Permanent recreation facilities or other permanent facilities are exempt (RRNF LRMP 4-41, 4-83, 4-97, 4-123, 4-177, 4-307). The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(2)(ii) – [The plan must include plan components to maintain or restore] "soils and soil productivity, including guidance to reduce soil erosion and sedimentation."

TABLE 2.1.3.4-1 (continued)

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Rogue River National Forest

Amendment #	Amendment	Description
RRNF-7	Reallocation of Matrix Lands to LSR	The Rogue River National Forest LRMP would be amended to change the designation of approximately 522 acres from Matrix land allocations to the LSR land allocation in Section 32, T.36S., R.4E. W.M., OR. This change in land allocation is proposed to partially mitigate the potential adverse impact of the Pacific Connector Pipeline Project on LSR 227 on the Rogue River National Forest. This is a plan level amendment that would change future management direction for the lands reallocated from Matrix to LSR. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(1)(i) – [the plan must include plan components to maintain or restore] "Interdependence of terrestrial and aquatic ecosystems in the plan area." § 219.8(b)(1) – [the plan must include plan components to guide the plan area's contribution to social and economic sustainability] "Social, cultural and economic conditions relevant to the area influenced by the plan." § 219.9(b)(1) "The responsible official shall determine whether or not the plan components required by paragraph (a) of this section provide the ecological conditions necessary to: contribute to the recovery of federally listed threatened and endangered species, conserve proposed and candidate species, and maintain a viable population of each species of conservation concern within the plan area", and § 219.9(a)(2)(ii)– [the plan must include plan components to maintain or restore: …] "(ii) Rare aquatic and terrestrial plant and animal communities".

If any of the proposed amendments to the Rogue River National Forest LRMP described above are determined to be "directly related" to a substantive rule requirement, the Responsible Official must apply that requirement within the scope and scale of the proposed amendment and, if necessary, make adjustments to the proposed amendment to meet the rule requirement (36 CFR 219.13 (b)(5) and (6)).

2.1.3.5 Proposed Amendments Specific to the Winema National Forest LRMP

The Forest Service proposes to amend the Winema National Forest LMRP. The proposed amendments are described in table 2.1.3.5-1.

TABLE 2.1.3.5-1

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Winema National Forest

Amendment #	Amendment	Description
WNF-1	Project -Specific Amendment to Allow Pacific Connector Pipeline Project in Management Area 3:	The Winema National Forest LRMP would be amended to change the Standards and Guidelines for Management Area 3 (MA-3) (LRMP page 4-103-4, Lands) to allow the 95-foot-wide Pacific Connector pipeline project in MA-3 from the Forest Boundary in Section 32, T.37S., R.5E., W.M., OR, to the Clover Creek Road corridor in Section 4, T.38S, R.5. E., W.M., OR. Standards and Guidelines for MA-3 state that the area is currently an avoidance area for new utility corridors. This proposed Pacific Connector Pipeline Project is approximately 1.5 miles long and occupies approximately 17 acres within MA-3. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.10(a)(1) – [the responsible official shall consider] "Aesthetic values,… scenery,... viewsheds...". § 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities,…and scenic character…"

TABLE 2.1.3.5-1 (continued)

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Winema National Forest

Amendment #	Amendment	Description
WNF-2	Project-Specific Amendment of VQO on the Dead Indian Memorial Highway:	The Winema National Forest LRMP would be amended to allow 10-15 years to achieve the VQO of Foreground Retention where the Pacific Connector right-of-way crosses the Dead Indian Memorial Highway at approximately pipeline MP 168.8 in Section 33, T.37S., R.5E., W. M., OR. Standards and Guidelines for Scenic Management, Foreground Retention (LRMP 4-103, MA 3A, Foreground Retention) requires VQOs for a given location be achieved within one year of completion of the project. The Forest Service proposes to allow 10-15 years to meet the specified VQO at this location. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment that would apply only to the Pacific Connector Pipeline Project in the vicinity of the Dead Indian Memorial Highway and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.10(a)(1) – […the responsible official shall consider: …] "(1) Aesthetic values,… scenery,... viewsheds...". § 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities,… and scenic character…".
WNF-3	Project -Specific Amendment of VQO Adjacent to the Clover Creek Road:	The Winema National Forest LRMP would be amended to allow 10-15 years to meet the VQO for Scenic Management, Foreground Partial Retention, where the Pacific Connector right-of-way is adjacent to the Clover Creek Road from approximately pipeline MP 170 to 175 in Sections 2, 3, 4, 11, and 12, T.38S., R.5E., and Sections 7 and 18, T.38S., R.6E., W.M., OR. This change would potentially affect approximately 50 acres. Standards and Guidelines for Foreground Partial Retention (LRMP, page 4-107, MA 3B) require that VQOs be met within three years of completion of a project. The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment that would apply only to the Pacific Connector Pipeline Project in the vicinity of Clover Creek Road and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.10(a)(1) – […the responsible official shall consider: …] "(1) Aesthetic values,… scenery,... viewsheds...". § 219.10(b)(i) – [the responsible official shall consider] "Sustainable recreation; including recreation settings, opportunities,…and scenic character…".
WNF-4	Project -Specific Amendment to Exempt Limitations on Detrimental Soil Conditions within the Pacific Connector Right-of-Way in All Management Areas:	The Winema National Forest LRMP would be amended to exempt restrictions on detrimental soil conditions from displacement and compaction within the Pacific Connector right-of-way in all affected management areas. Standards and Guidelines for detrimental soil impacts in all affected management areas require that no more than 20 percent of the activity area be detrimentally compacted, puddled, or displaced upon completion of a project (LRMP page 4-73, 12-5). The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(2)(ii) – [The plan must include plan components to maintain or restore…] "Soils and soil productivity, including guidance to reduce soil erosion and sedimentation"

TABLE 2.1.3.5-1 (continued)

LRMP Amendments Associated with the Pacific Connector Pipeline Project Specific to the Winema National Forest

Amendment #	Amendment	Description
WNF-5	Project-Specific Amendment to Exempt Limitations on Detrimental Soil Conditions within the Pacific Connector Right-of-Way in Management Area 8:	The Winema National Forest LRMP would be amended to exempt restrictions on detrimental soil conditions from displacement and compaction within the Pacific Connector right-of-way within the Management Area 8, Riparian Area (MA-8). This change would potentially affect approximately 0.5 mile or an estimated 9.6 acres of MA-8. Standards and Guidelines for Soil and Water, MA-8 require that not more than 10 percent of the total riparian zone in an activity area be in a detrimental soil condition upon the completion of a project (LRMP page 4-137, 2). The amendment would provide an exception from these standards for the Pacific Connector Pipeline Project and include specific mitigation measures and project design requirements for the project. This is a project-specific plan amendment applicable only to the Pacific Connector Pipeline Project and would not change future management direction for any other project. The 36 CFR 219 planning rule requirements that are likely to be directly related to this amendment include: § 219.8(a)(2)(ii) – [The plan must include plan components to maintain or restore…] "Soils and soil productivity, including guidance to reduce soil erosion and sedimentation".

If any of the proposed amendments to the Winema National Forest LRMP described above are determined to be "directly related" to a substantive rule requirement, the Responsible Official must apply that requirement within the scope and scale of the proposed amendment and, if necessary, make adjustments to the proposed amendment to meet the rule requirement (36 CFR 219.13 (b)(5) and (6)).

2.1.4 Mitigation Actions Specific to the Right-of Way Grant on Federal Lands

Representatives of the BLM, Forest Service, and Reclamation have worked cooperatively with the FERC staff and the Project proponent to incorporate BMPs, project design features, and project requirements which would avoid, minimize, rectify, reduce, or eliminate environmental consequences (40 CFR 1502.14(f) and 1508.20(a-d)). The agencies deem these BMPs, project design features, or project requirements necessary to meet the respective regulatory requirements, accomplish the goals and objectives of their respective management plans, and to prevent unnecessary and undue environmental degradation. The BMPs, project design features, or requirements specific to the authorized use of BLM, NFS, and Reclamation lands are included as attachments to the applicant's POD. There are 28 appendices in the POD; they include draft monitoring elements to ensure that the wide array of actions are implemented and assess consistency of the actions relative to the goals and objectives of the respective LMPs. Collectively, the POD is incorporated into the Project's description, and is summarized in section 2.6.3 below.

In addition to the POD, the Forest Service has identified compensatory mitigation requirements. Additional detail is provided in section 2.1.5 below and in appendix F.

Under existing authorities and policy, the BLM may not specify compensatory mitigation specific to its lands or facilities; however, the BLM may incorporate the compensatory mitigation requirements of other agencies into the Right-of-Way Grant.

Reclamation has not identified any off-site compensatory mitigation measures specific to its lands or facilities.

2.1.5 Mitigation Plan Specific to NFS Lands

These compensatory mitigation actions are addressed programmatically in this EIS and may require additional analyses and surveys to comply with NEPA. The Forest Service anticipates this EIS would provide the basis for tiering subsequent site-specific NEPA analyses, in accordance with the CEQ regulations at 40 CFR 1508.28(b). As applicable, the Forest Service would conduct supplemental environmental analysis and consultation efforts with various federal, state, and local entities, as well as tribal governments, prior to authorizing future site-specific mitigation actions described in the CMP. The public would have the opportunity to comment on specific project proposals at that time. Subsequent environmental analysis for mitigation actions would not preclude the BLM from issuing authorizations necessary for construction and operation of the proposed pipeline project.

Forest Service interdisciplinary teams have developed a CMP for the Pacific Connector Pipeline Project specific to the national forests that would be impacted by the proposed project. The CMP is based on the respective LRMPs, the recommendations of the (2011) NSO recovery plan, the recommendations of the final Southern Oregon/Northern California Coast (SONCC) Coho Salmon Recovery Plan (2014), applicable Late Successional Reserve Assessments, and fifth-field Watershed Analyses (WA) for watersheds where impacts of the Pacific Connector Pipeline Project would occur. Members of the interagency team used professional judgment and knowledge of the affected landscapes to develop the mitigation actions described below. Mitigation measures reduce or compensate for environmental consequences of an action. Off-site mitigation is a supplemental mitigation to address important LRMP management objectives and standards and guidelines that cannot be fully mitigated on-site. Proposed mitigation actions are intended to be responsive to LRMP objectives that include:

- Compliance with the Aquatic Conservation Strategy;
- Habitat for Threatened or Endangered (T&E) species including the NSO and coho salmon;
- Mitigation of impacts and compliance with standards and guidelines for LSRs;
- Compliance with National Forest Management Act 2012 planning rule sustainability criteria at 36 CFR §§ 219.8 through 219.11; and
- Specific resource issues as they occur by watershed.

A central provision of the Forest Service CMP is that it is to remain adaptable to new information and changed conditions.

Table 2.1.5-1 describes the individual mitigation projects related to LRMP management goals and objectives on NFS lands that are included in the proposed action. These projects would be implemented by the Forest Service as a subsequent phase of the Pacific Connector Project with funding provided by the applicant. The applicant is also responsible for providing funding to Forest Service for planning efforts related to these mitigation actions.

TABLE 2.1.5-1

Mitigation Projects to Address LRMP Objectives on NFS Lands

Unit	Watershed	Mitigation Group	Project Type	Project Name	Quantity a/	Unit
Umpqua National Forest	Days Creek - South Umpqua	Stand Density Fuel Break	Fuels Reduction	Days Creek - South Umpqua Matrix Integrated Fuels Reduction	194	acres
		Stand Density Fuel Break	Fuels Reduction	Days Creek - South Umpqua LSR Integrated Fuels Reduction	254	acres
		Terrestrial Habitat Improvement	Snag Creation	Days Creek - South Umpqua LSR Snag Creation	32	acres
		Terrestrial Habitat Improvement	Snag Creation	Days Creek - South Umpqua Matrix Snag Creation	14	acres
		Terrestrial Habitat Improvement	Lupine Meadow Restoration	Upper Cow Creek Lupine Meadow Restoration	23	acres
	Elk Creek - South Umpqua	Aquatic and Riparian Habitat	Fish Passage	Elk Creek Fish Passage Culverts	5	sites
		Road sediment reduction	Road Storm-proofing	Elk Creek Road Storm-proofing	9.2	miles
		Road sediment reduction	Road Decommissioning	Elk Cr. Road Decommissioning	5.9	miles
		Stand Density Fuel Break	Fuels Reduction	Elk Creek Matrix Integrated Fuels Reduction	176	acres
		Stand Density Management	Commercial Thinning	Elk Creek LSR Enhancement	91	acres
		Stand Density Management	Off-site Pine Removal	Elk Creek LSR Off-site Pine Removal	300	acres
		Terrestrial Habitat Improvement	LWD Upland Placement	Elk Creek LSR LWD Placement	99	acres
		Terrestrial Habitat Improvement	Lupine Meadow Restoration	Elk Creek LSR Lupine Meadow Restoration	101	acres
		Terrestrial Habitat Improvement	Noxious Weed Treatment	Elk Creek Roadside Noxious Weeds	6.7	miles
		Terrestrial Habitat Improvement	Snag Creation	Elk Creek LSR Snag Creation	68	acres
		Fire Suppression	Water Source Improvement	Elk Creek Pump Chance	2	sites
	Evans Creek	Stand Density Fuel Break	Road Shaded Fuel Break	Evans Cr LSR Road Shaded Fuel Break	63	acres
	Trail Creek	Road sediment reduction	Road Decommissioning	Trail Creek Road Decommissioning	0.3	miles
		Road sediment reduction	Road Storm-proofing	Trail Creek Storm-proofing	2.2	miles
		Stand Density Fuel Break	Fuels Reduction	Trail Creek Matrix Integrated Fuels Reduction	500	acres
		Stand Density Fuel Break	Road Shaded Fuel Break	Trail Creek LSR Road Shaded Fuel Break	175	acres
		Terrestrial Habitat Improvement	Snag Creation	Trail Creek Matrix Snag Creation	109	acres
		Stand Density Management	Pre-commercial	Trail Creek LSR PCT Enhancement	112	acres

a/ Acres are rounded to the nearest whole acre and miles to the nearest tenth of a mile.

These mitigation actions would be a condition of the Forest Service letter of concurrence and would be included in the Right-of-Way Grant, if one were issued for this project. Implementation and funding of these actions would be carried out through negotiated agreements between the Forest Service and the applicant. A more detailed description of these mitigation actions is included in appendix F of this EIS.

2.1.6 Right-of-Way Grant to Cross Federal Lands

Pursuant to the Mineral Leasing Act of 1920 and in accordance with federal regulation 43 CFR Part 2880, the Pacific Connector Pipeline Project must secure a Right-of-Way Grant from the BLM to cross BLM, NFS, and Reclamation lands. Pacific Connector has applied to the BLM for a

Right-of-Way Grant to cross federal lands. The BLM proposes to consider issuance of a Right-of-Way Grant that provides terms and conditions for construction and operation of the Pacific Connector Project on federal lands in response to the proponent's application. Issuance of the Right-of-Way Grant must be in accordance with 43 CFR Parts 429, 2800, and 2880 and relevant BLM manual and handbook direction. In making this decision, the BLM would consider several factors including conformance with BLM RMPs and impacts on resources and programs. Following adoption of this EIS and receipt of concurrence from the Forest Service and Reclamation, the BLM would issue a Record of Decision that documents the agency's decision whether to amend the BLM RMPs and issue the Right-of-Way Grant. The Right-of-Way would incorporate the stipulations, project design features and mitigation, including compensatory mitigation specified by the concurring agencies.

This Right-of-Way Grant would be in addition to any authorization for the Project issued by the FERC. The Right-of-Way Grant, if approved, would be authorized by issuance of a Temporary Use Permit for up to three years for the pipeline clearing and construction, which would terminate upon completion of construction, and issuance of a Right-of-Way Grant for ongoing pipeline operations and maintenance for a 30-year term. The Temporary Use Permit contains the specific temporary construction and work areas necessary to build the Project. Once the Project is constructed and in operation, the Right-of-Way Grant would be modified to reflect the final location of the Project and the associated 50-foot-wide maintenance corridor29 plus any roads on federal lands or under federal easements that are necessary for operations.

2.1.7 Mitigation on Non-Federal Lands

Both Jordan Cove and Pacific Connector are currently developing mitigation plans to address environmental impacts occurring on non-federal lands as part of their proposed action. Currently, these mitigation plans include the CMP for wetland impacts (see section 4.3), as well as the avoidance and minimization plans included in the POD30 (though initially developed for federally-managed lands, most of the POD attachments apply to non-federal lands as well). Mitigation and BMPs are discussed in conjunction with the respective affected resources in chapter 4 of this EIS.

2.2 NON-JURISDICTIONAL FACILITIES

Under the NGA, the FERC is required to consider, as part of a decision to authorize jurisdictional facilities, all facilities that are directly related to a proposed project where there is sufficient federal control and responsibility to warrant environmental analysis as part of NEPA environmental review for the Project. Some proposed projects have associated facilities that do not come under the jurisdiction of the Commission. These "non-jurisdictional" facilities may be integral to the need for the proposed facilities, or they may be merely associated as minor components of the jurisdictional facilities that would be constructed and operated as a result of authorization of the proposed facilities. Non-jurisdictional actions associated with the Project were identified in

[29] In this EIS, the 50-foot-wide corridor may be referred to as the "operational maintenance corridor," "permanent maintenance corridor," "permanent pipeline easement," "permanent pipeline right-of-way," or similar, depending on the resource discussion and context. On all federal lands, the 50-foot-wide corridor would be based on a 30-year Right-of-Way with the federal land managing agencies, and would not constitute a permanent easement on federal lands.

[30] The POD was filed with the FERC as Appendix F.1 in Resource Report 1 as part of Pacific Connector's application on September 23, 2017.

association with both the LNG facility and the pipeline, as described below. Available environmental data further characterizing the impacts of the non-jurisdictional facilities is provided in our cumulative impacts analysis (section 4.14).

2.2.1 LNG Carriers

LNG exported from the Jordan Cove terminal to overseas markets would be transported in vessels specially designed and built for that task (i.e., LNG carriers). Jordan Cove expects that its terminal would be visited by about 100 to 120 LNG carriers per year. These carriers would be loaded with LNG at the terminal and deliver the cargo to customers, most likely around the Pacific Rim. LNG carriers would be under the ownership and control of third parties, not Jordan Cove, and would not be regulated by the FERC. The third-party owners and operators of the LNG carriers would have agreements with Jordan Cove for the transportation of the LNG to designated ports or customers. We do not have any information about the exact carriers that would be used to transport the LNG from the terminal; however, the slip and berth would be designed to accommodate LNG carriers as large as 217,000 m3 in capacity. Neither do we know the exact destinations for the LNG cargo nor the specific routes across the Pacific Ocean to customers that would be taken by LNG carriers, outside of the waterway within 12 miles of the Oregon Coast.

2.2.2 Southwest Oregon Regional Safety Center

Jordan Cove would construct the SORSC, a non-jurisdictional multi-organizational office complex, in the South Dunes area of the LNG terminal site. The SORSC would house the Jordan Cove Security Center, Coos County Dispatch Center, Coos County Emergency Operations Center, and offices for various businesses and agencies.

2.2.3 Fire Department

Jordan Cove would construct a stand-alone fire department building located in the access and utility corridor adjacent to the fire water tanks. This building would house the Jordan Cove Fire Department chief and staff.

2.2.4 Trans-Pacific Parkway/U.S. 101 Intersection Widening

Jordan Cove would add a turning lane to the Trans-Pacific Parkway (approximately 600 feet in length) to manage traffic entering U.S. Highway 101 from the west, and the addition of an automated traffic control signal. Approximately 1,150 wood piles would be installed along the road as part of this road-widening effort. The general location of the intersection is shown on figures 2.1-1 and 2.1-3.

2.2.5 Utility Connections for the Pipeline Facilities

All of the aboveground pipeline facilities would require either electrical power and/or telephone service. At the Klamath Compressor Station, electricity would be supplied by Pacific Power, which would require upgrades to an existing substation and distribution line immediately adjacent to the compressor station. New disturbance would be limited to the extension of three-phase distribution onto the compressor station property, and Pacific Connector states that Pacific Power does not anticipate disturbance would be required in new areas outside of the existing road right-of-way or existing Pacific Power right-of-way or fenced facilities. Water would be provided from water wells located on property owned by Pacific Connector, immediately adjacent to the compressor station. Telecommunications would be provided by Cal-Ore, which would require a short tie-in from the existing service available immediately adjacent to the compressor station.

For the Jordan Cove Meter Station, Pacific Power would supply electricity through a connection to an existing powerline located adjacent to the Trans Pacific Lane southwest of Ingram Yard. Telecommunications would be supplied from three existing networks, ORCA Communications, LS Networks, and Frontier Communications, through extensions of fiber optic and cable that would be installed to the SORSC proposed by Jordan Cove.

Pacific Connector has located its automated mainline valve facilities near available electrical power facilities such that only short tie-ins would be required. If it were to become necessary, in lieu of purchased power, thermal power generation equipment would be installed to provide electricity for the minimal power requirement at these sites.

2.3 LAND REQUIREMENTS

2.3.1 Jordan Cove LNG Terminal Facilities

The Jordan Cove LNG Project would require the use of about 1,355 acres of land. When complete, the Jordan Cove LNG terminal would occupy about 197 acres. Jordan Cove owns about 295 acres at the terminal site and would acquire the use of the remaining area (e.g., via easements or lease). Table 2.3.1-1 lists the land requirements for the Jordan Cove LNG terminal facilities.

TABLE 2.3.1-1

Land Requirements for the Jordan Cove LNG Project a/

Facilities	Acres Required During Construction b/	Acres Required During Operation b/
JURISDICTIONAL FACILITIES		
Total for Jurisdictional Facilities	202.6	197.1
NON-JURISDICTIONAL FACILITIES		
Southwest Oregon Regional Safety Center	5.4	5.4
Fire Department	0.8	0.8
Total for Non-Jurisdictional Facilities	**6.2**	**6.2**
TEMPORARY CONSTRUCTION AREAS		
Total for Temporary Construction Areas	**368.1**	**0**
MITIGATION SITES		
Eelgrass Mitigation Area and Dredge Line	33.4	0
Kentuck Project and Dredge Line	135.6	0
Panhandle Site	132.6	0
Lagoon Site	320.3	0

Total for Mitigation Sites	**778.0**	**0.0**
GRAND TOTAL	**1,355.1**	**203.3**

a/ This table lists the acres of land that would be encompassed by Project components or mitigation areas, but may not directly relate to areas that would experience direct effects (e.g., the entire footprint of each of the mitigation areas may not experience direct effects such as clearing, but are included in this table to disclose the scope of the projects footprint). See chapter 4 for the acres of land and resources that would be affected by the Project.
b/ Columns may not sum correctly due to rounding.

2.3.2 Pacific Connector Pipeline and Associated Aboveground Facilities

Constructing and operating the Pacific Connector pipeline would require the use of about 4,946 acres of land, and about 1,403 acres of land, respectively. Table 2.3.2-1 lists the land requirements for the Pacific Connector Pipeline Project.

TABLE 2.3.2-1

Land Requirements for the Pacific Connector Pipeline Project a/

Project Component	Land Required During Construction (acres) b/	Land Required During Operation (acres) b/
Pipeline Right-of-Way	2,582.0	1,373.7 c/
Temporary Extra Work Areas	922.6 d/	0
Uncleared Storage Areas	676.4	0
Rock Source & Disposal Sites e/	41.2 e/	0
Contractor and Pipe Storage Yards	674.2	0
Access Roads	28.5 f/	2.2
Aboveground Facilities	21.4 g/	27.0 g/
Totals	**4,946.4**	**1,402.9**

a/ This table lists the acres of land that would be encompassed by Project components or designations (e.g., permanent easements), but may not directly relate to areas that would experience direct effects (e.g., the entire permanent easement would not be cleared during operation). See chapter 4 for the acres of land and resources that would be affected by the Project.
b/ Columns may not sum correctly due to rounding.
c/ 50-foot-wide permanent pipeline easement (on federal lands, 30-year maintenance corridor).
d/ Includes TEWAs, existing quarries, rock sources, and disposal areas that may be used as permanent storage areas. These areas would not be used during operation of the Project, and therefore are not included in the operational total.
e/ Includes rock source and disposal sites that would remain disturbed following construction but would not be used during operation of the Project and therefore are not included in the operational total.
f/ Road improvements would remain following construction, but these roads would not be used for operation of the Project and therefore are not included in the operational total.
g/ Construction impacts associated with the aboveground facilities are included in the construction land requirement for the pipeline right-of-way and TEWAs except the potential off-right-of-way communication tower sites and the Klamath Compressor station, which are included here. Portions of aboveground facilities that fall within the permanent pipeline easement are included under Pipeline Right-of-Way.

For private and non-federal lands crossed by the pipeline, Pacific Connector would need to negotiate a mutually agreed upon easement for its pipeline with the affected landowners. The agreement between Pacific Connector and the landowner would specify compensation for the easement, compensation for damage to property and loss of use during construction, and loss of renewable and nonrenewable or other resources. The agreement would also specify uses of the permanent right-of-way after construction. If the company is unable to reach an agreement with a landowner, and if the Project is authorized by the FERC, the Certificate would convey the right of eminent domain under section 7h of the NGA. In these situations, Pacific Connector could initiate condemnation proceedings, and the value of the easement and the amounts for compensatory damages would be determined by a local, state, or district court.

2.3.2.1 Pipeline

Construction Right-of-Way

As illustrated in figure 2.3-1, Pacific Connector would generally construct the pipeline using a 95-foot-wide right-of-way. Pacific Connector would also use, as necessary, temporary extra work areas (TEWAs) to accommodate construction across waterbodies, roads, steep terrain, dense forest, and other areas of concern.[31] Where feasible (i.e., where topographic conditions allow) through forested and scrub-shrub wetlands as well as stream crossings, the construction right-of-way would be narrowed to 75 feet in width to minimize impacts on these resources and be consistent with the FERC's *Procedures* (Section VI.A.3). See additional discussion in section 4.3 of this EIS.

[31] About 42 acres of the TEWAs would be existing quarries, rock sources, or rock disposal areas that would be permanent storage areas for excess rock, and these areas would remain as exposed rock sites following construction.

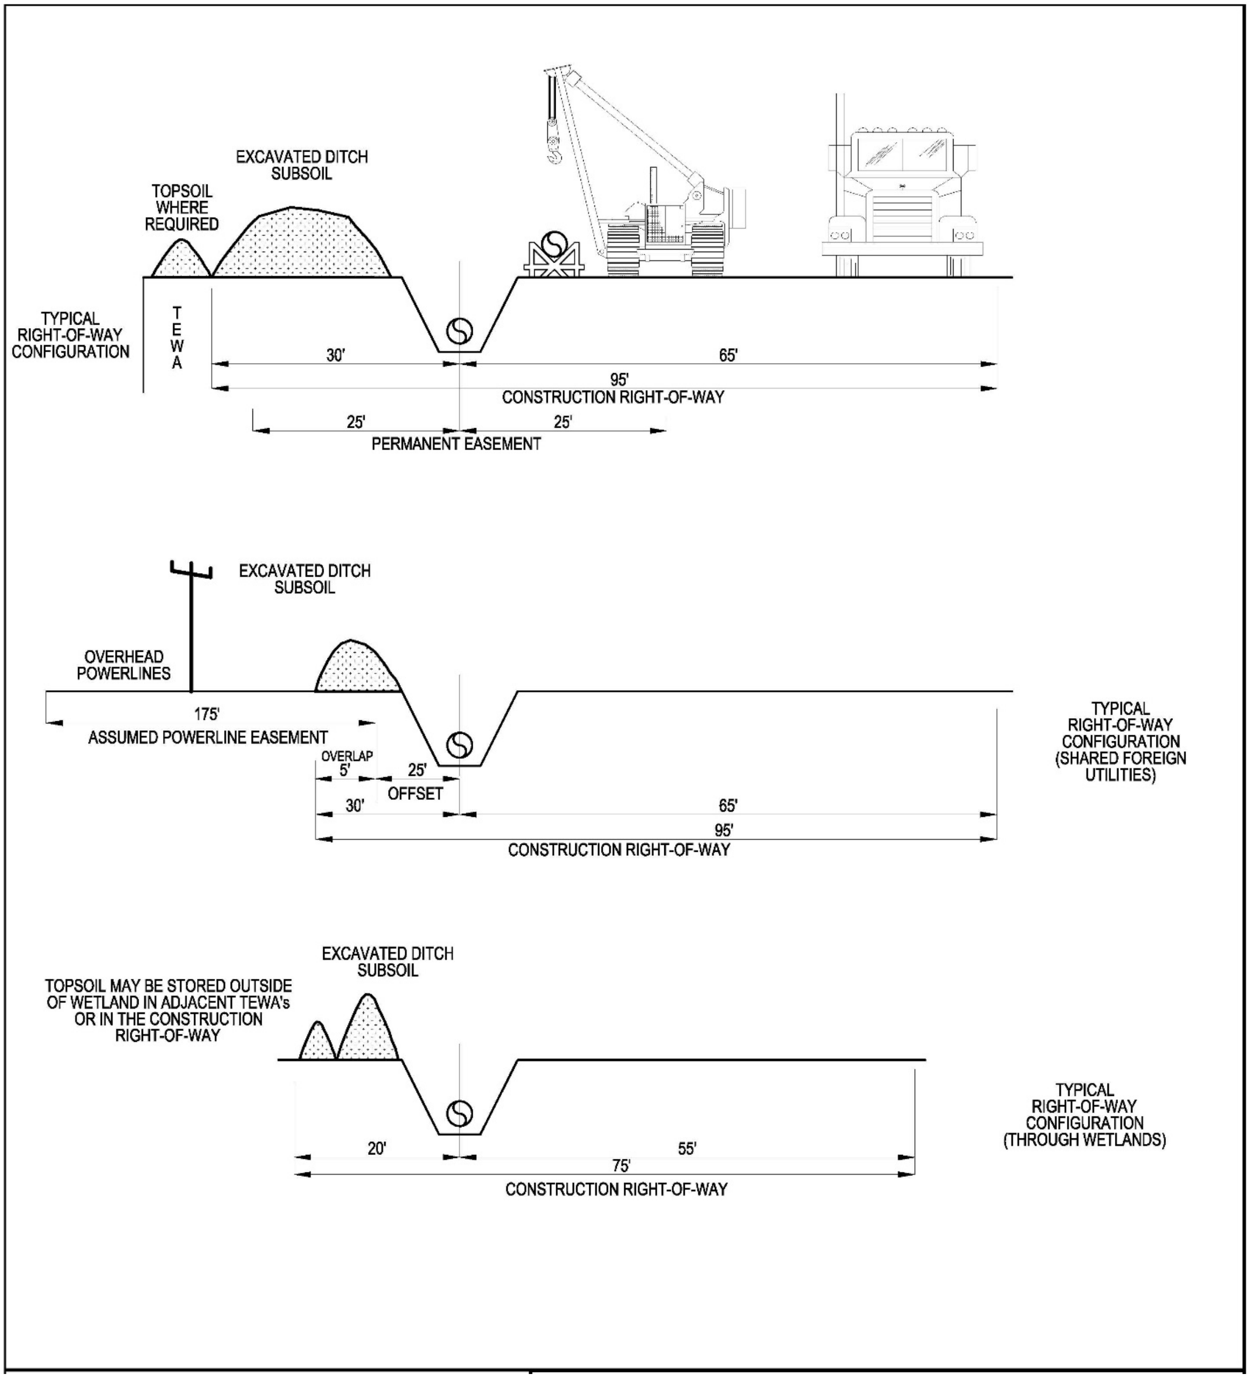

Figure 2.3-1. Typical Pipeline Right-of-Way Cross Sections

Pacific Connector would also use approximately 676 acres of uncleared storage areas (UCSA). UCSAs would not be cleared of trees during construction. UCSAs would be used to store forest slash, stumps, and dead and downed log materials that would be removed from the construction work area before construction and then scattered back across the right-of-way after construction.

In some locations, the UCSAs may be used to store spoil or to temporarily park equipment between the mature trees. However, storage and temporary parking of equipment/vehicles would not occur immediately adjacent to any trees so as to minimize tree damage. In extremely steep and side sloping topography, the UCSAs may be required as a contingency location to contain rock which rolls beyond the construction limits. Along extremely steep and narrow ridgeline areas, logs, slash, and dead and downed material may be used as cribbing to contain materials disturbed or excavated during right-of-way grading and trenching activities. During restoration, some of the materials that are pulled out of the cribbing may roll beyond the construction limits. Where feasible, Pacific Connector would retrieve materials that have rolled downhill using cables and chokers attached to standard on-site restoration equipment (i.e., bulldozers and trackhoes) to winch the material back to the right-of-way. There may be some cases where retrieval of the lost cribbing material may cause more harm to resources than allowing it to remain where it settled. On federal lands, Pacific Connector would protect trees within the UCSAs in accordance with the procedures outlined in its *Leave Tree Protection Plan* (Appendix P of its POD). After construction, the UCSAs would be restored to their pre-construction condition and use.

Operational Pipeline Right-of-Way

Pacific Connector would retain a 50-foot-wide permanent easement for the long-term operation and maintenance of the pipeline on non-federal lands. On federal lands, an operational right-of-way may be issued for a specific period of use, with potential for extension. After construction, workspace outside of the maintenance easement would be restored to its original condition and use (although mature forest would take many years to be re-established). The restoration and revegetation of the temporary construction right-of-way would be done in accordance with Pacific Connector's *Erosion Control and Revegetation Plan* (ECRP). On NFS and BLM lands where Riparian Reserves would be affected, up to a 100-foot riparian strip or to the edge of the existing riparian vegetation would be replanted adjacent to stream crossings.

Access Roads

Pacific Connector would primarily use existing roads to access pipeline workspaces. Existing roads that would be used for construction access are listed in table D-2 in appendix D of this EIS. Pacific Connector has identified 10 locations where it would be necessary to construct new temporary access roads (TARs). Pacific Connector has also identified 27 existing roads that would need to be modified to handle construction traffic. The roads would be stabilized using gravel and appropriate BMPs, as outlined in the ECRP, to minimize potential surface water runoff and to avoid potential sedimentation impacts. Following construction, new TARs would be removed, and the affected areas restored to pre-construction conditions.

Pacific Connector would construct 15 new permanent access roads (PARs) to access the pipeline and aboveground facilities. These roads would provide access during construction as well as during operations and maintenance activities. Most of the new PARs would be within Pacific Connector's operational pipeline easement.

Contractor and Pipe Storage Yards

Pacific Connector has identified 36 potential sites for yards and rail ports that may be used during construction to off-load and store pipe and stage contractor equipment (see table D-9 in appendix D). These sites are near the pipeline but generally not immediately adjacent to the proposed pipeline.

Pacific Connector has identified approximately 920 acres of TEWAs that would be disturbed during construction of the pipeline. All of these areas are considered temporary disturbance and would be restored upon completion of construction. All TEWAs that were forested prior to construction would be replanted with trees.

Rock Source and Permanent Disposal Sites

Pacific Connector has identified 20 potential rock source/disposal sites. These sites are indicated on the Mapping Supplement included as appendix C of this EIS. Of these locations, 15 sites are existing quarries/gravel pits or abandoned quarries/gravel pits. Although some of the existing/abandoned sites appear to have land use types other than quarries/gravel pits, Pacific Connector would not expand these sites beyond the existing or previously disturbed footprints.

Cathodic Protection System

Pacific Connector would protect the pipeline from corrosion over time through a cathodic protection (CP) system. The CP system would consist of below ground rectifier/anode beds that input a low voltage electrical charge into the pipeline. These rectifier/anode beds would be spaced about 30 to 40 miles apart and typically installed within previously disturbed areas near the permanent pipeline right-of-way. Each CP site would use electric power from a local utility. A typical CP site would include installation by a standard backhoe within an area up to 500 feet long by 15 feet wide and 5 feet deep. In limited locations a deep CP site may be required which would be installed by a truck-mounted drill rig. Identification of the CP sites and installation itself would occur about one year after pipeline installation to allow the trench to stabilize and for collection of post-construction data on electro-conductivity soil potentials, which is required before the system can be designed and installed. Pacific Connector would consult with appropriate federal, state, and local regulatory agencies after pipeline construction to determine the level of environmental compliance and agency authorizations necessary for the installation and maintenance of the CP system. On federal lands, any ground-disturbing construction and installation work to install the CP system would require separate authorization and environmental review.

2.3.2.2 Aboveground Facilities

Land required for construction and operation of the proposed aboveground facilities is listed in table 2.3.2-1 above. Operation of the aboveground facilities would require about 27 acres outside of the pipeline operational right-of-way.

2.3.2.3 Pipeline Facilities on Federal Lands

The Pacific Connector pipeline would cross 46.9 miles of federal land managed by the BLM, 30.6 miles managed by the Forest Service, and 0.31 mile managed by Reclamation (see table 2.3.2.3-1). The temporary and permanent acres of impact from the specific components are also provided in table 2.3.2.3-1. Tables 2.3.2.3-2 and 2.3.2.3-3 show the breakout by BLM District and by National Forest of the miles crossed through the various 2016 BLM RMP and Northwest Forest

Plan (NWFP) land allocations. Table 2.3.2.3-4 lists the Reclamation jurisdictional facilities, with their milepost locations, easement widths, acres of impact, and townships, ranges, and sections.

TABLE 2.3.2.3-1

Federal Lands Affected by the Pacific Connector Pipeline Project

Pipeline Facility/Component	Jurisdiction: BLM	Forest Service	Reclamation
Miles Crossed by Pipeline	46.9	30.6	0.31
Temporary Construction Acreage Requirements (acres)			
Construction Right-of-Way	535.02	349.75	3.69
TEWAs	166.26	102.76	0.46
UCSAs	183.75	123.17	0.00
Off-site Source/Disposal	6.99	9.26	0.00

a/ Reclamation Facility Name, (easement width) Reclamation ID, and Index No included as attributes in Bureau of Reclamation Pacific Connector-Crossing Shapefile provided to Pacific Connector - January 7, 2009. Easement widths determined from scanned easement plats provided by Reclamation.

b/ Waterbody ID from Pacific Connector wetland and waterbody surveys as shown on the Environmental Alignment Sheets in Appendix AA to the POD.

c/ The C-4-E Lateral is not crossed by the centerline but the easement for the lateral is within the construction right-of-way for approximately 270 feet.

d/ Canal easement widths not provided on easement plats provided by Bureau of Reclamation; therefore, crossing widths estimated based on photography and similar canal easements on adjacent canals.

In addition to the permanent and temporary access roads needed for construction listed in the preceding tables, existing federal roads would also be used. It is estimated that approximately 276 miles of BLM roads, 113 miles of Forest Service roads, and 2 miles of Reclamation roads would be utilized for construction activities.[32] All of the requirements for the use of federal roads are included in Appendix Y of the POD (i.e., the *Transportation Management Plan* [TMP]). This POD attachment outlines the requirements for road use permits, maintenance, modification and reconstruction, road decommissioning, culvert/bridge upgrades, new road construction (PARs and TARs), and traffic management. The federal agencies are continuing to coordinate with the applicant in refining the TMP, and road miles may vary as a result.

2.4 CONSTRUCTION PROCEDURES

Under the provisions of the Natural Gas Pipeline Safety Act of 1968, as amended, Jordan Cove would design, construct, operate, and maintain the LNG terminal facilities in accordance with the USDOT's Liquefied Natural Gas Facilities: Federal Safety Standards (49 CFR 193). The loading facilities and any appurtenances located between the LNG carriers and the last valve immediately before the LNG storage tank would be required to comply with applicable sections of the Coast Guard regulations in Waterfront Facilities Handling Liquefied Natural Gas (33 CFR 127).

The proposed pipeline facilities would be designed, constructed, operated, and maintained in accordance with USDOT regulations in Transportation of Natural and Other Gas by Pipeline: Minimum Federal Safety Standards (49 CFR 192). Among other design standards, these regulations specify pipeline material selection; minimum design requirements; protection from internal, external, and atmospheric corrosion; and qualification procedures for welders and operations personnel. In addition, Pacific Connector would comply with the siting and maintenance requirements of the FERC's regulations at 18 CFR 380.15, and other applicable federal and state regulations.

Jordan Cove and Pacific Connector would construct the Project in accordance with its project-specific *Erosion and Sediment Control Plan* (ESCP), its *Upland Erosion Control, Revegetation, and Maintenance Plan* (Jordan Cove's *Plan*) and its *Wetland and Waterbody Construction and Mitigation Procedures* (Jordan Cove's *Procedures*).[33] Jordan Cove adopted elements of the FERC's *Plan* and *Procedures* (May 2013 versions) into its *Plan* and *Procedures* as applicable for the Project (see appendix E for modifications). We have reviewed Jordan Cove's *Plan* and *Procedures* and find them to be consistent with the FERC's *Plan* and *Procedures*. In addition, Jordan Cove has prepared Spill Prevention, Containment, and Countermeasures (SPCC) Plans for both construction and operations.[34]

[32] Estimates derived from Table A.8-1 in Resource Report 8 of Pacific Connector's September 2017 application to the FERC.

[33] Jordan Cove's ESCP including its *Plan* and *Procedures* was attached as Appendix H.7 in Resource Report 7 as part of the Environmental Report included with Jordan Cove's September 2017 application to the FERC.

[34] Jordan Cove's construction and operation SPCC Plans were included as Appendices F.2 and G.2 of Resource Report 2, respectively, of its September 2017 application filed with the FERC.

2.4.1 Jordan Cove LNG Terminal

2.4.1.1 Upland Site Preparation

Temporary Concrete Batch Plant

One of the first construction procedures that Jordan Cove would undertake is the installation of a temporary concrete batch plant within the LNG terminal site or within a construction laydown area. The concrete batch plant would support construction of LNG terminal facilities that include concrete. A washout area would be located adjacent to the batch plant to allow for containment and disposal of waste water related to concrete batching operation.

Demolition and Clearing

Site preparation would include demolition, clearing, and removal and relocation of existing infrastructure to enable earthworks to progress. During this initial phase the IWWP and several existing utilities would be relocated. Other demolition and clearing activities would include:

- Removal and disposal of hydrocarbon contaminated soils – The South Dunes portion of the site contains small areas of hydrocarbon-contaminated soils remaining after the decommissioning of the former Weyerhaeuser paper mill. The contamination is located in the vicinity of the proposed site for the permanent buildings. Jordan Cove plans to conduct additional testing to further characterize the area of potentially contaminated soils and would develop a disposal plan for the approval of ODEQ and would remove and dispose of the contaminated soils in accordance with the approved plan.
- Clearing – The dune areas at the LNG terminal site would be cleared and any merchantable timber would be processed for commercial sale. Scrub and stumps would be processed into mulch for use during construction.

2.4.1.2 Material Deliveries

Transportation of materials, supplies, and staff to the LNG terminal site would be accomplished via a combination of road, marine transport, and rail. The larger and heavier pieces of equipment would be delivered to the site by marine transport in two phases. Initial marine deliveries would be via a temporary material barge berth, constructed in the existing shoreline within the footprint of the eventual marine slip. The temporary material barge berth would allow for material deliveries by barge while the permanent MOF is under construction and would be removed when construction of the MOF is completed.

Jordan Cove anticipates that some bulk materials, such as temporary buildings, construction equipment, steel reinforcement, pipe spools, cable drums, and insulation, would be delivered to the site by road. An existing rail line is located adjacent to the LNG terminal site and would be utilized for deliveries as permitted.

2.4.1.3 Earthworks and Soil Improvement

Earthworks would include removal of topsoil and storage for re-use, cut (excavation and dredging), fill (placement of excavated material), and grading of material to the approximate design elevations. The upland earthworks phase would include work by heavy equipment and require some periods of 24-hour operation. Jordan Cove would construct a temporary traffic overpass to allow separation of the traffic traveling to and from the existing Roseburg Forest Products Company from the large, off-road haul trucks and equipment required for the earthworks phase. During this phase boiler ash previously disposed on the site of the LNG terminal would be relocated to the South Dunes portion of the site where it would be buried within the fill.

The soil conditions at the site require improvement before any aboveground facilities can be constructed. These conditions include peat, clay, buried driftwood, and liquefiable soil, which could cause excessive settlement and stability concerns, or issues associated with liquefiable soils should a seismic event occur. Liquefiable soils within the LNG terminal site have been delineated in distinct soil layers from the groundwater table to various depths down to about 30 feet. A peat layer about 2-4 feet thick is present in areas of the site generally from just below the groundwater table to about 7 to 15 feet below grade. A layer of clay up to about 2.5 feet thick has been identified in areas of the South Dunes, and there are several areas in the South Dunes portion of the site where accumulations of buried driftwood are estimated to be present.

Jordan Cove plans to conduct additional site investigations to further characterize the existing subsurface conditions at the site and based on results would develop a plan for soil improvement, however potential soil improvements identified by Jordan Cove are listed below.

- Soil Densification Method 1 – Vibro-compaction could be utilized to condition liquefiable soils. This method consists of driving a vibration device into the sand layers to compact the soils.
- Soil Densification Method 2 – Sand compaction piles could be utilized to compact liquefiable soils, depending on the availability of suitable equipment.
- Organic Material Treatment Method 1 – Excavation and removal would be the preferred method to remove larger peat deposits where dewatering of the excavation pits is possible without affecting adjacent wetlands or waterbodies.
- Organic Material Treatment Method 2 – Excavation and removal of peat without dewatering the excavation pits may be attempted in areas with adjacent off-site wetlands and waterbodies.
- Organic Material Treatment Method 3 – Mixing of the mineral surface soils with peat layers may be attempted where excavation is not feasible.

During the operation of the Weyerhaeuser mill, boiler ash was deposited at Ingram Yard. Jordan Cove would dry excavate this boiler ash, and relocate it to South Dunes, where it would be buried with the fill.

2.4.1.4 Subsurface Civil Work

Piling

Construction of the LNG terminal and associated marine facilities would require the installation of temporary and permanent piles. Approximately 1,400 temporary piles and 17,800 permanent piles would be installed. Piles would be installed using vibratory hammering methods for the sheet piles (approximately 60 percent of the total piles), vibratory and drilled methods for the pier piles (15 percent of the total piles) and vibratory and impact methods for the pipe piles (25 percent of the total piles). Jordan Cove states that pile driving would be done over two 10-hour shifts per day, 6 days per week (not on Sundays or major holidays) over a 31-month period.

On-site Underground Utilities

Installation of underground utilities and services would be completed early in the site preparation phase to allow completion of site grading for stormwater control, completion of plant roadways, and installation of foundations and aboveground work. Underground work would be closely coordinated with the site preparation earthwork to install as much of the underground facilities as possible while the site is still being brought to grade.

Foundations

Major foundation work for equipment and structures would generally follow the installation of pilings and underground utilities. Typically, shallow isolated or raft foundations would be used for equipment and structures unless the design requires the use of deep foundations. All foundation loads, analysis, design, and construction would be in accordance with statutory and regulatory requirements. Where required, foundations would be evaluated and designed to mitigate the hazards associated with settlement, bearing capacity, overturning, sliding, buoyancy, erosion, and scour. Formwork for foundations would comprise a mix of metal form systems and job-built wooden forms. Rebar required for foundations would be fabricated off-site, delivered, and tied into place on-site. The temporary on-site batch plant would provide concrete as required for poured foundations.

2.4.1.5 Marine Facilities

Construction of the marine facilities would be done in three phases. The first phase would include upland excavation of the slip. The second phase would include excavation and dredging of the slip area above the natural earthen berm maintained in place to separate the freshwater construction activities from Coos Bay. Maintaining the berm would allow year-round work without being in contact with the waters of Coos Bay. The third phase would require work within Coos Bay and would include excavating the access channel (including area around MOF), removal of the berm and excavation/dredging of the berm area, and installation of MOF fender piles. This third phase would occur during periods when fisheries considerations allow in-water work, between October 1 and February 15. The estimated volume of material removed from each phase and component of excavation and dredging for the marine facilities are listed in table 2.1.1.8-1. Additional details for construction of the marine facility components are described below.

Construction of Sheetpile Walls

The sheetpile system would serve as a retaining wall for the shoreline on the east and west sides of the slip. It would be designed to support the dead loads of the soils and structures, as well as the live loads of the LNG carrier at berth and LNG transfer equipment; it would also be designed to meet the seismic criteria for the facility and water-imposed loads. The sheetpile wall system would include face sheet piles for retaining the soils as well as tail-walls for anchorage of the retaining wall. Sheet piles and tail-walls would be driven from the land during the first phase of marine facilities construction while the slip construction activities are isolated from Coos Bay.

Dry Excavation

The existing natural ground surface is at an elevation of approximately +20 feet NAVD88. The water table across the slip occurs at an elevation of approximately +10 feet NAVD88. Material above an elevation of approximately +10 feet NAVD88 would be removed by conventional earthmoving equipment such as excavators, scrapers, bulldozers, and front-end loaders. Excavated material would be hauled by trucks to upland disposal within the Ingram Yard, Access/Utility Corridor, South Dunes, and Roseburg site. A berm would be maintained as a barrier to the bay during this construction phase. The north slope of the slip would be finished at 2.5 to 1 horizontal to vertical slope. The same slope would be maintained on the slip side of the temporary berm to preserve the integrity of the berm during excavation and dredging. Contouring of the final slip perimeter above +10 feet NAVD88 would be performed during this step.

Slip Dredging

The material removed from the slip area that is at or below the water table would be removed by means of hydraulic dredging using a barge mounted cutter-suction dredge. The dredge would be delivered by ocean-going barge to the site, partially disassembled, and then pulled over the berm into the slip area. A dredge slurry pipeline would connect the dredge to the South Dunes portion of the site, and a decant water return pipeline would return the water to the slip area or purpose-built decant basin. The hydraulic dredge would be capable of dredging to the final slip depth.

The slurry and decant water pipelines would follow the shoreline and then the route of the future access and utility corridor. The pipes would be made of 18- to 20-inch-diameter seamless polypropylene pipe placed on the ground, braced as necessary, and would span any wetlands or waterbodies along the route. At any point along the pipeline route where the slurry pipeline could rupture, and the contents could potentially enter the waters of Coos Bay, secondary containment would be provided. When the hydraulic transport has been completed, the pipelines would be drained, flushed with clean water, and cut apart only in those areas where any residual material in the pipeline could not potentially be released into the bay, wetlands, or other waterbodies. The pipeline would be removed and taken off-site for reuse, recycling, or disposal in a permitted landfill.

Dredged material that would be disposed of at the Kentuck project site would be transported along the Federal Navigation Channel via marine transport barge and then deposited on the site using a temporary transfer pipeline. The materials would be dredged “in the dry” (i.e., the material would be dry when dredged), and then re-liquefied and piped through the transfer pipeline to Kentuck.

Access Channel and Proposed Modifications to the Marine Waterway

The access channel would be dredged using a barge mounted crane with clamshell bucket or hydraulic dredge system. The operation would start at the MOF and progress out to the navigation channel. Jordan Cove anticipates that access channel dredging would occur around the clock in order to complete within the available window for in-water work from October 1 to February 15. The channel dredging would occur during the second available in water work window (with the MOF being constructed during the first available in-water window). Dredged material would be loaded into material barges and the barges would be towed to shore and the material transferred to trucks for placement at Ingram Yard, the access and utility corridor, Roseburg Forest Products property, or the South Dunes portion of the site. Material dredged from the along the Federal

Navigation Channel (as part of the proposed marine waterway modification) would be transported to APCO Sites 1 and 2 by temporary dredge pipeline laid adjacent to the Coos Bay navigation channel (via a floating or submerged pipe).

Driving of Piling for Marine Structures

Marine piling for the tug dock would be driven "in-the-dry" by land-based mobile cranes, meaning the piles would be installed prior to or concurrent with the freshwater dredging of the slip and while the berm is still in place separating the slip from Coos Bay. All piles required for the LNG loading foundation, and all mooring and berthing structures for the LNG and emergency berths would be located behind the sheetpile walls and would be driven on dry land.

Connection of Slip to the Channel

After completion of the slip excavation and dredging while working behind the berm, the berm would be removed, and the remaining area of the slip would be dredged. This work would be conducted during the allowed in-water work window of October 1 to February 15. Dredging may be conducted from both the Coos Bay side and the slip side to reduce the duration of the activity. Additional dredging to contour the access channel at the connection of the channel and slip would also be conducted at this time. Material would be removed by hydraulic dredge or clam-shell dredge. A portion of the material may be transported to the Kentuck project to be used as fill, and the remainder would be placed at the South Dunes portion of the site. Armoring of the remaining unarmored slip side slopes would then be completed.

Restoration of Marine Facilities

Following the excavation activities, all areas disturbed by marine facilities construction, including exposed slopes, would be protected from erosion and stabilized with an erosion protection system and/or an approved seed mixture specified for the site. The northern slip face would be armored with rip rap to protect the slope from scour. The dredge slurry and decant water return pipelines would be removed, and any areas that are disturbed by the haul truck or pipelines route that do not become part of the access and utility corridor would be restored to pre-construction condition.

2.4.1.6 LNG Loading Platform and Facilities

The LNG carrier loading facilities would be constructed once the eastern sheet pile wall system is complete. All of the loading facilities would be on the shore side of the slip, with no facilities located in the water of the slip. The platform with the loading arms (inclusive of the loading and vapor return arms) would be constructed on a concrete pad at the edge of the slip. The LNG transfer piping would be located over LNG troughs that would contain any spills and divert the LNG to a containment basin. The LNG carrier loading facilities would be constructed using land-based equipment. Installation of berth piping and equipment, and hookup and commissioning of the loading system and utilities would follow.

2.4.1.7 LNG Storage and Support Facilities

LNG Storage Tank Construction

Construction of the LNG storage tanks would be the most time-consuming element in the development of the LNG terminal. General steps would include installation of the foundations and tank bottom slab, construction of the outer concrete container wall, insertion of the bottom carbon steel vapor liner, construction of the steel dome roof and suspended deck, installation of the 9 percent nickel steel inner tank, installation of the internal tank accessories (pump columns, instrumentation, and piping), installation of external tank accessories, installation of insulation, and installation of LNG pumps. Following a successful inner container hydrotest (see below), the tank would be washed down and cleaned. After installation of the LNG pumps, the tank would be closed and purged with nitrogen to a positive gauge pressure. At this point in the construction process, the tank would be ready for cooldown with LNG.

Support Facilities

Construction of buildings and installation of major mechanical equipment would occur once LNG storage tank construction is underway. Installation of mechanical equipment would be followed by electrical and instrumentation installation. As the construction of the process portion of the LNG terminal progresses, work would commence on the pre-commissioning activities, so that these activities would be completed concurrently with the completion of the LNG storage tanks.

2.4.1.8 Testing

Jordan Cove would conduct testing of the LNG storage tanks in accordance with API 620, while piping would be tested in accordance with the American Society of Mechanical Engineers (ASME) B31.3. Some of the tests are described below.

Testing of the LNG Storage Tanks

Jordan Cove proposes to use raw water from the existing CBNBWB raw water pipeline for hydrostatic testing of the LNG storage tanks. The inner container of each LNG storage tank would be hydraulically tested by filling the tank with water, and then pressurizing the tank. To minimize water usage, the two tanks would be hydrotested with the same water by transferring the water at the conclusion of the hydrotesting of one tank to the other tank. For both tanks combined, about 60 million gallons would be used during hydrostatic testing. Following testing, the water would be locally discharged, following ODEQ approval, to the stormwater system for infiltration or discharged into the IWWP according to applicable NPDES permit requirements. If the hydrostatic test water is discharged to the IWWP, it has the capacity to handle the anticipated discharge of 2.9 mgd. Jordan Cove would use a pneumatic test on the outer container for each LNG storage tank. The pneumatic test would be completed in accordance with API 620 Section R.7.

Testing of Pipework

Piping within the LNG terminal facility would be tested using hydrostatic or pneumatic methods. In general, cryogenic piping (piping that would transfer LNG) would be pneumatically tested with dry air or nitrogen. Non-cryogenic piping (piping that would transfer natural gas) would be hydrotested using clean water. Water used for testing of pipeworks would be discharged in the same manner as water used for hydrostatic testing of the LNG storage tanks, as described above.

2.4.2 Pacific Connector Pipeline and Associated Aboveground Facilities

Construction of the proposed pipeline would primarily involve standard cross-country pipeline construction as described in section 2.4.2.1. Special construction techniques would also be used when constructing across wetlands; waterbodies; roads, railroads, and other utilities; agricultural and residential areas; and rugged terrain. These special construction techniques are described in section 2.4.2.2. Construction of the aboveground facilities is discussed in section 2.4.2.3.

Minor alignment shifts or additional temporary workspace may be required prior to and during construction to accommodate currently unforeseeable site-specific constraints related to construction, safety, engineering, landowner, and/or environmental concerns. All such alignment shifts or workspace needs would be subject to review and approval by the FERC and the other permitting agencies prior to construction, as appropriate.

2.4.2.1 General Pipeline Construction Techniques

Figure 2.4-1 shows the typical steps of cross-country pipeline construction, which proceeds in the manner of an outdoor assembly line of specific activities that make a linear construction sequence. Typical steps include survey and staking of the right-of-way, clearing and grading, trenching, pipe stringing and bending, welding and coating pipe, lowering-in pipe and backfilling, hydrostatic testing, right-of-way cleanup, and restoration. Pacific Connector anticipates construction would be divided into eight separate construction spreads, with each spread consisting of all construction activities necessary to construct the pipeline along that spread, as follows:

- Early Works MPs 0.00-7.34R;
- Spread 1 MPs 7.34R-29.54;
- Spread 2 MPs 29.54-51.58;
- Spread 3 MPs 51.58-71.37;
- Spread 4 MPs 71.37-94.75;
- Spread 5 MPs 94.75-132.52;
- Spread 6 MPs 132.52-162.40; and
- Spread 7 MPs 162.40-228.81.

Figure 2.4-1

Typical Pipeline Construction Sequence

Surveying and Staking

Prior to the start of construction, the exterior limits of the approved construction right-of-way and boundaries of TEWAs would be civil surveyed and clearly staked and signed. Professional land surveyors licensed in the state of Oregon would perform all work and would hold a valid and current Certified Federal Surveyor certificate for federal land surveying and setting of monuments. All surveys would be performed in accordance with procedures found in the *Manual of Surveying Instructions* (U.S. Department of the Interior 2009), and all applicable state or county statutes, codes and regulations, and specifications of the County Surveyor. Pacific Connector's environmental inspectors (EIs) would verify the limits of the staked right-of-way and TEWAs, and would monitor the stakes throughout construction. Any pre-existing property line or survey monuments that occur within the construction right-of-way would be protected where possible, and if damage occurs during construction, these monuments would be replaced according to state and federal standards. Approved access roads would be signed. Also signed would be sensitive environmental areas that would be off-limits to construction crews.

Property line monuments or survey corners on BLM-managed and NFS lands would be reestablished according to federal standards if damaged during construction. Civil surveys on federal lands would adhere to guidelines established by the BLM, Forest Service, and Reclamation. Pacific Connector developed a *Right-of-Way Marking Plan* in consultation with the BLM and Forest Service as part of the POD (see Appendix T to the POD). This plan identifies the survey standards and types of survey markings that would be used on federally-managed lands.

Access to the Construction Right-of-Way

Equipment involved in pipeline construction would be moved onto the right-of-way using approved access roads and would then generally proceed down the right-of-way. The standard 95-foot-wide construction right-of-way would include a travel lane for construction equipment and vehicles. Pacific Connector would place mats over wetlands and bridges over waterbodies along the travel lane, in accordance with its *Plan* and *Procedures*, and install temporary erosion control devices in accordance with its ERCP. Pacific Connector has produced a TMP for federal lands as Appendix Y of its POD and also a TMP for non-federal lands.[35]

Clearing and Grading

The construction right-of-way and TEWAs would be cleared of brush and trees. Pacific Connector has produced a *Right-of-Way Clearing Plan for Federal Lands* as Appendix U of its POD. The general clearing procedures outlined in that plan would also apply to non-federal lands. During clearing existing fences crossed by the pipeline route would be cut and braced, and temporary gates installed to control livestock and limit public access to the right-of-way. Temporary erosion control devices would be installed at the end of clearing activities.

Hayfields, pastures, and grassy areas would not be cleared except in areas directly over the trench or where grading would be required to create a level working surface. Tall shrubs, such as sagebrush, would be mowed or scalped off with a motor-grader or a bulldozer. Cleared grasses

[35] Appendix F.8 in Resource Report 8 included as part of Pacific Connector's September 2017 application to the FERC.

and brush would be stockpiled along the edge of the right-of-way or within TEWAs or UCSAs, then mulched and spread back over disturbed areas during final cleanup and restoration.

In forested areas, timber would be cut and cleared from the right-of-way and TEWAs. Clearing would follow seasonal timing restrictions as discussed in section 4.5 of this EIS. Merchantable timber would be removed and/or sold according to landowner stipulations. In general, ground-based skidding and cable (where feasible) logging methods would likely be the standard method; however, in some isolated rugged topographic areas with poor access, helicopter logging may be used. See additional discussion in section 4.4 of this EIS.

Following clearing, the right-of-way would be graded where necessary to create a reasonably level working surface to allow safe passage and operation of construction equipment. During grading, topsoil would be separated from subsoils in certain areas, and each would be stored in segregated piles within the construction right-of-way and TEWAs. Where topsoil would be segregated on non-federal lands,[36] Pacific Connector has requested 10 additional feet of TEWA for topsoil storage in addition to its nominal 95-foot-wide construction right-of-way in uplands. On BLM-managed and Forest Service lands, Pacific Connector would segregate topsoil in all wetlands according to its *Procedures*. Pacific Connector may segregate topsoil in other areas as determined from the results of biological surveys for federal Survey and Manage species and Region 6 sensitive species including moss, lichen and fungi. Where these species are identified within the construction right-of-way, Pacific Connector would consult with the BLM and Forest Service to determine if topsoil segregation in these areas is a feasible and appropriate mitigation or management measure to minimize impacts on these species.

Trenching

A rotary trenching machine, rock trencher, track-mounted backhoe, or similar equipment would be used to excavate a trench for the pipeline. Spoil excavated during trenching would be temporarily stockpiled to one side of the right-of-way adjacent to the trench. The depth of the trench would vary according to site-specific conditions and USDOT requirements in 49 CFR 192.327, which specifies that the minimum depth of cover must be:

- 30 inches in normal soil and 18 inches in consolidated (solid) rock for Class 1 locations; and
- 36 inches in normal soil and 24 inches in consolidated rock for Class 2, 3, and 4 locations, and under drainage ditches, public roads, and railroad crossings.

Pacific Connector states that it would strive to exceed USDOT depth requirements where possible and bury its pipeline up to 36 inches deep in Class 1 areas with normal soils and 24 inches deep in Class 1 areas with consolidated rock. The trench may be deeper at stream crossings with scour concerns based on Pacific Connector's study of channel migration and scour analysis.

In areas where bedrock is found within the pipeline trench depth, Pacific Connector would first attempt to dig the trench with specialized equipment, such as rock saws, or ripping using hydraulic hammers. If these methods are ineffective, blasting may be necessary to achieve the required trench depth. Pacific Connector has identified a high potential for blasting for about 100 miles of

[36] For example, topsoil salvaging would occur in areas occupied by Applegate's milkvetch, Kincaid's lupine, and Gentner's fritillary, per the *Federally-listed Plant Conservation Plan* (see section 4.6).

the proposed pipeline route. All blasting would be done by licensed contractors under the terms of applicable regulatory requirements. Pacific Connector produced a *Blasting Plan* as Appendix C of its POD. Blasting is further discussed in section 4.1 of this EIS.

Stringing, Bending, and Welding

After trenching, pipe sections would be trucked to the right-of-way and strung along the route, using side-boom tractors to unload the pipe from the flatbed trucks. A hydraulic bending machine would bend some pipe sections to fit the contour of the trench bottom, and in some locations pipe sections would be factory bent, or special pre-fabricated pieces would be used. A separate, trained crew of welders would weld the pipe sections together and place them on wooden skids adjacent to the trench. All welds would be visually inspected, nondestructively tested (using radiographic or equivalent methods), and repaired, if necessary. Line pipe, normally mill-coated prior to stringing, would require field applied coating at the welded joints prior to final inspection and the entire pipeline coating would then be inspected and repaired as needed.

Lowering-in and Backfilling

After welding and coating, the pipe would be lowered into the trench by side-boom tractors and excavators, after first inspecting the trench to ensure it is free of rocks or debris that could damage the pipe or the coating, and after adding padding such as sandbags at the bottom of the trench. To prevent water from the trench from entering wetlands or waterbodies, Pacific Connector would install permanent trench plugs, consisting of sandbags, foam, or bentonite, at the base of slopes adjacent to wetlands and waterbodies. Drain tiles crossed by the pipeline would be checked, and if damaged, they would be repaired before backfilling. Segregated topsoil, where applicable, would be replaced after backfilling the trench with subsoil. Following backfilling, a small crown of material would be left over the trench line to account for any future soil settling that might occur.

Hydrostatic Testing

After backfilling, the pipeline would be hydrostatically tested in accordance with USDOT regulations to ensure that is capable of operating at the MAOP. During the test, sections of the pipeline would be filled with water and pressurized. Should a leak or break occur during testing, the line would be repaired and retested until the specifications are achieved. Pacific Connector produced a *Hydrostatic Testing Plan* as Appendix M of its POD, which provides the location of the proposed hydrostatic test water withdrawal locations.

The pipeline would be tested in approximately 35 sections, each with varying lengths and water volume requirements. Pacific Connector would reuse test water from one section to the next as much as practical and minimize release between test sections (called cascading). The required volume of test water would range between approximately 16 to 60 million gallons depending on how much water would be reused by cascading. Water for hydrostatic testing would be obtained from commercial or municipal sources or from surface water right owners. If water for hydrostatic testing is acquired from surface water sources, Pacific Connector would obtain all necessary appropriations and withdrawal permits prior to construction, including permits through the OWRD. As part of this process, ODEQ and ODFW would review OWRD applications reviewed to evaluate potential impact on water quality and fish and wildlife and their habitats. Pacific

Connector would negotiate water appropriations with private owners in the year prior to construction.

Pumps used to withdraw surface water would be screened according to ODFW and NMFS standards to prevent entrainment of aquatic species. In addition, Pacific Connector included BMPs in its *Hydrostatic Testing Plan* to avoid the potential spread of aquatic invasive species and pathogens of concern. BMPs were developed in consultation with the BLM, Forest Service, the Center for Lakes and Reservoirs and Aquatic Bioinvasion Research and Policy Institute, and ODEQ.

Following testing the hydrostatic test water would be released from the pipeline test sections, potentially at each of the 35 test section breaks, or at fewer sites if cascading of water between test sections is used. Hydrostatic test water would be discharged in upland areas into erosion control devises typically constructed of hale bales and silt fence, in accordance with Pacific Connector's ECRP and the POD. Water discharged during testing would not be used to fill existing or proposed fire suppression sources (e.g., heli-ponds). Pacific Connector would apply for permission from the ODEQ prior to discharge of hydrostatic test water. Additional discussion of hydrostatic testing discharges can be found in section 4.3 of this EIS.

Dust Control

Fugitive dust[37] may be created by pipeline construction activities. To control dust, Pacific Connector would use water trucks to spray the right-of-way. Water for dust control would be obtained from commercial or municipal sources, and all appropriate approvals and/or permits would need to be obtained prior to withdrawal. Pacific Connector produced an *Air, Noise, and Fugitive Dust Control Plan* as Appendix B to its POD. See additional discussion of dust control measures in sections 4.3 and 4.12 of this EIS.

Cleanup and Permanent Erosion Control

After the pipeline is installed and the trench is backfilled, Pacific Connector would complete final grading, returning the right-of-way to its approximate original contours or to a stable contour in areas of steep slope. Fences, gates, drainage ditches, culverts, and other structures that may have been temporarily removed or damaged during construction would be permanently repaired, returned to their pre-construction condition, or replaced. All construction debris, including excess rock, would be removed from the right-of-way and placed in authorized disposal locations. On federal lands, site-specific crossing restoration plans would be implemented for perennial stream crossings. The right-of-way would be mulched, seeded, and revegetated in accordance with Pacific Connector's ECRP. Erosion control fabric would be used on streambanks.

Pacific Connector would install permanent erosion control devices consistent with the requirements of Section V.B. of FERC's *Plan* and as described in its ECRP. The permanent erosion control measures include trench breakers, slope breakers, and revegetation to stabilize disturbed areas. Pacific Connector would consult with the BLM, Forest Service, and Reclamation regarding the installation of permanent erosion control structures on federal lands, and with the

[37] Fugitive dust consists of small particles of dust suspended in the air, which are an inadvertent by-product of construction or other project-related activities.

NRCS regarding such structures on non-federal lands. Table 2.4.2.1-1 lists specifics from Pacific Connector's ECRP for the installation of slope breakers.

TABLE 2.4.2.1-1

Permanent Slope Breaker Spacing from Pacific Connector's ECRP a/

Slope	Highly Erosive Granitic Soils b/	Soils with Moderate or Low Potential for Erosion
0 to 5 percent	None required	None required
5 to 15 percent	100 feet	200 to 300 feet
15 to 30 percent	50 to 75 feet	75 to 100 feet
Greater than 30 percent	50 feet	50 feet

a/ Actual spacing would be determined at the time of installation based on site-specific topographic conditions on the right-of-way to ensure proper slope breaker construction and proper drainage to stable off-site areas. On the Umpqua National Forest between about MPs 109 and 110, where the alignment would cross the historic Thomason cinnabar claim group, waterbars would be installed at 50-foot intervals as recommended by the Forest Service.

b/ Granitic formations would be crossed by the pipeline between: MPs 79.1 to 80.5; MPs 81.6 to 82.2; MPs 87 to 88.8; MPs 97.0 to 101.2; MPs 103.0 to 105.4; and MPs 114.8 to 115.0.

Revegetation

All areas disturbed by construction, including the construction right-of-way, TEWAs, UCSAs, and contractor yards as necessary, would be restored and revegetated in accordance with Pacific Connector's ECRP. A seedbed would be established to a depth of up to four inches where necessary. Consistent with the FERC's *Plan*, if final grading occurs more than 20 days after pipe installation and backfilling, Pacific Connector would apply mulch on all disturbed areas prior to seeding. Based on recommendations provided to Pacific Connector by the Oregon State University Extension Service related to the fertilization rates for nitrogen fertilizer on new pasture seedlings, Pacific Connector would use a standard fertilization rate of 200 pounds per acre bulk triple-16 fertilizer on disturbed areas to be seeded. The Natural Resources Conservation Service (NRCS) did not recommend the addition of lime or other soil pH modifiers. Fertilizer would not be used in wetlands unless required by the land-managing agencies and would not be applied within at least 100 feet of flowing streams that have domestic use or support fisheries and would not be applied during heavy rains or high wind conditions.

It is expected that seeding would be timed to begin in August and could extend into the winter months at lower elevations. Disturbed areas would be seeded within six working days of final grading, weather and soil conditions permitting. Seeding may be done by broadcast methods, drilling, or hydroseeding. Broadcast seeding, using a mechanical broadcaster seeder, is the preferred method of seeding on steep slopes. After broadcast, the seedbed would be lightly dragged by chains or other appropriate harrows to cover the seeds thinly with soil. A drill seeder pulled by a plow may be used as an alternative to broadcast seeding in gently sloping areas. Hydroseeding would be done in accessible upland areas. Seed mixtures were determined in consultations with land-managing agencies and the NRCS. The seed mixtures are listed in Pacific Connector's ECRP and are further discussed in section 4.4 of this EIS. During right-of-way easement negotiations, private landowners may select their own seed mixtures other than those proposed for elsewhere along the pipeline route. The seed mixtures on BLM land were developed based on BLM Instruction Memo-2001-014, which specifies the use of native species, if possible. The POD has additional requirements for revegetation on federal lands.

Mulch would be applied on slopes were necessary to stabilize the right-of-way after seeding. Mulch would consist of native wood, certified weed-free straw, or hydromulch. The BLM and Forest Service have established ground cover standards and fuel loading requirements that are further discussed in section 4.4 of this EIS.

In forested lands, Pacific Connector would replant vegetation according to state and federal reforestation requirements. Reforestation efforts would occur in any given area the first winter/spring (between December and April) after the pipeline is installed in that area. On all forest lands crossed by the pipeline, trees would be replanted across the construction right-of-way up to 15 feet from either side of the pipeline centerline. In riparian areas, shrubs and trees would be replanted across the right-of-way for a width of 25 feet from the waterbody bank. Within Riparian Reserves, Pacific Connector would replant shrubs and trees to within 100 feet of the ordinary high-water mark (OHWM). A list of species to be replanted is included in Pacific Connector's ECRP, and revegetation is further discussed in section 4.4 of this EIS.

2.4.2.2 Special Pipeline Construction Techniques

Construction in rugged topography; across wetlands and waterbodies; through agricultural, residential, commercial, and industrial areas; at road and railroad crossings; and across existing buried pipelines and other utilities may require special construction techniques. These techniques are described below.

Rugged Topography

The Pacific Connector pipeline route would cross several mountain ranges, with steep and rugged topography (e.g., along the Coast Range and foothills between MPs 6.53R to 69.00, as well as between MPs 70 and 127.00). Through those mountains, the pipeline route would follow ridgelines, where feasible, to minimize the amount of cut and fill, and to avoid steep slopes, geologic hazards, and waterbody crossings, and to reduce erosion potential. In areas of steep slopes, two-tone construction techniques may be necessary, creating two step-wise level surfaces within the construction right-of-way (see Drawing #3430.34-X-0019 in Attachment C of Pacific Connector's ECRP, included with Resource Report 1 filed with Pacific Connector's application to the FERC). In addition, Pacific Connector's *Geological Hazards and Mineral Resources Report* identified geological hazards along the pipeline route. Site-specific mitigation measures for the crossing of some of these hazards are discussed in more detail in section 4.1.

During construction through rugged topography, Pacific Connector would consider the following factors:

- Identify adequate work areas to safely construct the pipeline.
- Provide a safe working grade.
- Utilize appropriate construction techniques for site-specific situations.
- Construct during the dry season as much as possible.
- Install temporary erosion control devices during construction.
- Install trench breakers, as appropriate, on slopes and near waterbody and road crossings.
- Backfill the trench immediately after pipe installation.
- Install permanent erosion controls soon after completing rough grading.

- Revegetate slopes with quick germinating seed mixtures.
- Mulch or install erosion control fabric on slopes, as necessary.
- Monitor and maintain the right-of-way as necessary to ensure stability.

Additionally, Pacific Connector's ECRP outlines procedures for fill on slopes exceeding a gradient of 3H:1V, including fill materials, slope preparation, and fill placement and compaction. The POD includes additional factors that would be considered on federal lands.

Waterbody Crossings

Construction of the Pacific Connector pipeline would affect approximately 352 waterbodies[38]. Waterbodies would be crossed in accordance with the FERC's *Procedures* and applicable permits or approvals from other agencies. Pacific Connector filed a *Wetland and Waterbody Crossing Plan* as Appendix BB of its POD. Crossings of perennial streams on NFS lands would be subject to site-specific plans that include construction restoration and monitoring requirements to ensure consistency with the Aquatic Conservation Strategy, and on BLM lands would be subject to the requirements of the BLM's 2016 RMPs. A more detailed discussion of impacts on waterbodies is provided in section 4.3 of this EIS.

TEWAs would be located more than 50 feet away from the edge of waterbodies where possible, and Pacific Connector has identified locations where site-specific conditions or other constraints prevent a 50-foot setback (see appendix E). Hazardous materials, chemicals, fuels, and oils would be stored at least 100 feet from the edge of waterbodies and wetlands (150 feet on federal lands).

Construction equipment would cross waterbodies on temporary bridges. The bridges would be designed to span the entire OHWM of the waterbody, wherever possible. Soil would not be used to stabilize bridges. In order to construct the temporary bridges, waterbody crossings may require one machinery pass through the waterbody without isolation measures in place to construct temporary equipment bridges. On BLM and NFS lands, all streams, whether wet or dry, would be crossed with (1) a bridge, (2) a temporary culvert, or (3) a low water ford with a rock mat.

All waterbodies would be crossed during the in-water work window recommended by the ODFW, or within an approved in-water work window developed through consultation with the ODFW, NMFS, COE, and FERC. Pacific Connector would attempt to cross intermittent streams and irrigation canals and ditches when they are dry, using standard upland cross-country construction methods. The standard depth of cover would be five feet below channel bottom of intermittent streams and ditches.

Pacific Connector would use the following methods to cross waterbodies with flowing water at the time of construction: diverted open cut, dry open cut, conventional bore, HDD, or Direct Pipe® (DP) technique. These are briefly described below.

<u>Wet Open-Cut Crossing</u>

No wet open-cut crossings are currently proposed for this Project. However, an open-cut crossing method may be required if all other crossing methods are attempted and fail. If an open cut crossing method is required, then additional permitting and impact analysis may be required before

[38] This value does not include the wetlands that would be affected by the Project.

the applicable agencies could allow the crossing to occur. A wet open-cut crossing method involves excavation of the pipeline trench across the waterbody with a backhoe-type excavator while water is still present in a waterbody. The excavators operate from one or both banks of the waterbody. Spoil excavated from the trench is placed above the OHWM for use as backfill, with the top 12 inches being segregated for use as the top layer of backfill. The pipe segment needs to be weighted, as necessary, to provide negative buoyancy prior to installation. Once the pipe is installed and the trench backfilled, the banks and stream bottom are restored to pre-construction contours and stabilized. However, as indicated above, this crossing method is not currently proposed, and would only be implemented if all other crossing methods (described below) fail, and may require additional analysis and permitting requirements.

Diverted Open Cut Crossing

Pacific Connector would use a diverted open cut for the eastern (second) crossing of the South Umpqua River at about MP 94.7. The river at this location is too wide for a typical dry crossing using either dam and pump or flume methods, and geotechnical studies indicate that subsurface conditions are not suitable for an HDD or conventional boring. At the proposed crossing location, the South Umpqua River channel is sufficiently flat, wide (175 feet bank to bank), and shallow (varying from a few inches to 15 feet deep), with flow slow enough to allow water to be diverted to one side while work is conducted on the opposite bank. Pacific Connector developed a site-specific plan for the eastern crossing of the South Umpqua River at MP 94.7.[39]

Dry Open Cut

Flume

The flume method would be used to cross streams less than 100 feet across. Water would be directed across the work area through one or more flume pipes. Sandbag and plastic sheeting would be used to support and seal the ends of the flume and to direct stream flow into the flume and over the construction area. Temporary dams at both the upstream (inlet) and downstream (outlet) sections of the flume would contain stream channel disturbance. After fish are salvaged from the confined area between the dams, water would be pumped out, through an upland dewatering structure, to create a dry work area for pipeline installation. Spoil from trenching would be stored in TEWAs located at least 10 feet away from the stream banks; with piles surrounded by silt fence. In-stream work (trenching, pipeline installation, and backfilling) would be conducted while the flume is in place, and the flume would be removed immediately after backfilling and bottom recontouring is completed. Details about stream fluming procedures were attached to the application filed with the FERC.[40]

Dam-and-Pump

The dam-and-pump method is an alternative dry construction technique that can be used to cross small or intermediate width waterbodies that are classified as coldwater fisheries. This method is preferred where the stream bottom is bedrock, and blasting may be necessary during trench excavation. Two temporary in-stream dams would be installed, with sandbags with plastic liner or other structures such as steel plates or water bladders. Stream flow would be diverted around the work area by pumping water through hoses. Intakes would be screened to prevent the entrainment of aquatic species. An energy-dissipation device would be used to prevent scouring

[39] See Appendix E.2 in Resource Report 2 as part of Pacific Connector's September 2017 application to the FERC.

[40] See Appendix C.2 in Resource Report 2 as part of Pacific Connector's September 2017 application to the FERC.

of the streambed at the downstream discharge location. The area between the dams would be dewatered, and the trench then excavated. Spoil would be stored in TEWAs located at least 10 feet from the banks; surrounded by silt fence. After pipeline installation and backfilling the dams would be removed and stream banks restored and stabilized. Pacific Connector would cross streams using the dam and pump method during the ODFW recommended in-water work windows. Details about dam and pump procedures were attached to the application filed with the FERC.[41]

Conventional Bore

Pacific Connector proposes to use conventional bore methods to cross under the Medford Aqueduct at MP 133.4, and all Reclamation water conveyance facilities (canals, laterals, and drains) associated with the Klamath Project. During a standard boring operation, pits are excavated on both ends of the bore, and the pipe fabricated and installed horizontally from one pit to the other beneath the feature being crossed. The walls of the bore pits may be supported by trench boxes or metal sheet piling. If groundwater seeps in to the bore or bore pits, a dewatering system would need to be used.

When crossing irrigation canals associated with Reclamation's Klamath Project, Pacific Connector committed to complying with Reclamation's Engineering and O&M Guidelines for Crossings – Bureau of Reclamation Water Conveyance Facilities (Canals, Pipelines, and Similar Facilities) unless otherwise described in the *Klamath Project Facilities Crossing Plan* (Appendix O of its POD). All crossings would require Professional Engineer–stamped design drawings approved by Reclamation prior to installation.

Horizontal Directional Drilling

Pacific Connector proposes to use the HDD method to cross under the Coos Bay Estuary (MPs 0.3–1.0 and 1.5–3.0) and three major waterbodies (Coos River at MP 11.1R; Rogue River at MP 122.7; and Klamath River at MP 199.4). This technique involves drilling a pilot hole under the feature being crossed, then enlarging that hole through successive reaming until large enough to install the pipeline. High pressure drilling fluids, usually consisting of a slurry made of bentonite clay mixed with water, would be jetted under pressure through the inside of the drill pipe to the drill head to advance the hole, and would then flow back to the drill entry point along annular space between the outside of the drill pipe and the drilled hole. Pipe sections long enough to span the entire crossing would be staged and welded along the construction work area on the opposite side of the waterbody, hydrostatically tested, and then pulled through the drilled hole. Upon completion of HDDs, the drilling mud returns would be hauled off-site and disposed of at an approved disposal facility in accordance with all applicable federal and state regulations. The right-of-way between the entry and exit hole of an HDD would generally not need to be cleared or graded, except for the area of the guide wires, and direct impacts on the waterbody and adjacent riparian vegetation would be avoided.

Pacific Connector prepared an HDD Feasibility Analysis.[42] That study showed that the HDD under the Coos Bay Estuary could be completed in two sections with a total length of about 8,970 feet and a maximum depth of about -190 feet; the HDD under the Coos River would be about

---

[41] See Appendix D.2 in Resource Report 2 as part of Pacific Connector's September 2017 application to the FERC.

[42] Attached as Appendix G.2 of Resource Report 2 as part of Pacific Connector's 2017 application to the FERC.

1,602 feet long with a maximum depth of -65 feet; the HDD under the Rogue River would be about 3,050 feet long with a maximum depth of -76 feet; and the HDD under the Klamath River would be about 2,309 feet long with a maximum depth of -71 feet. In case of an HDD failure, or the unanticipated release of drilling mud, Pacific Connector prepared a contingency plan.[43]

Direct Pipe Technology

DP technology is a trenchless construction method that can be used to install pipelines underneath rivers or roads without surface impacts. It is a combination of a micro-tunneling process and HDD. DPs are completed using an articulated, steerable micro-tunnel boring machine (MTBM) mounted on the leading end of the pipe or casing. Bentonite slurry is used to increase lubrication and advance the MTBM. The pipeline is pre-fabricated and welded in sections to the back of subsequent sections as the MTBM advances.

Pacific Connector proposes to use DP technology to install its pipeline under the western crossing of the South Umpqua River at about MP 71.3 and the associated crossings under I-5, Dole Road, and the Central Oregon & Pacific Railroad. This DP crossing would be about 1,680 feet long, with a maximum depth of -90 feet. Further details are available in Pacific Connector's I-5/South Umpqua River Direct Pipe Feasibility Evaluation and a separate site-specific crossing plan.[44]

Wetland Crossings

Pacific Connector would construct the pipeline across wetlands in accordance with the FERC's *Procedures*. The construction right-of-way through wetlands would be limited to a 75-foot width or less, where possible, and TEWAs would be located at least 50 feet away from wetlands, except where topographic constraints prevent this. Grading and stump removal in wetlands would only occur over the trench. Silt fence and straw bales would be installed at the edges of the construction right-of-way through wetlands. Trench plugs would be put in where the pipeline enters and exits wetlands. In saturated wetlands, Pacific Connector may use low ground weight equipment operating off pre-fabricated wooden mats. Pipe stringing in saturated wetlands may be done next to the trench or in adjacent TEWAs. If the wetland is flooded, Pacific Connector may use "push-pull" or "float" techniques. Pipeline installation through wetlands is further discussed in section 4.3 of this EIS.

Agricultural and Residential Areas

The FERC's *Plan* requires topsoil segregation in all residential areas, cultivated or rotated agricultural lands, pasture, and hayfields, or where requested by landowners. In these areas, topsoil would be stripped and segregated from either the full construction right-of-way, or over the trench line and subsoil storage area. Pacific Connector identified areas, in addition to most wetlands, where it intends to salvage and segregate topsoil along the pipeline route (see table D-4 in appendix D). Where topsoil segregation is proposed, Pacific Connector has requested 10 feet of TEWA in addition to the 95-foot construction right-of-way to stockpile segregated soils. Agricultural lands are further discussed in section 4.2 of this EIS and residential lands in section 4.7.

[43] Attached as Appendix H.2 to Resource Report 2 as part of Pacific Connector's 2017 application to the FERC.

[44] The former is attached as Appendix J.2 and the latter as Appendix E.2 to Resource Report 2 as part of Pacific Connector's 2017 application to the FERC.

Another requirement of the FERC's *Plan* is that excess rock should be removed from at least the top foot of soil in all actively cultivated or rotated cropland, pasture, hayfields, and agricultural lands. Pacific Connector would use rock pickers where necessary to remove excess rocks from these areas during cleanup. Rocks would be removed consistent with the size, density, and distribution in areas adjacent to the right-of-way. Excess rock would be disposed of in existing rock quarries and permanent disposal sites (see table D-7 in appendix D). Pacific Connector also attached an *Overburden and Excess Material Disposal Plan* as Appendix Q to its POD.

The FERC's *Plan* requires that soils in agricultural and residential areas be tested for compaction after construction, and any compaction should be alleviated. According to Pacific Connector's ECRP, during restoration activities soil compaction would be relieved by regrading and scarifying. This may include ripping and chisel plowing up to 18 inches deep.

Pacific Connector would work with individual landowners in agricultural areas to determine how the right-of-way would be restored where the pipeline would cross cropland, orchards, nurseries, or vineyards. If requested by the landowner, the landowner would restore the agricultural land and Pacific Connector would compensate the landowner. In residential areas, Pacific Connector would restore disturbed lawns, ornamental shrubs, gardens, and other landscape features in accordance with their agreement with the landowner. A contractor familiar with local horticultural or landscape practices would do the restoration work in residential areas, or Pacific Connector may choose to compensate a landowner to restore their property.

Pacific Connector has developed site-specific construction mitigation plans for residences within 25 feet of work areas. Some of the typical measures to be taken in residential areas include notification of landowners, limiting hours of construction, dust control, maintaining access, fencing, reducing the width of the right-of-way to increase the buffer to the pipeline, and replacing landscaping (see section 4.7 of this EIS).

Road, Railroad, and Utility Crossings

The Pacific Connector pipeline would include multiple road and railroad crossings. Conventional bores are typically used to cross under railroads, with DP and HDD technology proposed for one crossing each (see table D-2 in appendix D). Roads would either be bored or open cut. At least five feet of cover would be maintained over pipeline crossings of paved county, city, and state roads, as well as railroad crossings.

Pacific Connector would obtain all necessary permits from applicable county, state, or federal land-managing agencies for public roads to be crossed, and permission to cross private roads from the landowners. Pacific Connector produced a TMP for federal lands (as Appendix Y to the POD) and a TMP for non-federal lands.[45] Transportation management is discussed in more detail in section 4.10 of this EIS.

Pacific Connector would endeavor to notify agencies and private landowners at least seven days in advance of any road work or closures caused by pipeline construction activities. During an open cut crossing, Pacific Connector would try to keep one lane of the road open for traffic, with detours around construction, plating over the open trench, or other methods. However, in some situations

[45] Attached as Appendix F.8 in Resource Report 8 as part of Pacific Connector's September 2017 application to the FERC.

the road may have to be closed for a day when the pipeline would be installed across it. Where road closures occur, Pacific Connector would provide access around the construction site for local residents and emergency vehicles. Advanced signage would be used to provide notice of construction activities. In addition, Pacific Connector would utilize traffic control measures, such as signs, lights, barriers, and flaggers to ensure public safety and provide for efficient movement of traffic through or around the construction area, and to protect workers.

The Pacific Connector Pipeline would cross numerous existing utilities, including other pipelines, powerlines, and cables. Prior to construction, Pacific Connector would contact the local "One Call" or "Call Before You Dig" system to determine the location of utilities to be crossed and these utility crossings would then be marked in the field during pre-construction surveys. Pacific Connector would coordinate with each utility owner/operator to design crossings. In most instances, the new pipeline would have to be installed beneath the existing buried utility to maintain the necessary depth of cover.

2.4.2.3 Aboveground Facility Construction

Aboveground sites would be cleared and graded as applicable to accommodate the planned facilities. Excavation would be performed as necessary to accommodate the new reinforced concrete foundations for meter and compressor station equipment. The meter and compressor station equipment would be shipped to the site by truck. All components in high-pressure natural gas service would be strength tested prior to placing in service. Before being placed in service, all controls and safety equipment and systems would be checked and tested. MLVs would be installed within Pacific Connector's operational easement. The installation of the MLVs would meet the same standards and requirements established for pipeline construction.

2.5 CONSTRUCTION SCHEDULE AND WORKFORCE

The date for the start of construction would depend on completion of all required environmental and safety reviews and receipt of all necessary permits, approvals, and Commission authorization. Jordan Cove states that construction of the LNG terminal and slip we be expected to take five years. All in-water work for the terminal, including placement of material for the MOF, dredging, and work required to remove the berm separating the slip and the access channel would occur during an in-water work window between October 1 and February 15. Jordan Cove estimates that the construction workforce would average about 1,020 workers with a peak of about 2,000 workers occurring in year 3 of construction.

Pacific Connector states that construction and restoration of the pipeline and associated facilities would take place over the course of five years. Early works, including the two HDD crossings of Coos Bay, would begin in year one. Some forest clearing along the pipeline would beginning during year 2. Mainline pipeline and aboveground facility construction would take place during years 3 and 4, with the pipeline being placed into service by about the middle of year 4. Right-of-way restoration would begin during year 4 and continue into year 5. The total workforce during construction of the pipeline and associated facilities is estimated to range between about 88 and 4,242 workers, with an average of about 886 workers, with the peak occurring during summer and fall of year 1 of mainline construction (see section 4.9).

2.6 ENVIRONMENTAL INSPECTION, AND COMPLIANCE MONITORING

2.6.1 Jordan Cove Environmental Inspection Program

During construction, Jordan Cove and Pacific Connector would provide contractors with all Project design documents, including environmental alignment sheets, and copies of all applicable federal, state, and local permits. Jordan Cove would provide environmental training before a contractor or Jordan Cove employee steps out to a work area, and training records would be kept to demonstrate training activities. Numerous individuals, including company Chief Construction Inspectors, would supervise construction activities. Environmental Inspectors (EI) would be hired to ensure compliance with approved construction methods and all applicable permit and consultation requirements and conditions.

EIs would have peer status with all other activity inspectors along with the authority to stop activities that violate the environmental conditions of the FERC authorization, other permits, or landowner/land managing agency requirements, and to order appropriate corrective actions. The EIs would also be responsible for advising the chief construction inspector when conditions (such as wet weather) make it advisable to restrict construction activities. EI duties would include maintaining status reports and training records.

The EI's responsibilities would include:

- ensuring compliance with the requirements of the Jordan Cove and Pacific Connector's *Plan* and *Procedures* (including modifications), the environmental conditions of the section 3 and Certificate authorization, the mitigation measures proposed by the applicant (as approved and/or modified by FERC's authorization), other environmental permits and approvals, and environmental requirements in landowner easement agreements;
- verifying that the limits of authorized construction work areas and locations of access roads are properly marked before clearing;
- verifying the location of signs and highly visible flagging marking the boundaries of sensitive resource areas, waterbodies, wetlands, or areas with special requirements along the construction work area;
- identifying erosion/sediment control and soil stabilization needs in all areas;
- ensuring that the location of dewatering structures and slope breakers would not direct water into known cultural resources sites or locations of sensitive species;
- verifying that trench dewatering activities do not result in the deposition of sand, silt, and/or sediment near the point of discharge into a wetland or waterbody. If such deposition is occurring, the dewatering activity would be stopped and the design of the discharge would be changed to prevent reoccurrence;
- identifying, documenting, and overseeing corrective actions, as necessary to bring an activity back into compliance; and
- keeping records of compliance with the environmental conditions of the FERC Certificate, and the mitigation measures proposed by the Project sponsor in the application submitted to the FERC, and other federal or state environmental permits during active construction and restoration.

2.6.2 FERC Environmental Compliance Monitoring

During construction of the Project, third-party Compliance Monitors representing the FERC would be present on a full-time basis to inspect construction procedures and mitigation measures and provide regular feedback on compliance issues to the FERC and Jordan Cove and Pacific Connector's environmental inspection team. Construction progress and environmental compliance would be tracked and documented by the Compliance Monitors. The Compliance Monitors would report directly to a Compliance Manager who would report directly to the FERC Project Manager. Other objectives of the third-party Compliance Monitoring program would be to facilitate the timely resolution of compliance issues in the field; provide continuous information to FERC regarding noncompliance issues and their resolution; and review, process, and track construction-related variance requests. Changes to previously approved mitigation measures, construction procedures, and construction work areas due to unforeseen or unavoidable site conditions would require various levels of regulatory approval, with the delegation of some authority to the third-party Compliance Monitors. FERC would also receive regular construction status reports filed by Jordan Cove and conduct periodic field inspections during construction and restoration of the Project. FERC would have the authority to stop any activity that violates an environmental condition of the FERC authorization issued to Jordan Cove. Other federal, state, and local agencies could also monitor the Project to the extent determined necessary by the agency.

2.6.3 Monitoring by Land Managing Agencies on Federal Lands

Monitoring is an essential element of project implementation (CEQ 2011). If the BLM issues a Temporary Use Permit and a Right-of-Way Grant for the Pacific Connector Pipeline Project, those authorizations would provide the terms and conditions for construction, operation, maintenance, and eventual termination of the facility on federal public lands. As cooperating agencies with jurisdiction by law for activities that occur on lands they administer, the BLM, Forest Service, and Reclamation have a responsibility to monitor implementation of the Pacific Connector Pipeline Project to assure that the terms and conditions of the Right-of-Way Grant are carried out (43 CFR 2885.24). This monitoring would be in addition to the Environmental Compliance Monitoring carried out by third-party Compliance Monitors representing the FERC.

CEQ regulations for NEPA (40 CFR 1505.3) also provide that a monitoring and enforcement program should be adopted as part of the decision to implement the Project. Many of the requirements of the POD that are a part of the BLM Right-of-Way Grant on federal lands are project design measures that reduce the environmental consequences of the Project on-site. The Forest Service has also proposed off-site compensatory mitigation plans (see section 2.1.5). In addition to monitoring implementation of the Temporary Use Permit and the Right-of-Way Grant, the BLM, Forest Service, and Reclamation also have a responsibility to monitor authorized actions, whether they are project design features described in the POD or off-site mitigation measures included in Forest Service mitigation plans. As needed, agency representatives of the BLM, Forest Service, and Reclamation would participate in the monitoring process to assure that agency priorities are accomplished and agency obligations are fulfilled. Reclamation agency representatives would be on-site during all crossings of Reclamation facilities. Reclamation would require a minimum 48-hour notice for each crossing to ensure that Reclamation agency representatives are able to be on-site during the crossing installations.

Pacific Connector worked closely with the BLM and Forest Service to minimize impacts on federal lands during the proposed pipeline route selection and construction footprint design process. In developing the POD interdisciplinary teams of the BLM and Forest Service worked with Pacific Connector to implement project design features that would reduce impacts on LSR, Riparian Reserves, soil resources, water quality, recreation, and other resources as described in the POD attachments below. Additional discussion on the steps taken to avoid or reduce impacts on LSR and Riparian Reserves is included in appendix F. The POD developed by Pacific Connector is part of the Right-of-Way Grant application and includes monitoring requirements to ensure that impacts from construction and operation of the Project are minimized and that objectives of the respective land management plans are accomplished. The POD includes 28 attachments, 27 of which were developed in cooperation with the BLM, Forest Service, and Reclamation (the remaining attachment is the Environmental Alignment Sheets for the Project). These attachments are individual plans detailing Pacific Connector's proposed method for construction and operation of the proposed pipeline on federal lands. A description of the POD is summarized in table 2.6.3-1. Ongoing discussion between the applicant and agencies may result in refinements to the POD. Because the proposed actions specific to federal lands include amendments to LMPs, the regular monitoring and reporting programs of the respective BLM RMPs and Forest Service LRMPs would be used in addition to those identified in the POD.

TABLE 2.6.3-1

Pacific Connector's Plan of Development

Appendix	Appendix Title	Description
A	Aesthetics Management Plan for Federal Lands	The purpose of this Plan is to outline methods that Pacific Connector would implement to ensure compliance with agency land and resource management plans pertaining to visual and aesthetic resources within the Pipeline Project area. This Plan establishes goals for managing visual resources as they relate to construction, reclamation and management of the Pacific Connector Pipeline Project and describes actions to be taken by Pacific Connector to minimize impacts on visual resources.
B	Air, Noise and Fugitive Dust Control Plan	This Plan describes the practices that would be implemented during construction of the Pacific Connector Pipeline Project to minimize or control the potential impacts on air quality or the impacts caused by noise or fugitive dust on federal lands crossed by the pipeline project. The minimization and control measures described in this plan are also important to protecting the safety of construction workers, visiting agency personnel, and the general public that may use the public roads during the construction activities or reside near the construction right-of-way.
C	Blasting Plan	The purpose of this Blasting Plan is to provide guidelines for the safe use and storage of blasting materials proposed for use during construction of the Pacific Connector Pipeline Project. This Blasting Plan is intended to help ensure the safety of construction personnel, the public, nearby facilities and sensitive resources.
D	Communication Facilities Plan	The purpose of this plan is to describe the construction, modification, operation and maintenance of communication facilities necessary for the operation of the Pacific Connector Pipeline Project on federal lands managed by the BLM and the Forest Service. The communication facilities are necessary to enable communications between facilities constructed in conjunction with the pipeline project and the Pacific Connector gas control center.
E	Contaminated Substances Discovery Plan	The purpose of the Contaminated Substances Discovery Plan is to outline practices to protect human health and worker safety and to prevent further contamination in the event of an unanticipated discovery of contaminated soil, water, or groundwater during construction of the Pacific Connector Pipeline Project.

TABLE 2.6.3-1 (continued)

Pacific Connector's Plan of Development

Appendix	Appendix Title	Description
F	Corrosion Control Plan	Pacific Connector would implement methods to protect the pipeline system from external, internal, and atmospheric corrosion in accordance with USDOT 49 CFR 192. Corrosion Control is critical to public safety and the safe/reliable operation of the pipeline. This plan will illustrate methods used to identify the corrosion control needs for the pipeline project, as well as methods to provide the required protection and mitigation.
G	Environmental Briefings Plan	The purpose of this Plan is to outline the environmental reporting procedures, briefings, or notifications that Pacific Connector would provide to the federal land-managing agencies prior to construction, during construction, post construction, and during operations of the Pacific Connector Pipeline. Detailed compliance management documents would be developed based on the conditions in the permits/authorizations issued for the project and would be provided to the federal land-managing agencies prior to construction.
H	Emergency Response Plan	The purpose of this Emergency Response Plan is to identify the standards and criteria that Pacific Connector would follow to minimize the hazards during pipeline operation resulting from a gas pipeline emergency in accordance with the Pipeline and Hazardous Materials Safety Administration's regulations in 49 CFR 192.615 and 192.617.
I	Erosion Control and Revegetation Plan	The Erosion Control and Revegetation Plan outlines the erosion control and revegetation procedures that Pacific Connector would utilize during construction of the pipeline to minimize erosion, sedimentation and enhance revegetation success on all lands crossed by the pipeline.
J	Plant Conservation Plan	The purpose of this plan is to describe the conservation measures that Pacific Connector would implement to minimize the potential effects on federally-listed plants, including one plant identified as a species of concern, that have been documented during Pipeline project survey efforts to-date, or that may be documented during subsequent survey efforts prior to ground-disturbing activities. The plan outlines avoidance, minimization, propagation, restoration and other mitigation measures for federally-listed plant species.
K	Fire Prevention and Suppression Plan	The Fire Prevention and Suppression Plan describes the measures to be used by Pacific Connector and its contractors (Contractor) to ensure that fire prevention and suppression techniques are carried out in accordance with federal, state and local regulations.
L	Fish Salvage Plan	The fish salvage plan has been developed to minimize adverse effects on Endangered Species Act (ESA) listed salmonids (Southern Oregon/Northern California Coast coho salmon and Oregon Coast coho salmon), non-listed salmonids (Chinook, steelhead, cutthroat trout) and ESA-listed catostomids (Lost River sucker and shortnose sucker) during construction of the Pacific Connector Pipeline Project as well as other aquatic organisms.
M	Hydrostatic Test Plan	In accordance with USDOT 49 CFR Part 192, Pacific Connector would strength test (or hydrostatic test) the pipeline system (in sections) after it has been lowered into the pipe trench and backfilled. The purpose of the hydrostatic test is to verify the manufacturing and construction integrity of the pipeline before placing it in service to flow natural gas.
N	Integrated Pest Management Plan	This plan would provide Pacific Connector's management and staff with the necessary BMPs to address the control of noxious weeds, invasive plants, forest pathogens, and soil pests across the route of the Pipeline. The BMPs have been created to minimize the potential spread of invasive species and minimize the potential adverse effects of control treatments.
O	Klamath Project Facilities Crossing Plan	The Plan identifies the locations within Klamath County, Oregon where the Pacific Connector alignment crosses facilities within the Klamath Project that are administered by the Klamath Basin Area Office of Reclamation and the methods proposed to construct the pipeline project across Reclamation facilities.
P	Leave Tree Protection Plan	The purpose of this plan is to describe the measures that would be implemented during construction of the Pacific Connector to identify, conserve and protect selected trees (living and snags) within or along the edges of the pipeline project's certificated work limits.
Q	Overburden and Excess Material Disposal Plan	The purpose of this Plan is to identify the proposed locations on federal lands that may be used for the permanent and temporary storage of excess rock, timber, and spoil generated during timber removal and pipeline construction of the Pacific Connector Pipeline Project.

TABLE 2.6.3-1 (continued)

Pacific Connector's Plan of Development

Appendix	Appendix Title	Description
R	Prescribed Burning Plan	The Prescribed Burning Plan describes the protocols that Pacific Connector would follow to obtain appropriate agency authorization on all lands (federal, state and private) crossed by the pipeline, where it is necessary to dispose of forest slash by burning. This plan also outlines the appropriate BMPs that would be utilized to safely conduct slash burning operations.
S	Recreation Management Plan	The purpose of the Plan is to assist in the management of existing recreation resources on lands within the pipeline project area or impacted by the pipeline. This Plan establishes goals for managing recreation in the vicinity of the pipeline and describes actions to provide continued safe access, prevent resource damage, and to avoid potential user conflict.
T	Right-of-Way Marking Plan	The purpose of this Plan is to identify the survey standards and types of survey markings that would be used by Pacific Connector on federal lands during the pre-construction, construction, and operational phases of the pipeline project.
U	Right-of-Way Clearing Plan	The purpose of this Right-of-Way Clearing Plan (Plan) is to outline the methods that Pacific Connector would implement during timber (and other vegetation) removal within the construction right-of-way and TEWAs. This Plan was developed utilizing applicable BMP compliance protocols outlined in the Erosion Control and Revegetation Plan for the pipeline project.
V	Safety and Security Plan	The purpose of this plan is to describe safety standards and practices that would be implemented to minimize health and safety concerns related to the construction of the pipeline project.
W	Sanitation and Waste Management Plan	The purpose of the Plan is to outline the procedures that would be implemented by Pacific Connector and its contractors to manage sanitation and waste materials during construction and operations of the Pacific Connector Pipeline Project.
X	Spill Prevention, Containment, and Countermeasures Plan	The Plan identifies measures to be taken by Pacific Connector and its contractors to prevent, contain and respond to spills during the construction of the pipeline project.
Y	Transportation Management Plan	The purpose of the plan is to cover all pipeline project transportation-related activities involving Agency-jurisdiction roads or rights-of-way and identifies ongoing cooperative procedures.
Z	Unanticipated Discovery Plan	This plan provides the procedures Jordan Cove, Pacific Connector, its personnel and consultants would follow in the event that unanticipated discoveries of historic properties, archaeological objects, archaeological sites, or human remains are made during the construction and operation of the Project.
AA	Environmental Alignment Sheets	A set of photo-based maps depicting the centerline and construction right-of-way at a scale of 1":200' and the associated environmental features and requirements.
BB	Wetland and Waterbody Crossing Plan	The Plan outlines the construction methods, restoration procedures, and BMPs that Pacific Connector would utilize during construction of its pipeline. The measures set out in this plan would be employed to avoid, minimize, and restore potential impacts associated with wetland and waterbody crossings, as well as to minimize potential effects on aquatic resources.

2.7 OPERATION AND MAINTENANCE PROCEDURES

2.7.1 LNG Terminal Facilities

Jordan Cove would operate and maintain its facilities in compliance with 49 CFR 193, 33 CFR 127, National Fire Protection Association (NFPA) 59A, and other applicable federal and state regulations. Before commencing operation of the LNG terminal, Jordan Cove would prepare and submit for approval operation and maintenance manuals that address specific procedures for the safe operation and maintenance of the LNG storage and processing facilities. Jordan Cove would also prepare an operations manual that addresses specific procedures for the safe operation of the ship unloading facilities in accordance with 33 CFR 127.305. Operating procedures would address normal operations as well as safe startup, shutdown, and emergency conditions.

All operations and maintenance personnel at the terminal would be trained to properly and safely perform their jobs. Jordan Cove states that operators would meet all the training requirements of the Coast Guard, USDOT, ODOE, Oregon State Fire Marshall, Coos Bay, Coos County Fire Department, and other regulatory entities. The SORSC would provide on-site resources and assets, including a Sherriff's office and fire department.

The LNG terminal and related facilities would be staffed with about 180 full-time equivalent employees working three shifts, so there would be coverage 24 hours a day, 365 days a year. The terminal's full-time staff would conduct routine maintenance and minor overhauls. Major overhauls and other major maintenance would be handled by bringing in maintenance personnel specifically trained to perform the maintenance. All scheduled and unscheduled maintenance would be entered into a computerized maintenance management system.

2.7.2 Pipeline and Associated Aboveground Facilities

Pacific Connector would test, operate, and maintain the proposed facilities in accordance with USDOT regulations provided in 49 CFR Part 192; the FERC's guidance at 18 CFR 380.15; rules and regulations promulgated by PHMSA; and maintenance provisions of its ECRP. The pipeline right-of-way would be clearly marked where it crosses public roads, waterbodies, fenced property lines, and other locations as necessary. All pipeline facilities would be marked and identified in accordance with applicable regulations.

The aboveground facilities would be inspected for the life of the pipeline at intervals that meet USDOT requirements. Pipeline personnel would perform routine checks of the facilities, including calibration of equipment and instrumentation, inspection of critical components, and scheduled and routine maintenance of equipment. Safety equipment, such as pressure-relief devices, fire detection and suppression systems, and gas detection systems, would be tested for proper operation. Corrective actions would be taken for any identified problem. Vegetation at aboveground facilities would be periodically maintained using mowing, cutting, trimming and the selective use of herbicides.

To facilitate periodic pipeline corrosion/leak surveys, a corridor centered on the pipeline and up to 10 feet wide would be maintained in an herbaceous state, with no vegetation greater than 6 feet in height. Trees that are located within 15 feet of the pipeline and that are greater than 15 feet in height would be cut and removed from the right-of-way. Vegetation within the permanent easement would be periodically maintained by mowing, cutting, and trimming (either by mechanical or hand methods). Maintenance activities are expected to occur approximately every three to five years depending on the growth rate. During maintenance, trimmed or cut vegetation would be scattered across the operational easement to naturally decompose and to discourage off-highway vehicle (OHV) traffic. Occasionally, where site conditions allow, chipping of this material may also occur. Herbicides would not be used for brush control; however, if noxious weed infestation occurs on the permanent easement, selective use of herbicides would be used to control these species. Herbicides would not be used in or within 100 feet of a waterbody's mean high-water mark.

Pacific Connector would employ a permanent staff of 15 employees, including six operations technicians in the Coos Bay pipeline office in Coos County, five employees in the Medford pipeline office in Jackson County, and four employees at the compressor station near Malin in Klamath County. In addition, the pipeline and aboveground facilities would be monitored all the time using Pacific Connector's gas control communication system and radio towers reporting back to a command center at the Williams' office in Salt Lake City, Utah.

3.0 ALTERNATIVES

As required by NEPA, Commission policy, and in cooperation with the COE, BLM, Forest Service, Reclamation, and the other NEPA cooperating agencies, we identified and evaluated reasonable and practical alternatives to the facilities (and locations) proposed by Jordan Cove and Pacific Connector as described in section 2.1 of this document. Specifically, and consistent with the Purpose and Need of the Project as described in section 1.2, we evaluated the No Action Alternative, System Alternatives, LNG Terminal Site Alternatives, and Pipeline Alternatives (including Federal Lands Alternatives and Compressor Station Alternatives). To satisfy its responsibilities per the CWA Section 404(b)1(1) Guidelines, the COE also evaluated whether alternatives would be practicable.[46]

Our evaluation of alternatives is based on Project-specific information provided by the applicants, affected landowners, and other concerned parties; publicly available information; our consultations with federal and state resource agencies; federally recognized tribes; and our expertise and experience regarding the siting, construction, and operation of LNG export facilities and interstate natural gas transmission facilities and their potential impact on the environment. In evaluating alternatives, we considered and addressed, as appropriate, the comments provided to the Commission regarding possible alternatives.

As described in section 1.4, the Commission received thousands of letters and comments expressing concern about the Project. Many of these letters requested that we evaluate alternatives to the Project. In response to these comments, we required the applicants to provide additional environmental information, requested they assess the feasibility and practicability of alternatives as proposed by the commenters (including other federal agency alternatives requests); conducted site visits and field investigations; met with affected landowners and local representatives and officials; and consulted with federal and state regulatory agencies and tribes. All comments concerning alternatives were considered, and many, but not all, of these alternatives are included in this analysis. Not included in this analysis is an assessment of renewable energy resources as an alternative to the Project. Renewable energy resources include, but are not limited to, wind, solar, and hydroelectric power. These resources are alternatives to electrical power production. Because the Project's purpose is to transport natural gas across southern Oregon and convert it to LNG for export to overseas markets, not generate electricity, the development and use of renewable energy resources would not meet the purpose of the Project, and therefore is not a reasonable or practicable alternative to the proposed action and is not considered further in this analysis.

The purpose of this analysis is to satisfy NEPA requirements that agencies take a "hard-look" at a project's impacts, inform the public of these impacts, and determine whether the adoption and implementation of an alternative(s) would be preferable to the proposed action. As described below, we consider numerous reasonable and practicable alternatives to the proposed action. In consultation with the NEPA cooperating agencies, using our collective professional judgment, and through environmental comparison, each alternative is considered until it is clear that the

[46] When making a decision on whether to issue a permit for the Project, the COE must consider whether the proposed Project represents the least environmentally damaging practicable alternative pursuant to the CWA section 404(b)(1) guidelines. The term "practicable" means available and capable of being done after taking into consideration cost, existing technology, and logistics in light of the overall purpose of the Project. The COE may only permit discharges of dredged or fill material into waters of the U.S. that represent the least damaging practicable alternative, so long as the alternatives do not have other significant adverse environmental consequences.

alternative would not satisfy one or more of the evaluation criteria (see below). Furthermore, it is important to note that the Commission's role under the NGA is to review applications filed with it, not to develop a general plan for energy infrastructure. Thus, comments suggesting that the Commission require applicants to pursue alternatives that are substantially different than their proposals will be considered, but may not result in a reasonable alternative that would be addressed in our alternatives analysis.

Evaluation Process

The purpose of this evaluation is to determine whether an alternative would be preferable to the proposed action. To determine if an alternative would be preferable to a proposed action, we generally evaluate an alternative using three criteria:

1. does the alternative meets the stated purpose of the project;
2. is technically and economically feasible and practical; and
3. offers a significant environmental advantage over a proposed action.

The alternatives were reviewed against the evaluation criteria in the sequence presented above. If the alternative would not meet the Project's purpose, or is not feasible or practical, we did not compare environmental information to determine if the third evaluation criterion was satisfied.

The first consideration for including an alternative in our analysis is whether or not it could satisfy the stated purpose of the Project. As described previously, the purpose and need of the Jordan Cove Project is to export natural gas supplies derived from existing interstate natural gas transmission systems to overseas markets; and the purpose and need of the Pacific Connector Project is to connect the existing interstate natural gas transmission systems of GTN and Ruby with the proposed Jordan Cove LNG terminal. Alternatives that do not achieve these purposes cannot be considered as feasible or reasonable alternatives to the Project. Furthermore, the Commission cannot simply ignore a project's purpose and substitute a purpose it or a commenter deems more suitable.

The only location where the GTN and Ruby pipeline systems interconnect is near Malin, Oregon. Malin is a major natural gas trading hub providing access to multiple supply basins in the United States and Canada. GTN and Ruby have a combined natural gas transportation capacity of 3.8 Bcf/d at Malin providing access to diverse and abundant supplies to support Jordan Cove's export operations. Therefore, in the alternatives analyses below, all pipeline alternatives originate near Malin, Oregon. All of the alternatives considered here, except the No Action Alternative, are able to meet the Project purpose stated in section 1.2 of this EIS.

Not all conceivable alternatives are technically and economically feasible and practical. Technically feasible alternatives, with exceptions, would generally involve the use of common LNG facility and pipeline construction methods. Economically practical alternatives would result in an action that generally maintains the price competitive nature of the proposed action. An alternative that would involve the use of a new, unique, or experimental construction method(s) may be technically feasible, but not economically practical. Generally, we do not consider the cost of an alternative as a critical factor unless the added cost to design, permit, and construct the alternative would render the project economically impractical.

To determine if an alternative is practicable and would provide a significant environmental advantage over the proposed action, we compare the impacts of the alternative and the proposed action (e.g., number of wetlands/waterbodies affected by the alternative and number of wetlands/waterbodies affected by the proposed action). To ensure consistent environmental comparisons and to normalize the comparison of resources, we generally use "desktop" sources of information (e.g., publicly available data, aerial imagery) and assume the same construction and operation right-of-way widths and general workspace requirements. We evaluate data collected in the field if surveys were completed for both the proposed action and the corresponding alternative. Our environmental comparison uses common factors such as (but not limited to) total amount, length/distance, and acres affected of a resource. Furthermore, this analysis considers impacts on both the natural and human environments. The natural environment is generally characterized by vegetation, waterbodies, wildlife, and other biological resources; while the human environment includes land use, existing infrastructure, and community (socioeconomic) characteristics. Where appropriate and available, we also use site-specific information. In comparing the impact between resources, we also consider the magnitude of the impact anticipated on each resource. As applicable, we assess impacts on resources that are not common to the alternative and the proposed action (e.g., an alternative affects old growth forest whereas the proposed action affects agricultural lands). Our determinations attempt to balance the overall impacts (and other relevant considerations) of the alternative(s) and the proposed action. Recognizing the often-competing interests driving alternatives and the differing nature of impacts resulting from an alternative (i.e., impacts on the natural environment versus impacts on the human environment), we also consider other factors that are relevant to a particular alternative or discount or eliminate factors that are not relevant or may have less weight or significance. Ultimately, an alternative that is environmentally comparable or results in minor advantages in terms of environmental impact would not compel us to shift the impacts from the current set of landowners to a new set of landowners.

The factors considered for an aboveground facility alternative are different than those considered for a pipeline route alternative because an aboveground facility is a fixed location rather than a linear facility which is routed between two points. In evaluating aboveground facility locations, we consider the amount of available land, current land use, adjacent land use, location accessibility, engineering requirements, stakeholder comments, and impacts on the natural and human environments.

3.1 NO ACTION ALTERNATIVE

NEPA requires federal agencies to consider and evaluate a No Action Alternative. Additionally, a No Action Alternative serves as a baseline against which the impacts of the proposed action are compared and contrasted. Under the No Action Alternative, the proposed action would not occur, the permits and authorizations listed in section 1.5 would not be required, and as a result, the environment would not be affected.

Under the No Action Alternative, the RMPs of the Coos Bay, Roseburg, Medford, and Klamath Falls Resource Area of the Lakeview District and the LRMPs of the Rogue River, Umpqua, and Winema National Forests would not be amended to make provision for the Project. Furthermore, the Forest Service would not consent to the BLM to grant an easement because construction of the Project would not be consistent with the National Forest LRMPs. The BLM would not issue a Right-of-Way Grant for the Project because the Project would not be a conforming use of federal land. Under the No Action Alternative, there would be no need for Reclamation to concur with BLM with respect to issuance of a Right-of-Way Grant. Also, the FWS and NMFS would not issue Biological Opinions (BO) because there would be No Effect on species listed under the ESA.

Under the No Action Alternative specific to the COE's role in the Project review, construction of the Project would result in a modified project design or location that eliminates work that would require a Department of the Army permit (i.e., avoidance of aquatic resource impacts) or the COE's denial of the permit.

In Order No. 3041-A issued July 20, 2018, the DOE amended its previous authorization to export LNG from the Jordan Cove LNG Project to countries with which the U.S. has a FTA(DOE 2018). By law, under Section 3(c) of the NGA, applications to export natural gas to FTA nations that require national treatment for trade in natural gas are deemed to be consistent with the public interest. The DOE also issued a conditional authorization to the Jordan Cove Project to export to non-Free Trade Agreement countries in Order No. 3413 on March 24, 2014. For the non-Free Trade Agreement conditional authorization, granted under Section 3(a) of the NGA, the DOE determined that exports from the Jordan Cove Project were not inconsistent with the public interest, provided the Project successfully completes the environmental review. In its application, Jordan Cove states the purpose of its Project is to export natural gas supplies derived from existing interstate natural gas transmission systems (linked to the Rocky Mountain region and Western Canada) to overseas markets, particularly Asia. According to Jordan Cove, the Project is a market-driven response to increasing natural gas supplies in the U.S. Rocky Mountain and Western Canada markets, and the growth of international demand, particularly in Asia.

Given that the Project is market-driven, it is reasonable to expect that if the Jordan Cove LNG Project is not constructed (the No Action Alternative), export of LNG from one or more other LNG export facilities could also be authorized by the DOE and eventually be constructed. Thus, although the environmental impacts associated with constructing and operating the Project would not occur under the No Action Alternative, equal or greater impacts could occur at other location(s) in the region as a result of another LNG export project seeking to meet the demand identified by Jordan Cove.

As stated in the introduction to this section, the No Action Alternative would not meet the Project's purpose and need. Therefore, we conclude that the No Action Alternative does not meet the Project purpose (criterion 1) and an alternative project to meet the market demand has not been proposed but would require a similar footprint. Although the resources that would be affected by an alternative project are not defined, we conclude that it would not likely provide a significant environmental advantage over the proposed action (criterion 3). Therefore, we do not consider the No Action Alternative further. However, the other NEPA cooperating agencies, consistent with their review and regulatory responsibilities, may choose to select this alternative.

3.2 SYSTEM ALTERNATIVES

System alternatives would make use of existing or other proposed LNG facilities and pipelines to meet the purpose of the Project. Implementing a system alternative would make it unnecessary to construct all or part of the Project, although some modifications or additions to existing LNG facilities or pipeline transmission systems/facilities, or other proposed LNG or pipeline transmission systems/facilities might be necessary. The pipeline portion of a system alternative would involve the use of all or portions of other natural gas transmission systems to transport natural gas from near Malin, Oregon, to the proposed terminal near Coos Bay, Oregon. Existing natural gas pipelines in southern and central Oregon include the jurisdictional interstate transportation systems operated by Northwest, GTN, and Ruby, and the non-jurisdictional intrastate Coos County Pipeline (figure 3.2-1).

As of the issuance of this EIS, there are no existing LNG export (or import) terminal facilities located on the west coast of the contiguous United States (Washington, Oregon, and California). Additionally, we are not aware of any proposed LNG export (or import) terminals on the west coast of the contiguous United States. Existing and proposed East Coast and Gulf Coast LNG export facilities are located 2,000 – 3,000 miles from Oregon, and would not be reasonable alternatives. According to USDOT PHMSA, there are four LNG storage facilities (peak-shaving plants) in Oregon and Washington connected to natural gas pipeline systems. These facilities are not designed to export LNG, are insufficient to meet the purpose of the Project, and would require significant modifications to meet the Project's purpose. Additionally, an LNG storage facility is being built in Tacoma, Washington (i.e. the Tacoma LNG) that would provide fuel for marine vessels and natural gas service for local residential and commercial customers. However, this facility which is located on a 30-acre site in a highly industrialized area is physically constrained with insufficient land available for the expansion necessary to meet the Project's purpose. Therefore, we conclude that there are no reasonable LNG system alternatives in the contiguous United States.

We received several comments suggesting this analysis consider existing and proposed LNG export facilities located in Alaska, Canada, and Mexico. In Alaska, there is an idle LNG export facility on the Kenai Peninsula. The Commission is also currently reviewing an application (FERC Docket No. CP17-178-000) to construct and operate a new LNG export facility in Nikiski, Alaska. These facilities are not connected to the "lower-48" natural gas transmission pipeline network and although constructing a pipeline from the existing GTN and Ruby pipelines systems near Malin, Oregon to the existing or proposed facility in Alaska (a distance of close to 3,000 miles) is technically feasible, it is not economically practical. Furthermore, constructing a pipeline to Alaska from Malin would result in significantly more environmental impacts than the proposed Project as this pipeline would be an order of magnitude longer than the currently proposed pipeline. Based on the length of the Pacific Connector Pipeline and the total footprint, including all extra workspace, the pipeline would affect about 21.6 acres per mile of length. Therefore, adding 2,700 miles would affect as much as 58,320 acres of land. Consequently, we conclude that an LNG system alternative making use of the existing or proposed Alaska LNG facilities would not provide a significant environmental advantage and do not consider it further in this analysis.

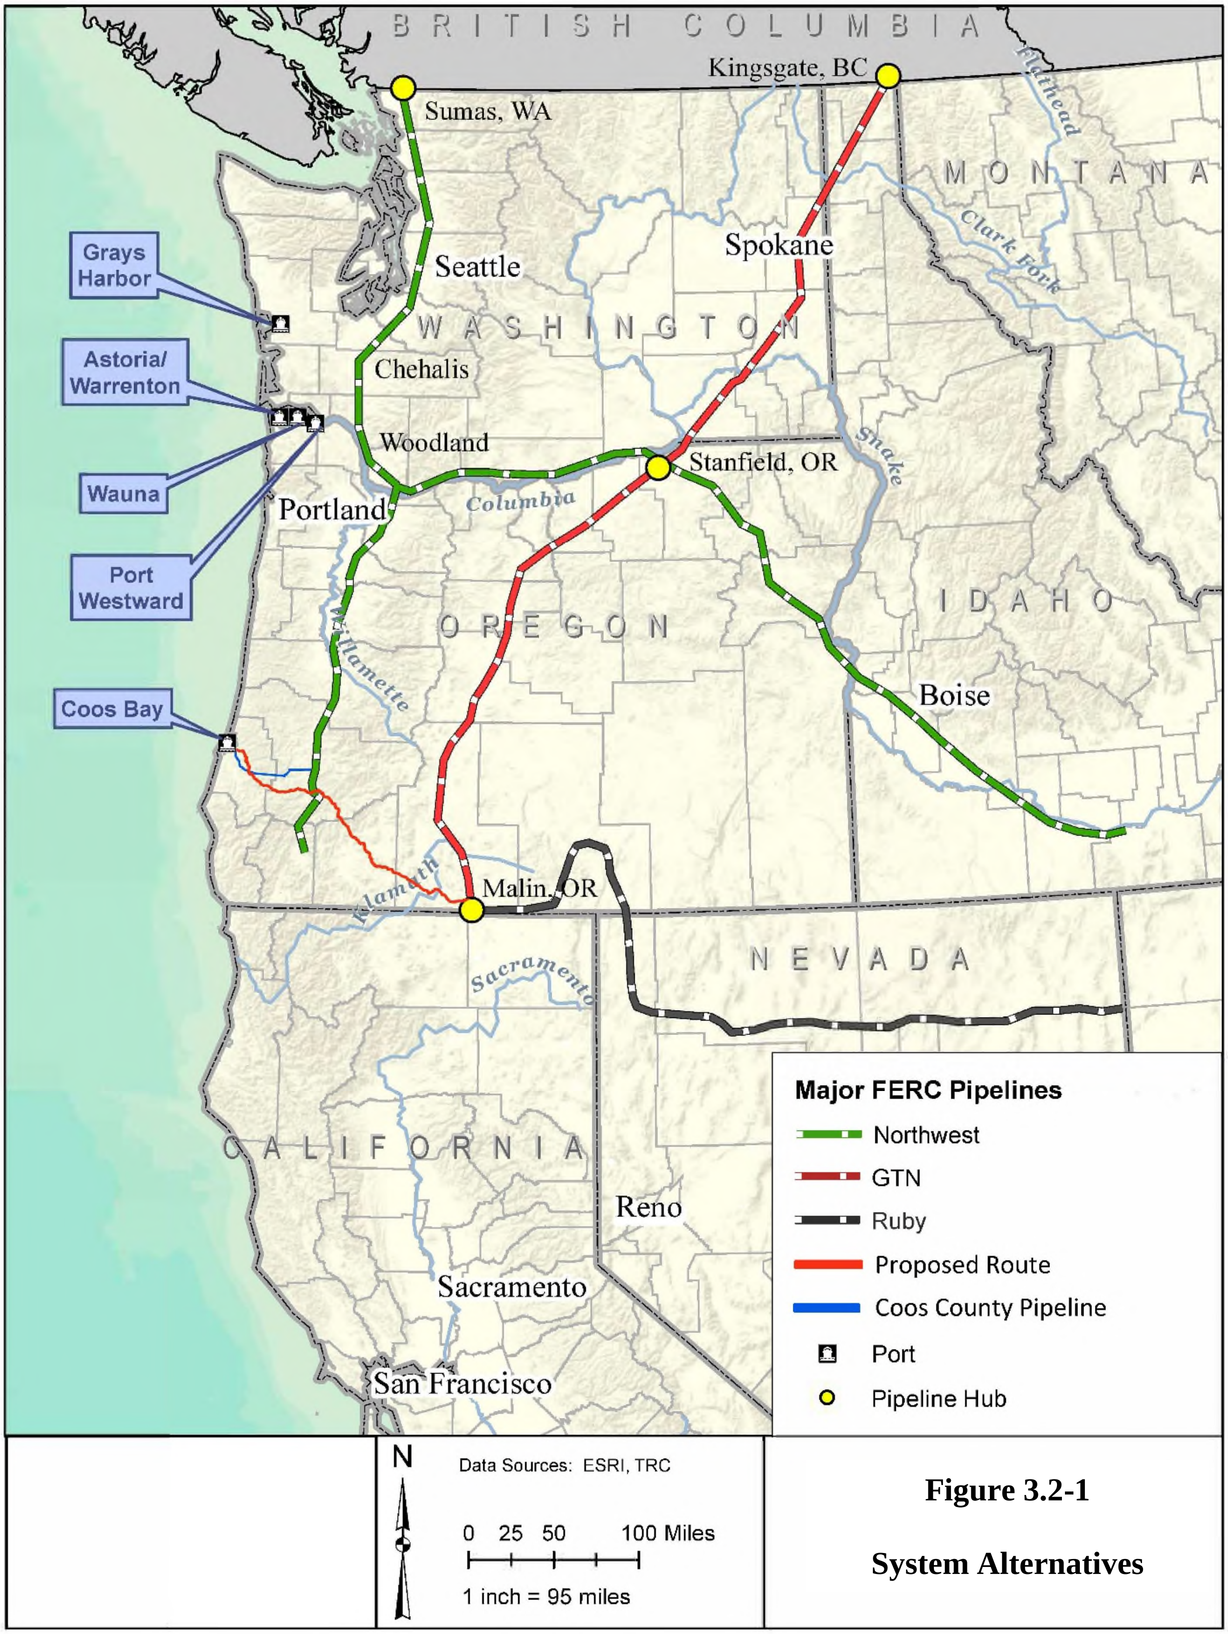

Figure 3.2-1

System Alternatives

According to Natural Resources Canada (2018), 13 LNG export facilities have been proposed in British Columbia, Canada (see table 3.2-1). The final specifications and permitting/ construction statuses of these facilities are unknown. Assuming these facilities have been designed to accommodate a pre-determined need/level of service, it may be possible that with modifications, one or more of these facilities would be able to provide an equivalent level of service to that which would be provided by the Project. However, we are unable to determine what modifications would be necessary and what the impacts of those modifications would be. Furthermore, although constructing a pipeline from the existing GTN and Ruby pipelines systems to western Canada (a distance ranging from 700 to 1,400 miles) is technically feasible, it would increase the Project footprint by between about 10,100 and 25,300 acres. Therefore, we conclude that an LNG system alternative making use of a proposed western Canada LNG facility would not provide a significant environmental advantage and do not consider it further in this analysis.

TABLE 3.2-1

Proposed Canadian LNG Projects

Project	Terminal Location	Output (Max Bcf/d)
Cedar LNG Project	Near Kitimat, B.C.	0.8
LNG Canada Project	Port Edward, Prince Rupert Island, B.C.	3.5
WesPac LNG Marine Terminal	Tilbury Island, B.C.	0.6
Kitimat LNG Project	Kitimat, B.C.	1.3
New Times Energy Ltd.	Prince Rupert area, B.C.	1.6
Orca LNG Project	Prince Rupert area, B.C.	3.2
Steelhead LNG Project	Sarita Bay, Vancouver Island, B.C.	4.3
Woodfibre LNG Project	Near Squamish, B.C.	0.3
Stewart Energy Project	Stewart, B.C.	4.0
Discovery LNG Project	Campbell River, Vancouver Island, B.C.	2.6
Kitsault Energy Project	Kitsault, B.C.	2.7
Triton LNG Project	Floating facility – TBD near Kitimat or Prince Rupert, B.C.	0.3
Watson Island LNG	Watson Island, near Prince Rupert, B.C.	Unknown

There are no existing LNG export facilities on the west coast of Mexico. However, there are two import facilities—the Costa Azul LNG Project in Baja California, and the Manzanillo LNG Project in Colima. The owner of the Costa Azul Project (Sempra Energy) is proposing to convert this project into an LNG export terminal. We are not aware of any other proposed LNG facilities in Mexico; however, we acknowledge that additional proposals may exist. Similar to the proposed Canadian LNG facilities, the final specifications and permitting/construction status of the Costa Azul LNG Project is unknown. Assuming this facility has also been designed to accommodate a pre-determined need/level of service, it may be possible that with modifications, it would be able to provide an equivalent level of service to that which would be provided by the Project. However, we are unable to determine what modifications would be necessary and what the impacts of those modifications would be. Although constructing a pipeline from the existing GTN and Ruby pipelines systems to Baja California (a distance of about 900 miles) is technically feasible, it would increase the Project footprint by about 14,500 acres. Therefore, we conclude that an LNG system alternative making use of the Costa Azul LNG facility would not provide a significant environmental advantage and do not consider it further in this analysis.

The Northwest Pipeline is an approximately 3,900-mile-long bi-directional interstate natural gas transmission system. This system crosses the states of Washington, Oregon, Idaho, Wyoming, Utah, and Colorado. This transmission system provides access to British Columbia, Alberta, Rocky Mountain, and San Juan Basin natural gas supplies. In Oregon, two lateral pipelines connect to the Northwest mainline system. The Camas to Eugene and the Eugene to Grants Pass Lateral are generally parallel to I-5, running north to south through western Oregon. The laterals begin in the north as dual 20-inch-diameter pipelines, and consist of a single a 10-inch-diamter pipeline at the southern end. The only portion of the Northwest Pipeline system that could potentially serve as a system alternative to move gas from near Malin to the LNG terminal in Coos Bay would be a portion of the north-south Eugene to Grants Pass Lateral. Such an alternative would require modifying roughly the eastern one-half of the proposed pipeline to connect to the southern end of the Grants Pass Lateral, then constructing about 70 miles of "looping" pipeline north along the Grants Pass Lateral to near Sutherlin, Oregon, and then constructing about 50 miles of new pipeline west to Coos Bay. Such an alternative would result in roughly the same length of pipeline as proposed; however, may affect more forested area, and could result in similar or greater environmental impacts. Therefore, the implementation of a system alternative involving the use of the Northwest Pipeline Grants Pass Lateral would not provide a significant environmental advantage over the proposed action.

The GTN interstate natural gas transmission system includes about 600 miles of 36- and 42-inch pipeline beginning at Kingsgate, British Columbia, traversing through northern Idaho, southeastern Washington, and central Oregon, and terminating near Malin. Natural gas for the GTN pipeline originates primarily from western Canadian supplies; although it can receive Rocky Mountain gas through interconnections with Northwest near Spokane and Palouse, Washington and Stanfield, Oregon. The Ruby interstate natural gas transmission system includes about 680 miles of 42-inch-diameter pipeline beginning near Opal, Wyoming, and extending west through Montana and Idaho to Malin. Neither GTN nor Ruby would be suitable as system alternatives and neither would be able to meet the purpose of the Project because both systems terminate near Malin and would require a connection to a west coast LNG facility similar to the proposed pipeline route from Malin to Coos Bay. Therefore, systems alternatives involving these systems would not provide a significant environmental advantage over the proposed action.

The Coos County Pipeline is a non-jurisdictional 12-inch-diameter local distribution company (LDC)[47] pipeline that extends about 60 miles from the Northwest Grants Pass lateral, near Roseburg, to Coos Bay. The Coos County Pipeline has a MAOP of 1,000 psig and was designed to bring gas to the communities around Coos Bay. The terminus of the Coos County Pipeline is approximately 7.7 miles south of the proposed Jordan Cove LNG terminal. Northwest Natural built a pipeline lateral from the terminus of the Coos County pipeline across Coos Bay to the North Spit, as part of its LDC system. The diameter and available capacity of the Coos County Pipeline are too small to meet the purpose of the Project. The Coos County Pipeline does not connect to the GTN and Ruby Pipeline systems. Expanding the Coos County Pipeline as needed to provide the required natural gas capacity from the GTN and Ruby Pipeline systems would result in similar impacts as that of the proposed action. For these reasons, the Coos County Pipeline as an existing system cannot meet the Project purpose and expanding it to meet the purpose would not provide a significant environmental advantage.

3.3 LNG TERMINAL SITE ALTERNATIVES

We received numerous comments stating that LNG site alternatives in California, Washington, Canada, and Mexico be considered. Commenters suggested that sites in these states and countries could be more suitable for an LNG terminal. We do not evaluate in this EIS alternative projects

[47] LDCs (local distribution company) are intrastate systems that are regulated by the state, and do not come under the jurisdiction of the FERC.

or LNG terminal sites located in Canada or Mexico. Below we address the potential for an LNG terminal to be sited in California, and then we address potential alternative sites in Oregon and Washington.

As stated previously, the Commission's staff evaluates a proposal and reasonable alternatives. While we may ask the project proponent to evaluate alternative technologies in order to minimize impacts, we do not redesign proposals. However, some alternative technologies or facility designs represent such a large departure from the applicant's proposal that they could significantly affect the feasibility and economic practicality of the proposal. Consequently, we are not evaluating offshore site alternatives that would require specialized LNG carriers. We do however, evaluate the concept of an inland (non-waterfront) alternative (see section 3.3.4).

3.3.1 LNG Terminal Site Alternatives in California

California has 11 public ports. The closest deepwater port to Coos Bay in California is the Port of Humboldt Bay. The Port of Humboldt Bay is located approximately 185 miles south of Coos Bay and 225 miles north of San Francisco (the next closest deepwater port is in San Francisco bay). The Samoa Peninsula lies between the Pacific Ocean and Humboldt Bay and hosts several active and former marine facilities, berths, docks, and terminals. According to the 2018 Humboldt Bay Maritime Industrial Use Market Study, 948 acres of land have been designated for Coastal-Dependent Industry (CDI) on the Samoa Peninsula including the approximately 344-acre Eureka Municipal Airport site which has waterfront access and is the largest single property on the peninsula. It is unknown whether a combination of other CDI properties equaling approximately 200 acres is available. The channel system leading into and within Humboldt Bay varies in length, width, and depth. The Bar and Entrance Channel is approximately 8,500 feet long, 500 to 1,600 feet wide, and is authorized to a depth of 48 feet mean low level water (MLLW). The North Bay Channel which serves the Samoa Peninsula is 18,500 feet long, 400 feet wide, and is authorized to a depth of 38 feet MLLW. The distance by air from Malin, Oregon to Humboldt Bay is about 170 miles (the distance from Malin, Oregon to Coos Bay by air is also about 170 miles). We estimate the pipeline distance between these two points would be at least 200 miles, which is comparable to the proposed pipeline.

An LNG terminal in Humboldt Bay would impact the environment in a manner similar to that of the proposed Project, including; permanent conversion of land use, dredging, turbidity, loss of wetlands, visual impacts, air quality and noise. Concerns at this location such as marine traffic restrictions, socioeconomic impacts, tsunamis, and public safety would also be the same as the proposed Project. A natural gas transmission pipeline from Malin, Oregon to Humboldt Bay, California would traverse Klamath County, Oregon as well as Siskiyou and Humboldt Counties, California. The environment crossed by a pipeline from Malin to Humboldt Bay would be similar to that of the proposed route, including; mountainous terrain, several large rivers, three national forests, and BLM-managed lands. This pipeline route would also cross the ranges of over 20 federally-listed threatened and endangered species including NSO, MAMU, and salmon. Concerns with this pipeline route such as rural property values, socioeconomic impacts, and public safety would also be the same as the proposed Project.

Based on the expected similar impacts of an LNG terminal in Humboldt Bay and the associated natural gas transmission pipeline from Malin, Oregon to Humboldt Bay, we conclude this alternative would not result in a significant environmental benefit when compared to the proposed action.

3.3.2 LNG Terminal Site Alternatives in Oregon and Washington (LNG Terminal Site Characteristics)

As provided in Jordan Cove's application and identified in table 3.3.2-1, we are evaluating four terminal site alternatives. We determined that a reasonable LNG terminal site alternative should include the following site characteristics.

1. **Available Land –** a parcel or combination of parcels available[48] for development and large enough to accommodate the proposed LNG terminal facilities and associated safety exclusion zone, about 200 acres.
2. **Deep Channel Access –** a channel with depth of at least 36 feet MLLW in order to accommodate the draft of anticipated LNG carriers.
3. **Waterfront Access –** a site that can safely accommodate the mooring of an LNG carrier and the facilities required to transfer LNG from the terminal to the carrier.
4. **Comparable Pipeline –** a site that could be reached by a comparable natural gas transmission pipeline from the intersection of the GTN and Ruby pipeline systems.

For the purposes of our alternatives analysis of sites, we do not further evaluate sites that do not or could not satisfy these LNG site requirements. For example, sites that are of insufficient size or are unavailable for purchase or lease are not carried forward into this analysis.

Locations having the four necessary characteristics were identified in Astoria, Wauna, and Port Westward, Oregon, and Grays Harbor, Washington (figure 3.2-1). An environmental comparison and discussion of these LNG terminal site alternatives is provided below.

Each alternative site would require construction of new natural gas pipelines, and in some cases modifications and upgrades to existing transmission pipelines to access western Canadian and U.S. Rocky Mountain natural gas sources from the intersections of the GTN pipeline and Ruby pipeline near Malin, to meet the stated Project purpose. An estimate of the pipeline length required for each alternative is included in table 3.3.2-1. In each of these alternatives, the associated natural gas supply pipeline would need to cross the Cascade Mountains.

[48] Section 3 of the NGA does not grant the authority of eminent domain. In some cases, a site may be of adequate size for an LNG terminal, but the owner is unwilling to sell or lease the property.

TABLE 3.3.2-1

LNG Terminal Port Alternatives Comparison

Feature	Proposed (Coos Bay)	Alternative Port: Astoria, OR	Alternative Port: Wauna, OR	Alternative Port: Port Westward, OR	Alternative Port: Grays Harbor, WA
Available Site Size (acres)	412	519	321	336	272
Supply pipeline length (miles)	229	399	375	332	379
Pipeline construction footprint (acres) a/	4,946	8,618	8,100	7,170	8,186
Freshwater wetland impacts (acres) b/	83	143	49	51	61
Estuarine/open water impacts (acres) b/	35	130	35	60	42
Number of listed species with potential habitat	21 c/	10	15	16	9
Existing residences within 1 mile (number)	116	975	5	828	1,637

a/ Estimated using the average area per mile that would be affected by the proposed pipeline, including all extra temporary work space (21.6 acres/mile).
b/ Assuming all mapped resources within the site would be affected.
c/ This includes the LNG terminal site and LNG carrier transit in the waterway. There are only seven federally listed species that may occur at the LNG terminal site itself.

As shown in table 3.3.2-1, environmental features and potential impacts from use of the alternative sites would vary when compared to the proposed site. Three sites (Astoria, Port Westward, and Grays Harbor) would have a significantly greater number of residences located within 1 mile, while one site (Wauna) would have significantly fewer. Three sites (Wauna, Port Westward, and Grays Harbor) would have less impact on freshwater wetlands than the proposed site, while one site (Astoria) would have more. One site (Astoria) is estimated to require significantly more impact on estuarine and open water habitats than the proposed site. All four alternative sites would require at least 100 more miles of supply pipeline than the proposed site, ranging from an estimated 103 miles (Port Westward) to 170 miles (Astoria) of additional pipeline required, which would require an estimated 2,224 to 3,672 additional acres of disturbance for pipeline construction. When evaluating these potential impacts, we have not identified an alternative site that would result in a significant environmental advantage over the proposed site. Therefore, we conclude that none of the regional alternative sites would result in a significant environmental advantage over to the proposed site in Coos Bay.

3.3.3 Coos Bay Terminal Alternatives

We evaluated one alternative site for the LNG terminal facilities within Coos Bay. The alternative site is located west of the swinging railroad bridge and on the western side of the Coos Bay Navigation Channel. The swinging railroad bridge is an impediment to vessel traffic and the eastern side of the channel does not contain any sufficiently sized parcels due to the presence of the North Bend and Coos Bay communities. Sites along the west side of the North Spit are not suitable because navigational accessibility is limited by exposure to the open ocean.

The Jordan Point alternative site is located about 1 mile east of the proposed LNG terminal site at about river mile 8.5 of the Coos Bay Federal Navigation Channel (figure 3.3-1). The Jordan Point site would be approximately the same size as the proposed site, and Jordan Cove indicates the site would be available for development of an LNG facility. The alternative site overlaps part of the South Dunes portion of the proposed site. A comparison of major environmental factors between the Jordan Point site and the proposed site are listed in table 3.3.3-1.

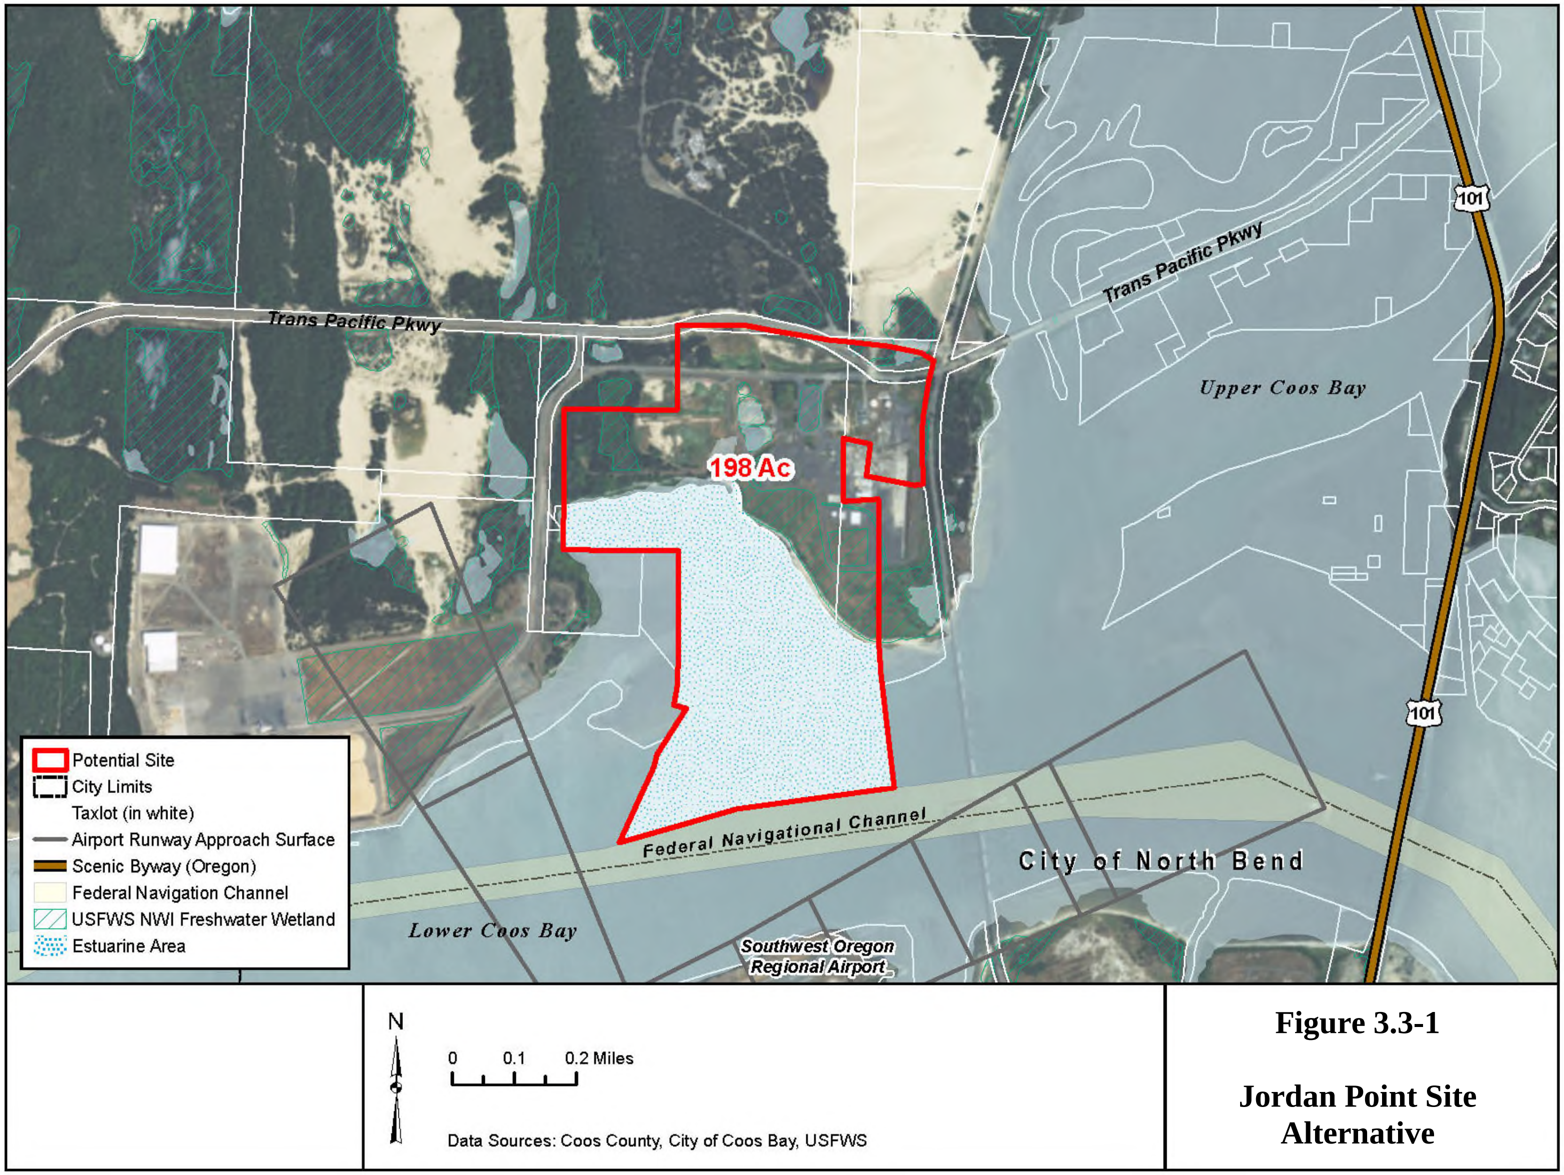

Figure 3.3-1

Jordan Point Site Alternative

TABLE 3.3.3-1

Comparison of Proposed and Jordan Point Alternative LNG Sites

Environmental Factor	Proposed Site	Jordan Point Site
Estuarine Area (acres) a/	32	101
Wetland Area (acres) b/	2	22
Threatened and Endangered Species (number) c/	9	9
Approximate Site Size (acres)	199	198
Land Availability	Y	Y
Federal Land Affected (acres) d/	0	0
Within Airport Runway Approach Zone	No	No
Adequate Area for Safety Exclusion Zone	Y	Y
Existing Residences within 1 Mile (number) d/	116	128

a/ Based on approximate boundary of shoreline to the edge of the Federal Navigation Channel or waterward extent of the potential site boundary.
b/ Based on NWI wetland GIS data within potential site boundary, See Figures 10.3-9 to 10.3-11 in Jordan Cove Resource Report 10.
c/ Based on FWS 2017a and NMFS 2015.
d/ Based on GIS tax lots.

The number of residences within 1 mile would be slightly more for the Jordan Point site (128) than for the proposed site (116), and LNG carriers would have to travel about 1 mile farther along the Federal Navigation Channel to reach the site. Based on NWI mapping, the Jordan Point site would also include more wetlands (approximately 22 acres) compared to the proposed site (approximately 2 acres). The primary disadvantage of the alternative site is its farther distance from the Federal Navigation Channel, which would require a greater area of dredging within the estuarine area between the site and channel (approximately 101 acres) compared to the proposed site (32 acres). For the reasons described above, the Jordan Point site would not provide a significant environmental advantage over the proposed site.

3.3.4 Inland (Non-Waterfront) Alternative

We received comments from the COE requesting that we evaluate an inland LNG terminal site, in order to reduce impacts on wetlands and Coos Bay. An inland alternative site would locate the liquefaction and LNG storage facilities at an upland location outside of Coos Bay and would be connected to the proposed marine loading facilities by an LNG cryogenic pipeline or LNG trucking system. At the proposed site, approximately 86.1 acres of wetlands would be affected by construction and approximately 22.3 acres of wetlands would be permanently lost (see table 4.3.3.1-1). An inland site would not completely eliminate impacts on wetlands as numerous operational and safety facilities would still be required along the shoreline to support the marine loading and LNG carrier berth facilities. Operational and safety facilities would include spill containment systems and utilities such as compressed air, nitrogen, potable water, utility water, fire water, and electrical equipment. An inland site would also require the use of a marine berth and turning basin; therefore, dredging in Coos Bay would still be necessary. As a result, impacts on Coos Bay would not be substantially reduced by an inland terminal site. In either scenario, impacts on Coos Bay would be localized and relatively short term.

Due to the presence of the Oregon Dunes National Recreation Area immediately north of the proposed site, the cities of North Bend and Coos Bay, immediately south, and the Pacific Ocean to the west, any inland site alternative would need to be located at least five miles east of the proposed site. Furthermore, due to the steep topography east of Coos Bay, the distance from the marine loading facilities to a suitable parcel of land for the terminal facilities would likely be greater than five miles and likely require a larger site with more ground disturbance (50 acres or more) to accommodate the significant earthwork (spoil storage, leveling, and slope considerations) that would be required to create an appropriate site. The marine loading facilities would remain at the proposed site because LNG carriers are prevented from travelling farther east by the rail and Highway 101 bridges across Coos Bay.

An LNG cryogenic pipeline, which would be subject to expansion and contraction due to temperature fluctuations, could be located aboveground or underground within a tunnel system. Regardless of the pipeline placement, the USDOT's siting requirements and regulations would apply. In order to ensure pipeline integrity and public safety, the USDOT may require the operating company to obtain legal control of activities up to 400 feet on each side of the pipeline, resulting in an additional 450 acres of land encumbered by the permanent easement. The subsequent amount of affected land when compared to the amount of land typically affected by a natural gas pipeline would be significantly greater. In addition, the USDOT siting requirements for LNG cryogenic pipelines require security features (fencing and exclusion zones) and spill containment systems. At a minimum, an LNG cryogenic pipeline system would need to accommodate the LNG ship loading pipe, an LNG recirculating and cooldown pipe, and the ship vapor return pipe as well as access points for inspection and maintenance work. The cryogenic pipelines would also require insulation along the entire length to maintain (low) operating temperatures. These facilities would require a larger permanent operational easement and would likely require a larger construction right of way, both of which would increase impacts on the environment. Unlike an interstate natural gas pipeline regulated under Section 7 of the NGA that provides for the use of eminent domain, temporary and permanent easements required for an LNG cryogenic pipeline regulated under Section 3 of the NGA must be obtained without the use of eminent domain which could result in a longer pipeline route further increasing impacts on the environment. An LNG cryogenic pipeline would also require pump stations to ensure LNG flows and pressures are maintained. These pump stations would need additional provisions for electrical power, security, firewater, control room, etc. and would require the permanent use of additional lands and impacts on the environment. A cryogenic pipeline transporting LNG from an inland terminal site to the marine loading facilities is technically feasible, but would require numerous design and siting changes, resulting in additional environmental impacts, and could affect the economic competitiveness of the Project.

An inland LNG terminal alternative could impact a larger footprint than the proposed site and would affect other resources. Because the proposed site has been previously disturbed, the impacts of an inland LNG terminal could be greater than the impacts at the proposed site. Furthermore, constructing a LNG cryogenic pipeline would require several additional systems and measures to be designed and implemented to ensure safety and integrity. Ultimately, when considering the footprint of the inland terminal, the marine loading facilities, power infrastructure for the pumps, and the difficulties and costs associated with a redesigned pipeline, we conclude that while perhaps feasible, an inland site would not be practical.

A trucking system transporting LNG from an inland terminal site to the marine facilities at the proposed output volumes would require thousands of truck trips per day. This amount of traffic on area roads would be a significant impact and would greatly increase public safety concerns. In addition, exhaust emissions from the trucks would impact local air quality. Therefore, we conclude that an inland terminal with a trucking system would not provide a significant environmental advantage over the proposed LNG terminal.

3.4 PIPELINE ROUTE ALTERNATIVES AND VARIATIONS

We evaluated numerous pipeline route alternatives and variations to determine whether their implementation would be preferable to the proposed corresponding action. Major route alternatives are generally greater than 50 miles in length and can deviate from the proposed route by a significant distance. Route variations are generally less than 50 miles in length and deviate from the proposed route to a lesser degree than a major route alternative.

Route alternatives and variations were identified based on public comments, information provided by Pacific Connector, agency consultations, and our independent review of the Project. Also, as required by Subsection 28 (p) of the Mineral Leasing Act, the agencies considered opportunities for co-location with existing rights-of-way where the proposed pipeline would cross federally managed lands. In addition to alternatives and variations evaluated in this EIS, during the course of refining the proposed route, Pacific Connector incorporated a number of minor route modifications to address agency concerns and landowner requests, constructability issues or constraints, to avoid cultural resources or geological hazards, or reduce impacts on special status, threatened, or endangered species. These include minor modifications recommended by the BLM between MPs 119.5 and 119.8, at MP 126.0, and at MP 131.5, and between MPs 183.9 and 187, and recommended by the Forest Service between MPs 154.7 and 155.1, MPs 157.1 and 158.7, and MPs 171.2 and 173.0.

3.4.1 Major Route Alternatives

Elements we considered during our analysis of potential alternatives included pipeline length, use of or co-location with existing rights-of-way, forest land, agricultural land, waterbody and wetland crossings, residences, known cultural resources, habitat for federally listed threatened or endangered species, and geological hazards and slope stability.

3.4.1.1 All Highway Alternative

We evaluated the All Highway Alternative as a potential alternative that would follow existing highways as much as possible in order to co-locate rights-of-way and reduce the creation of new corridors through resource areas. This alternative would follow Highway 50 west from Malin to Highway 39, northwest to Klamath Falls, then along Highway 140 west to Medford, then along I-5 north to Winston, then west along Highway 42, and then north along Highway 101 to Coos Bay. This route would be approximately 281 miles long, or about 52 miles longer than the proposed route, resulting in approximately 600 acres of additional construction right-of-way disturbance.

The potential advantage of the All Highway Alternative is that the pipeline would be co-located with the existing highway right-of-way, co-locating new disturbance and associated impacts with existing disturbance. However, as explained below, the pipeline would be placed adjacent to, but not within, highway rights-of-way, and therefore the alternative would still require acquisition of new right-of-way. The Federal Highway Administration (FHWA) historically prohibited the installation of new utility facilities within the rights-of-way of access-controlled freeways except in some extraordinary cases. This prohibition was consistent with the American Association of State Highway Transportation Officials (AASHTO) policies for longitudinal accommodation. However, with a 1988 amendment to the FHWA regulations, the FHWA's policy changed to allow each state to decide whether to permit new utility facilities within these rights-of-way, or continue to adhere to the stricter AASHTO policies (FHWA 2014). Oregon defines its policy for accommodating utilities in highway rights-of-way in OAR 734-055-0080. In general, Oregon does not allow utilities to occupy interstate rights-of-way with the exception of perpendicular crossings (Caswell 2008).

In addition to the further disturbance that would result from the longer length of the alternative, there are disadvantages related to its location parallel to highways. The pipeline route paralleling the highway rights-of-way has constraints such as highway cuts and fills; elevated roadway sections, bridges, overpasses and underpasses; clover leaf and other interchanges; as well as commercial, industrial, and residential developments located immediately adjacent to the rights-of-way and interchanges. For these reasons, we have determined that implementation of the All Highway Alternative would not result in a significant environmental advantage and is not preferable to the proposed route.

3.4.1.2 Federal Lands Route Alternative

We considered a conceptual Federal Lands Alternative that would place the pipeline entirely on federal lands as a potential alternative to avoid or significantly reduce impacts on private property. Given the patchwork nature of federal land holdings in the Project area in southern Oregon, with federal blocks scattered between private tracts, we were unable to identify a route between Malin and Coos Bay that would be entirely on federal lands and not cross private lands. Therefore, a route that would be entirely on federal land and would avoid private property is not feasible and is not considered further in this EIS.

3.4.1.3 Federal Lands Avoidance Route Alternative

We attempted to identify a pipeline route alternative that would avoid crossing federally managed lands. However, given the extensive Forest Service lands and the checkerboard nature of BLM-managed lands in southwest Oregon (see figure 1.1-1), we were unable to identify a route between Malin and Coos Bay that would avoid crossing federally managed lands. We also attempted to identify a pipeline route that would avoid crossing federally managed lands by heading in any direction from Malin and eventually reaching Coos Bay, regardless of length. Again, due to the extensive and connected Forest Service lands to the north, east, south, and southwest of Malin, we were unable to identify a route that could reach Coos Bay without crossing federally managed lands. Therefore, a federal lands avoidance route alternative is not feasible and is not considered further in this EIS.

3.4.2 Pipeline Variations

3.4.2.1 Coos Bay Estuary Variations

We received a number of comments concerning the impact of the pipeline crossing of the Coos Bay estuary, including comments from the Coos Tribe. Pacific Connector proposes to cross the Coos Bay estuary using HDD in two segments between MPs 0.3–1.0 and MPs 1.5–3.0. We evaluated several pipeline variations in this area that would modify the crossing location and method to determine if any alternatives might reduce effects on the estuary, including a North Route Variation, a Modified North Route Variation, and a Haynes Inlet East Avoidance Variation (see figure 3.4-1).

The North Route Variation and the East Avoidance Variation would begin at the pipeline terminus and cross north of Haynes Inlet to the north of Sherwood, and both include HDDs to avoid impacts on the Mangan and Wetle Natural Resource Conservation Service Wetland Reserve Program (WRP) easements on the west and east side of Haynes Inlet (see figure 3.4-1). The Modified North Route Variation would have the same route as the North Route Variation until a point north of Sherwood where it includes an HDD (approximately 5,200 feet in length) that extends from ridgeline to ridgeline on either side of the inlet.

A comparison of major environmental and land use features crossed by each of these variations compared to the corresponding segment of proposed route is included in table 3.4.2.1-1. The potential advantage of the variations is avoidance of pipeline-related disturbance on the North Point area of North Bend, and avoidance of the Federal Navigation Channel that would be crossed twice, by HDD, at MP 0.66 and MP 1.6 of the proposed route. However, activities proposed by Jordan Cove, which would still occur with use of any of these variations, would affect both the North Point area and the Federal Navigation Channel, essentially negating any benefit of avoiding these areas with the pipeline. The North Point would still be used for construction laydown yards and dredge spoil disposal (within APCO sites 1 and 2, see sections 2.1.1.8 and 2.1.1.10) and the Federal Navigation Channel would still be affected by dredging for the access channel and the marine waterway modifications (see section 2.4.1.5).

The primary disadvantages of the Coos Bay Estuary variations are greater pipeline length and greater associated construction disturbance. Other disadvantages include greater number of waterbody crossings, more forest clearing, and greater number of private land parcels affected.

For the reasons described above, we have determined that implementation of these alternatives would not result in a significant environmental advantage and are not preferable to the proposed route.

TABLE 3.4.2.1-1

Comparison of Coos Bay Estuary Variations with Proposed Route

Impact/Issue		**Proposed Route**	**North Route Alternative**	**Modified North Route Alternative**	**Haynes Inlet East Avoidance Alternative**
Variation length (miles) a/		3.43 (2.20 HDD)	7.15 (1.65 HDD)	6.55 (2.54 HDD)	7.55 (1.65 HDD)
Construction right-of-way (acres) b/		9.3	65.5	52.4	67.9
Temporary extra work areas (TEWA) (acres)		54.9	60.9	49.3	64 c/
Total acres of construction disturbance		64.2	126.4	101.7	131.9
Operational easement (acres) d/		9.8	36.3	30.0	45.8
Land ownership (miles)	0.2	5.5	5.1	5.3	0.2
	3.3	1.7	1.4	2.3	3.3
	0.0	0.0	0.0	0.0	0.0
Number of residences within 50 feet of the construction right-of-way		0	0	0	1 (HDD)
Number of waterbodies crossed e/		3	7	6	16
Length of wetland crossings (feet) e/		3,168	3,711	950	12,936
Agricultural land affected (miles)		0.5	0.5	0.2	2.2
Forest lands affected (miles) f/		0.0	3.5	3.8	2.8
Miles of right-of-way parallel or adjacent to existing rights-of-way (percent of route length)		0.2	1.9	1.9	2.5
COE 408 facilities g/		2	0	0	0
NRCS WRP Easements h/		0.0	0.4	0.0	0.9
Miles of critical habitat for federal T&E species and EFH species		0 (2.2 avoided by HDD)	0 (1.3 avoided by HDD)	0 (1.2 avoided by HDD)	0 (1.3 avoided by HDD)

General: All values are rounded (acres to nearest whole acre, miles to nearest tenth of a mile, feet to nearest whole foot).

a/ Variation lengths are measured from the point where they deviate from and then return to the proposed route. Lengths cannot be accurately calculated by comparing mileposts due to shifts in the alignment.

b/ The construction right-of-way for the proposed route and Alternatives is 9 feet wide in upland areas and, where HDDs are proposed, the right-of-way width has been removed.

c/ TEWAs for the Haynes Inlet East Avoidance Variation are estimated.

d/ The assumed permanent easement width is 50 feet.

e/ NWI coverages and photo interpretation were used for the Proposed Route and the Haynes Inlet East Avoidance Variation.

f/ Includes all forestland types: Evergreen forest, Mixed conifer, Regenerating forests and clear-cuts. The routes do not cross late successional nor old-growth forests.

g/ The proposed route would traverse under the Coos Bay Federal Navigation (shipping) Channel twice at MPs 0.66 and 1.6 by HDD. The alignment of the Haynes Inlet East Avoidance Variation was realigned to avoid crossing dikes associated with the Larson Inlet Flood Damage Reduction (FDR) Project located along Larson Slough. According to the National Levee Database (http://geoplatform.usace.army.mil/home), the Larson Inlet FDR Project is a federally authorized and constructed and a non-federally operated and maintained, agricultural flood-protection project.

h/ The Mangan WRP would be crossed by both North and East Avoidance Variation on the west side of Haynes Inlet for approximately 1,150 feet. The Wetle WRP would be crossed on the east side of Haynes Inlet by the North Route Variation for approximately 1,130 feet and by the East Avoidance Variation for approximately 3,450 feet.

3.4.2.2 Blue Ridge Variation

Based on comments received during scoping and concerns expressed by the BLM regarding steep topography, late-successional old-growth (LSOG), and potential impacts on threatened and endangered terrestrial species, we evaluated an alternative between about MPs 11 and 25 referred to as the Blue Ridge Variation. The 15.2-mile-long Blue Ridge Variation, which is depicted in figure 3.4-2, would deviate from the proposed route near MP 11 just south of the Coos River, continuing southwest across Catching Slough, turning south/southeast, generally co-located with an existing utility right-of-way before rejoining the proposed route near MP 25. Table 3.4.2.2-1 compares the variation to the corresponding segment of the proposed route. Additional details regarding the assessment of this variation can be found in appendix F.

When compared to the corresponding segment of the proposed route, the Blue Ridge Variation would require clearing less (about 32 acres less) LSOG forest (late-successional forest stands greater than 80 years old); would substantially reduce the number of occupied and presumed occupied (3 and 14 less, respectively) MAMU stands affected as well as acres of suitable MAMU habitat removed (about 29 acres less); and cross five fewer miles of LSRs and 0.47 mile less of NSO home range. As discussed in more detail in section 4.4.2.1, LSOG forest stands have a well-defined, multi-tiered canopy, which creates microhabitats for many species (Bingham and Sawyer, Jr. 1991; Spies and Franklin 1996), including the federally listed NSO and MAMU. Additionally, the variation would affect 3 fewer acres of designated Riparian Reserves on BLM-managed lands and about 15 acres less of NSO High NRF and NRF habitat. However, the variation is longer and would affect about 14 additional acres of land. It would also more than double the number of private parcels (24 to 53) and miles of private lands crossed (6.46 to 13.76). The variation would also increase the number of perennial waterbodies crossed by 27, and would increase the number of known and assumed anadromous fish-bearing streams crossed from 4 to 18, which would also increase the clearing of upland riparian vegetation associated with each crossing.

As indicated in the comparison table, the above discussion, and the analysis contained in appendix F, the primary trade-offs between the proposed route and the variation are between terrestrial (e.g., LSOG forest and MAMU stands/habitat) and aquatic resources (e.g., waterbody crossings and anadromous fish habitat), as well as public and private lands. With respect to terrestrial and aquatic resources, the measures that would be implemented to avoid or minimize these impacts differs considerably. Constructing and operating the pipeline along the proposed route would result in a permanent loss of LSOG forest and would adversely affect MAMU (see sections 4.4 and 4.6 for discussions regarding these resources); the applicants have very minimal options available for avoidance and minimization measures to address these permanent effects to upland resources (i.e., LSOG and MAMU), and have not proposed mitigation for these permanent effects. In contrast, some of the impacts on aquatic resources, waterbodies, and anadromous fish are expected to be temporary to short-term with implementation of Jordan Cove's and Pacific Connector's proposed impact minimization and waterbody restoration measures (e.g., Jordan Cove's *Plan*, *Procedures*, and ECRP), as well as our recommendations (see sections 4.3 and 4.5 for discussions regarding these resources). The applicants have also proposed some mitigation for the effects to waterbodies and anadromous fish as part of the BLM's right-of-way grant application and proposed plan amendments (see appendix F). However, some permanent unmitigated effects on waterbodies and anadromous fish would occur in the form of the permanent loss of mature riparian areas associated with affected waterbodies.

Our experience from reviewing stream crossings by FERC-regulated pipelines constructed in numerous habitats across the U.S. has confirmed that the short duration of the crossing and the prompt restoration of the stream bed and stabilization of the stream banks results in very few impacts on waterbodies that extend in time beyond the construction and initial restoration of the right-of-way. This is in part due to implementation of best management practices such as dry crossing methods, timing and duration, and restoration methods that are required by the FERC's *Plan* and *Procedures*, which are methods that the applicants have incorporated into their proposal. By comparison, the removal of LSOG habitat is a permanent impact for the operational right-of-way and, even in temporary work areas, recovery of the habitat would take at least 80 years.

We acknowledge that the variation would increase the number of private parcels crossed. Numerous public comments in the Commission's administrative record express concerns about how these lands would be affected. However, we note that although many additional private parcels are affected by the variation, only one residence is located within 50 feet of the construction right-of-way. This EIS addresses numerous measures to be employed during and following construction that would reduce impacts and facilitate restoration of the right-of-way.

We also acknowledge the concerns expressed by the NMFS and the COE regarding the increased impacts on waterbodies, threatened and endangered aquatic species, and adjacent riparian vegetation; and the BLM, FWS, and Tribes regarding the impacts on LSOG forest, threatened and endangered terrestrial species, and other upland managed resources. As stated previously, there are considerable trade-offs between the proposed route and the variation.

In the alternatives methodology described at the beginning of this section, we state that an alternative would be preferable if it meets the stated purpose of the Project; is technically and economically feasible and practical; and if implemented would result in a significant environmental advantage when compared to the proposed action. We also state that when making an alternatives determination we attempt to balance the overall impacts (and other relevant considerations) of the alternative and the proposed action. Therefore, recognizing the trade-offs between the proposed route and the variation; the differences between terrestrial and aquatic resource impacts in regard to temporal effects, as well as the scope of avoidance, minimization, and mitigation for these effects; and the magnitude of the effects, we have determined that the Blue Ridge Variation would result in an overall environmental advantage when compared to the corresponding segment of the proposed route. Our conclusion is based primarily on the variation's ability to reduce long-term to permanent impacts on particularly valuable LSOG habitat affected by the proposed route. Both the sensitivity and value of this habitat and the duration of the impact contribute to this finding. Therefore, **we recommend that:**

- **Prior to construction, Pacific Connector should file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the Blue Ridge Variation into its proposed route between MP 11 and MP 25.**

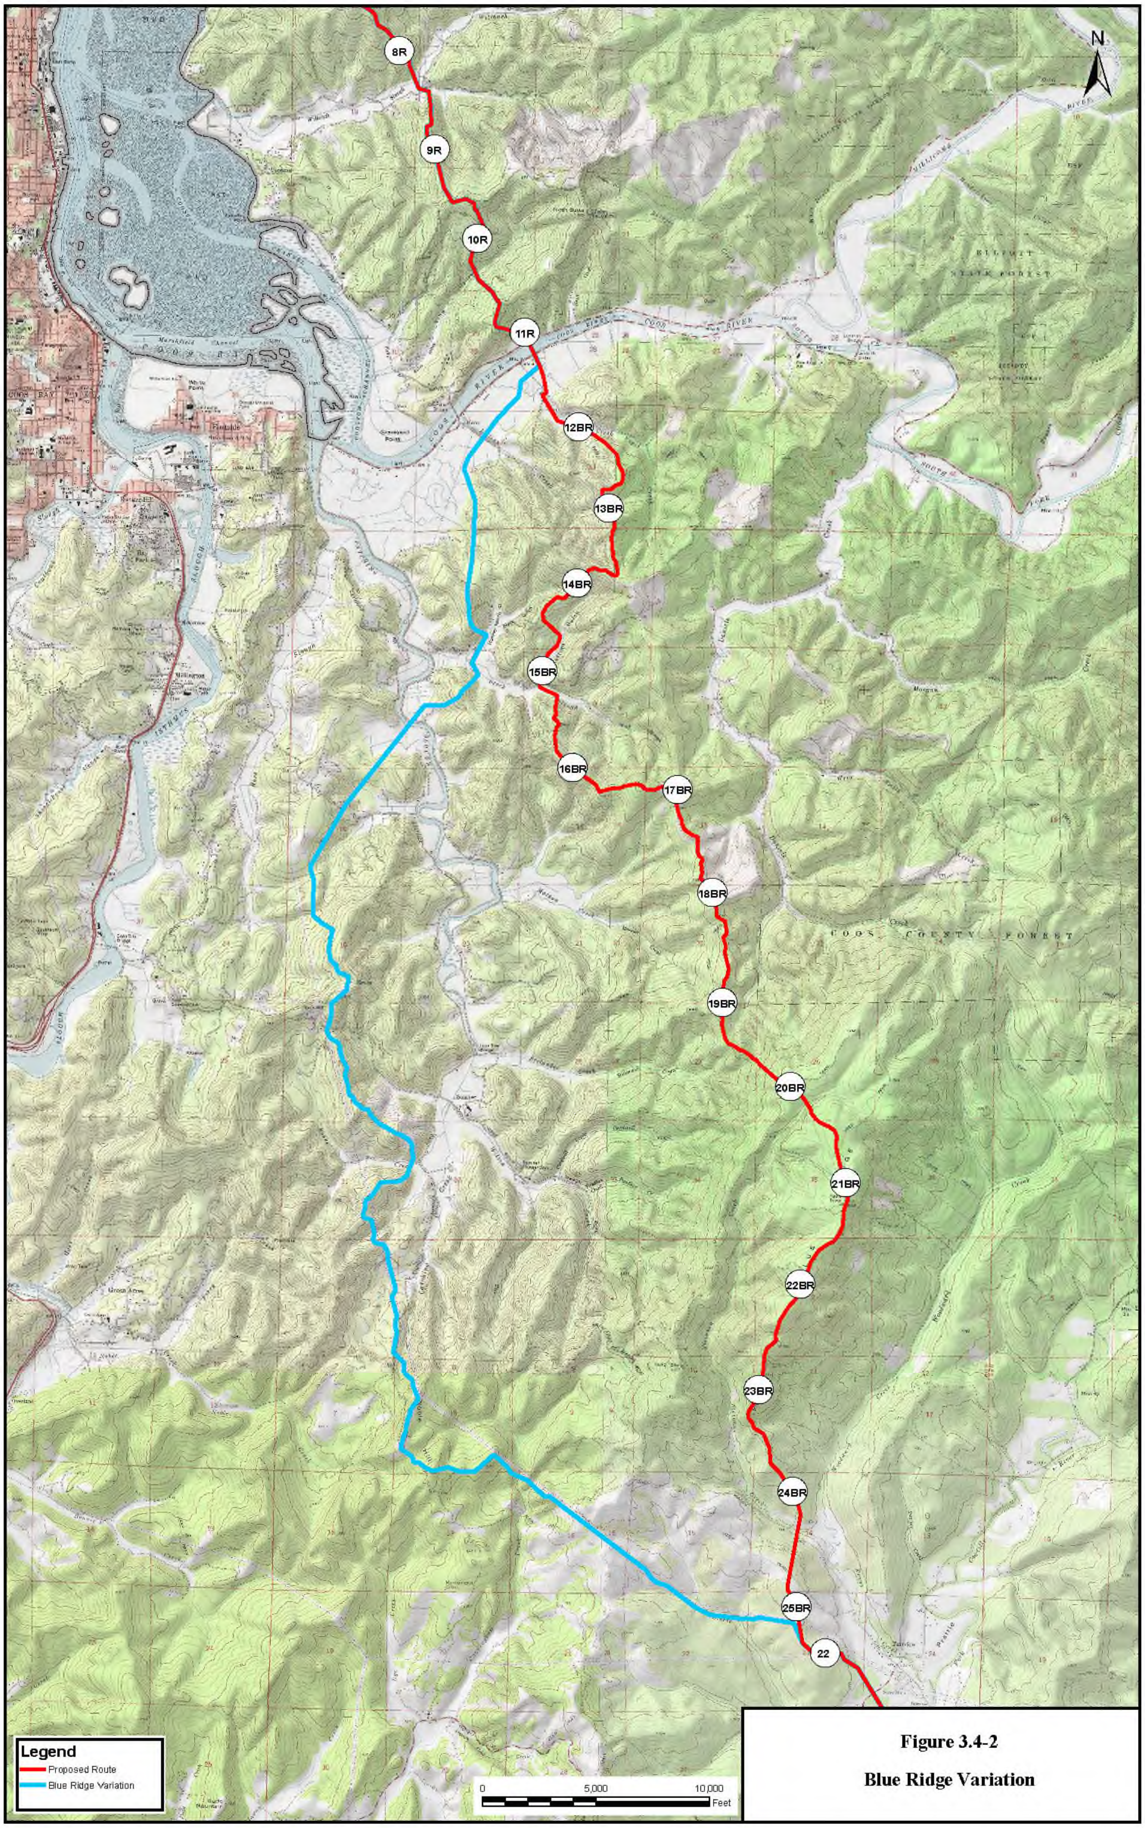

Figure 3.4-2

Blue Ridge Variation

TABLE 3.4.2.2-1

Comparison of Blue Ridge Variation with the Proposed Route

Impact/Issue		**Proposed Route**	**Blue Ridge Variation**
Length (miles) a/		14.0	15.2
Construction right-of-way (acres)		161.4	175.5

General: All values are rounded (acres to nearest whole acre, miles to nearest tenth of a mile, feet to nearest whole foot).
a/ Route Alternative lengths are measured from the point where they deviate from and then return to the proposed route. Lengths cannot be accurately calculated by comparing mileposts due to shifts in the alignment.
b/ Acres of permanent easement calculated based on a 50-foot-wide permanent easement.
c/ OWRD (2017).
d/ Includes waterbodies not crossed by the centerline but within the right-of-way.
e/ Field surveys on BLM lands and desktop analysis on private lands.
f/ Evergreen Forest: LSOG (late successional/old-growth forest) = 80+ years; Mid-seral = 40 to 80 years; C-R (Clear-cut/regenerating forest) = 0 to 40 years.
g/ Acreage is based on 2017 updated NSO habitat coverage for the pipeline project (nesting, roosting, and foraging habitat: NRF, High NRF).
h/ "Presumed occupied stands" have not been surveyed following the species-specific survey protocol (Mack et al. 2003). "Occupied stands" are confirmed occupied based on the species-specific survey protocol.
i/ Acreage is based on 2017 updated MAMU habitat coverage for the pipeline.
j/ ODF (2017). Each crossing would include clearing of some riparian vegetation.
k/ NMFS (2008a).
l/ NMFS (2009).

TABLE 3.4.2.2-1 (continued)

Comparison of Blue Ridge Variation with the Proposed Route

m/ Based on published sources, including the Oregon Department of Geology and Mineral Industries (DOGAMI) open file report 0-11-01 and Statewide Information Database for Oregon (SLIDO).
n/ Surveys are incomplete on approximately 6.0 miles (43 percent) of the route on private lands.).
o/ The historic Barker-Morris Families Cemetery, dating to 1872, is located on private land in Township 27 S, Range 12 W, Section 14. The historic cemetery is situated at MP 24.3 of the proposed route. The cemetery is shown on the McKinley 7.5-minute quadrangle approximately 24 meters east of the construction right-of-way. However, cultural surveys have not been conducted on this privately-owned parcel, and the exact location of the cemetery has not been verified. The cemetery is listed in the Oregon Burial Site Guide but has not been recorded as an archaeological site with the Oregon State Historic Preservation Office.
p/ Surveys are incomplete on route deviations that are outside the cultural survey corridor for the 2015 FEIS Route.
q/ Approximately 5.3 miles (35 percent) of the Blue Ridge Variation is co-located/adjacent to a BPA Powerline corridor, whereas the proposed route is adjacent/co-located with logging roads.

3.4.2.3 Weaver Ridge Variations

At the request of the BLM, we evaluated several route variations between MPs 42.7 and 49.8 to determine if impacts on MAMU and NSO critical habitat could be reduced. As illustrated in figure 3.4-3, we evaluated the Deep Creek Variation, Weaver Ridge Variation 1, Weaver Ridge Variation 2, Weaver Ridge Variation 2a, Weaver Ridge Variation 3, Weaver Ridge Variation 3a, and Weaver Ridge Variation 4.

The Weaver Ridge Variation 1 would deviate from the proposed route around MP 46.0 crossing the logging spur road north of a reservoir and head almost due east on the north side of a tributary of Wildcat Creek over ridges, reconnecting with the proposed route at about MP 49.8. This alternative would be slightly shorter than the proposed route. However, the Weaver Ridge Variation 1 would cross more miles of critical habitat for MAMU and NSO, and would cross two MAMU occupied stands (compared to one along the proposed route) and five NSO home ranges (compared to four along the proposed route).

The Weaver Ridge Variation 2 would start at the same location as Variation 1 but deviate from Variation 1 east of the proposed route at about MP 46, crossing a logging spur road, pass the Signal Tree Quarry, then follow Signal Tree Road for about 3 miles. It would head south over ridges, then join Variation 3 along Wildcat Creek. Weaver Ridge Variation 2a would deviate from Variation 2 just across the Coos County line along Signal Tree Road, cutting diagonally along Wildcat Creek to rejoin Variation 2 Route across the Douglas County line.

The Weaver Ridge Variation 3 would deviate from the proposed route at about MP 42.6. It would follow ridges for about 3.5 miles, crossing Signal Tree Road and Upper Rock Creek. The variation would then turn east and follow ridges for almost 4 miles, crossing Wildcat Creek before rejoining the proposed route at about MP 48.5. Weaver Ridge Variation 3a would deviate from Variation 3 and follow Wildcat Creek for 1.5 miles to join the proposed route at about MP 49.0.

A comparison of the environmental features of the Weaver Ridge Variations and the corresponding segment of proposed route are shown in table 3.4.2.3-1. Weaver Ridge Variations 2, 2a, 3, and 3a are all longer than the corresponding segment of proposed route and would cross more miles of MAMU and NSO critical habitat. Variations 3 and 3a would cross six NSO home ranges, while Variations 2 and 2a would cross five NSO home ranges (compared to four for the corresponding segment of proposed route). Compared to the proposed route, these variations would require clearing more LSOG and affect more acres of LSR on lands managed by the BLM. As a result, none of these variations within this area would ultimately reduce impacts on MAMU and NSO critical habitat. Therefore, we have determined that implementation of Weaver Ridge Variations 2, 2a, 3, and 3a would not result in a significant environmental advantage and are not preferable to the proposed route.

Weaver Ridge Variation 1 would be shorter than the corresponding segment of proposed route and would cross less waterbodies than the proposed route; however, it would have greater impacts on forested habitats, cultural resources, as well as MAMU and NSO critical habitat. Therefore, we have determined that implementation of Weaver Ridge Variation 1 would not result in a significant environmental advantage and is not preferable to the proposed route.

Number of 30-acre nest patches crossed	0	0	0	1	1	0	0	0
NSO 30-acre nest patches crossed (miles)	0	0	0	0.1	0.4	0	0	0

General: All values are rounded (acres to nearest whole acre, miles to nearest tenth of a mile, feet to nearest whole foot).
a/ Variation lengths are measured from the point where they deviate from and then return to the proposed route. Lengths cannot be accurately calculated by comparing mileposts due to shifts in the alignment.
b/ Assumes a 95-foot-wide construction right-of-way for all variations.
c/ TEWAs for all route variations have not been designed and are not included in the total acres of disturbance.
d/ The assumed operational easement is 50 feet; however, Pacific Connector would only maintain vegetation within 15 feet of the pipeline centerline for a total of 30 feet during operation.
e/ Waterbodies from PNW Hydrography Framework Clearinghouse.
f/ NWI CONUS data.

Weaver Ridge Variation 4 would deviate from the proposed route at about MP 46.3 and head southeast over ridges on the north side of Deep Creek, crossing the logging spur road south of the reservoir and reconnecting with the proposed route at about MP 48.0. The Deep Creek Variation would deviate from the proposed route at about MP 46.3 and follow a ridge north of Holmes Creek Spur Road and an unnamed four-wheel-drive road back to the proposed route at about MP 47.0 and cross to the north side of the proposed route and parallel that route for about 1 mile before reconnecting with the proposed route near MP 48.0. The Deep Creek Variation would be about 0.1 mile longer than the corresponding segment of proposed route. Based on a geotechnical review, a high risk of landslides and surface erosion were identified where the Deep Creek Variation would cross the eastern flank of Weaver Ridge above a first order stream. Similarly, where Weaver Ridge Variation 4 would cross Weaver Ridge, it would traverse an extremely steep, narrow rock outcrop that would require blasting. These areas would be avoided by the proposed route where it would ascend Weaver Ridge westward from a forest plantation near MP 46.5 up the slope to the north avoiding the rock outcrop. For these reasons, we have determined that implementation of the Deep Creek Variation and Weaver Ridge Variation 4 would not result in a significant environmental advantage and are not preferable to the proposed route.

3.4.2.4 Camas Valley Northern Variation

Pacific Connector had initially identified a potential variation through the Camas Valley between MPs 50 and 53 to minimize impacts on MAMU habitat (i.e., the Camas Valley Northern Variation), and we evaluated this variation to see if it would be environmentally preferable to the proposed route. This variation is illustrated on figure 3.4-4 and compared in table 3.4.2.4-1.

The Camas Valley Northern Variation would deviate from the proposed route at about MP 50.2 and head northeast across the Camas Valley then turn southeast over forested hills before rejoining the proposed route near MP 53.0. This variation would cross habitat and one occupied stand for MAMU and habitat for NSO on BLM-managed lands. For this reason, the BLM found it unacceptable. We agree and have determined that implementation of the Camas Valley Northern Variation would not result in a significant environmental advantage and is not preferable to the proposed route.

o/ Variation has not been completely surveyed.

3.4.2.5 Umpqua National Forest Variations

In consultation with the Forest Service and to evaluate potential options to reduce impacts on forested lands, we evaluated three route variations within the Umpqua National Forest between MPs 104.8 and 111.5. The proposed route and variations are shown on figure 3.4-5.

Variation 1 would generally follow along Wildcat Ridge close to the proposed route between MPs 105 and 109, where it would then turn east and then southeast, crossing near Long Prairie, then south before rejoining the proposed route near MP 111.2. Environmental features crossed or affected by Variation 1, and a comparison to the corresponding segment of proposed route, are included in table 3.4.2.5-1.

Critical Habitat g/				
Federally listed critical habitat for NSO affected (acres)	52	33	34	40 (95-foot ROW only)
Federally listed critical habitat for NSO crossed (miles)	6.4	6.7	6.3	7.5
Number of NSO core areas crossed (0.5-mile buffer of nest site)	3	4	3	3

General: All values are rounded (acres to nearest whole acre, miles to nearest tenth of a mile, feet to nearest whole foot).
a/ Variation lengths are measured from the point where they deviate from and then return to the proposed route. Lengths cannot be accurately calculated by comparing mileposts due to shifts in the alignment.
b/ Assumed construction right-of-way 95 feet wide.
c/ TEWAs for the variation have not been designed but are estimated assuming they would be comparable to the proposed route.
d/ The assumed operational easement is 50 feet.
e/ Based on slopes that are greater than 50 percent (based on 10-meter digital elevation model).
f/ Waterbodies identified using USGS National Hydrography Dataset, and wetlands identified using FWS National Wetland Inventory mapping.
g/ Includes acres of impact associated with the construction right-of-way and TEWAs. This analysis used the final revised critical habitat designation (2008).
h/ Variation 2 follows existing Forest Service Road 3200 which is assumed would require extensive side-cuts, therefore, miles crossed considered habitat adjacent to the road.

Most environmental impacts from Variation 1 would be similar to those from the proposed route. The primary environmental advantage would be fewer waterbodies crossed (1 compared to 7), and less NSO critical habitat affected (34 compared to 52 acres) than the corresponding segment of proposed route. The primary disadvantage of the variation is that it has the potential to impact an important traditional cultural property as identified by the Forest Service and Cow Creek Tribe.

Based on this concern, we have determined that implementation of Variation 1 would not result in a significant environmental advantage and is not preferable to the proposed route.

Variation 2 would follow a route suggested by the Forest Service that would follow existing Forest Service Road 3200 between about MPs 104.8 and 111.5 of the proposed route. The rationale for this variation is to utilize the existing cleared road corridor to minimize forest fragmentation and reduce impacts on LSRs. Variation 2 would be about 1.1 miles longer and result in about 19 additional acres of construction disturbance and would follow 7.3 miles of existing roadway (97 percent) compared to 5.6 miles (88 percent) along the proposed route. Environmental features crossed or affected by Variation 2, and a comparison to the corresponding segment of proposed route, are included in table 3.4.2.5-1.

Most environmental impacts from Variation 2 would be similar to those of the proposed route. The primary environmental advantage would be its location along an existing roadway which would reduce creation of a new linear forest clearing. The primary disadvantages of Variation 2 would be that more perennial waterbodies would be crossed (13 compared to 7) and that the route would be located adjacent to steep sideslopes along the existing narrow Forest Road 3200. A high risk of landslide occurrence from pipeline installation has been identified along Forest Service Road 3200 headwall swales and constructed fill slopes that would be required to create a working surface for pipeline installation. Steep side slopes along Forest Road 3200 would require significant excavations to construct a 95-foot-wide construction corridor. Pacific Connector estimates the cut slope required to create the work space would be between 100 to 135 feet in height and extend at least 50 feet upslope of the existing cut slope along the road. The required extra cut and fill construction impact area would negate any advantage from following the existing roadway. For these reasons, we have determined that implementation of Variation 2 would not result in a significant environmental advantage and is not preferable to the proposed route.

Variation 3 would begin at MP 108.5 where it would turn south from the proposed route, and then turn southeast and then east, rejoining the proposed route at MP 111.1. Environmental features crossed or affected by Variation 3, and a comparison to the corresponding segment of proposed route, are included in table 3.4.2.5-1.

The Forest Service has stated that Variation 3 would cross an area planned for expansion of the Peavine rock quarry and therefore considers the variation an incompatible use, and identified concerns with potential slope instability and aquatic impacts at the crossing location of the East Fork Cow Creek. The Peavine quarry is the largest and most extensively developed quarry within the upper reaches of the watershed and is of strategic importance to the Umpqua National Forest. For these reasons, we have determined that implementation of Variation 3 would not result in a significant environmental advantage and is not preferable to the proposed route.

3.4.2.6 Rogue River National Forest Variations

To evaluate potential alternatives that may reduce impacts on LSR and Riparian Reserves, we consulted with the Forest Service and evaluated two route variations within the Rogue River National Forest in the vicinity of Robinson Butte and Cox Butte between about MPs 155.1 and 168.9. Table 3.4.2.6-1 provides a comparison of Variation 1 and Variation 2, and the corresponding segment of proposed route. These variations and the proposed route are shown on figure 3.4-6.

Visual Resources				
Visual Impacts along existing Forest roads		Moderate where parallel to existing roads (4.4 miles)	Minimal except at existing road crossings	Existing road corridors expected to be significantly altered from 95-foot-wide construction footprint along 13.6 miles of Forest roads.
Cultural Resources				
Number of previously identified cultural resources along route		1	1	0 g/
Habitat for Federally Listed Species				
Federally listed critical habitat for the NSO (acres) h/		159	148	180
Number of NSO activity centers crossed		2 - ½ mile buffer of site	2 - ½ mile buffer of site	2 - ½ mile buffer of site

General: All values are rounded (acres to nearest whole acre, miles to nearest tenth of a mile, feet to nearest whole foot).
a/ Route Alternative are measured from the point where they deviate from and then return to the proposed route. Lengths cannot be accurately calculated by comparing mileposts due to shifts in the alignment.
b/ The construction right-of-way for the preferred route and original proposed alignment is 95 feet.
c/ Pacific Connector estimates that the Variation 1 would likely require more TEWAs compared to the compromise route because of side slope construction between approximately MPs 149 and 152.9 and because of the increased number of stream crossings along the Variation 1. However, because they have not been designed, we have estimated the area of TEWAs based on a comparable length of the proposed route.
d/ TEWAs have not been designed for this route; however, we have estimated the area based on a comparable length of the proposed route.
e/ The assumed operational easement for all routes is 50 feet. However, Pacific Connector would only maintain vegetation within 15 feet of the pipeline centerline for a total of 30 feet in the long term.
f/ Waterbodies from PNW Hydrography Framework Clearinghouse.
g/ Surveys are incomplete or in progress on the proposed route.
h/ Includes acres of impact associated with the construction right-of-way.

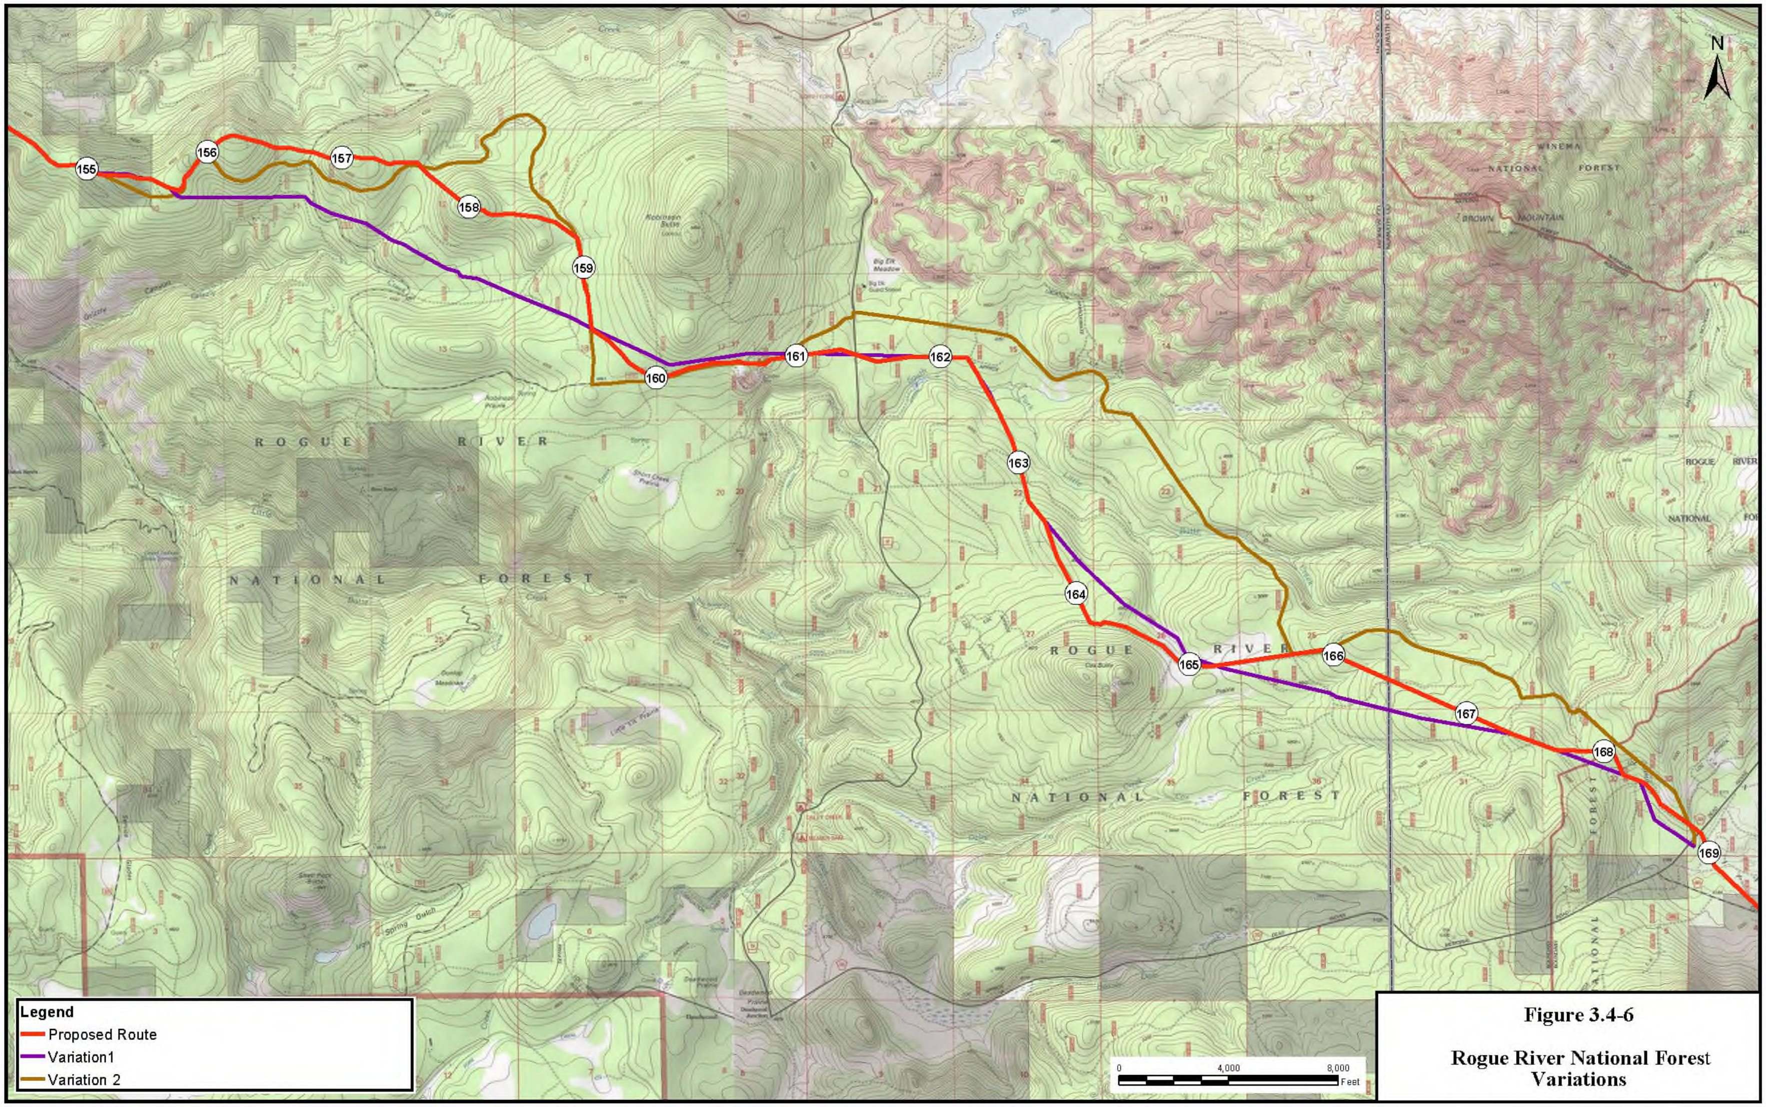

Figure 3.4-6

Rogue River National Forest Variations

Variation 1 would deviate from the proposed route at about MP 155 and remain south of it on the south side of Robinson Butte near MP 159. From that point, Variation 1 would closely follow the proposed route but would be straighter and cross through older forests, which provide NSO habitat. Variation 1 would cross Big Elk Road, cross northeast of Cox Butte, and would cross Daley Prairie, then cross into Klamath County and rejoin the proposed route near MP 169. Variation 1 would be about a mile shorter than the corresponding segment of proposed route. The variation would be adjacent to existing rights-of-way for 1.6 miles (12 percent) compared to 4.4 miles (32 percent) for the corresponding segment of the proposed route.

The primary advantage of Variation 1 is it would require less construction disturbance (194 compared to 209 acres), cross fewer waterbodies (2 compared to 6), cross less LSR (11.5 compared to 12.5 miles), and affect less critical habitat for NSO (148 compared to 159 acres) than the corresponding segment of the proposed route.

The primary disadvantages of Variation 1 are that it would affect more forest (12.8 compared to 12.0 acres) and more riparian reserves (1.5 compared to 0.4 acres) than the corresponding segment of proposed route. As described above, the variation would have some environmental advantages and some environmental disadvantages over the corresponding segment of proposed route. Overall, we do not believe that the advantages overcome the disadvantages, and for this reason we have determined that implementation of the Rogue River National Forest Variation 1 would not result in a significant environmental advantage and is not preferable to the proposed route.

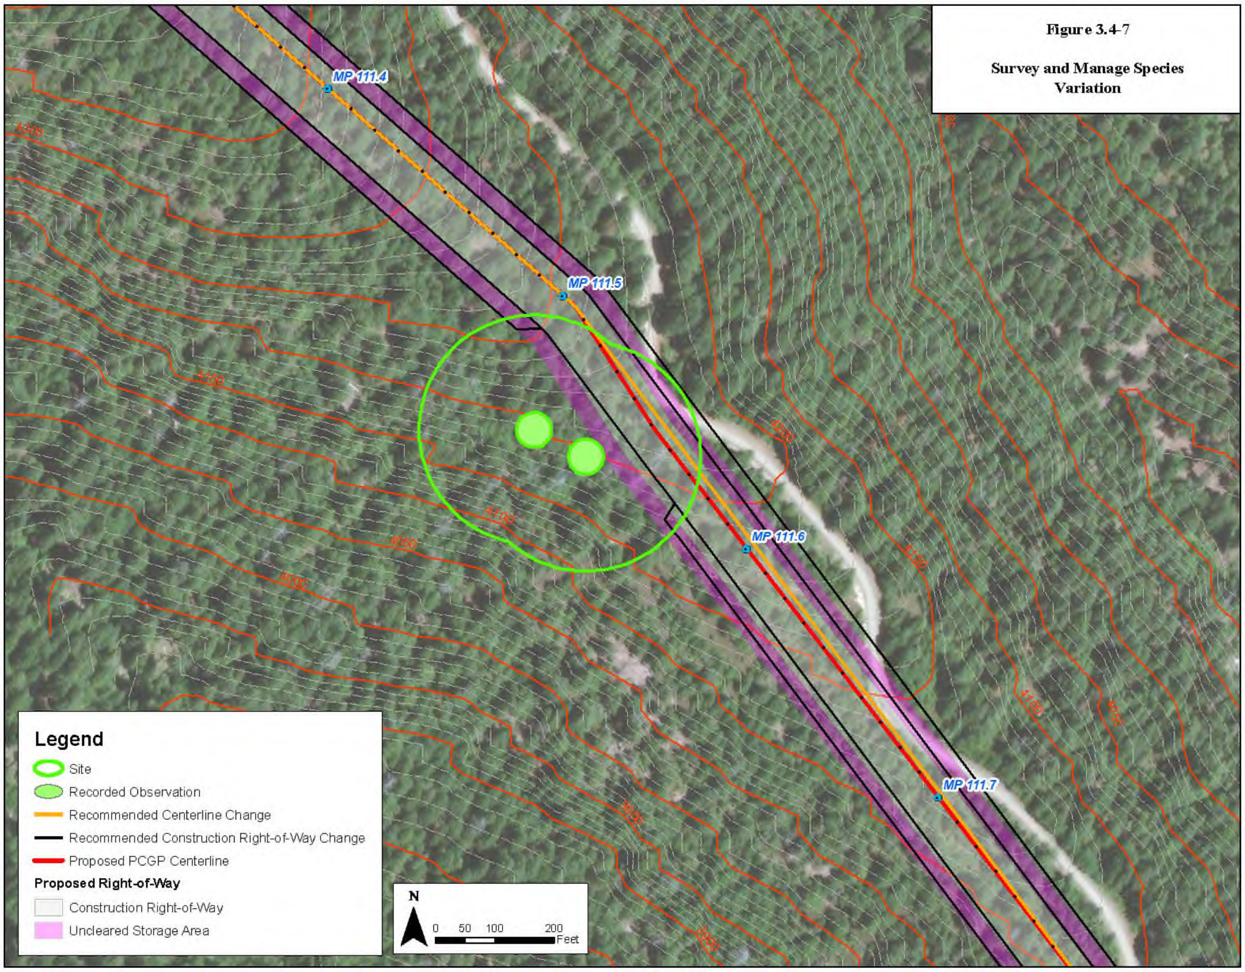
The rationale for evaluating Variation 2 was to evaluate the potential for reducing forest vegetation clearing by utilizing the existing cleared roadways as part of the construction corridor, thereby reducing some of the forest fragmentation and habitat loss in LSR 227. Also, this variation would cross the Pacific Crest Trail (PCT) along an existing road, reducing potential impacts on trail users by eliminating a separate crossing. Variation 2 would deviate from the proposed route at about MP 155, north of Grizzly Canyon, and head east along Forest Service Roads 410 and 300, around the south side of Robinson Butte along Forest Service Road 3730, south of Big Elk Guard Station along Forest Service Road 3705, across the South Fork Little Butte Creek, turn east along Forest Service Road 3720, entering Klamath County, to Forest Service Road 700, cross the PCT several miles south of Brown Mountain, then head southeast cross-county into the Winema National Forest, across Dead Indian Memorial Highway, and would rejoin the proposed route along Clover Creek Road north of Burton Butte just east of MP 169.

Variation 2 would be about 3 miles longer than the proposed route and would require widening the existing roads, which are generally between 20 and 30 feet wide. This would require cutting mature forest in portions of the right-of-way. Based on input from the engineering review conducted by Pacific Connector, the pipeline would not be constructible along portions of some roads due to the steep terrain and side slope and the tight radius turns. For this reason, we have determined that implementation of the Rogue River National Forest Variation 2 is not technically feasible and do not consider it further.

3.4.2.7 Survey and Manage Species Variation

In consultation with the Forest Service, we evaluated a route variation between MPs 111.5 and 111.6 to avoid impacts on *Sarcodon fuscoindicus,* a Survey and Manage fungi species). This variation would provide a no-disturbance buffer for *Sarcodon fuscoindicus*. The buffer is necessary to protect these sites to comply with the 2001 Survey and Manage Record of Decision to maintain the persistence of the affected species within the range of the NSO (see section 4.6.4.3, Survey and Manage).

Under this variation, the construction right-of-way between MPs 111.5 and 111.6 would be shifted at least 25 feet to the northeast, and the UCSA on the southwest side of the construction right-of-way would be eliminated. As a result, at least one of the two known occurrences of this species within the site would be at least 100 feet from any Project-related disturbance (see figure 3.4-7).



The primary advantage of this variation is that a buffer would be provided to protect known sites of *Sarcodon fuscoindicus*. No disadvantages have been identified for this variation. As a result, this variation would result in an environmental advantage and is preferable to the proposed route. Therefore, **we recommend that:**

- **<u>Prior to construction</u>, Pacific Connector should file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the Survey and Manage Species Variation into the proposed route between MPs 111.5 and 111.6, and provide documentation of consultation with the Forest Service.**

3.4.2.8 East Fork Cow Creek Variation

In consultation with the Forest Service, we evaluated a route variation between MPs 109.7 and 109.8 that considered a modified crossing of the East Fork Cow Creek (EFCC) to avoid the parallel pipeline alignment between the upper reaches of the perennial streams in this area. In the EFCC Variation, the pipeline from MP 109.6 would proceed southeasterly crossing a reach of the EFCC and then continue east crossing an upper reach of the EFCC. The variation then follows a gentle ridgeline to the south rejoining the proposed route at MP 109.9 (see figure 3.4-8). This variation would negate the need for amendment UNF-2 on the Umpqua National Forest.

The primary advantage of the variation is that it would reduce the amount of pipeline (about 535 feet) parallel to tributaries to EFCC between MPs 109.7 and 109.8 (see figure 3.4-8). In this area between the tributaries, the proposed route alignment also traverses a narrow ridgeline that supports old-growth forest/high NRF habitat within Riparian Reserves. Avoidance of this area would reduce the potential for long-term restoration and monitoring of hydrologic features affected during construction. The route variation incorporates crossings that are perpendicular to the hydrologic features, reducing the risk of site destabilization and increasing the likelihood of successful stream channel restoration.

The EFCC Variation is the same length as the proposed route and would result in less disturbance (0.12 acre) than the proposed route because of neck-downs along the construction right-of-way at the crossings of EFCC (see table 3.4.2.8-1). The EFCC Variation would also affect slightly less old growth and northern spotted owl suitable habitat than the proposed route. No environmental disadvantages have been identified for this variation.

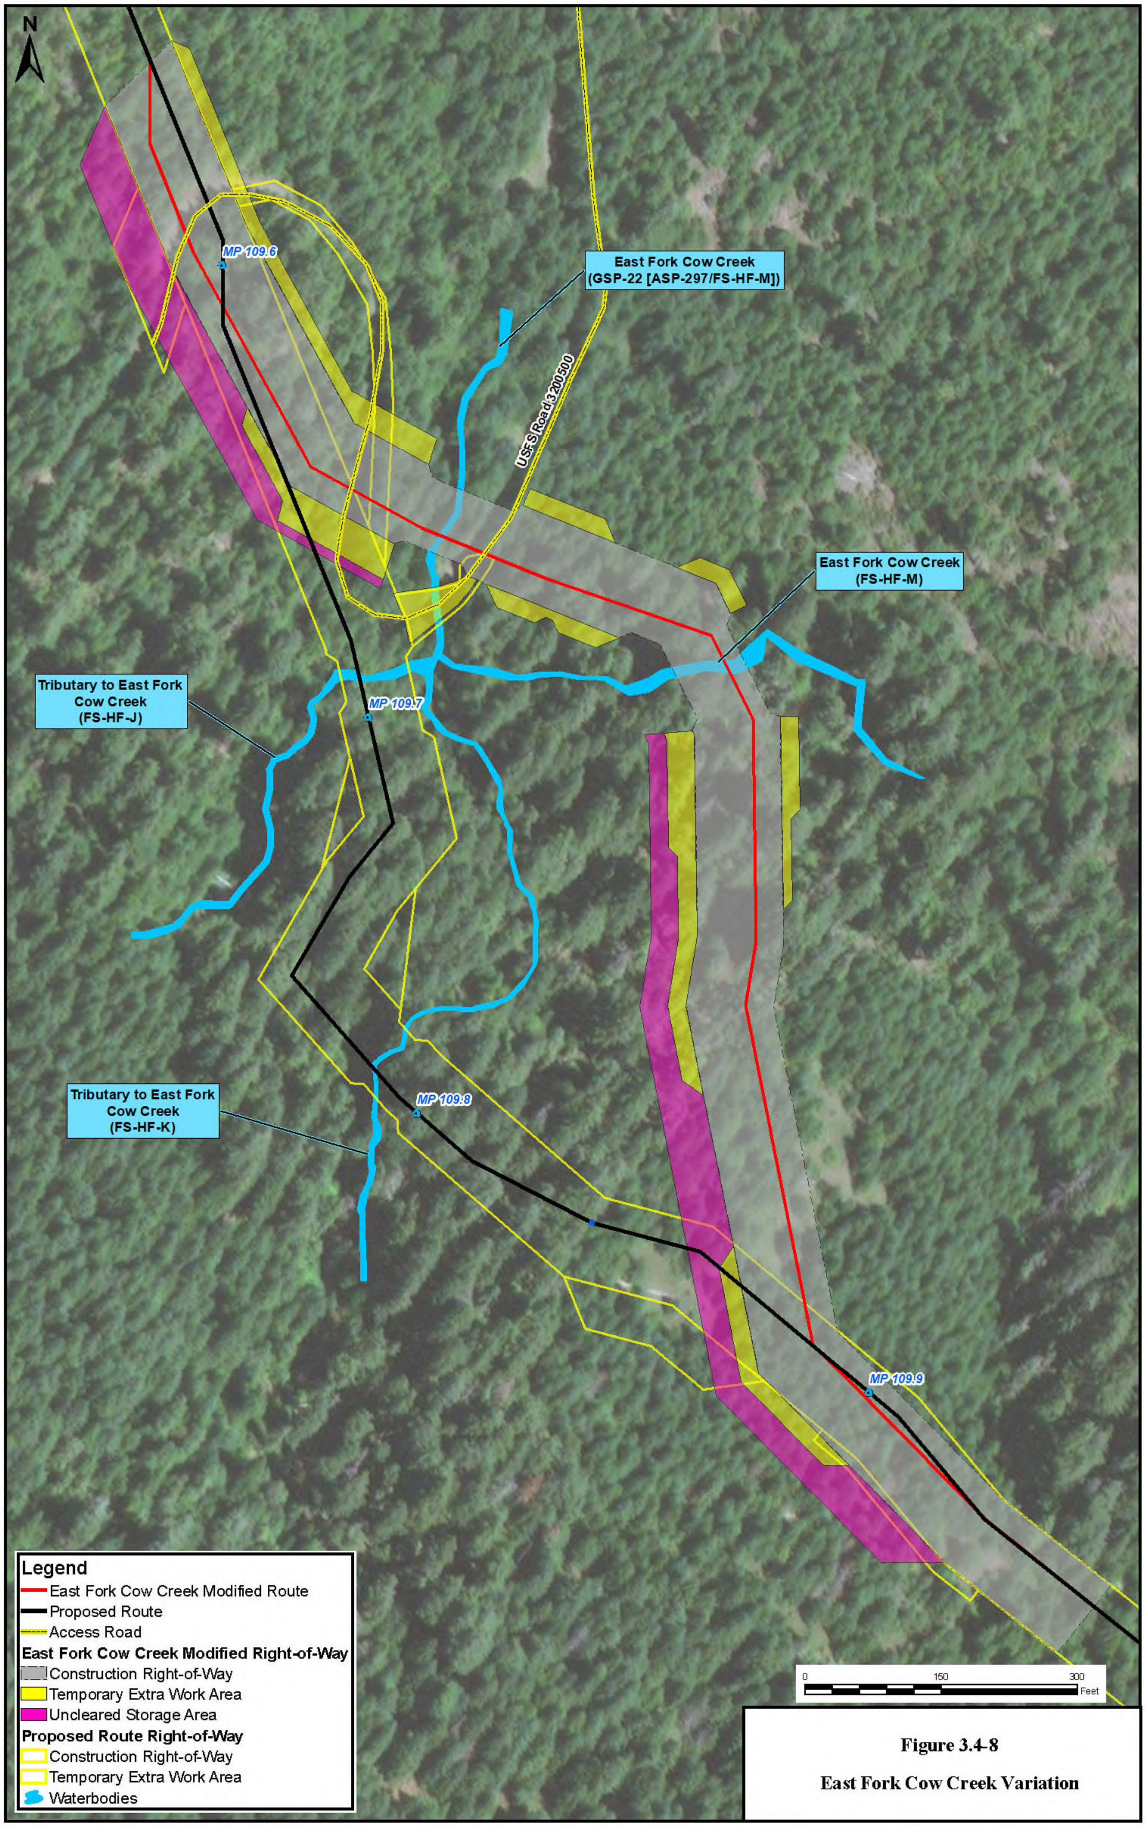


Figure 3.4-8

East Fork Cow Creek Variation

TABLE 3.4.2.8-1

East Fork Cow Creek Variation

Alternatives Analysis	Proposed Route	EFCC Variation
General		
Length (miles)	0.42	0.42
Construction right-of-way (acres)	4.75	4.63
Number of temporary extra work areas (TEWAs)	7	9
Acres of TEWAs	0.91	1.0
Number of Uncleared Storage Areas (acres) a/	0 (0.00)	2 (1.34)
Permanent Easement (acres) b/	2.55	2.55
Land Use		
Miles of right-of-way parallel or adjacent to existing rights-of-way (percent of alternative length) c/	0.02 (6.7%)	0.00 (0.00)
Riparian Reserves - Federal Land Use Designation (acres)	4.26	4.41
Waterbodies and Wetlands		
Number of waterbodies crossed d/	2	2
Length of waterbody crossings (feet) e/	17	12
Alignment parallel to waterbody (feet) d/	535	0
Vegetation		
Total forest clearing (acres)		
Acres clear-cut/regenerating (0-40 years)	2.22	2.19
Acres mid-seral forest (40-80 years)	0.26	0.51
Acres Late Successional Forest (80-175 years)	0.00	0.00
Old Growth Forest (175 +)	2.70	2.65
Biological Resources		
Northern Spotted Owl Suitable Habitat Crossed (High NRF & NRF) (acres) f/	2.70	2.65
Northern Spotted Owl nest patch/cores (NSO)	0	0
Northern Spotted Critical Habitat Crossed (acres)	5.66	5.64

General: All values are rounded (acres to nearest whole acre, miles to nearest tenth of a mile, feet to nearest whole foot).
a/ Acres of Uncleared Storage Areas are not included in the impact comparison (acres) of the various resources because grading and tree clearing will not occur in these areas.
b/ Acres of permanent easement calculated based on a 50-foot width.
c/ Based on inventoried roads included in Umpqua NF Road data and BLM GTRN data (https://www.blm.gov/or/gis/data.php).
d/ Based on field surveys (see Table A.2-3 to Appendix A.2 to Pacific Connector's Resource Report 2 and supplemental wetland delineation report filed in May 2018).
e/ Based on the proposed alignment between the tributaries to EFCC (FS-HF-J and FS-HF-K) (MPs 109.7 to 109.8). In this area the alignment follows a narrow ridge.
f/ See Section 3.3.4.2 in Applicant-Prepared Draft Biological Assessment.

The EFCC variation would result in a significant environmental advantage and is preferable to the proposed route. Therefore, **we recommend that**:

- **Prior to construction, Pacific Connector should file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the East Fork Cow Creek Variation into its proposed route between MPs 109.6 and 109.9, and provide documentation of consultation with the Forest Service.**

3.4.2.9 Pacific Crest Trail Variation

In consultation with the Forest Service, we evaluated a variation that would include an alternative crossing location of the PCT. The variation would co-locate the pipeline with an existing Forest Service Road (3720-700) north of MP 167.8 (see figure 3.4-9). This variation would minimize potential impacts on trail users by realigning the pipeline to an area of the trail that is adjacent to existing disturbance/intrusion from Forest Service Road 3720-700.

The primary advantages of the PCT Variation are that it would minimize potential visual impacts on PCT trail users by locating the crossing at an existing road, and it would be co-located with existing road rights-of-way for 1.37 miles (77.4 percent of its length). The variation would avoid crossing the PCT in an old-growth forest stand and corresponding recreation corridor that lies between Peterson Snow Park and the Brown Mountain Shelter, thereby reducing visual impact from pipeline clearing on trail users. This would also alleviate the need for a multiple-year revegetating/screening plan at the proposed crossing location, which is expected to require ongoing monitoring to ensure new vegetation is successfully established post construction. The PCT Variation would also be located about 1,000 feet farther from the Brown Mountain Shelter, which would minimize potential noise disturbance to shelter users during construction and potentially during restoration efforts. The water well at the shelter is proposed as an irrigation source for replanted trees for restoration of the trail crossing along the proposed route. Further, the PCT Variation would minimize potential construction-related traffic effects because traffic would follow the construction right-of-way at the trail crossing, which is co-located with the existing Forest Service Road 3720-700. The PCT Variation would also cross approximately 0.5 mile less of northern spotted owl nest patch and core areas and would impact less old growth habitat (175 + years old) than the proposed route (see table 3.4.2.9-1). The PCT Variation would also avoid the potential impacts from geotechnical borehole investigation that would be required for the HDD crossing along the proposed route.

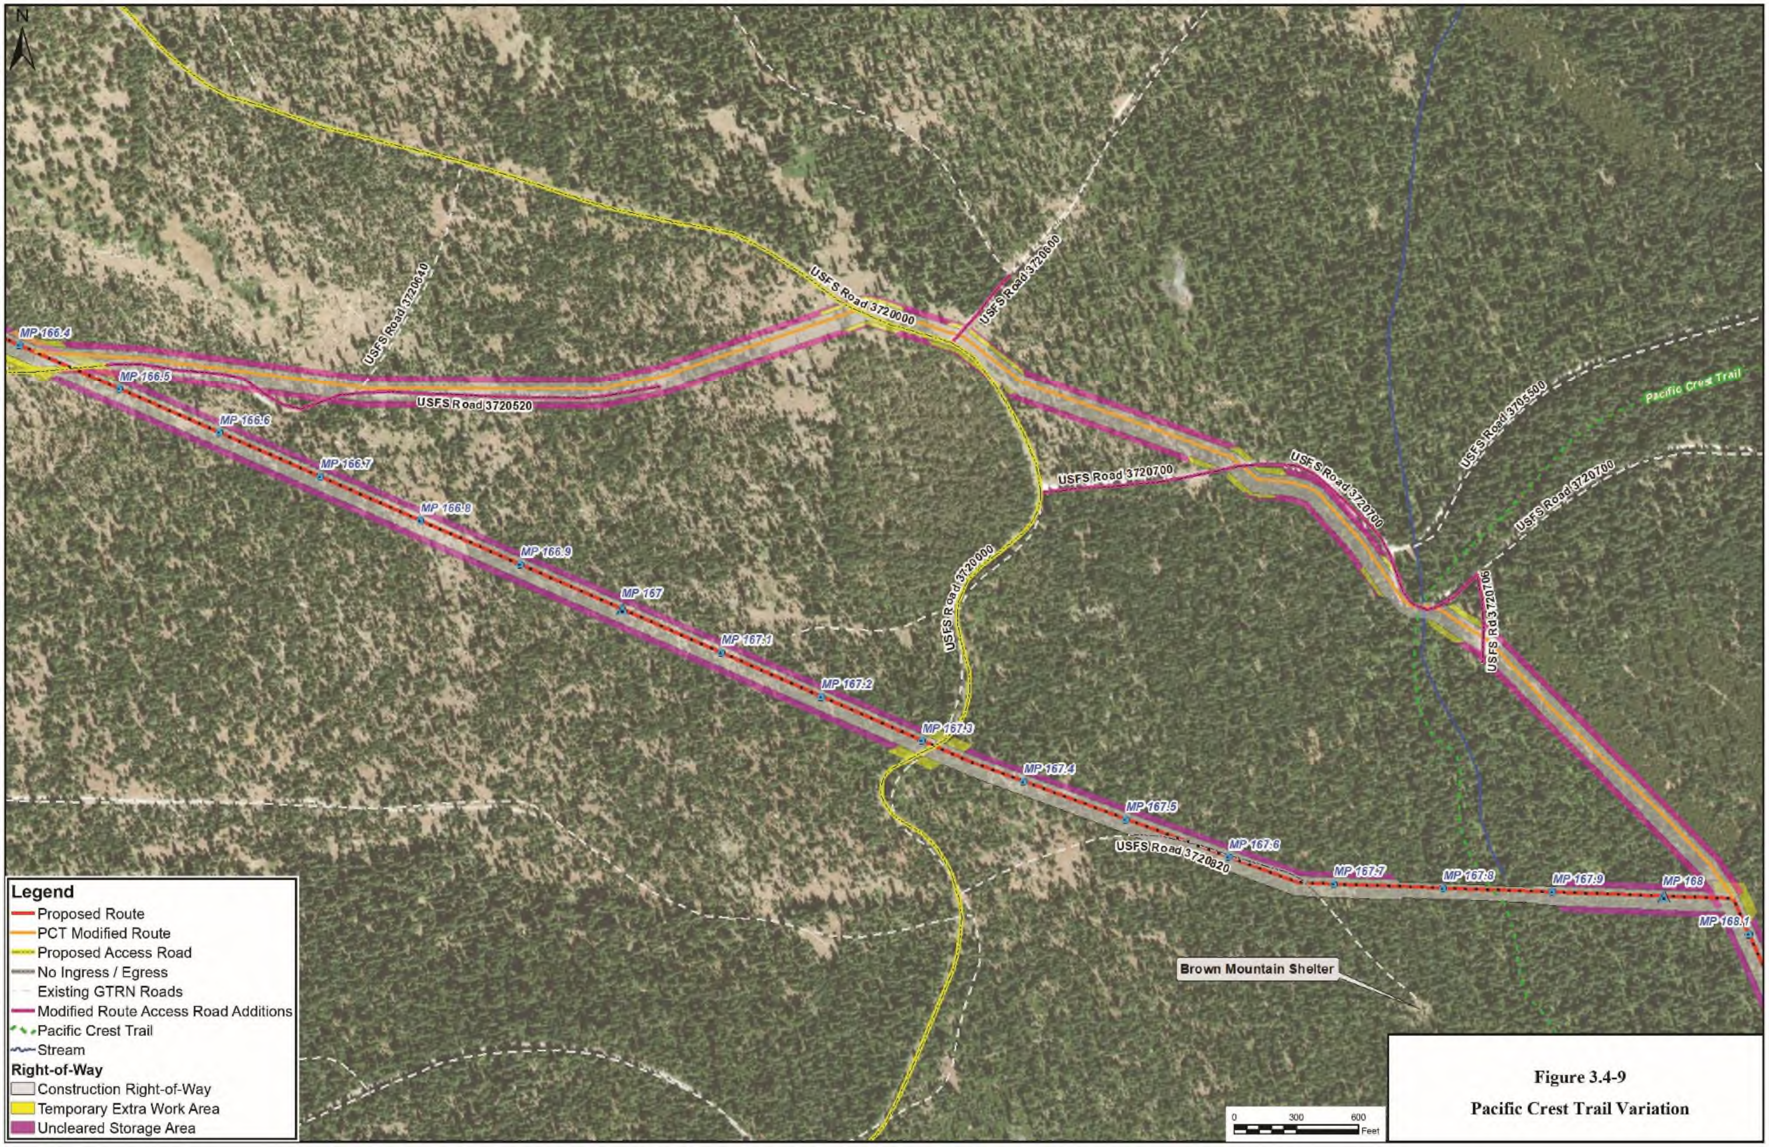

Figure 3.4-9. Pacific Crest Trail Variation

TABLE 3.4.2.9-1

Comparison of the PCT Variation with the Proposed Route

Alternatives Analysis		**Proposed Route**	**PCT Variation**
General			
Length (miles)		1.65	1.77

Number of waterbodies crossed f/		0	1
Length of waterbody crossings (feet) f/		0	4
Vegetation			
Total forest clearing (acres)			
Acres clear-cut/regenerating (0-40 years)		16.95	8.70
Acres mid-seral forest (40-80 years)		0.00	5.64
Acres Late Successional Forest (80-175 years)		0.00	2.77
Old Growth Forest (175 + years)		2.75	0.68
Biological Resources			
Northern Spotted Owl Suitable Habitat Crossed (High NRF & NRF) (acres) g/		2.75	4.94
Northern Spotted Owl nest patch/core area (NSO) (acres)		3.39	2.87
Northern Spotted Critical Habitat Crossed (acres)		20.01	21.95

General: All values are rounded (acres to nearest whole acre, miles to nearest tenth of a mile, feet to nearest whole foot).
a/ Acres of Uncleared Storage Areas are not included in the impact comparison (acres) of the various resources because grading and tree clearing will not occur in these areas.
b/ Acres of permanent easement calculated based on a 50-foot width.
c/ Based on inventoried roads included in Rogue River-Siskiyou NF travel route data and BLM GTRN data (https://www.blm.gov/or/gis/data.php).
d/ Based on inventoried roads included in Rogue River-Siskiyou NF travel route data and BLM GTRN data (https://www.blm.gov/or/gis/data.php), as well as non-inventoried roads identified during civil surveys (June 2018).
e/ FGPR = Foreground Partial Retention; FGR = Foreground Retention
f/ Based on field surveys (see Table A.2-3 to Appendix A.2 to Pacific Connector's Resource Report 2 and supplemental wetland delineation report filed in May 2018) and subsequent site visit (May 31, 2018). The pipeline centerline stream crossing on the PCT Modified Route would occur within the FS 3720700 Road, where the stream is culverted.
g/ Rogue River-Siskiyou National Forest (Forest Service 2017a)

The primary disadvantages of the PCT Variation are that it would be slightly longer than the proposed route (0.12 mile) resulting in slightly larger construction right-of-way impacts (1.5 acres), and would cross one headwater stream and lands designated as Riparian Reserve. It would also affect more acres of NSO suitable habitat (High NRF & NRF) (4.94 acres) compared to the corresponding segment of proposed route (2.75 acres).

As described above, the PCT Variation would include some environmental advantages and some disadvantages compared to the proposed route. Overall, because the variation reduces impacts on old growth forests greater than 175 years old and would move the pipeline crossing of the PCT to be co-located with Forest Service Road 3720-700, the PCT Variation would result in a significant environmental advantage and is preferable to the proposed route. Therefore, **we recommend that**:

- **<u>Prior to construction</u>, Pacific Connector should file with the Secretary, for review and written approval by the Director of OEP, revised alignment sheets that incorporate the Pacific Crest Trail Variation into the proposed route between MPs 166.4 and 168.1, and provide documentation of consultation with the Forest Service.**

3.5 CONCLUSION

We reviewed alternatives to the proposed action based on our independent analysis and comments received. Although many of the alternatives appear to be technically feasible, we identified only four alternatives that would provide a significant environmental advantage over the Project. We have included recommendations that these modifications be adopted. Based on these findings, we conclude that the proposed Project, as modified by our recommendations, is the preferred alternative that can meet the Project purpose.

4.0 ENVIRONMENTAL ANALYSIS

In this section, we describe the existing natural and human environment, and assess the impacts on it resulting from construction and operation of the Project. Our independent analysis and discussion prepared in consultation with the NEPA cooperating agencies considers the affected environment, the applicants' proposed construction methods, their impact minimization and mitigation measures, and, as appropriate, makes recommendations (boldface and bulleted text) to avoid or further reduce/minimize impacts on the environment. This analysis also considers cumulative impacts that may result when the Project's impacts are added to those of past, present, and reasonably foreseeable future projects. The analysis is organized by resource, includes as appropriate information pertaining to federal lands, and by resource concludes with a determination of significance.

For the purposes of this analysis, we discuss four impact durations: temporary, short-term, long-term, and permanent. A temporary impact generally occurs during construction with the resource returning to preconstruction condition almost immediately afterward. A short-term impact could continue for up to three years following construction. An impact is considered long-term if the resource would require more than three years to recover. A permanent impact would occur if an activity modifies a resource to the extent that it would not return to preconstruction conditions during the life of the Project. Permanent impacts may also extend beyond the life of the Project. For example, we consider the clearing of mature forests a permanent impact because it would take several decades for these habitats to attain their pre-construction condition. The construction and operation of aboveground facilities would also cause permanent impacts. When determining the significance of an impact(s), we consider the duration of the impact; the geographic, biological, and/or social context in which the impact would occur; and the magnitude and intensity of the impact. The duration, context, and magnitude of impacts vary by resource and therefore significance varies accordingly. Lastly, our analysis considers and addresses direct and indirect; and primary and secondary impacts on resources collectively.

The structure of this EIS follows the standard format used by the Commission with respect to the order and content of the resources affected by the Project. Each resource section in chapter 4 includes a focused discussion of effects on federally managed lands (i.e., lands managed by the BLM, Forest Service, and Reclamation). As described in chapter 2, the BLM and Forest Service have identified the need to amend their respective land and resource management and resource management plans in order to ensure any action authorized by FERC would be compliant with these plans. While specific effects on federally managed lands are addressed in each resource section, section 4.7.3 of this chapter provides a detailed discussion of consistency with these management plans and evaluations of the proposed plan amendments.

The Project would cross ecologically diverse areas from Coos Bay to the Klamath Basin (see figure 4-1). The Project lies within four ecoregions: (1) the Coast Range; (2) the Klamath Mountains; (3) the Cascades; and (4) the Eastern Cascades Slopes and Foothills (Bryce et al. 2003). This diversity in ecoregions crossed results in a wide variety of conditions, habitats, and environments that could be affected by the Project.

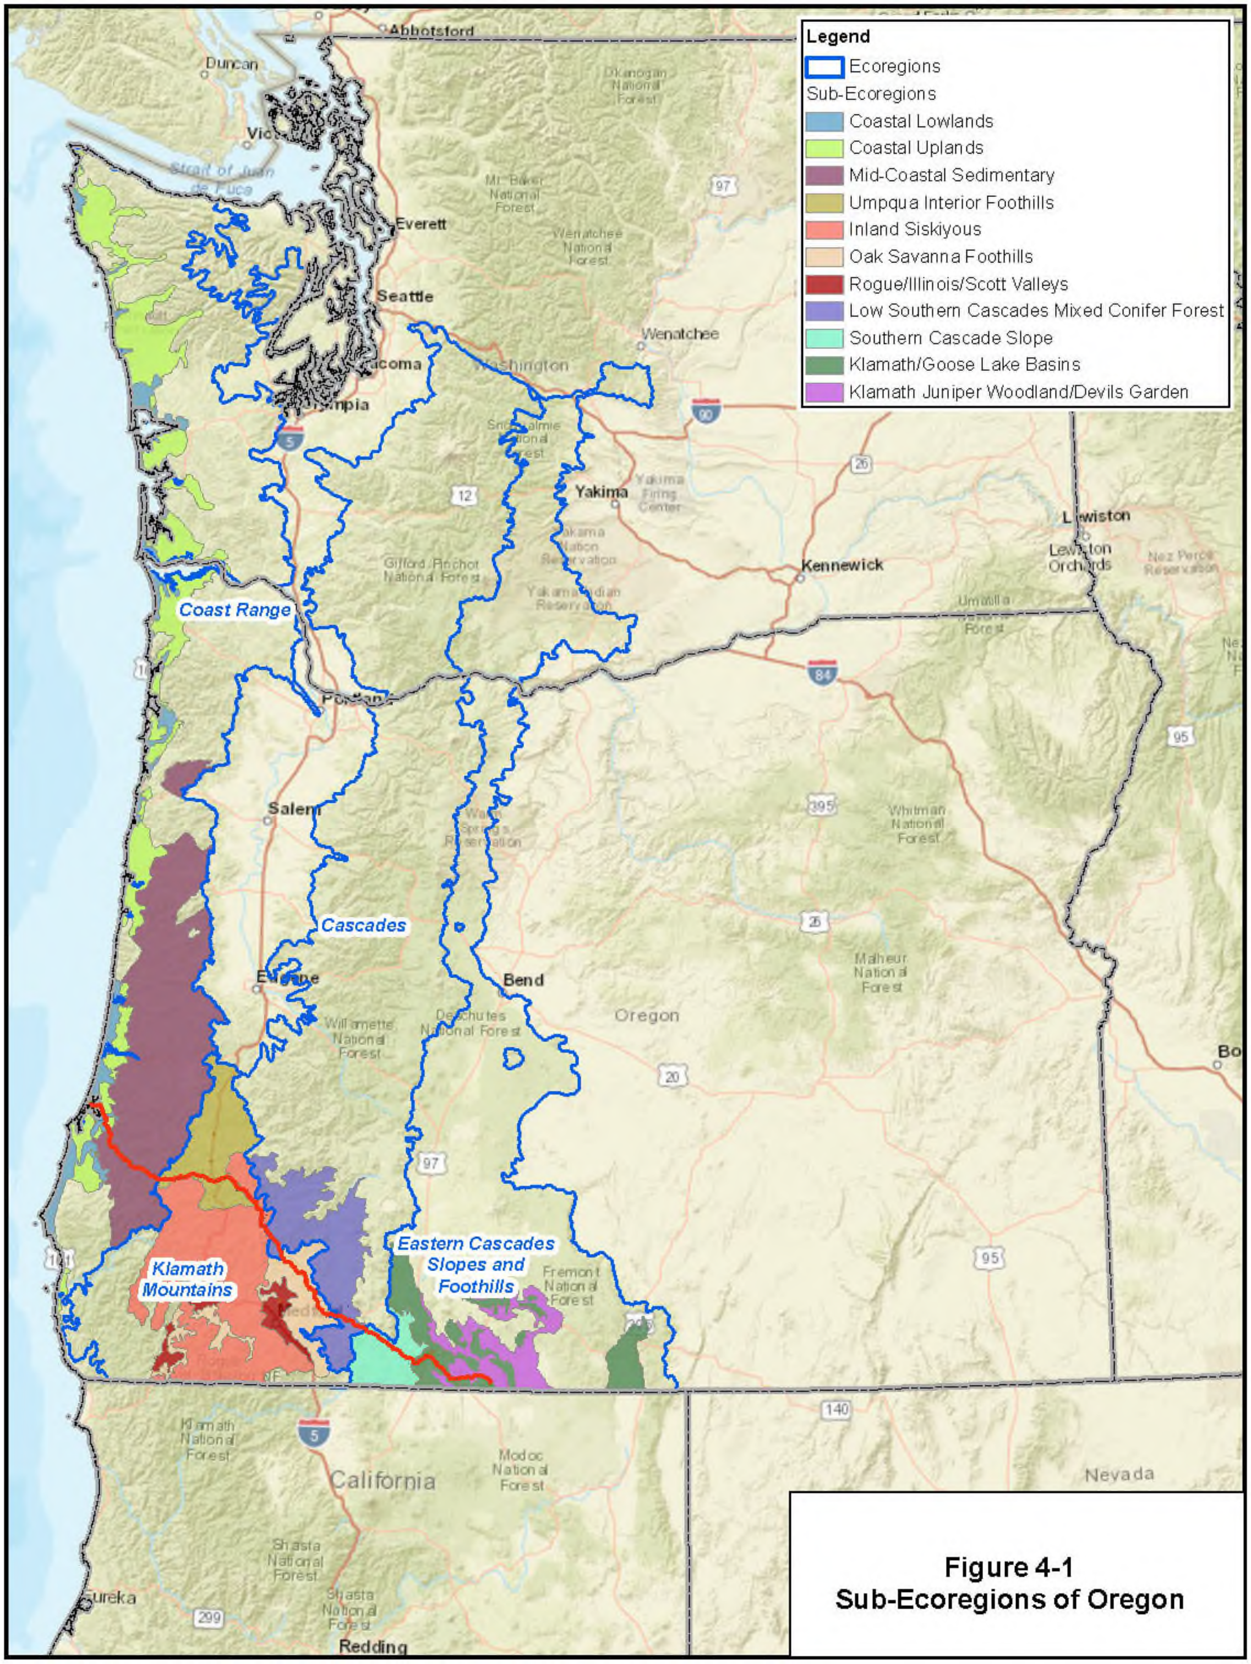

Figure 4-1
Sub-Ecoregions of Oregon

4.1 GEOLOGICAL RESOURCES

The following section describes geological resources and potential impacts related to the various aspects of the Project, including the Jordan Cove LNG terminal and the Pacific Connector pipeline and associated facilities.

4.1.1 Jordan Cove LNG Project

4.1.1.1 Geologic Setting

The Jordan Cove LNG Project site is located within the Pacific Border physiographic province at the western edge of the coastal headlands of the Central Coast Mountain Range, on the North Spit of Coos Bay. The North Spit of Coos Bay marks the southern edge of the Holocene-age Coos Bay Dune Sheet (Peterson et al. 2005).

The LNG terminal site is underlain by loose to dense fill and a relatively clean, fine-grained sand, which is in turn underlain by a weathered sandstone. Fill depths are typically 10 to 15 feet at the Ingram Yard and up to 25 feet at the mill site. The clean, fine-grained sand is a dune sand of Holocene and Pleistocene age (Peterson et al. 2005) with thicknesses of over 100 feet. Sand fill is also present to a depth of about 15 feet at the location of the Trans-Pacific Parkway/U.S. 101 intersection. The lower-lying portions of the Kentuck project site are mantled and underlain by soft alluvial deposits to depths of more than 100 feet in some areas.

Bedrock underlies these sands and includes Eocene marine interbedded siltstones and sandstones of the Coaledo Formation (Baldwin et al. 1973). The upper member of the Coaledo Formation is composed of gray, coarse to fine-grained weathered, very dense, weakly cemented sandstone with silt and minor amounts of coal. Weathered sandstone is generally encountered beneath the dune sands to a depth of about 125 feet (GRI Geotechnical and Environmental Consultants [GRI] 2007a).

Jordan Cove completed 11 deep borings GRI (2007a) at the location of the LNG storage tanks to obtain geotechnical information for the design of the LNG terminal. These subsurface explorations identified sand extending to depths of 124 to 133 feet. Organic mill waste was encountered in the fill at the ground surface at the Ingram Yard and also in several landfills in the vicinity of the mill site. A geotechnical report by GRI (2017a) provides additional geotechnical subsurface investigations performed in 2012 and 2013, and more recently continuing into 2017, at the Jordan Cove site. As noted in the geotechnical report, Jordan Cove plans to conduct additional subsurface investigations to support detailed design.

Jordan Cove also conducted two overwater geophysical seismic reflection surveys between the LNG terminal site and the Southwest Oregon Regional Airport located on the east side of the Coos Bay navigation channel. The subsurface profile indicates shallow bedrock, which becomes progressively deeper toward Pony Slough (southeast of the airport), to a depth of approximately 150 feet below the bay floor (GRI 2007a), and to a depth of approximately 120 feet near the south edge of the proposed slip (DEA 2017a).

Effects on surface geology would be limited primarily to the construction phase of the LNG terminal, when the topographic features at specific locations on the site would be altered by clearing, mechanical excavation, dredging, and fill placement. Construction of the slip and access channel would change the surface geology of the site as a result of excavation and dredging. No blasting would be required during any phase of construction of the LNG terminal because the entire site consists of unconsolidated material. Any shoreline areas disturbed by construction would be armored to protect against erosion or shifting beyond the Jordan Cove project design limits.

4.1.1.2 Mineral Resources

The principal mineral production of Oregon in order of value was crushed stone, construction sand and gravel, Portland cement, diatomite, and crude perlite (USGS 2013a). Mineral resources available in Coos County, Oregon, include chromium, gold, clay, manganese, sand and gravel, silica, stone, and titanium. Coal was mined historically in Coos Bay, starting in 1855 until the early decades of the twentieth century. Coal deposits are known to occur in the upper and lower members of the Coaledo Formation (Newton 1980). The Steva coal seam and the Hardy coal seam have been identified within the vicinity of the Kentuck project site (Diller 1914). The closest major productive coal mine was known as the Libby, which operated until about 1920, located south of city of Coos Bay at the head of Coalbank Slough.

Based on the State of Oregon Mineral Information Layer for Oregon-Release 2, there are no permitted coal mines or oil and gas wells within 0.25 mile of the LNG terminal site (DOGAMI 2017). There are three permitted sand and gravel mines within 0.25 mile of the LNG terminal site; however, all three of these mines are closed and are not producing material (DOGAMI 2017). Based on available database information, construction and operation of the LNG terminal is not anticipated to have effects on identified mineral resources, active mines, or oil and gas production facilities.

4.1.1.3 Seismic and Related Hazards

Seismic-related hazards including earthquakes, ground-shaking, volcanic hazards, surface rupture, soil liquefaction, lateral spreading, tsunamis, subsidence, and scour hazards are addressed in section 4.13 of this DEIS (i.e., the Reliability and Safety section).

4.1.1.4 Paleontological Resources

There are no state or federal laws or regulations that protect paleontological resources on private lands (Niewendorp, DOGAMI, personal communication, 2008). The Antiquities Act of 1906 protects "objects of antiquity" on federal lands. The Paleontological Resources Preservation Act of 2009 applies to federal lands including BLM and NFS lands, as well as "Indian" lands, but does not apply to private land. See section 4.1.3.

4.1.2 Pacific Connector Pipeline Project

The pipeline would be constructed by conventional cross-country techniques as described in chapter 2. Typical pipeline trench depth would range from 6 to 10 feet, although it would be deeper at stream crossings with scour concerns or areas with geological hazards. In Class 1[49] areas, the pipeline would have 36 inches of cover and 24 inches of cover in Class 1 areas with consolidated rock. Excavation

[49] Pipeline Class designations are described in 49 CFR § 192.5 as locations within 220 yards of the pipeline centerline. A Class 1 location has 10 or fewer buildings intended for human occupancy; and a Class 2 location has more than 10 but fewer than 46 buildings intended for human occupancy.

of the trench would encounter a range of soil and rock materials. Special construction methods for crossing rugged terrain were also previously discussed in chapter 2.

The proposed route would cross a wide variety of terrain and geological conditions. The proposed route was evaluated for seismic, landslide, erosion and scour, mine, and volcanic hazards that may potentially occur across or near the alignment and that could adversely affect the pipeline. In addition, an evaluation was made of the potential impact that pipeline construction and operation could have on the natural geological environment and geological processes in the pipeline vicinity. During route planning, Pacific Connector identified and attempted to avoid geological resource areas and hazards.

Pacific Connector selected the proposed route with input from agencies, stakeholders, and land managers/owners to avoid areas with high risk of geological hazards. The initial proposed route was changed in numerous locations to avoid high hazard areas as more detailed data were collected. During construction, Pacific Connector would implement site-specific construction techniques and BMPs to mitigate local geological hazards that could not be completely avoided. The following sections discuss these hazards and how they would be mitigated.

4.1.2.1 Geologic Setting

The proposed route crosses four regional physiographic provinces in Oregon: the Coast Range, Klamath Mountains, Cascade Range, and Basin and Range. The proposed route begins within the Klamath Basin, which is part of the larger Basin and Range physiographic province of the Great Basin; an area characterized by ridges and valleys that are separated by faulting (Burns 1998). The route would then head westward over the High Cascades sub-province, a chain of geologically active volcanoes with high andesitic peaks, and the Western Cascades sub-province, an ancestral range of deeply eroded (extinct) volcanoes. The proposed route then passes through the Klamath Mountains physiographic province, which consists of several complex geological terrains composed of metamorphosed and fractured volcanic and marine sedimentary rocks. The proposed route would proceed over the Coast Range physiographic province, an area underlain by estuarine and alluvial deposits in lowland areas and sedimentary rocks in the uplands and terminate at the Oregon Coast. Between the mountain ranges are several valleys, predominantly filled with recent alluvial materials. Some of the major river valleys and their tributaries crossed by the proposed route heading west to east include the Coquille River Valley, Umpqua River Valley, Rogue River Valley, and Klamath River Valley (see section 4.3 of this EIS for more information about waterbodies).

The pipeline alignment is located within varying soil and lithologic units ranging from soft sediments to hard granite and basaltic rock. Unconsolidated silt, sand, and cobbles occur locally in streambeds, alluvial fans, and valley floodplains in all four physiographic provinces. Detailed descriptions of geology along the proposed route are included in Table B-1 in Appendix B of the *Geologic Hazards and Mineral Resources Report* (GeoEngineers 2017a) filed with Resource Report 6 of Pacific Connector's application to the FERC. Below is a west to east description of the physiographic provinces crossed by the pipeline.

Coast Range

The proposed route passes through the southernmost part of the Coast Range province for approximately 71 miles (approximately MP 0 to MP 71). The Coast Range is 30 to 60 miles wide and averages 1,500 feet in elevation, although the highest point (Mary's Peak) reaches an altitude of 4,097 feet (Orr and Orr 2012).

The Coast Range is composed of relatively soft marine sedimentary rock units that overlie basalt at depth. The wet conditions of the western slopes of the Coast Range, along with steep terrain composed of relatively weak rock, contribute to an active erosional environment with frequent landslides.

Uplift of the Coast Range deposits has deformed the bedrock units with folds and faults. Coastal uplift of the present Coast Range over the past 10 to 15 million years has been simultaneous with stream incision and coastal erosion and depositional processes. Ocean-cut terraces exist near the shoreline, some of which have been elevated to altitudes of up to 1,600 feet (Orr and Orr 2012). Low-lying areas near the coast are underlain by modern beach deposits, sand dunes, estuarine mud and alluvial sediments.

Klamath Mountains

The proposed route passes through the northeast corner of the Klamath Mountain physiographic province for approximately 49 miles (approximately MP 71 to MP 120). The province has a rugged landscape of high peaks and deep canyons, with a total local relief of 2,000 to 5,000 feet (Baldwin 1964). The highest peak of the Klamath Mountains in the state of Oregon is Mt. Ashland, at 7,530 feet (Burns 1998). Most of the Klamath Mountain physiographic province is composed of highly deformed volcanic and marine sedimentary rocks, as well as metamorphic terranes. The physiographic province also contains deformed pieces of the oceanic crust (accreted terrain from the Cascadia subduction zone [CSZ]) and granitic intrusive bodies (Walker and MacLeod 1991). Bedrock is often intensely metamorphosed and fractured.

The proposed route passes through three tectonic geological terranes in the Klamath Mountain segment of the alignment. West to east and youngest to oldest, these terranes are: (1) the Franciscan and Dothan belt; (2) the Western Jurassic terrane; and (3) the Western Paleozoic and Triassic terrane. The alignment crosses through the northernmost part of the Franciscan and Dothan belt, an area composed of turbidite sandstone, mudstone, and chert formed on the continental slope and subsequently scraped off the ocean floor during accretion. East of the Franciscan and Dothan belt, the alignment passes through the northern section of the Western Jurassic terrane, an area composed of volcanic flows and ash altered to greenstone, ophiolite, and metamorphosed ocean sediments, including conglomerate, siltstone, and sandstone. Between the Western Jurassic terrane and the Western Paleozoic and Triassic terrane, the alignment crosses the White Rock pluton (a large body of intrusive igneous rock that solidified within the crust). The Western Paleozoic and Triassic terrane is composed of metamorphosed pieces of ocean crust (ophiolites) and metamorphosed ocean-island basalt (Orr and Orr 2012).

Cascade Range

Approximately 40 miles (approximately MP 120 to MP 160) of the route crosses Oregon's southern Cascade Range. The Cascades consist of two north-south trending mountain chains: (1) the older, more weathered Western Cascades; and (2) the younger, higher-elevation High Cascades. The Western Cascades drain westward and reach altitudes of 5,800 feet. The southern High Cascades drain toward the east and the west and reach altitudes of up to 9,493 feet at the summit of Mt. McLoughlin (USGS 2006).

Precipitation of 60 to 100 inches annually on the western side of the Cascades results in extreme weathering of bedrock and soil deposits and the existence of larger rivers in the physiographic province (Orr and Orr 2012). Both the Western Cascades and the High Cascades consist primarily of volcanoes formed as a result of the subduction of the Juan de Fuca oceanic plate beneath the North American continental plate. The Western Cascades terrain consists of deeply dissected volcanoes that formed between about 42 and 8 to 10 million years ago (USGS 2006). The volcanoes of the High Cascades began erupting about 5 million years ago. As the High Cascades volcanoes erupted, their magma chambers emptied and collapsed, creating calderas (large craters). Crater Lake, north of the pipeline alignment in Klamath County, is one of these caldera lakes. During the Quaternary, andesitic cones formed the range's notable high peaks.

After the formation of the high-altitude andesitic peaks, volcanic activity in the High Cascades has continued intermittently to the present. Minor volcanic vents manifest near the pipeline alignment. These include Brown Mountain, which is a Quaternary-aged volcano situated about 3 miles north of the proposed route near MP 167.

Repeated glaciation of the High Cascades during the Pleistocene Epoch produced glacial U-shaped valleys, cirques, and jagged mountain ridges. No active glaciers exist along or near the pipeline alignment.

Basin and Range

Approximately the easternmost 45 miles (approximately MP 160 to MP 224) of the pipeline alignment pass through the southwestern corner of the Basin and Range province in Oregon, a geographic area named the Klamath Basin. The Basin and Range province contains the Upper Klamath Lake and Lower Klamath Lake National Wildlife Refuge, which, unlike the rest of the province, drain to the Pacific Ocean via the Klamath River.

The Basin and Range is a complex series of alternating uplifted mountain blocks (horsts) and down-dropped basins (grabens). These mountain ranges and valleys are separated by generally north-south trending normal (extensional) faults. The altitude of the Basin and Range province is generally over 4,000 feet, and the summit of Steens Mountain in southeast Oregon reaches 9,670 feet.

Crustal extension is responsible for development of the Basin and Range physiographic province. The extension occurred in two phases, the first of which happened between 20 and 10 million years ago and produced widespread volcanic activity resulting in thousands of feet of basaltic flows and tuffs. The second phase of extension occurred in the last 10 million years and produced the distinct horst and graben block faulted topography.

The low precipitation and runoff rates east of the Cascades restrict the amount of erosional debris that can be transported from watersheds. As a result, sediment has accumulated in the basins, in thicknesses greater than 1,000 feet in some places. Eroded material is deposited in alluvial fans and channels around the margins of the basins and as marsh and lake deposits in the lower elevations. During the wetter and cooler periods of the ice ages, the basins were occupied by much larger lakes; at maximum extent, Pluvial Lake Modoc extended over the pipeline alignment from Klamath Marsh, north of Upper Klamath Lake, to the Tule Lake basin in northern California (Orr and Orr 2012:304).

4.1.2.2 Mineral Resources

Mineral resources that occur in the pipeline area include the following metals: chromite, copper, gold, manganese, mercury, and silver. Other rock and mineral resources include basalt, cinders, coal, conglomerate, limestone, natural gas (including coal bed methane), sand and gravel, sandstone, shale, silica, talc, and tuff/breccia (DOGAMI n.d.). Most of the non-metal minerals are mined to produce aggregate. Mineral resources, surface and subsurface mines, mining claims and leases, mineral material disposals, and oil and gas fields located within one-half mile of the Pacific Connector pipeline construction right-of-way were identified from USGS topographic maps, BLM and Forest Service mineral resource databases (including oil and gas leases, geothermal leases, and mining claims), ODOT aggregate resources Geographic Information System (GIS) data, DOGAMI GIS data, published reports, published and unpublished maps, county mineral overlay maps, and the updated Oregon MILO-2 mineral information layer (DOGAMI n.d.).

Portions of the pipeline alignment cross six areas with county zoning that recognizes the potential for future mineral resource development. This zoning implies that mines and oil and gas wells could be sited at any location within these areas in the future as long as the zoning remains compatible with the resource extraction operations.

Table B-5 of Appendix B from GeoEngineers (2017a) identified the active, inactive, and planned mineral resources or mining sites (organized by MP) within 0.25 mile of the pipeline. Twenty-nine mineral or mine locations were identified as within 500 feet of the pipeline. Sixteen of these mines identified within 500 feet of the alignment are aggregate or quarry-related mines. The aggregate or quarry-related mines generally consist of open excavations and the primary potential hazards at these mines would be related to failure of steep slopes and/or high walls. Pacific Connector's civil survey crews did not observe such conditions along or adjacent to the alignment. Pacific Connector would provide a more comprehensive evaluation of such conditions during the final detailed design.

The remaining seven non-aggregate-related mines were investigated by Pacific Connector through field reconnaissance on January 23 and 24, 2007, and June 13 and 15, 2007. The reconnaissance of the seven mines did not identify any apparent mine workings located within 500 feet of the pipeline alignment. However, adits associated with the Nivinson Prospect/Mars Fraction Lode and Thomason mines were identified within 500 feet of the proposed pipeline. Therefore, Pacific Connector conducted a site-specific mine hazards assessment for those prospects as well as the nearby Red Cloud Mine, and the findings of that study were provided in a stand-alone report dated August 23, 2007, and its 2009 addendum (GeoEngineers 2007a, 2009a). The reports document the existence of naturally occurring mercury in the vicinity of the mines. Six samples were collected along a previous pipeline route and indicated that very low concentrations of naturally occurring mercury mineralization exists. Mercury was not detected in any of the samples at levels that exceed applicable ODEQ and EPA screening levels for protection of worker health. However, a 2,000-foot section of the pipeline route was moved 2,500 feet to avoid the area of the mines.

No mine hazards related to subsidence or slope stability have been identified by the research and investigations completed by Pacific Connector to date. Pacific Connector's ECRP includes erosion and sediment control measures that would be employed to avoid potential impacts from the naturally occurring mercury concentrations identified in the vicinity of the Nivinson Prospect/Mars Fraction (MP 108.7).

Pacific Connector also identified areas where the pipeline would cross: (1) areas where county land-use zoning allows mineral resource extraction, or (2) federal land that has been or is available for mineral resource or geothermal leases (GeoEngineers 2017a). The BLM & Mineral Legacy Rehost 2000 System, LR 2000, was accessed on April 26, 2013 and again in September 2017 by Pacific Connector to include the more recent information. The BLM would review and verify the validity of this database query by Pacific Connector during their right-of-way permit review. Coos County recognizes three coal-basin resource areas between MPs 0 and 7.6; and one between MP 13.2BR and 13.4BR. Eighteen oil and gas areas are located between MP 10.4R and 45.7 in Coos County. Two mining claims are located between MPs 0 and 1.4 in Coos County. Seven oil and gas areas, two placer mining claims, one mine, four lode mining claims, a chromite resource, and a quarry are located in the vicinity of the pipeline alignment between MPs 46.9 and 110 in Douglas County. Ten oil and gas areas and two lode mining claims are located in the vicinity of the pipeline alignment between MPs 115.4 and 166.4 in Jackson County. One lode mining claim, one oil and gas area, and two geothermal resources areas are located in the vicinity of the pipeline alignment between MPs 170.1 and 216.8 in Klamath County.

Constructing and operating the pipeline could affect future mineral extraction operations. Surface mining activities (including materials storage) across the permanent pipeline easement would be prohibited and heavy equipment crossings of the pipeline would be restricted to specific crossing locations. Sub-surface mining could occur, but would require coordination between the pipeline and the mining company, and the implementation of measures to ensure pipeline integrity.

Mine Hazards

Mine hazards potentially exist in areas underlain by or adjacent to underground mine workings and surface mines that have not been properly stabilized, closed, and made safe in accordance with applicable local, state, and federal laws. Pacific Connector identified surface and subsurface mines within 0.5 mile of the proposed construction right-of-way from USGS topographic maps, BLM and Forest Service databases, and LR 2000 (2017). DOGAMI GIS data, published reports, published and unpublished maps, and county mineral overlay maps. No mine hazards, were identified at the aboveground facilities locations.

The primary hazards involve the potential for:

- subsidence in areas underlain by or adjacent to air shafts, tunnels, underground workings, and mine tailings;
- rockfalls and slides caused by the failure of unstable benches, slopes, and tailing piles in nearby surface mines, including those benches and slopes occurring within water-filled pits; and
- the presence of tailings or waste piles containing naturally occurring metals.

According to Pacific Connector's application (Table B-5 of Appendix B from GeoEngineers 2017a), the pipeline alignment was identified as being located within 500 feet of potential mine hazards based on the information provided in the databases at 29 locations. Sixteen of the 29 mines identified within 500 feet of the alignment are aggregate or quarry-related mines. Aggregate or quarry-related mines generally consist of open excavations. The primary potential hazards at these mines would be related to failure of steep slopes and/or high walls. These are expected to be localized conditions. Civil survey crews involved with surveying the right-of-way did not observe these conditions along or adjacent to the alignment. Consequently, these potential hazards are not expected to pose a threat to the pipeline.

The remaining non-aggregate-related mines were investigated by field reconnaissance on January 23 and 24, 2007, and June 13 and 15, 2007. The database indicated that these mines are located at MPs 9.8, 10.0, 16.2, 58.8, 75.3, 105.6, 108.7, 109.3, 109.4, 110.7 142.6, and 150.5. The reconnaissance of these mines did not identify any apparent mine workings located within 500 feet of the pipeline alignment. Adits [50] associated with the Nivinson Prospect/Mars Fraction Lode and Thomason mines were identified within 500 feet of the pipeline location. Therefore, a site-specific mine hazards assessment was completed for those prospects as well as the nearby Red Cloud Mine, and the findings of that study were provided in a stand-alone report dated August 23, 2007, and its 2009 addendum (GeoEngineers 2007b, 2009a). The following summarizes the report findings with regard to the proposed route.

<u>Nivinson Prospect/Mars Fraction Mercury Mine</u>

The pipeline alignment at MPs 108.6-108.7 does not cross the Nivinson Prospect mercury mine but is approximately 200 feet upslope from mine adits. Based on documented excavated depths, trends, and distances from the pipeline, it was concluded from the field investigation that the adits of the Nivinson Prospect mercury mine likely do not extend into the right-of-way and do not pose a risk to the pipeline. However, the pipeline route was moved 2,500 feet from these areas to avoid potential risks.

<u>Red Cloud Mercury Mine</u>

The pipeline alignment is approximately 400 feet west of the Red Cloud mercury mine at MP 109.3. No evidence of the mine was observed during site reconnaissance of the alignment.

<u>Thomason Mine (Inactive)</u>

The pipeline alignment at MP 109.4 crosses the mapped location of the Thomason Mine. No evidence of the Thomason Mine was observed during site reconnaissance of the alignment. Approximately 260 feet downslope of the mapped Thomason Mine location at MP 109.4, the proposed route crosses East Fork Cow Creek. The proposed route crosses the East Fork Cow Creek outside of the Thomason Mining Group boundaries and all other mining groups mapped by Brooks (1963).

<u>Heppsie Quarry</u>

The proposed alignment at MP 150.5 is located within approximately 80 feet northeast of the Heppsie quarry, and parallels the length of the quarry. The Heppsie quarry is a regional hard rock quarry and to utilize this rock quarry it is necessary to blast the rock. The BLM and Pacific Connector determined that due to the proximity of the pipeline to the quarry and the incompatibility of production blasting the rock quarry near the pipeline; that 70,000 cubic yards of rock would be blasted at the expense of Pacific Connector and left on site. The BLM is requiring this blasting because the BLM will not assume unknown risk associated with complications, limitations, or liability associated with utilizing this quarry in the future. Based on aerial

[50] A horizontal passage leading into a mine for the purposes of access or drainage.

photographs and the BLM data Pacific Connector has shown that the pipeline parallels the quarry. Pacific Connector has told the BLM that it would use this quarry to purchase approximately 70,000 cubic yards of rock to crush, per 43 CFR 3600. The BLM has provided Pacific Connector with core drill logs, maps, and a development plan for use of the quarry.

4.1.2.3 Seismic and Related Hazards

The proposed route crosses a complex geological area that has developed through extensive crustal deformation and volcanic activity. Two primary mechanisms for generating earthquakes of design significance exist along the pipeline alignment: (1) a major, regional earthquake associated with the CSZ; and (2) local earthquakes associated with a seismic hot spot near Klamath Falls. Based on the catalogs of recorded earthquakes from the Pacific Northwest Seismograph Network, 1872 to September 2017, and the Earthquake Database for Oregon, 1833 to 1994 (Wong and Bott 1995; Johnson et al. 1994), 336 earthquakes have been recorded within 100 miles of the Pacific Connector pipeline alignment. Table 4.1.2.3-1 lists the recorded historical earthquakes by magnitude range and by epicentral distance to the nearest segment of the Pacific Connector pipeline. Major historical earthquakes near the proposed route include two events in 1873: (1) an estimated magnitude 7.0 earthquake at the southwestern tip of Oregon; and (2) a magnitude 6.3 earthquake near Coos Bay. In addition, a magnitude 6.0 event occurred in 1938 approximately 75 miles south of Coos Bay. Closer to the planned alignment, two earthquakes occurred within about 2 hours of each other on September 21, 1993 that had epicenters located about 15 miles northwest of Klamath Falls: both were magnitude 6.0 earthquakes (Yelin et al. 1994; Braunmiller et al. 1995). However, most of the pipeline construction area has experienced very few earthquakes during the period of historical record.

Geological maps of the pipeline area show many faults that cross the pipeline alignment or are located near the pipeline corridor (Walker and MacLeod 1991). However, with the exception of the Klamath Falls area, these mapped surface faults are not considered active based on evidence of recent Quaternary tectonic activity and are not believed to be capable of renewed movement or earthquake generation (USGS 2009a, 2010). Many earthquakes of magnitude 2.0 and larger have occurred during historical times in the Klamath Falls area. Most earthquake epicenters are clustered northwest of Klamath Falls, near the southwest shoreline of Upper Klamath Lake. Epicenters of these earthquakes are typically at depths of about 3 to 5 miles. These events seem to be associated geographically with the boundary between the Basin and Range province and the Cascade Range province. The earthquake clusters also may be associated with volcanic activity (Cole and Bugni 1993).

TABLE 4.1.2.3-1

Historical Earthquakes within 100 Miles of the Proposed Pacific Connector Pipeline a/

Magnitude Range b/	Number of Earthquakes	Epicenter Distance From Alignment (miles)
3.0 to 3.99	174	5 to 100
4.0 to 4.99	143	3 to 99
5.0 to 5.99	15	8 to 100
6.0 to 6.99	3	9 to 74
7.0 to 7.99	1	82

a/ Earthquake catalog data from the USGS Earthquake (i.e. the Comcat database) Search (January 1, 2006, to August 28, 2013), Pacific Northwest Seismograph Network (2006) and the Earthquake Database for Oregon, 1833 to 1993 (Johnson et al. 1994).

b/ Earthquakes with less than magnitude 3.0 are termed micro-earthquakes and are not usually felt (Reiter 1990). Earthquakes of magnitude 5.0 and greater are generally considered to have engineering significance.

The primary seismic hazards to pipelines include potential strong ground shaking, surface fault rupture, soil liquefaction (and related lateral spreading), earthquake-induced landslides, and regional ground subsidence. The degree of risk from these hazards varies and depends on several factors, including the magnitude (or size) of the earthquake, the distance of the earthquake origin from the pipeline facilities (lateral and vertical), soil/rock conditions, and slope angle of the ground.

Empirical reviews of historical earthquakes demonstrate that welded steel pipelines are not prone to failure due to earthquakes. Modern buried pipes with welded joints have low vulnerability to elastic ground displacement related to earthquake shaking. Ground displacements from wave propagation occur over widespread areas and lack the local strain concentrations necessary to damage a modern welded pipeline. A 1996 study of earthquake performance data for steel transmission lines and distribution supply lines operated by Southern California Gas over a 61-year period found that post-1945 arc-welded transmission pipelines in good repair have never experienced a break or leak during a southern California earthquake and are the most resistant type of piping, vulnerable only to very large and abrupt ground displacement (e.g., severe landslides), and are generally highly resistant to traveling ground wave effects and moderate amounts of permanent deformation (O'Rourke and Palmer 1994). The study included evaluation of pipeline performance during the 1933 Long Beach earthquake (magnitude 6.4), the 1952 (magnitude 7.3) and 1954 Kern County earthquakes (magnitude unknown) the 1971 San Fernando earthquake (magnitude 6.5-6.7) and the 1994 Northridge earthquake (magnitude 6.7). A study of water transmission pipeline response to the 2011 Tohoku earthquake (magnitude 9) indicated that steel pipe over 137 kilometers required 12 repairs – a rate of approximately 0.1 repair per kilometer (Wakamatsu et al. 2016). Similar studies for large (magnitude 8 and greater) earthquakes were not available for natural gas transmission pipelines.

In addition to ground shaking, subsidence and ground rupture from seismic activity, tsunamis can be generated by strong ground motions associated with offshore earthquakes or submarine landslides. Coastal areas of Oregon, including Coos Bay, could experience the effects of tsunamis. The portion of the pipeline near the LNG terminal occurs in the relatively sheltered areas of Coos Bay, where the effects of a tsunami on the pipeline would be expected to be relatively minor (GeoEngineers 2017a).

Seismic hazards for the pipeline were evaluated by reviewing available historical data, by researching geological evidence of prehistoric earthquakes for the Pacific Northwest, and by qualitatively evaluating the potential risk to the pipeline along the overland sections of the alignment. Quantitative evaluation of the potential for liquefaction, lateral spreading, and tsunami inundation was accomplished for the Coos Bay crossing, where liquefaction and lateral spreading hazard were identified during the initial assessment (GeoEngineers 2017a).

Cascadia-type earthquakes are discussed in section 4.13 (i.e., the Reliability and Safety section) for the Jordan Cove LNG Project. If a Cascadia-type earthquake of magnitude 8 or greater occurred during the operating life of the pipeline, the ground shaking and possible ground subsidence would be strongest in the Coast Range province and in low-lying areas near Coos Bay. Although ground shaking would likely be felt throughout the length of the pipeline from a Cascadia event, hazards would diminish in the eastward direction, with increasing distance from the offshore epicenter. Documented subsidence zones associated with the 1960 subduction zone earthquake in Chile (Plafker and Savage 1970) indicate subsidence on the order of 3 to 6 feet vertically distributed over a wide trough of approximately 60 miles. Pacific Connector studies (GeoEngineers 2017a) have indicated that the resultant strain accrual on a welded steel pipeline distributed over that length of pipe would not pose a substantial risk to the integrity of the pipeline.

Ground Shaking and Peak Horizontal Ground Acceleration

Earthquake magnitude and ground motion are two different parameters discussed in relation to CSZ events. Earthquake magnitude describes the earthquake source, and peak horizontal ground acceleration (PGA) describes the effect of the earthquake at a certain distance from the source and based on the geological conditions. The PGA used to design for a certain earthquake is therefore based on the earthquake magnitude as well as other factors. As described below, the pipeline would be designed using PGA values that correspond with an 8-9 magnitude CSZ earthquake and the specific return period.

Using the historical seismicity record including the records for CSZ earthquakes and the available data on Quaternary faults in the United States, the USGS (2009a) has produced probabilistic seismic hazard mapping for the United States in general, and for the region that would be crossed by the pipeline in particular. This mapping has generally been used to address two risk levels: (1) a 10 percent probability of exceedance in 50 years (475-year return period); and (2) a 2 percent probability of exceedance in 50 years (2,475-year return period). The output from the seismic hazard mapping includes estimates of the PGA and spectral accelerations for 0.2 and 1.0 second structural periods. The PGA values are given in percentages, or decimal fractions, of the acceleration of gravity (g). The acceleration resulting from gravitational forces (g) is defined as 32 fps2. PGAs for the Project were calculated for the specific 475-year and 2,475-year return periods and the site-specific PGA of 0.5g for each corresponding milepost interval of the pipeline alignment (GeoEngineers 2017a).

The 10 percent probability of exceedance in 50 years (475-year return period) is defined by the American Society of Civil Engineers (ASCE) Technical Council on Lifeline Earthquake Engineering as the contingency design earthquake for pipeline design (ASCE 1984). The highest 475-year return period PGAs expected along the pipeline alignment are about 17 percent (MP 0 to 2.0 and MP 9R to 16BR) of gravity. The University of Washington (2001) noted that these intensities are moderate and relate Instrumental Intensity VIII and a “Moderate to Heavy” potential damage to aboveground structures as described by the Modified Mercalli Intensity scale as follows:

> *Steering of cars affected. Damage to masonry C; partial collapse. Some damage to masonry B; none to masonry A. Fall of stucco and some masonry walls. Twisting, fall of chimneys, factory stacks, monuments, towers, elevated tanks. Frame houses moved on foundations if not bolted down; loose panel walls thrown out. Decayed piling broken off. Branches broken from trees. Changes in flow or temperature of springs and wells. Cracks in wet ground and on steep slopes.* (USGS 1931)

The USGS (1931) indicates that instrumental intensities of IX up to XII are seismic conditions where damage to pipelines may occur. It is noted that the intensity scale was created in 1931 and that modern pipeline materials and design protocols have improved considerably, as discussed in the following section. The potential damage to buried pipelines from the ground-shaking intensity at the site (intensity of VIII or greater) is, therefore, considered to be low. The pipeline would be designed to shut down automatically if a mechanical failure poses risk to the equipment or otherwise constitutes a hazard. Additional discussion of public safety concerns related to potential earthquake damage to the pipeline is provided in section 4.13 (i.e., the Reliability and Safety section).

Surface Rupture Potential from Faulting

Differential, or shear, movements of fault surfaces can be entirely subsurface, or they can extend to the ground surface as surface fault rupture. The nature of the shear movements at the surface depend on the character of fault movement. In general, surface fault rupture across a pipeline alignment can result in rapid differential ground displacements across the pipe, with displacement magnitudes ranging from a few inches to several feet. The typical mechanics of fault movement in the Basin and Range province (crossed by the pipeline between MP 160 to MP 224) is normal faulting at near-vertical inclinations (dip angle) caused by crustal extension. This extension forms grabens, or down-dropped blocks of the earth's crust bounded on both sides by normal faults. Although deep earthquakes occur beneath the continent within the subducting Juan de Fuca Plate in association with the CSZ, there is no risk of fault offsets at the ground surface associated with these deep earthquakes.

Based on the USGS Faults and Folds Database (USGS 2014b) and the DOGAMI geologic mapping (Black and Madin 1995; Personius 2002a; Mertzman et al. 2007; Mertzman 2008; Hladky and Mertzman 2002), and review and interpretation of light detection and ranging (LiDAR) data available from DOGAMI (http://www.oregongeology.org/lidar/), the pipeline alignment crosses the following regional Quaternary and Holocene age fault zones:

- Sky Lakes fault zone (includes Lake of the Woods Fault), near MPs 172 to 182;
- West Klamath Lake fault zone, near MP 187;
- Lower Klamath Lake section of the Klamath Graben Fault system near MPs 204 to 206 (4-5 crossings); and
- The South Klamath Lake section of the Klamath Graben Fault system near MPs 212 to 213 (Stukel Mountain fault).

The mapped Holocene age fault (defined by the USGS as active within the last 10,000 years) that would be crossed by the pipeline alignment occurs within the South Klamath Lake section of the Klamath Graben fault system, in the vicinity of Klamath Falls near MP 213. This fault is specifically named the Stukel Mountain Fault. Review of USGS data sources (Personius 2002a, 2002b) does not provide potential earthquake magnitude along this fault, but provides other information about slip rate and fault length. LiDAR imagery of recent alluvial sediments in this area does not show linear features typical of fault movements at the ground surface. Recently acquired color stereo aerial photographs do not show linear features or changes in soil color indicative of fault movement at the ground surface.

The location of the Stukel Mountain Fault was evaluated further by completing a seismic reflection survey (NORCAL Geophysical Consultants 2015) in the vicinity of the mapped fault location. The survey confirmed that a near-vertical normal fault extends southeastward from Stukel Mountain into the valley fill area and that the structural offset in bedrock is large—about 1,800 feet to 850 feet—and indicates that the graben is increasing in depth to the north. The disturbed zones from the two seismic lines align well with the USGS and DOGAMI interpretations of fault extensions into the valley fill. The fault offset extends from the bedrock surface (at about 325 feet deep) to shallower than 60 feet, the shallowest depth that could be explored by the seismic reflection survey. Thin alluvial cover over the disturbed sediments indicates that little time has passed since the fault displaced, supporting a conclusion that the Stukel Mountain fault is active.

The data generated by NORCAL indicates that the faulting in bedrock and valley fill commenced long ago and has continued intermittently into the Holocene; this affirms the published classification that the fault is active and has the potential for surface rupture. Based on the NORCAL survey locational information, a fault crossing assessment and design is needed between about MP 212.8 and MP 212.9, a 600-foot-wide zone of potentially active faulting.

Pacific Connector conducted a detailed hazard assessment and mitigative design for the fault crossing (SSD, Inc. 2017). The design fault displacement was computed using a simple and conservative MCE approach, which neglects probabilistic seismic hazard methods and assumes that the entire fault is capable of rupturing all at once. The fault is relatively short and is capable of, at most, about 3.3 feet of differential movement. The force on the pipe would be limited to the weight of backfill on top of the down-dropped side based on the nature of the fault. Therefore, detailed numerical simulation of the pipe-soil interaction of a potential maximum 3.3-foot offset was performed using a proprietary software called PIPLIN. The preliminary results of the Stukel Mountain numerical simulation analyses indicate that mitigative construction is not necessary.

Pacific Connector would further evaluate and select specific designs for fault mitigation during the final detailed design. In general, Pacific Connector would follow published guidance to estimate the potential amount and direction of fault offsets as well as the magnitude of strain accumulation at the pipe crossing location (Takada et al. 2001; Honegger and Nyman 2004). Based on trench observations during pipeline construction by EIs, if mitigation becomes necessary at any of the suspected Quaternary fault crossings, it is anticipated that the mitigation design would consist of trenches with shallow-angled sidewall slopes that are backfilled with loose, cohesionless sand and/or gravel. Site-specific numerical simulation would be used to develop optimum trench geometry for the pipeline alignment where the mitigation is implemented. If backfill material is obtained from federal land and not sourced from within the right-of-way itself, 43 CFR 3600 regulations must be followed. This applies to any material required for constructing access roads and pads. This mitigation option would use trenches with shallow-angled sidewall slopes that are backfilled with loose, cohesionless sand and/or gravel material. Pipeline load reduction with low-strength backfill is likely the most cost-effective mitigation approach for fault rupture hazards. This mitigation option also involves the use of isolation valves on opposite sides of a fault crossing. In the event of a fault-induced rupture or leak of the pipeline, the isolation valves would detect the pressure loss and close automatically, thus preventing flow of gas to the location of the rupture. Such mitigation options are typically only utilized if warranted by site conditions.

The performance of a buried pipeline subjected to fault rupture can be improved further by using different backfill material surrounding the pipe, such that the pipeline is less restrained to movement, thereby reducing shear and bending stresses (ALA 2001, 2002). Also, a coating material can be applied to the pipe to reduce the soil-pipe interface friction, such that the tensile and compressive stress of the pipe can be reduced. This technique has been used by All American Pipe Line Company for its pipeline that crosses the San Andreas Fault in California, by the Sakhalin II Pipeline (Sakhalin Energy Investment Corp. 2008) that crosses multiple active faults in Russia, and by the BTC Pipeline in the Republic of Georgia. In addition, use of stronger material (additional wall thickness) would increase the load capacity of the pipeline, hence increasing the amount of ground movement tolerable by the pipeline. Pacific Connector would consider, evaluate, and implement the best mitigation options for specific conditions during the final detailed design in coordination with the FERC.

Liquefaction and Lateral Spreading Potential

The potential for soil liquefaction from an earthquake is a function of the intensity or strength of the earthquake shaking (high PGA), the duration of strong earthquake shaking, the nature of the soil (it must generally be loose to medium dense and granular such as silt or sand), and groundwater conditions (the soil must be saturated with a shallow groundwater table). In general, liquefaction that results in permanent ground deformation or buoyant displacement of buried pipelines has the potential to result in pipeline damage (O'Rourke and Liu 1999). Pipeline damage associated with liquefaction typically occurs where a sharp transition exists between liquefiable and non-liquefiable materials. Shear or bending movements at such sharp transitions can damage pipelines. In addition, liquefaction can change the buoyancy forces such that the pipeline may float if not mitigated during design. The evaluation of liquefaction potential is complex and depends on numerous site parameters, including soil grain size, soil density, age of soil deposit, depth of the water table, site geometry, static stresses, and design accelerations.

In addition to settlement or pipeline buoyancy, the possibility exists that liquefaction could result in lateral spreading. Lateral spreading involves lateral displacement of surficial blocks of non-liquefied soil as the underlying soil layer liquefies. Lateral spreading generally develops in areas where sloping ground is present, such as along the banks of rivers, sloughs, canals, or lakes. Because lateral spreading is associated with liquefaction of soils, the potential for lateral spreading along the pipeline alignment was evaluated based on the same criteria as liquefaction potential.

The potential for liquefaction along the Pacific Connector pipeline was evaluated based on topography and soil conditions obtained from geological maps, NRCS soil surveys, and, at some sites, limited geotechnical boring data. Areas along the proposed pipeline that are subject to being under water-saturated soils within the pipeline depth are generally limited to valley floors. The groundwater table is not expected to be encountered within the trench depth along mountainous terrain. Excavation depths within the gently sloping valley floors crossed by the pipeline would be limited to the pipeline trench. The pipeline trench backfill is not considered to be of sufficient volume to liquefy during an earthquake. Additionally, trench breakers would be installed in the pipeline trench at regular intervals to prevent the trench from capturing and conveying near surface groundwater.

Liquefaction potential was identified for portions of the proposed route that would be expected to encounter loose to medium dense sandy soils (generally occurring in alluvial valleys or near rivers, streams, sloughs, lakes or other waterbodies). The characteristics were incorporated by Pacific Connector into a numerical liquefaction analysis used to characterize the potential risk of liquefaction. Based on an initial numerical analyses, sites that were underlain by strata with a safety factor against liquefaction of less than 1 are shown as having a "High" risk for potential liquefaction. These areas are listed in table 4.1.2.3-2 as having potential for liquefaction and/or lateral spreading. Those listed as low potential include sites with subsurface conditions of fine-grained soils that are not susceptible to liquefaction or soils that are not expected to be saturated. Those listed as high potential include sites that are underlain by potentially saturated loose to medium dense granular soils. The unknown potential site is an area of private property where no site-specific subsurface information is available due to lack of access.

TABLE 4.1.2.3-2

Summary of Potential Liquefaction and Lateral Spreading Hazards

From MP	To MP	Feature	Liquefaction Potential/ Lateral Spreading Potential	Ownership
1.4R	3.0R	Coos Bay	High/Low	Private, State
3.00R	6.50R	Kentuck Inlet	High/High	Private, State
8.26R	8.47R	Willanch Slough	High/High	Private, State
11.0R	11.3R	Coos River	High a/	Private, State
10.10	10.40	Stock Slough	Low/Low	Private
10.80	11.40	Catching Slough	Low/Low	Private, State
15.72	15.77	Boone Creek	Low/Low	Private
22.60	23.10	North Fork Coquille River	Low/Low	Private
27.00	27.15	Park Creek (aka Middle Creek)	Low/Low	BLM, Private
29.41	30.20	East Fork Coquille River	Low/Low	Private
48.02	48.40	Deep Creek	Low/Low	County, Private, BLM
49.70	50.45	Middle Fork Coquille River	Low/Low	Private
55.80	56.60	Alluvial Valley	Low/Low	Private
56.90	59.00	Olalla Creek	Low/Low	Private
66.85	67.05	Willis Creek	High/High	Private
68.95	69.80	South Umpqua River #1	High a/	ODOT
88.20	88.65	Days Creek	Low/Low	Private
94.55	94.80	South Umpqua River #2	High a/	Private
122.55	122.75	Rogue River	High a/	Private, State
128.50	128.70	Indian Creek	Unknown b/	Private
131.80	132.00	Neil Creek	Low/Low	Private
191.60	199.00	Klamath Valley	High/Low	Private
199.00	201.00	Klamath River	High a/	Private, State, Reclamation
201.00	214.00	Lost River Valley	Low/Low	Private, State, Reclamation
217.10	218.33	Alluvial valley	Low/Low	Private
221.80	224.40	Alluvial valley	Moderate/Low	Private

a/ A potential for occurrence may exist, but hazard would be mitigated.
b/ Landowner permission to evaluate site was not granted.

Mitigation for liquefaction conditions can include avoidance by routing around or under the potentially liquefiable materials, by reinforcing the pipe with thicker walls, and/or by weighting the pipe with a concrete coating. Potential ground improvement measures would also be considered including vibroflotation [51], stone columns, compaction grouting, and deep dynamic compaction. Primary geotechnical factors involved in selecting the type of mitigation include: the depth of liquefiable soils, fines content, groundwater depth, the potential for obstructions (i.e., buried logs), and the density of overburden soils over the liquefiable soils.

Pacific Connector proposes to cross four river crossings (Coos River, Rogue River, Klamath River, and South Umpqua River) using trenchless crossing methods including HDD and DP technologies in order to minimize the environmental impacts of construction and to install the pipeline below

[51] Vibroflotation is a technique for improving the strength and bearing capacity of unsaturated, granular soils.

zones of potentially liquefiable soil. Regardless of the performance standard that is established Kentuck Slough and Coos River sites would be constructed with special backfill placed around the pipeline in areas where the pipeline transitions from rock to soil to alleviate potential stress resulting from differential movement in accordance with the pipeline operator's design basis specifications. For the pipeline segments that transition from the alluvial soils to rock, the special backfill would extend approximately 40 feet into the rock from the soil/rock interface. The special backfill material would consist of clean, imported, processed sand of alluvial origin (crushed materials would not be used). The special backfill material would completely surround the pipe, with a minimum of 1 foot of sand backfill covering the crown of the pipe. This backfill would help to alleviate stresses induced by differential settlement between the rock and the alluvial soils. The pad of special sand backfill beneath the pipe and the sand backfill adjacent to and above the pipe would be placed in lifts not greater than 12 inches in loose thickness and lightly tamped with hand-operated vibratory equipment; and the native backfill above the imported sand would be lightly compacted with mechanical equipment.

4.1.2.4 Landslide Hazards and Slope Stability

Many types of landslides occur that can affect property and public safety. However, most landslides can be placed in two general categories: (1) shallow-rapid landslides (debris slides/flows) and (2) deep-seated landslides. Shallow-rapid, or rapidly moving, landslides generally originate on very steep slopes, often where no prior indications of movement are present. In the Coast Range, especially in the Tyee formation, recurring debris flows produce debris chutes. These are evident by narrow concave gullies containing activity indicators such as bare rock, soil generation, and vegetation stratification. Fans and coalescing fans (from multiple chute discharges) form plains. Mass-movement of rapid-shallow landslides is typically triggered by large, infrequent storm events.

Deep-seated landslide movement can occur where no previous movement is evident, but commonly occurs where topographic and vegetative indications of past or chronic slope movements are present. Deep-seated landslides range in depth from tens to hundreds of feet and can occur anywhere on a hill slope. The larger deep-seated landslide complexes may occupy several square miles of terrain. These features can usually be identified on topographic maps or aerial photos based on distinctive contour or vegetative patterns. Slope movement can vary from rapid to nearly imperceptible and may entail small to large displacements. The greatest risk of deep-seated landslide movement arises from existing (dormant) features that can reactivate in response to land management practices, seismic activity, stream erosion and/or prolonged periods of precipitation. Movement can be complex, ranging from slow to rapid, and may include small to large slope displacements. The greatest risk of deep-seated landslide movement is from existing (dormant) deep-seated landslides reactivating in response to human activity, seismic activity, stream erosion, or heavy precipitation. Assuming unchanged conditions, it is much less common for a deep-seated landslide to occur on a previously undisturbed and intact slope than reactivation of an existing landslide feature.

Risk is greatest where the direction of slide movement is across (perpendicular to) the pipeline alignment. This typically occurs where the pipeline crosses a slope instead of descending straight down the fall line. Although the greatest risk is where a pipeline crosses a landslide, headward (upslope) expansion of the slide could eventually involve a pipeline located upslope of an active landslide. Strain within a pipeline can develop slowly from a deep-seated landslide as a result of long-term slow movement, or it can develop quickly as a result of a single movement event. Shallow-rapid landslides are unlikely to induce long-term strain to a pipeline, but rather more likely to expose the pipe and result in a loss of support where it crosses a debris slide source area. Once mobilized into a debris flow, shallow-rapid landslides often have tremendous erosional potential. Debris flows that originate upslope of the pipeline also have the potential to scour, expose, and damage the pipeline by debris impact; however, as discussed in the following sections, moderate and high-risk landslide areas have been avoided during routing of the pipeline.

Construction along side slopes can also result in instability during construction, restoration, and operation, and could be a source of debris flows. Construction factors that may increase the potential for slope failure and debris flow could include trenching along slopes and the burden of construction equipment on unstable surfaces. Cut slopes and fill slopes along the pipeline right-of-way could be a source of debris flow in the Project area triggered by intense and/or prolonged rainfall events. A typical debris flow pathway consists of an upper initiation site or source area, a main path down a slope and then into and down a stream channel, and then a lower depositional area or run out zone on an alluvial fan at the base of the mountain. Fill slopes, especially inadequately constructed and maintained fill slopes, are a potential source of debris flows. Fill slope failures could become debris flows that damage not only the pipeline corridor but also the slopes, stream channels, or other resources hundreds or thousands of feet downslope from the corridor. Cut slope or fill slope failures pose a risk to pipeline construction workers, the public, and natural resources. As a result, the cut-and-fill slopes would be designed for slope stability by taking into account slope percent and other engineering geology and geotechnical engineering factors such as the orientation of the bedrock surface as well as geologic structure. The ODF has developed guidelines for the identification of high risk areas for rapidly moving landslides (including debris flows) that have a substantial risk to public safety (ODF 2000). Additional discussion of public safety concerns related to potential landslide hazards is provided in section 4.13 (i.e., the Reliability and Safety section).

An initial landslide hazards evaluation was conducted in three phases: initial office review, aerial reconnaissance, and surface reconnaissance. The purpose of the first phase study was to identify existing landslides as well as areas susceptible to landslides within one-quarter mile of the initial alignment by reviewing published maps and digital data (Burns et al. 2011a, 2011b), aerial photographs and LiDAR-generated hillshade models. The purpose of following two phases was to further evaluate only those landslide hazard sites that represent potentially moderate or high risk to the pipeline, based on the results of the previous phase of evaluation. These initial evaluation phases are described in greater detail below. No landslide hazards were identified at the aboveground facility locations.

Rapidly Moving Landslide Risk Assessment

An assessment of rapidly moving landslides (RMLs) was conducted based on available detailing mapping, risk assessment methods, and on follow-up site reconnaissance in areas of concern. DOGAMI, in cooperation with other agencies, produced a map of Potential Rapidly Moving Landslide Hazards in Western Oregon (Hofmeister et al. 2002). This map was limited to western Oregon because the vast majority of historical RML occurrence has been within that portion of the state. Pacific Connector has provided geologic hazards maps in Appendix F of the *Geologic Hazards and Minerals Resources Report* (GeoEngineers 2017a) that show the slopes in and around the pipeline alignment in western Oregon that have been mapped as potential RML hazards.

Creation of the map involved the use of GIS modeling, checking and calibration with limited field evaluations, and making comparisons with historical landslide inventories. The intent was to identify areas that have some potential to be affected by RMLs so that they would be considered and evaluated appropriately.

The Blue Ridge Reroute was identified and evaluated after the RML mapping by DOGAMI had been discontinued and is no longer being used to evaluate RML hazard risk. Other methods were used to evaluate RML hazards (such as LiDAR hillshade and aerial photograph interpretation). No RML hazards were identified along the Blue Ridge Reroute that pose a threat to the proposed pipeline alignment.

The portion of the pipeline alignment that crosses the Coast Range physiographic province has the greatest risk of being affected by rapidly moving landslides because of rugged terrain composed of relatively weak sedimentary bedrock and relatively high precipitation rates. In particular, studies indicate that the Tyee Core Area within this province has a higher susceptibility to rapidly moving landslides than other areas of the pipeline (Robinson et al. 1999).

The potential for rapidly moving landslides to occur east of MP 166 (east of the Cascade Range) generally is considered to be relatively low based on geological conditions, relatively little rainfall, and statistically fewer past historical rapidly moving landslide occurrences (Hofmeister et al. 2002). Climate change models predict a drier climate east of the Cascade Range, including less snowpack (and snowmelt), more rain instead of snow in low elevation basins, lower summer and early fall streamflows, and decreased soil moisture (University of Oregon 2008). These conditions are not likely to increase the potential for rapidly moving landslides in this region. Slopes east of MP 166 were reviewed to identify high-risk sites based on general guidelines of the ODF (ODF 2000). Based on available topographic mapping, no slopes along the pipeline alignment east of MP 166 exceed 65 percent or appear to be at high risk of rapidly moving landslide occurrence.

Pacific Connector conducted an initial risk assessment to evaluate the potential risk (high, moderate, and low) where the pipeline alignment crosses the mapped hazard areas using some of the input parameters used for the DOGAMI model (Hofmeister et al. 2002). Using LiDAR where available, 10-meter digital elevation model, and aerial photography, Pacific Connector identified moderate and high risk RML sites along the proposed route. Pacific Connector then conducted a surface reconnaissance of these sites to further evaluate potential risk. In general, the risk of landslide occurrence and mobilization increases with slope gradient and with the degree of convergence (concavity).

A total of 304 pipeline segments were initially identified within rapidly moving landslide hazard areas. Based on the risk assessment, approximately 128 of these sites were considered to be a potentially moderate or high risk and were selected for further study. Site-specific reconnaissance was conducted in certain areas with the potential for shallow-rapid landslide hazards, as documented on Tables B-3a and B-3b of Appendix B in GeoEngineers (2017a).

Deep-seated Landslide Risk Assessment

Larger, deep-seated landslides can usually be identified from topographic maps (including LiDAR) and aerial photographs. Areas susceptible to deep-seated landslide movement were identified from existing geological maps and from topographic or photographic indications of historical or ancient landslide movement.

Table B-2 from GeoEngineers (2017a) lists the identified deep-seated landslides, the data source, and the initial risk to the pipeline. High hazard landslides were identified where the alignment crosses landslide mass or is located on the slope such that the slide could move or expand to involve the pipeline. Surficial, geomorphic, and vegetative features suggest that the landslide is active or dormant historic (past movement less than 100 years ago) (Keaton and DeGraff 1996). Moderate hazard landslides were identified where the alignment crosses landslide mass or is located on the slope such that the slide could move or expand to involve the pipeline, and where surficial, geomorphic and vegetative features suggest that the landslide is dormant-young (last movement 100 to 5,000 years ago) (Keaton and DeGraff 1996). Fifteen of the landslides were judged to pose a moderate to high potential risk to the pipeline. In these instances, Pacific Connector either rerouted the pipeline route to avoid the hazard or assessed the feature further through aerial reconnaissance and risk assessment. The subsequent aerial reconnaissance of the deep-seated landslides identified as moderate to high risk included assessments of geomorphic and vegetative conditions. These data were incorporated into a model of potential risk related to each deep-seated landslide. Pacific Connector then identified potential alternative routes around moderate- to high-risk landslides that appeared to be active or to have the potential to reactivate. Six landslides were identified as posing a moderate to high potential risk and were evaluated further in the field. Five of these six landslides are located in Coos County within the Coast Range physiographic province (at MPs 14.7-14.8, 23.8-24.2, 24.4-24.6, 65.2-65.5, 65.3-65.5, and 72.7-72.9).

Seismically Induced Landslides and Rockfalls

Strong ground shaking associated with an earthquake may induce landslide failures at great distances from the earthquake source (Keefer 1984). The potential exists, at least locally along portions of the proposed route, for ground shaking to induce rockfalls, landslides, or soil slumps (USGS 2010, 2002). Potential areas of seismically induced landslides include the mapped existing landslides summarized in Table B-2 of GeoEngineers (2017a) Geologic Hazards and Mineral Resources Report from Pacific Connector's application to the FERC.

Areas of potential ground shaking of sufficient intensity to initiate landslides or rockfalls include the areas of greatest seismic activity: the Klamath Falls region (with relatively recent events of magnitudes 5.9 and 6.0) and the Coos Bay region (with the potential for very large, long recurrence interval, Cascadia megathrust events).

Landslide Hazards Avoidance and Minimization of Adverse Effects

For the purposes of landslide hazard evaluation in this report, a distinction is made between the hazard associated with a landslide and the risk associated with that hazard. In the following discussions, statements of risk apply to the potential for damage or failure of the pipeline from earth movements. It is recognized that the consequences of a pipeline failure may be catastrophic and involve fire and/or explosion. However, those consequences are location-specific and are not considered in the following evaluations of risk to the pipeline. Pacific Connector has worked to avoid landslides along the proposed route. Ridgetops are generally considered to be stable and, therefore, an attempt has been made to route the vast majority of the pipeline along ridgetops.

Risks associated with landslides include both the risk that installation of the pipeline may adversely affect slope stability, and that post-construction land movements could damage the pipeline. Pacific Connector selected its proposed route to avoid existing landslides and areas susceptible to landslides (i.e., unstable slopes where construction-induced landslides could occur). In addition, the potential for construction-induced landslides would be avoided through appropriate construction techniques and BMPs included in the ECRP. Appendix B, Table B-2 from GeoEngineers (2017a) identifies where Pacific Connector's initial proposed route was changed to avoid identified landslides and landslide hazard areas.

Table B-2 from the GeoEngineers (2017a) indicates where reroutes were completed to avoid identified landslides. Tables B-3a and B-3b from the same report indicate where reroutes were incorporated into the proposed route to avoid moderate- and high-hazard RML hazard areas. All of the moderate- and high-hazard deep-seated landslides identified along the alignment were avoided where feasible during final route selection.

All known hazardous landslides thought to pose a risk to the pipeline have been avoided through routing. At this time, no sites have been identified (through the use of LiDAR interpretation, helicopter-based reconnaissance, and ground-based reconnaissance) as requiring additional monitoring beyond the standard monitoring protocols for the entire pipeline. Pacific Connector would develop monitoring protocols and/or mitigation measures prior to construction if warranted based on findings from the ground-based reconnaissance. There are two primary ways in which pipeline construction has the potential to adversely impact slope stability: (1) deep excavation into and across the slope where the pipeline is oriented in the "side-slope" direction; and (2) capturing, concentrating and conveying surface or near surface water along the pipeline right-of-way surface or within the pipeline trench and routing it to potentially unstable slopes. The current proposed pipeline alignment generally avoids traversing steep slopes perpendicular to slope direction (side-hill) to the extent practicable.

GeoEngineers identified segments along the proposed pipeline centerline that are oriented at an angle of 45 degrees or less from contour and where slope gradients are greater than 30 percent. The slope gradients were analyzed using GIS software and a combination of LiDAR-based digital elevation model (DEM) and publicly available 10-meter DEM. Following Pacific Connector's proposed BMPs described in the ECRP would limit potential adverse impacts on slope stability for those side slopes segments that are less than 30 percent gradient. In general, these BMPs include using well-drained structural fill placed in lifts and compacted for the side slope sites with gradients of 30 percent or greater oriented perpendicular to the pipeline. At sites where import of large volumes of structural fill is not practical, alternative methods would be implemented to construct the fill slopes with native soils. For example, perforated drain pipes can be installed within the inside edge of the construction right-of-way prior to placement of the fill to improve drainage of the native soils. Perforated drains would be surrounded by 12 inches of drain rock, all of which would be wrapped in a geotextile filter fabric. After drains are installed, the fills would be placed in horizontal lifts and compacted.

Pacific Connector would further identify steep side slope pipeline construction segments during the final design phase. Fill slope construction details and specifications would be designed for all identified pipeline segments that traverse steep side slopes (30 percent or greater).

Pipeline Construction BMPs for Landslides and Slope Stability

Pacific Connector has prepared and would implement the ECRP included in its POD to avoid and minimize impacts from pipeline construction, including reducing the potential for construction to adversely affect slope stability. Because the pipeline would cross extensive areas of rugged terrain, there is potential for previously unidentified landslides or new landslides to affect the pipeline after it is installed. Monitoring higher-risk areas along the pipeline can aid in detecting landslide occurrence and movement so that action can be taken to prevent damage to the pipeline. Monitoring can range from visual surface observations from the air or ground to the use of strain gauges and subsurface instrumentation, such as inclinometers, to detect and measure slope movements (typically, these instrumentation methods are used only on pipeline segments affected by active slope movement). Monitoring is further described in the section below.

Pacific Connector's ECRP includes several BMPs that are intended to reduce the potential for pipeline construction to change or alter natural stormwater runoff and/or near surface groundwater. The following summarizes these BMPs:

1. Trench breakers would be installed in the pipeline trench on slopes prior to backfilling to prevent water from flowing along the pipeline and eroding trench backfill materials (see ECRP, Section 4.2.1). Spacing of trench breakers would be based on slope gradient. Slopes greater than 30 percent in mountainous terrain would receive trench breakers spaced at least every 100 feet. Pacific Connector would utilize sandbags (foam trench breakers may be used if approved by the State of Oregon) for trench breaker construction (see Section 4.2.1 of the ECRP for additional trench breaker details).
2. Pacific Connector would install temporary slope breakers to reduce runoff velocity, concentrated flow and to divert water off the construction right-of-way to avoid excessive erosion. Temporary slope breakers may be constructed of materials such as soil, silt fence, staked straw bales, straw wattles, or sand bags. The outfall of each temporary slope breaker would be to a stable, well-vegetated area or to an energy dissipating device at the end of the slope breaker and off the construction right-of-way. Pacific Connector would install temporary slope breakers on all slopes greater than 5 percent according to the spacing in Table 4.1-1 of the ECRP, unless the EI determines that a closer spacing is required.
3. Permanent slope breakers (waterbars) would be installed across the right-of-way on slopes. The purpose of these structures is to minimize erosion by reducing runoff velocities, by shortening slope lengths, preventing concentrated water flow, and by diverting water off the construction right-of-way. Slope breakers would be constructed with a 2 to 8 percent outslope so that water does not pool or erode behind the breaker. Outflow would be diverted to a stable area off the right-of-way consistent with FERC's Plan. Slope breakers would be installed along the right-of-way based on slope gradient and soil characteristics (see Table 4.2-2 of the ECRP.) All slopes greater than 30 percent gradient would receive slope breakers spaced at least every 50 feet.
4. Project-wide, slash from timber clearing would be stockpiled at the edge of the right-of-way and scattered/redistributed across the right-of-way during final cleanup and reclamation according to the BLM and Forest Service fuel loading specifications to minimize fire hazard risks. However, much of the slash generated during timber-clearing operations would remain on the ground and in place to provide cover to minimize erosion over the winter following construction. Pacific Connector has designated UCSAs that would not be cleared of trees along the route. Generally, slash would not be stored in UCSA in riparian reserves on federal lands. Minimizing overall disturbance would reduce the potential for erosion, especially on steep slopes.

Pipeline Monitoring

Pacific Connector intends to implement a like level of landslide and pipeline easement monitoring currently performed on existing Williams-owned pipeline facilities in southwestern Oregon. Monitoring would consist of weekly air patrol, annual helicopter survey, and quarterly class location. Class location consists of land patrol (including leak detection), semi-annual class 1 and class 2 location land patrol, and annual cathodic protection survey. All the identified ancient landslides crossed by the proposed pipeline fall within class 1 or 2 areas. Observed areas of active third-party activities such as logging or development and areas affected by unusual events such as landslides, severe storms, flooding, earthquake or tsunami may require additional inspection and monitoring determined on an individual basis.

The purpose of the monitoring would be to detect potential movement or pipe strain before it compromised the structural integrity of the pipeline. If movement were detected, immediate action would be taken to reduce the risk to the pipeline. Every landslide is unique, and there are no standard methods for reducing or eliminating landslide-related risks to buried pipelines. However, in concept, initial response actions generally include measures to reduce the stresses in the pipeline caused by slide movements. Secondary response actions are directed at improving the stability of the slide so that movements in the vicinity of pipeline are halted or the impacts on the pipeline are minimized. Tertiary response actions involve rerouting the pipeline to avoid landslide hazards by relocating the pipeline to a safer location.

Although the pipeline route does not cross active or recently active landslides, if any landslides do occur or become reactivated after the pipeline is installed, Pacific Connector would monitor the slide movement so that mitigation can be identified and implemented prior to damage occurring to the pipeline. The frequency of landslide monitoring would be based on the activity level (rate of movement) of each landslide and also includes consideration of precipitation. High-risk landslides (active or dormant-young) that pose a hazard to a pipeline would be instrumented so that movement can be measured. Instrumentation typically includes installation of slope inclinometer casing to measure landslide movement, and installation of strain gages on the pipeline to measure strain induced by slope movement.

Response Actions

Exposure of the pipe by excavation is the initial response action typically taken to reduce stresses in the pipe. By exposing the pipe on both sides, the pipe is allowed to rebound to a position where it carries little residual stress.

Improvements in surface drainage also are important initial response measures. Typical drainage improvement measures include: (1) placement of impermeable liners over the ground surface to limit infiltration of precipitation and erosion; (2) ditching to divert surface water around landslide areas; and 3) routing surface flows across slide areas within tightline drain pipes. If surface drainage improvements would impact jurisdictional resources under Section 404 of the CWA these impacts would need to be permitted as appropriate. See section 4.3 of this EIS.

Once the landslide area is initially stabilized, a decision of permanent action must be made. Permanent mitigation can include repairs and stabilization of the landslide area. Permanent repairs can include drainage improvements, loading and/or stabilization of the toe of the slope, decreasing the load at the head of the slope, or retaining structures at the base or within the slope. If the landslide is large and complex and stabilization is not a reasonable option, rerouting the pipeline around the slide may be the preferred mitigation.

Specialized trench backfill is utilized where pipelines cross landslides or fault zones where differential movement or shearing across the pipeline is expected. For steep slopes, trench breakers and water bars are utilized to minimize the potential for erosion or mass wasting of trench backfill. Section 11.0 of the ECRP provides special backfill and compaction criteria for restoring site grades on slopes greater than 3H:1V. Specifications include use of structural fill, benching slopes to receive fill, and compaction of fill in lifts.

Because the geological and other natural hazards are important considerations for the design, construction, and operation of the facility, information on the final mitigation measures and monitoring protocols of the pipeline in areas which were not accessible during previous studies are required to evaluate slope stability conditions. Six moderate risk, deep-seated landslides were identified for additional surface inspection; the landslides are identified in Pacific Connector's Resource Report 6[52] (as #AM, #126, #127, #AV, #AW, and #AU) and are located at MPs 14.3-14.4, 23.8-24.2, 24.4-24.6, 65.2-65.5, 65.3-65.5, and 72.7-72.9. These areas represent approximately 1.2 miles of the pipeline route. Therefore, **we recommend that:**

- **<u>Prior to construction</u>, Pacific Connector should file with the Secretary, for review and written approval by the Director of OEP, the final monitoring protocols and/or mitigation measures for all landslide areas that were not accessible during previous studies.**

4.1.2.5 Rock Sources and Permanent Disposal Sites

Pacific Connector has identified 20 potential rock source and permanent disposal sites that total approximately 86 acres along the proposed route. Of these 20 rock source/disposal sites, all of the sites (5 of which are temporary extra work areas [TEWAs]) are existing quarries/gravel pits. These sites are listed in table 4.1.2.5-1. The table lists the rock source and disposal sites, their sizes, approximate mileposts in relation to the pipeline, jurisdiction, and existing land use. Only the disposal sites (and not the TEWAs) listed in table 4.1.2.5-1 are being proposed for use as permanent disposal sites.

Rock source sites may contain useable mineral deposits that may be extracted and/or purchased for use during construction. Disposal sites were identified for final placement of unusable, non-merchantable materials. These sites are typically exhausted areas within active quarries or abandoned quarries and may include commercial sites. Other permanent storage sites, including some TEWAs, were identified for permanent storage of excavated material. The material disposed of in these areas would be properly graded, drained (if necessary), and revegetated. The sites identified are not proposed for expansion beyond their proposed permitted or authorized boundaries. Use of any site would be permitted as required by the appropriate jurisdiction or landowner, and Pacific Connector would comply with applicable permits/stipulations. The disposal of mineral material to Pacific Connector from rock sources proposed to be utilized on BLM lands would follow regulations in 43 CFR 3600.

[52] See Appendix B, Table B-2 in Resource Report 6 submitted as part of Pacific Connector's application to the FERC.

TABLE 4.1.2.5-1

Rock Source and/or Permanent Disposal Sites

Site	Size (acres)	Milepost	Land Use	Jurisdiction
Coos County				
TEWA 38.90-W/ Sandy Creek Quarry	4.50	38.90	Strip mines, quarries, and gravel pits, clearcut forest land, regenerating evergreen forest land, transportation, communication, utilities corridors	Private
Douglas County				
Signal Tree Road Quarry – Sec. 3	1.22	45.86	Quarries	BLM Roseburg District
Signal Tree Road Quarry – Sec. 35	1.09	47	Quarries	BLM-Coos Bay District
Weaver Road Quarry Site 1	1.62	47	Quarries	BLM-Coos Bay District
Weaver Road Quarry Site 2	1.30	47	Quarries	BLM-Coos Bay District
Private Quarry Benedict Road	1.49	56.75	Quarries	Private
Roth – Existing Quarry #1	0.77	72.61	Quarries	Private
Roth – Existing Quarry #2	0.34	72.76	Quarries	Private
TEWA 79.85-N (BLM Quarry Site)	3.61	79.85	Quarries, transportation, communication, utilities corridors, regenerating evergreen forest land	BLM-Roseburg District
Hatchet Quarry MP 102.30	2.00	102.30	Strip mines, quarries, gravel pit, transportation, communication, utilities corridors	FS-Umpqua
Rock Disposal MP 104.12	3.36	104.12	Mines, quarries, and gravel pits, transportation, communication, utilities corridors, regenerating forest land	FS-Umpqua

Source: Pacific Connector's Resource Report 1, Table 1.2-3, filed with the FERC September 2017.

1

If Pacific Connector acquired rock from these sources or permanently disposed of excavated material, all available topsoil would be salvaged. The salvaged topsoil would be used to restore the site as required by landowner stipulations. Rock resource areas managed and developed by Pacific Connector would need quarry Operation and Reclamation Plans, to the extent required by DOGAMI's regulatory authority (OAR 632-030-0005 through 0070 and ORS 517.750 through 990). Appropriate BMPs would be implemented, such as those in Norman et al. (1998). No impacts are anticipated from the rock sources and permanent disposal sites.

4.1.2.6 Blasting During Trench Excavation

Blasting could be required for pipeline trench excavation in areas where hard, non-rippable bedrock occurs. The bedrock units where blasting could be necessary would consist primarily of volcanic and metavolcanic rocks in the Klamath Mountains and volcanic rocks in the Cascade Range as well as along the ridges in the Basin and Range physiographic province. In addition, local areas of well-lithified sedimentary rock may need to be blasted in the Coast Range.

Pacific Connector identified areas where blasting may be necessary by reviewing the NRCS soils maps and descriptions to identify soil units that typically contain bedrock within 5 feet of the ground surface. Soils data, geological maps, and topographic relief were used to rank the qualitative likelihood for blasting along the pipeline as follows:

- No Potential – Areas containing deep soils and alluvial, fluvial, lacustrine, and estuarine sediments that could be readily excavated. General occurrence: the coastal and Klamath basin lowlands and the major valleys and floodplains in all of the physiographic provinces.
- Low Potential – Areas containing soft sedimentary rock and tuff that can typically be excavated without ripping. General occurrence: Coast Range, and local areas of the Klamath Mountains, Cascade Range, and the Basin and Range physiographic provinces.
- Moderate Potential – Areas containing fractured, faulted, or weathered metamorphic or volcanic rocks that generally can be excavated with ripping, but that could require local blasting. General occurrence: local areas in the Klamath Mountains, Cascade Range, and the Basin and Range physiographic provinces.
- High Potential – Areas containing hard or fresh plutonic (for example, granitic) and volcanic rocks that could not be excavated without blasting. General occurrence: local areas of the Klamath Mountains physiographic province, portions of the Cascade Range physiographic province, and local areas in the Basin and Range physiographic province.

Table 4.1.2.6-1 provides a summary of the blasting potential along the pipeline. Blasting is less likely to be required to construct the first 78 miles of the pipeline because the materials are expected to consist of soil, sediments, and rippable sedimentary rocks. Although the blasting potential is classified as high for about 100 miles of the proposed route, this distance estimate includes local areas as much as 0.9 mile in length that contain valley fill, thick soils, and soft volcanic rocks (such as tuffs) that would not need to be blasted. In addition, some of the proposed route classified as having a high or moderate potential for blasting may contain weathered rock that could instead be ripped by conventional excavation equipment.

TABLE 4.1.2.6-1

Source: Table 2.1.2-9 of the Applicant Prepared Draft Biological Assessment, filed December 2017.

Pacific Connector would conduct all blasting in accordance with all federal, state, and local regulations and Pacific Connector Construction Specifications. Pacific Connector would include specifications in any blasting contract to control adverse impacts, including measures to minimize vibrations and flyrock, measures for safe blasting practices near active pipelines, and seasonal restrictions to protect wildlife, as needed. Pacific Connector would have blasting inspectors present to ensure that all specifications were met and to perform pre- and post-blast inspections of nearby structures and wells.

Drilling and blasting would be done with the Pacific Connector inspector present and with the inspector's approval to proceed prior to each blast. Blasting operations would be conducted by or under the direct and constant supervision of experienced personnel legally licensed and certified to perform such activity in the jurisdiction where blasting occurs. Pacific Connector would require their contractor to provide site-specific Blasting Plans at least 5 working days prior to any proposed blasting-related activity, and the contractor would be required to obtain Pacific Connector approval in writing prior to starting work. The Blasting Plan would include the following information:

- explosive type, product name and size, weight per unit, density, and equivalent energy release ratio (N) (the blasting agent Ammonium Nitrate and Fuel Oil [ANFO] would not be allowed);
- delay type, sequence, and delay (milliseconds);
- initiation method (detonating cord, blasting cap, or safety fuse);
- stemming material and tamping method;
- hole depth, diameter, and pattern;
- explosive depth, distribution, and maximum weight per delay;
- number of holes per delay;
- distance and orientation to nearest aboveground structure;
- distance and orientation to nearest underground structure, including pipeline;
- procedures for storing, handling, transporting, loading, and firing explosives, fire prevention, inspections after each blast, misfires, fly rock and noise prevention, stray current accidental-detonation prevention, signs and flagmen, warning signals prior to each blast, notification prior to blasting, and disposal of waste blasting material;
- seismograph company, personnel, equipment, and sensor location, if required;
- copies of all required federal, state, and local permits;
- blaster's name, company, copy of license, and statement of qualifications;

- magazine type and locations for explosives and detonating caps; and
- typical rock type and geology structure (solid, layered, or fractured).

Pre-blast inspections would be completed for structures and wells that are within the influence zone of the blasting. The pre-blast inspections would include but not be limited to an inventory of existing structural integrity and signs of structural distress such as cracks. Post-blasting inspections would include an inspection and comparison of the same elements observed for the pre-blast inspection. If blast related damage is identified by Pacific Connector inspectors and confirmed to be a result of the blasting activities, then damaged structures or wells would be returned to pre-construction conditions or better.

Blasting for grade or trench excavation would be utilized only after all other reasonable means of excavation have been used and are unsuccessful in achieving the required results. Pacific Connector may specify locations (foreign line crossings, near-by structures, etc.) where consolidated rock would be removed by approved mechanical equipment such as rock-trenching machines, rock saws, hydraulic rams, or jack hammers in lieu of blasting.

Every precaution would be taken to prevent damage to aboveground and underground structures during blasting operations; and every precaution would be taken to prevent injuries and damage to persons or inconvenience to the general public. Blasting mats or padding would be used on all shots where necessary to prevent scattering of loose rock onto adjacent property and to prevent damage to nearby structures and overhead utilities. Blasting would not begin until occupants of nearby buildings, residences, places of business, places of public gathering, and farmers have been notified sufficiently in advance to allow for protection of personnel, property, and livestock. Maximum ground motion velocities of 2 inches/second specified at the locations of structures would be required for any structures identified within 200 feet of the pipeline construction area.

Blasting for trench excavation could result in impacts on wells, wetlands, slopes, structures, and other adjacent buried utilities, as described below. The use of Pacific Connector's proposed monitoring and mitigation measures would avoid or reduce the likelihood of local failures of unstable rock and soil, and damage to structures or utilities from blasting vibrations.

Water Wells and Springs

Blasting could affect groundwater quality by temporarily increasing groundwater turbidity near the construction right-of-way. In addition, turbidity and blasting agent by-products could possibly temporarily degrade groundwater quality and potentially have temporary effects on wells in the immediate proximity of the blasting. In general, vibration effects on wells would be expected to be limited to the immediate proximity of the blasting. A common measurement unit for vibration is the peak particle velocity (PPV) of blasting-induced ground motion in inches per second. Siskind (1999) summarizes information on four blasting studies conducted to evaluate vibration effects on wells. One study showed, "There were no physical vibration effects on the wells even as close as 300 feet." The maximum velocities for this testing ranged from 0.84 to 5.44 inches per second, with four of the five sites exceeding 2 inches per second. In another study, a well was tested for casing cement bond damage. The study indicated initial bond losses occurred at 4.7 inches per second. A third study indicated that wells outside the blast pattern were exposed to as much as 8.7 inches per second at a distance of 31 feet and no damage occurred; however, the construction details for these wells are not described in the Siskind (1999) report.

A discussion of water supply wells within 150 feet of the construction right-of-way and measures proposed by Pacific Connector to avoid or minimize impacts on wells, including from blasting, is included in section 4.3. Pacific Connector would employ measures in the Blasting Plan including development of site-specific blasting operation and monitoring plans to address site variables (soil and rock types, etc.), which would incorporate known locations of existing groundwater wells or springs and seeps. Maximum ground motion velocities (or PPV) of 2 inches/second would be set for blast locations within 150 feet of water wells and springs.

Pacific Connector would request authorization from landowners to test and document the baseline condition, yield, and water quality of any private wells located within 200 feet of the pipeline construction right-of-way. This testing would occur before the pipeline construction starts in the nearby area, and the testing results would be shared with the property owner, if requested. Similar information would be gathered for any public water wells located within 400 feet of the pipeline construction right-of-way. Based on testing results, if it is determined after construction that there has been an impact on groundwater supply (either yield or quality), Pacific Connector would work with the landowner to ensure a temporary supply of water, and, if determined necessary by the landowner, Pacific Connector would provide a permanent water supply. Mitigation measures would be coordinated with the individual landowner in order to meet the landowner's specific needs. Mitigation measures for groundwater wells, springs, and seeps would be specific to each property and would be determined during landowner negotiations.

Wetlands

Blasting could potentially redirect surface water and groundwater flows to and from wetlands. In addition, turbidity and blasting agent by-products could possibly temporarily degrade surface water and groundwater quality.

Any turbidity resulting from blasting is expected to be temporary and to dissipate shortly after blasting. Water quality impacts on wetlands from blasting agents, if any, would be expected to be temporary and localized because only small amounts of blasting agents generally would be needed for trenching. Specific blasting agents would be listed in the *Blasting Plan*[53] prior to the initiation of any blasting. The use of ANFO would not be allowed.

Slopes

Unstable rock and soil slopes could locally fail as a result of blasting vibrations. Pacific Connector would complete a reconnaissance of slopes in the vicinity of the blasting, including measuring slope inclinations and observing areas adjacent to planned blasting locations for potential indicators of unstable slopes. Identified slope areas that could be impacted by blasting would be monitored and evaluated for hazards to people and property during the blasting operations.

Structures

Blasting vibrations and flying debris could potentially damage aboveground structures. If structures were present in areas where blasting was necessary, Pacific Connector would request authorization from landowners to inspect structures located within 200 feet of the pipeline construction right-of-way before and after blasting. Blasting mats or padding also would be used when blasting near structures to limit potential damage from flying rocks. To limit potential

[53] The *Blasting Plan* was included in Pacific Connector's January 2018 application to the FERC as Appendix C of the POD.

damage to structures, maximum ground motion velocities (or PPV) of 2 inches/second would be specified at the locations of structures, which is consistent with the language of the *Blasting Plan*.

As an additional precaution, Pacific Connector would require the contractor conducting blasting to limit the size of charges in accordance with the scaled distance factor (SD) guidelines developed by the Office of Surface Mining Reclamation and Enforcement (OSMRE). The SD is equal to the distance from the blast to an aboveground structure divided by the square root of the charge (pound per delay). For distances less than 300 feet, OSMRE states that the SD shall exceed 50 feet, which specifies a maximum blasting charge of 1.0 pound/delay.

Adjacent Pipelines and Buried Utilities

Blasting vibrations could potentially damage adjacent underground pipelines and utilities. In general, blasting would not be allowed within 10 feet of an existing pipeline or buried utility. In cases where blasting near an existing utility was necessary, the pipeline or utility owner would be notified in advance of the blasting, and measures would be taken to minimize the potential for utility damage (as outlined in the *Blasting Plan*).

4.1.2.7 Paleontological Resources

There are no known paleontological resources along the pipeline route.

4.1.3 Environmental Consequences on Federal Lands

4.1.3.1 Geologic Hazards on Federal Lands

The seismic hazard evaluation included surface rupture from faulting, liquefaction potential, and lateral spreading as discussed in section 4.1.2.3 above. In general, seismic hazard risks are low for the proposed pipeline. In addition, liquefaction potential and scour would be avoided by employing HDD construction of the pipeline across streams. The potential exists locally along portions of the proposed route on federal lands for seismically induced ground shaking to induce rockfalls, landslides, or soil slumps. Pacific Connector selected its proposed route to avoid existing landslides and areas susceptible to landslides to the extent practicable.

The pipeline would cross the BLM-Coos Bay District from MP 13.0BR to MP 27.5; and from MP 28.4 to MP 45.7. The western portion of this area is within the outer limit of the Cascadia event impact area. Evaluation of hazards for the design earthquake indicate that the pipeline (designed to standards) would not be susceptible to risks from seismic events. One landslide site located near MP 36.92 on land managed by the BLM Coos District could not be avoided. Additional investigation of this site resulted in a final risk determination of low (GeoEngineers 2017a). The landslide risk at this site is not considered hazardous enough to require additional mitigation or rerouting.

The pipeline would cross the BLM-Roseburg District from MP 46.9 to MP 102.3. Recent faults are not present in this area; and steep slopes and landslides have been avoided in this section of the pipeline route. The pipeline would cross the Umpqua National Forest from MP 99.3 to MP 113.2. Recent faults are not present in this section of the pipeline route; and steep slopes and landslides have been avoided in this section of the pipeline route. The pipeline would cross the BLM Medford District from MP 115.1 to MP 141.9; and from MP 148.3 to MP 153.8. Recent faults are not present in this section of the pipeline route. Steep slopes and landslides have been avoided in this section of the pipeline route. The pipeline would cross the Rogue River-Siskiyou

NF from MP 153.8 to MP 168. Recent faults are not present in this section of the pipeline route. Steep slopes and landslides have been avoided in this section of the pipeline route.

The pipeline would cross the Fremont-Winema National Forest from MP 168 to MP 175.4. The Quaternary-age Sky Lakes fault zone is located from MP 172 to MP 182. Some areas of this route section have a high potential for blasting during construction. Steep slopes and landslides have been avoided in this section of the pipeline route. The pipeline would cross the BLM Lakeview District from MP 176.2 to MP 216.8. The Quaternary-age Sky Lakes fault zone is located from MP 172 to MP 182; the Klamath Lake fault is located near MP 187; the Lower Klamath Lake fault system is located near MP 204 to MP 206; and the Stukel Mountain fault is located near MP 212 to MP 213. Some areas of this route section have a high potential for blasting during construction. Steep slopes and landslides have been avoided in this section of the pipeline route.

Mitigation for pipeline sections that cross recent faults has been discussed in section 4.1.2.3. During construction, Pacific Connector would have the pipeline trench carefully examined by a qualified professional for evidence of stratigraphic offsets potentially related to ground rupture. If such features are observed, Pacific Connector would implement additional mitigation measures, with the specific mitigation developed at that time. Such measures could include burying the pipe in a wide trench that was backfilled with loose gravel or sand, which would allow for relatively unrestrained movement of the buried pipe within the zone of fault movement.

Because the pipeline would cross a predominance of rugged terrain within BLM and NFS lands, there is potential for previously unidentified landslides or new landslides to affect the pipeline after it is installed. To minimize landslide risk, Pacific Connector would implement its ECRP during pipeline construction, which would reduce the potential for construction to adversely affect slope stability. As described in the ECRP, temporary construction BMPs would include sediment barriers, slope breakers, and application of mulch prior to seeding; permanent measures would include installation of permanent slope breakers and revegetation. In addition, as part of its pipeline operation, Pacific Connector would conduct regular monitoring of the pipeline right-of-way, which would aid in detecting landslide occurrence or slope movement. On federal lands, Forest Service and BLM representatives would conduct monitoring with Pacific Connector personnel. Mitigation could include the use of shutoff valves. If movement is detected, immediate action would be taken to reduce the risk to the pipeline. Actions would include initial response to reduce the stresses on the pipeline, and follow-up actions to stabilize the slide. If the slide is large and complex enough such that stabilization would not be feasible, the pipeline could be relocated around the slide area.

Pacific Connector intends to implement a level of landslide and pipeline easement monitoring like that currently performed on existing Williams-owned pipeline facilities in southwestern Oregon. Similar to the Williams-owned pipeline, monitoring would consist of weekly air patrol, annual helicopter survey, and quarterly class location. Class location consists of land patrol (including leak detection), semi-annual class 1 and class 2 location land patrol, and annual cathodic protection survey. Observed areas of active third-party activities such as logging or development and areas affected by unusual events such as landslides, severe storms, flooding, earthquake or tsunami may require additional inspection and monitoring determined on an individual basis.

4.1.3.2 Mineral Resources on Federal Lands

Sixteen oil and gas areas are located between MP 10.4R and 45.7, and two mining claims between MPs 0 and 1.4 in Coos County on BLM land. Seven oil and gas areas, two placer mining claims, one mine, two lode mining claims, and a chromite resource are located in the vicinity of the pipeline alignment between MPs 46.9 and 97 in Douglas County on BLM land. Two load mining claims and a quarry are located in the vicinity of the pipeline alignment between MPs 101.8 and 110 in Douglas County on NFS land. Nine oil and gas areas and two lode mining claims are located in the vicinity of the pipeline alignment between MPs 115.4 and 154.9 in Jackson County on BLM land. One oil and gas area is located in the vicinity of the pipeline alignment between MPs 155.4 and 166.4 and one between MPs 205.2 and 205.7 in Jackson County on NFS land. One lode mining claim in the vicinity of the pipeline alignment is located between MPs 170.1 and 171.1 in Klamath County on NFS land. Two geothermal resources areas are located in the vicinity of the pipeline alignment between MPs 192.7 and 216.8 in Klamath County on BLM land. It is noted that the status of these mining claims are all listed as "closed" or "unknown", so they are not considered as active at this time.

The Green Butte Quarry was identified at MP 101.8 within the Umpqua National Forest. However, GeoEngineers (2017a) indicated that this quarry was never opened and there are no plans for its future development. The proposed route between MPs 108.6 and 110.9 avoids the Peavine Quarry within the Umpqua National Forest. The pipeline alignment at MP 150.5 is within approximately 100 feet northeast of the Heppsie Mountain quarry on BLM land and parallels the length of the quarry. The Heppsie quarry is a regional hard rock quarry and to utilize this rock quarry it is necessary to blast the rock. It was determined by the BLM and Pacific Connector that due to the proximity of the pipeline to the quarry and the incompatibility of production blasting the rock quarry near the pipeline, that 70,000 cubic yards of rock will be blasted at the expense of Pacific Connector and left on site. The BLM is requiring this blasting because the BLM will not assume unknown risk associated with complications, limitations, or liability associated with utilizing this quarry in the future.

Based on aerial photograph review of the quarry depths, trends, and distances from the pipeline, it was concluded that the quarry likely would extend into a stable rock outcrop that currently parallels the proposed route and does not pose a risk to the quarry or the pipeline project (GeoEngineers 2017a). POD attachments include the Blasting Plan, ROW Clearing Plan, and ROW Marking Plan, all of which would serve to ensure the avoidance of quarries.

Near MP 109, the pipeline would be about 0.3 mile and 0.5 mile east of the Nivinson and Red Cloud mercury mines, respectively. These mines are located within NFS lands. Construction and operation of the pipeline would not affect these mines. The proposed route would cross areas mapped as volcanic and volcanogenic rocks at the current crossings of the East Fork Cow Creek. These bedrock units have not been identified as a substantial source of naturally occurring mercury. Naturally occurring mercury in this area typically is associated with metamorphic bedrock units such as amphibolite.

The Forest Service reports that naturally occurring mercury exists in the vicinity of the Mars Prospect located near MP 108.7 (Broeker 2010). Broeker concluded that naturally occurring mercury is present in the disrupted soil regolith and underlying bedrock strata throughout the upper reaches of the East Fork Cow Creek watershed. Although localized, mercury values are sufficiently high enough to have warranted exploration, development and minor production between the 1930s and 1960s. Geochemical analysis of six soil samples collected along a 2,000-foot section of Pacific Connector's previously proposed route in this area that crossed partly through the historic Thomason mining claims near the East Fork Cow Creek determined the area to have very low concentrations of naturally occurring mercury mineralization. Pacific Connector subsequently rerouted its proposed route in this area approximately 2,500 feet from where the samples were taken.

Based on the analytical results, mapped bedrock at the proposed route, and the distribution/location of mercury mines, it is unlikely that the soils underlying the currently proposed crossing of the East Fork Cow Creek would have concentrations of naturally occurring mercury exceeding those measured in samples obtained from the previous crossing location and most likely would have lower levels. Additional details on the literature research, field observations and soil sampling and analysis completed for the prospects and mines located near MPs 108 to 110 are provided in GeoEngineers (2017a). Soil sampling and analysis results also support that mercury specific health and safety protocols would not be needed for the construction activities. It is expected that the planned erosion and sediment control measures described in the Pacific Connector's ECRP would protect the ecological health of upland and in-stream areas from the naturally occurring mercury concentrations.

The pipeline could potentially interfere with future mining and reclamation activities on lands adjacent to and within the right-of-way. Future expansions of surface mines near the right-of-way potentially could be limited or precluded in some cases because mineral resources could not be extracted from immediately up or downslope up of the pipeline right-of-way or from beneath the pipeline. Similarly, the presence of the pipeline could limit or preclude the stockpiling of mineral resources or development of a processing area immediately up or downslope of the pipeline. These considerations also could limit or preclude reclamation activities at mine sites near the pipeline because of the potential to disturb the slopes above and below the pipeline and right-of-way. Any impact would be site-specific and would depend on topography, drainage, and subsurface conditions in that area. If existing mining claims are identified within the Project's proposed right-of-way during the BLM's review, the BLM may require that the Project be microsited outside of these claims.

4.1.3.3 Rock Sources and Permanent Disposal Sites on Federal Lands

Rock source sites may contain useable mineral deposits that may be extracted and/or purchased for use during construction. Disposal sites were identified for final placement of unusable, non-merchantable materials. These sites are typically exhausted areas within active quarries or abandoned quarries and may include commercial sites. Other permanent storage sites, including some TEWAs, were identified for permanent storage of excavated material. The material disposed of in these areas would be properly graded, drained (if necessary), and revegetated. The sites identified are not proposed for expansion beyond their proposed permitted or authorized boundaries. Use of any site would be permitted as required by the appropriate jurisdiction or landowner, and Pacific Connector would comply with applicable permits/stipulations. The disposal of mineral material to Pacific Connector from rock sources proposed to be utilized on BLM lands would follow regulations in 43 CFR 3600.

Pacific Connector has identified 20 potential rock source and permanent disposal sites that total approximately 86 acres along the pipeline route. Of these 20 rock source/disposal sites, 12 are located within federal lands as shown in table 4.1.2.5-1. All of these sites have been previously used and disturbed by quarry operations and/or strip mining. Most of these sites continue to have ongoing quarry operations. Only the disposal sites (and not the TEWAs) listed in table 4.1.2.5-1 are being proposed for use as permanent disposal sites.

Pacific Connector does not intend to expand these sites beyond the existing or previously disturbed footprints. If Pacific Connector acquired rock from these sources or permanently disposed of excavated material, all available topsoil would be salvaged. The salvaged topsoil would be used to restore the site as required by landowner stipulations. Rock resource areas managed and developed by Pacific Connector would need quarry Operation and Reclamation Plans, to the extent required by DOGAMI's regulatory authority (OAR 632-030-0005 through 0070 and ORS 517.750 through 990). Appropriate BMPs would be implemented, such as those in Norman et al. (1998). No impacts are anticipated from the rock sources and permanent disposal sites.

4.1.3.4 Blasting During Trench Excavation on Federal Lands

Pacific Connector identified areas where blasting may be necessary by reviewing the NRCS soils maps and descriptions to identify soil units that typically contain bedrock within 5 feet of the ground surface. Soils data, geological maps, and topographic relief were used to rank the qualitative likelihood for blasting along the pipeline.

Table 4.1.2.6-1 provides a summary of the blasting potential along the pipeline including BLM and NFS areas that would be crossed. Although the blasting potential is classified as high for about 100 miles of the proposed route, this distance estimate includes local areas as much as 0.9 mile in length that contain valley fill, thick soils, and soft volcanic rocks (such as tuffs) that would not need to be blasted. In addition, some of the proposed route classified as having a high or moderate potential for blasting may contain weathered rock that could instead be ripped by conventional excavation equipment. The BLM-Coos Bay District portion of the pipeline alignment has a low potential for blasting during construction.

The pipeline route within the BLM-Roseburg District has low to moderate potential for blasting during construction. Portions of the pipeline route within the Umpqua National Forest, the BLM Medford District, the Rogue River-Siskiyou National Forest, the Fremont-Winema National Forest, and the BLM Lakeview District have a high potential for blasting during construction.

Blasting for grade or trench excavation would be utilized only after all other reasonable means of excavation have been used and are unsuccessful in achieving the required results. Pacific Connector may specify locations (foreign line crossings, near-by structures, etc.) where consolidated rock would be removed by approved mechanical equipment such as rock-trenching machines, rock saws, hydraulic rams, or jack hammers in lieu of blasting.

Pacific Connector would conduct all blasting in accordance with all federal, state, and local regulations and Pacific Connector Construction Specifications. Pacific Connector would include specifications in any blasting contract to control adverse impacts, including measures to minimize vibrations and flyrock, measures for safe blasting practices near active pipelines, and seasonal restrictions to protect wildlife, as needed. Pacific Connector would have blasting inspectors present to ensure that all specifications were met and to perform pre- and post-blast inspections of nearby structures and wells.

Drilling and blasting would be done with the Pacific Connector inspector present and with inspector's approval to proceed prior to each blast. Blasting operations would be conducted by or under the direct and constant supervision of experienced personnel legally licensed and certified to perform such activity in the jurisdiction where blasting occurs. Pacific Connector would require their contractor to provide a Blasting Plan at least five working days prior to any blasting-related activity, or two weeks prior to blasting on federal lands, and the contractor would be required to obtain Pacific Connector approval in writing prior to starting work.

4.1.3.5 Paleontological Resources on Federal Lands

Paleontological resources on federal lands are regulated, as outlined in 36 CFR Ch. 11 261.9 (i). Pacific Connector consulted with federal land management agencies for information on potential paleontological resources crossed by or within the pipeline right-of-way. Based on the consultation, the BLM required an assessment of the potential for paleontological resources on the portion of the right-of-way located on the lands it manages. The assessment indicates that there is a limited potential for encountering paleontological resources on BLM lands and only localized monitoring would need to occur during pipeline construction. The following sections summarize the findings from the paleontological resource assessment. The full assessment report is contained in *Final Paleontology Assessment, Pacific Connector Gas Pipeline Project, Coos Bay to Malin, Oregon* (GeoEngineers 2017c).[54]

Potential Paleontological Resources on NFS Lands

Pacific Connector states that consultation with staff of the Real Estate and Mineral Resources Section of the Umpqua National Forest reported that there were no known paleontological resources on the portions of the pipeline right-of-way located within the boundaries of the Umpqua, Rogue River, and Winema National Forests. According to Paleontology Associates, only the Umpqua and Rogue River National Forests bear potentially favorable lithologic units for fossil content along the pipeline corridor. These units occur in:

- Umpqua National Forest MPs 106 to 109—Fisher formation-volcanic ash and lacustrine siltstone;
- Umpqua National Forest MPs 109.5 to 115.5—Little Butte and Colestin formations-tuffaceous sediments;
- Rogue River National Forest MPs 120 to 121—Colestin formation-tuffaceous sediments; and
- Rogue River National Forest MPs 155 to 158—No formal formation designation-tuffaceous sediments, lahars, waterlaid tuffs.

Based on the information provided regarding the lack of identified paleontological resources within the pipeline right-of-way on NFS lands, no measures appear necessary for the avoidance and minimization of adverse effects on paleontological resources on NFS lands. Pacific Connector does not plan to monitor for lithologic units on NFS lands.

Potential Paleontological Resources on BLM Lands

The BLM required an assessment of the potential for paleontological resources on the portion of the right-of-way located on the lands it manages. Pacific Connector completed an assessment that indicates there is a limited potential for encountering paleontological resources on BLM lands and only localized monitoring would need to occur during pipeline construction. The following

[54] Appendix M to Appendix A-6 of Resource Report 2 in Pacific Connector's September 2017 filing with the FERC.

sections summarize the findings from the paleontological resource assessment. The full assessment report is contained in the *Final Paleontology Assessment, Pacific Connector Gas Pipeline Project, Coos Bay to Malin, Oregon* (GeoEngineers 2017c).

A formal analysis of existing paleontological data was completed for the portions of the pipeline right-of-way on BLM lands. The analysis, completed by Dr. William Orr, who is recognized by the BLM as a qualified paleontologist, was conducted in general accordance with BLM Manual H-8270-1 (BLM 1998).

Fossil-bearing rock formations along the portions of the right-of-way located on BLM lands range in age from the Jurassic period (almost 200 million years old) to the Pleistocene Epoch (about 12,000 years before present). Between MPs 17 and 54, the right-of-way on BLM lands almost entirely traverses Eocene units of the southern Coast Range. The units span the entire epoch, with a wide variety of clastics ranging from coarse conglomerates to very fine-grained deep water silts and shales. Paleocene Epoch intervals in the lower Roseburg Formation could potentially contain plants, invertebrates, reptiles (turtles) and odontocete cetacea (primitive toothed whales). In addition, Pleistocene intervals in localized swamp boggy areas of the Roseburg Formation could potentially yield bones of large Ice Age mammals.

The portion of the BLM lands in the Klamath Mountain interval between MPs 54 and 97 has some of the oldest and most complex rocks in Oregon. Because most of the Klamath rocks are mapped as tectonic accretionary terranes, even the most fragmentary fossils discovered would be an important find.

BLM lands would be crossed between MPs 110 and 123, MPs 128 and 137, and MPs 167 and 172 in the Cascade Range. Two formations in this region, the Colestin and Little Butte, have a potential for producing plant fossils. Both of these formations were deposited in nonmarine, continental settings with volcanogenic ash, tuff and silts mixed with extrusive volcanics of basalt, basaltic andesite and related igneous rocks. Despite the wide range of ages and environments, the floral lists at any given site for either formation are limited. As a result, any new taxa recorded or salvaged in the course of the construction activities would add to the knowledge of the Cascade geologic history.

Between MPs 216 and 217, the pipeline right-of-way crosses BLM lands in the Basin and Range province. Lake sediments of Cascade ash dating between 5 million to 11,000 years ago in this area bear a limited, but stratigraphically important fauna.

<u>Paleontology Field Monitoring Protocols for BLM Lands</u>

Pacific Connector conducted a field survey of the above-referenced portions of the pipeline right-of-way that occur on BLM lands. The locations observed during the survey were selected using the results of the formal analysis of the existing data and a mile-by-mile evaluation of the geologic formations along the right-of-way.

The field survey results were used to classify the potential for encountering paleontological resources on BLM lands during construction. The classifications used for the project were consistent with classes 1 through 5 in the BLM Potential Fossil Yield Classification procedure (revised H-8270-1).

All but 1 mile of the right-of-way on BLM lands has been classified as meeting Class 3a or 3b, based on the formal analysis and the field survey. An approximately 0.25-mile segment from MP

216.5 to 216.75 is classified as Class 4a. For approximately 25 miles of the Class 3a or 3b lands, the BLM would require limited spot monitoring during pipeline construction because the potential presence of fossils cannot be completely eliminated. The 1-mile-long area not classified as Class 3 is divided into two approximately 0.5-mile-long areas classified as Class 1 and Class 2. To satisfy BLM requirements, Pacific Connector would continuously monitor both of these segments for the potential presence of paleontological resources during pipeline construction. The spot or continuous monitoring during construction would be conducted by a field paleontologist working under the supervision of the lead paleontologist.

Procedures for Recovering Significant Discoveries of Vertebrate or Invertebrate Fossil Remains on BLM Lands

Although the likelihood of discovering paleontologically significant fossils on BLM lands is considered remote, such a discovery could potentially occur during the proposed surveys, brush clearing, or construction activities. The field inspector or field paleontologist identifying a fossil of potential interest would be responsible for notifying the lead paleontologist immediately of the discovery. The lead paleontologist would, in turn, evaluate the significance of the finding relative to the salvage parameters. If the fossil was considered salvageable material, it would be recovered under the direction of the lead paleontologist and Pacific Connector. Pacific Connector proposes to designate the University of Oregon Museum of Natural and Cultural History as the repository for any salvageable material recovered from the portion of the pipeline right-of-way located on BLM lands.

4.1.4 Conclusion

Much of the Project is located in the CSZ tectonic area (an area of potential earthquake and tsunami activity). Based on the documentation that mineral resources are not present along the Project; Jordan Cove and Pacific Connector's proposed construction and operations procedures, methods, and plans to appropriately design for geologic hazards; and their implementation of minimization and mitigation measures, we conclude that constructing and operating the Project would not significantly affect geology and would not be significantly affected by geologic hazards.

4.2 SOILS AND SEDIMENTS

4.2.1 Jordan Cove LNG Project

Soils at the proposed LNG terminal and the South Dunes site have been previously disturbed by the operations of the Menasha and Weyerhaeuser companies and from the placement of fill material derived from COE dredging of the Coos Bay Federal Navigation Channel in the 1970s. This fill material (composed predominantly of sand with a small percentage of silt) overlies much of the LNG terminal tract and is more than 10 feet deep in some areas. Recent testing and grading to support a 2014 geotechnical exploration program in a 2-acre area of the LNG terminal revealed the presence of ash-amended soils from 12 to 60 inches (SHN 2015).

Jordan Cove performed geotechnical investigations in the area of the proposed LNG storage tanks and process area in April through May 2013 (GRI 2013). The subsurface data revealed that surficial material in this area is generally fine-grained sand with traces of silt that is underlain by weathered sandstone. The sand layer extends from the surface to a depth of at least 124 feet. Another geotechnical investigation was performed in April 2012 (GRI 2012) in the South Dunes portion of the site. The upper 10 to 20 feet of the South Dunes site was found to be reworked dune sand fill that is underlain by weathered siltstone. Based on geotechnical borings, the sands in the access and utility corridor are composed of areas of fill and native material. Organics and peat were encountered only in the western end of the access and utility corridor at depths of approximately 11 feet below grade. At depths below 30 feet, the conditions for the access and utility corridor are similar to those described for the LNG terminal site. Geotechnical explorations at the proposed Kentuck project site found that surface fill is 1 to 2 feet deep, underlain by native sand and silt to a depth of about 35 feet, and silt to depths of about 70 to 100 feet.

4.2.1.1 General Impacts

Soil types and characteristics in the Jordan Cove LNG Project area were assessed using the NRCS Soil Survey geographic database (NRCS 2017). Construction of the Jordan Cove LNG Project would disturb several soil types, as shown in table 4.2.1.1-1.

The following discussion addresses the soil type characteristics that would be affected in order from highest total impact to lowest, as listed in table 4.2.1.1-1. Soil characteristics for soils that cover 1 percent or less of the total area are not discussed or described in detail.

Dune Land is mapped within approximately 18 percent (180 acres) of the Jordan Cove LNG Project area. It consists of fine and medium textured sands on hills and ridges, formed from aeolian deposits. Permeability is very rapid, and runoff is slow. This soil is severely susceptible to wind erosion and slightly susceptible to water erosion.

Waldport Fine Sand comprises approximately 15 percent (149 acres) of the Jordan Cove LNG Project area. The Waldport Fine Sand is a deep, excessively drained soil occurring on stabilized sand dunes. It is formed from aeolian deposits. Permeability of the Waldport soil is very rapid, but runoff is slow. This soil is severely susceptible to wind and water erosion.

TABLE 4.2.1.1-1

Acres of Impacts at the Jordan Cove LNG Project, by Soil Type a/

Soil Type / Map Unit	Acres b/	Percent (subtotal)
Permanent Operation Areas		
Beaches / 3	1.0	<1
Dune land / 16	23.3	14%
Heceta Fine Sand / 28	39.7	23%
Udorthents level / 57	0.4	<1%
Waldport Fine Sand / 59D	1.1	1%
Waldport Fine Sand / 59E	82.7	48%
Waldport-Dune land complex	0.1	<1%
Waldport-Heceta Fine Sand / 61D	23.5	14%
Subtotal	***171.8***	***100%***
Temporary Construction Areas		
Braillier mucky peat / 7	5.8	2%
Chetco silty clay loam	0.3	<1%
Dune Land / 16	116.8	36%
Heceta Fine Sand / 28	23.3	7%
Heceta Waldport Fine Sand / 29B	1.9	1%
Udorthents, level / 57	46.8	14%
Waldport Fine Sand / 59D	11.4	4%
Waldport Fine Sand / 59E	42.2	13%
Waldport Dune Land complex / 60D	0.1	<1%
Waldport-Heceta Fine Sand	76.9	24%
Subtotal	***325.5***	***100%***

a/ Values exclude aquatic areas that are encompassed by the Project but which do not contain "soils" as well as mitigation areas that are not considered jurisdiction areas.
b/ The totals shown in this table may not equal the sum of addends due to rounding. Acreages are rounded to nearest tenth acre, percentages are rounded to nearest whole value (values below 1 are shown as "<1%").

Bullards sandy loam comprises 12 percent (110 acres) of the Jordan Cove LNG Project area. This is a well-drained soil occurring on dissected marine terraces. It formed in mixed aeolian and marine deposits. Permeability of this soil is moderate, and runoff is medium. This soil is severely susceptible to wind erosion and moderately susceptible to water erosion.

Waldport-Heceta Fine Sands comprise approximately 10 percent (100 acres) of the Jordan Cove LNG Project area. This soil is composed of 50 percent Waldport Fine Sand and 50 percent Heceta Fine Sand (both described herein). This soil is severely susceptible to wind erosion and moderately susceptible to water erosion.

Heceta Fine Sand comprises 10 percent (93 acres) of the Jordan Cove LNG Project area. This is a deep, poorly drained soil found in deflation basins and depression areas between dunes. It is formed on aeolian materials. Permeability of this soil is rapid, and runoff is ponded. This soil is slightly susceptible to water erosion.

Coquille silt loam comprises 8 percent (77 acres) of the Jordan Cove LNG Project area. The Coquille silt loam is a deep, very poorly drained soil that is formed in alluvium on floodplains. Permeability of this Coquille soil is slow. This slow is slightly susceptible to wind and water erosion.

Udorthents soils comprise 5 percent (52 acres) of the Jordan Cove LNG Project area. They occur on floodplains, marshes, and tidal flats and in areas that have been filled and leveled for commercial and industrial uses. Areas on floodplains are made up of sandy, silty, or clayey material; and areas on marsh and tidal flats are made up of dredging spoil, dune sand, and wood chips.

Bandon sandy loam comprises 4 percent (40 acres) of the Jordan Cove LNG Project area. This is a deep, well-drained soil that occurs on dissected marine terraces and formed in sandy marine deposits. Permeability of this soil is generally moderate, and runoff is slow. This soil is slightly susceptible to water erosion and severely susceptible to wind erosion.

Nestucca silt loam comprises 3 percent (30 acres) of the Jordan Cove LNG Project area. This is a deep, somewhat poorly drained soil formed in alluvium on floodplains. Permeability is moderately slow, and runoff is very slow. This soil is slightly susceptible to wind and water erosion.

4.2.1.2 Project-Specific Soil Limitations

Prime Farmland

The NRCS defines prime farmland as land that has the best combination of physical and chemical characteristics for growing food, feed, forage, fiber, and oilseed crops. Prime farmland can include land that possesses these characteristics but is being used currently to produce livestock and timber. Urbanized land and open water are excluded from prime farmland. Prime farmland typically contains few or no rocks, is permeable to water and air, and is not excessively erodible or saturated with water for long periods. Unique farmland is land that is used for production of specific high-value food and fiber crops. In addition, soils may be considered of statewide or local importance if those soils are capable of producing a high yield of crops when managed according to accepted farming methods.

There are no soils at the Jordan Cove LNG Project site that are classified as prime or unique farmland soils. However, Coquille silt loam, Heceta Fine Sands, Bandon sandy loam, Bullards sandy loam, Chetco silty clay loam, Heceta-Waldport Fine Sand, Nestucca silt loam, and Wintley silt loam are classified as farmland of statewide importance. These areas comprise a total of approximately 338 acres (25 percent) of the Jordan Cove LNG Project area. This classification includes areas of soils that nearly meet the requirements for prime farmland and that economically produce high yields of crops when treated and managed according to acceptable farming methods. The criteria for defining and delineating farmland of statewide importance are determined by the appropriate state agencies. Farmland of statewide importance may include tracts of land that have been designated for agriculture by state law (NRCS 2006). No areas within the Jordan Cove LNG Project area are currently being used for cropland, and much of the Project area has been previously modified by industrial activities and the placement of dredged material. Therefore, no farmland of statewide importance would be taken out of production by construction and operation of the Jordan Cove LNG Project.

Erosion Potential

Erosion is a continuing natural process that can be accelerated by human disturbances. Factors that influence soil erosion include soil texture, structure, length and percent of slope, vegetative cover, and rainfall or wind intensity. Soils most susceptible to erosion by wind or water are typified by bare or sparse vegetative cover, non-cohesive soil particles with low infiltration rates, and moderate to steep slopes. The soils at the LNG terminal site occur within an area of high wind intensity and are in wind erodibility groups 1 (extreme) and 2 (high), which are the most susceptible to wind erosion.

Soils with severe wind erosion potential include Bandon sandy loam, Bullards sandy loam, Chetco silty loam, Dune Land, and Waldport Fine Sand. Approximately 487 acres (36 percent) of the total area is characterized by the potential for severe wind erosion. Approximately 107 acres (52 percent) of the permanent operations area of the site includes soils with the potential for severe wind erosion. Soils with moderate to high potential for water erosion include Bandon sandy loam, Beaches, Bullards sandy loam, Chetco silty clay loam, Waldport fine sand, and Waldport-Dune complex. Approximately 291 acres (22 percent) of the total area is characterized with the potential for moderate to high water erosion. Approximately 85 acres (41 percent) of the permanent operations area of the site includes soils with the potential for moderate to high water erosion.

To minimize potential for soil loss due to erosion, temporary erosion controls would be installed and maintained in accordance with Jordan Cove's Plan. Permanent erosion control measures would be installed, as necessary, and in compliance with county and state BMPs. Permanent erosion control measures may include vegetation, vegetated swales, infiltration or settling basins, stormwater runoff diversion and control through ditches, check dams, or other velocity dissipaters. For portions of the storm surge/tsunami barrier and terminal areas above +25 feet in elevation, which are not expected to normally be subjected to severe wind or water conditions (but may be affected by storm surge or tsunami events), alternative erosion control would be used. Alternative erosion control for protection from potential tsunami runups in slope areas would include using concrete cellular mattresses, grout injected geotextile fabric mattresses, or other suitable means as determined during detailed design. The design of the slope protection against waves would be developed through consultation with DOGAMI. Erosion of the engineered slopes within the marine slip is not anticipated under normal wave, tide, and marine vessel traffic conditions. The proposed pile dike rock apron along the access channel side slope would be implemented in coordination with the COE to arrest slope migration and prevent effects on Pile Dike 7.3. The erosion control measures would be designed in accordance with the ODOT Erosion Control Manual. By implementing these erosion control measures, construction and operation of the Project would not result in significant soil erosion by water or wind.

Compaction Potential

Soil compaction is the process by which air spaces in the soil are reduced in size because of physical pressure exerted on the soil surface. Compaction results in soil conditions that reduce infiltration, permeability, and gaseous and nutrient exchange rates. Fine-textured soils with poor internal drainage are the most susceptible to compaction. Compaction can result from construction equipment traveling over wet soils, and could further disrupt soil structure, reduce pore space, increase runoff potential, and cause rutting.

Previous activities at the Roseburg tract and the LNG terminal site have already compacted soils. Jordan Cove would test subsoil for compaction at regular intervals in areas disturbed by construction activities; and would implement BMPs—especially in areas that have not been historically disturbed by industrial land use—as described in Jordan Cove's ECRP. Such BMPs would include limiting construction in wet weather conditions and application of soil amendments to facilitate plant establishment.

Potentially Contaminated Soils and Groundwater

The site of the LNG terminal was a livestock ranch until 1958. After it was acquired as part of the mill complex, the tract was occasionally used for log-sorting activities. In 1972/1973, the COE spread materials dredged during maintenance of the Coos Bay navigation channel on the site. From the late 1970s through the early 1980s, sand, boiler ash, and wood debris from milling operations were placed on the majority of what is defined as the LNG terminal site. Weyerhaeuser, which acquired the mill in 1981, spread decant solids from its wastewater treatment facility at the LNG terminal site between 1985 and 1994. The South Dunes site was originally developed as a sulfite pulp and paper mill by the Menasha Wood Ware Corporation in 1961. It was acquired by Weyerhaeuser in 1981 and converted to a recycle paper mill in 1995. The mill was closed in 2003. Between 1981 and 1992, Weyerhaeuser leased the southern portion of the property adjacent to the geographic Jordan Cove portion of Coos Bay to a fish hatchery operation. The buildings for both the mill and the fish hatchery have been removed.

Jordan Cove conducted multiple Phase I and Phase II Environmental Site Assessments at the terminal tract to assess for environmental contamination. Phase I protocols consist of record searches, inventories, site visits, and other non-intrusive information gathering. Phase II protocols consist of intrusive environmental media sampling. Phase II Environmental Site Assessments were conducted to address the findings of the Phase I Environmental Site Assessments (CH2M Hill 1996; Thiel Engineering 2004; GRI 2005; PES Environmental 2006; GRI 2007b; GSI Water Solutions 2012; GRI 2017b; SHN 2017; SHN 2018). The details of these investigations are all included in FERC filings for the Project and are only generally summarized in the following section.

A Phase I Environmental Site Assessment of the APCO site conducted by SHN in 2013 (SHN 2013a) identified dredge spoils that may have been affected by historical industrial activities upstream of the site as a recognized environmental condition.[55] The existing Boxcar Hill site is being used as a recreational facility with all-terrain vehicle (ATV) rentals, riding trails, and camping. A Phase I Environmental Site Assessment of the Boxcar Hill site did not identify any recognized environmental conditions in connection with the site (SHN 2017). A limited (specifically for the Port Laydown area and not entire property parcels) Phase I Environmental Site Assessment was conducted for the Port Laydown site in February 2018 (SHN 2018) which identified numerous concerns including a potential off-site source of contamination (D.B. Western facility cited for violations including illegal disposal of solid and hazardous waste), potentially contaminated dredge material, burn piles within the site, and the potential for lead in soil from target shooting activities. Contaminants identified as both soil and groundwater concerns include: tributyl tin, heavy metals (arsenic, barium, lead, cadmium, chromium, mercury, selenium and silver), copper, polychlorinated biphenyls (PCB), polycyclic aromatic hydrocarbons (PAH), semivolatile organic compounds (SVOC), volatile organic compounds (VOC), total petroleum hydrocarbons (TPH), dioxins and furans, and formaldehyde. A Phase II Environmental Site Assessment to assess for soil and groundwater contamination is planned for this site.

The following Phase II Environmental Site Assessment investigations were conducted at the proposed LNG terminal site to determine if contaminated soils and/or groundwater are present:

- In 1996, Weyerhaeuser conducted Phase II Environmental Site Assessment investigations which found that VOCs, SVOCs, metals, petroleum hydrocarbons, and PCBs (analytes tested) in the fill were below levels that would necessitate cleanup work (CH2M Hill 1996).

[55] The presence or likely presence of any hazardous substances or petroleum products in, on, or at a property: (1) due to release to the environment; (2) under conditions indicative of a release to the environment; or (3) under conditions that pose a material threat of a future release to the environment.

With the exception of arsenic and PCB, material present at the site is below the current (1996) Oregon residential soil cleanup standards. PCB in one ash discrete sample exceeded the residential standard, but was well below the industrial soil standard. Arsenic detected at the site is within typical background concentration levels for the western United States and, therefore, does not represent any substantial environmental issue.

- Phase II Environmental Site Assessment investigations were conducted by PES Environmental, Inc. (PES) in April 2006 (PES 2006). These investigations focused on the South Dunes site (inclusive of the portions of this site to be used for the LNG terminal) as well as the Ingram Yard site.
- Another Phase II Environmental Site Assessment investigation was completed at the LNG terminal site by GRI in October 2006 (GRI 2007b). The assessment was conducted at test pits in the area of the former Ingram Yard and along a wastewater pipeline
- GRI performed a Phase II Environmental Site Assessment investigation in 2005 of the Roseburg property (GRI 2005), which has been used for wood-processing activities since 1968.
- GRI conducted a Phase II Environmental Site Assessment in July 2017 (GRI 2017b) of the APCO site.

Grading for the north access road and the ground improvement geotechnical test site required excavation of between 12 inches and 60 inches of soil from a 2-acre area from April 7 through April 15, 2014. During the grading activities, ash-amended soils were encountered, with a total of 5,600 cy of ash/soil mixture excavated and stockpiled in the area of the north access road in berms as indicated in the 1200C permit. On May 8, 2014, the ODEQ determined that these actions, while not prohibited, required a solid waste letter of authorization before commencement of grading activities. The ODEQ required Jordan Cove to obtain a solid waste authorization letter; on July 16, 2014, a solid waste authorization letter was submitted to the ODEQ. Jordan Cove would be required by the ODEQ to provide prior notice to the ODEQ should any grading or ground disturbance activities be planned to occur on the LNG terminal site. Provisions for long-term disposal of disturbed LNG terminal site soils and any other specific mitigation measures would be specified in detail in the final engineering design.

The results of Phase II environmental sampling activities at the LNG terminal site identified contaminants in soil at levels below or slightly exceeding the applicable ODEQ risk-based concentrations (RBC) and EPA screening levels at several locations. Analytical results from samples collected from the LNG terminal site found low concentrations of PAHs, TPH, metals, VOCs, SVOCs, PCBs, dioxins, furans, and butyltin compounds in soil samples. It is noted that regulatory updates to toxicity values for some compounds have changed the screening levels used in preliminary risk assessments since the preparation of these environmental site assessment reports. Table 4.2.1.2-1 presents a subset of chemicals detected at the site and represents contaminants that either exceed or approach current ODEQ and EPA regulatory screening levels or were present in multiple sample locations at both the South Dunes site and LNG terminal site. Table 4.2.1.2-1 includes applicable ODEQ RBCs for the soil ingestion, dermal contact, and inhalation exposure pathway under the occupational and construction worker scenarios (ODEQ 2015) and the EPA regional screening levels for industrial soils (EPA 2018a). Table 4.2.1.2-1 also includes ODEQ-established natural background concentrations for naturally occurring metals in soil. The maximum detected concentrations for selected compounds generally encountered in on-site soils, as summarized by previous environmental investigations, are also included in table 4.2.1.2-1 (CH2M Hill 1996; GRI 2005; PES 2006; GRI 2007b). As a part of the investigations, a screening-level human and ecological risk assessment of residual contamination was conducted and concluded that residual contaminants did not exceed ODEQ's screening levels for the occupational and construction worker exposure scenarios (PES 2006). Based on the findings of previous environmental investigations, the ODEQ has recommended a "No Further Action" determination for the former Weyerhaeuser mill and the LNG terminal site. A copy of this determination letter is provided in Jordan Cove's September 2017 application to the FERC.[56] A "Condition" of the No Further Action determination states that "While surface soils at the LNG terminal site meet human health and ecological screening criteria, they contain low levels of potentially bio-accumulating chemicals and must not be placed in waters of the state." Implementation of erosion controls for runoff during and construction and operation, as well as revegetation plans would prevent the low-level contamination from entering surface waters. Jordan Cove's ECRP lists the specific measures to be used for erosion and sediment control practices, wind erosion and dust control, and clearing and grading. Peripheral erosion and sediment control would be provided along the site perimeter, and at all operational drain inlets and outlets at all times during construction. Sediment basins would be employed if necessary.

TABLE 4.2.1.2-1

Summary of Applicable ODEQ and EPA Screening Levels Concentrations (in parts per million [ppm])

			ODEQ			EPA
Compound	**Max. Detected Concentration**	**Data Source a/**	**Occupational**	**Construction Worker**	**Natural Background**	**Screening Value**
Petroleum Hydrocarbons						
Diesel	11,000	2	14000	4600	Not Applicable	Not Established

[56] Included in Resource Report 7, Appendix G.7, as part of Jordan Cove's September 2017 application to the FERC.

Jordan Cove continues to work with the ODEQ toward the determination of appropriate regulatory requirements for the handling of contaminated soil and sediment. The ODEQ approved Jordan Cove's *Revised Work Plan for Joint Regulatory Closure Settling Basins, Petroleum-Contaminated Soil, Asbestos Waste, and Mill Waste Former Weyerhaeuser Mill Site and Ingram Yard Properties (LNG terminal site)* on July 22, 2013. The plan describes redevelopment of the South Dunes site that would involve increasing existing site grades a minimum of 3 feet with clean structural fill consisting of sand from the new slip to be excavated on the LNG terminal site (Ingram Yard property). Development over the existing mill wastewater system settling basins would require over-excavation of geotechnically unsuitable (highly organic) sludge in the basins and replacement with clean, compacted structural fill. A qualified contractor familiar with handling potentially contaminated materials would be mobilized, and a dredge would be used to remove the basin sludge to a dewatering system. Potentially contaminated material would be transported off-site to an approved ODEQ-regulated facility that would be identified prior to construction. In addition, landfill materials would be removed and handled according to the overall *Mill Site Closure Plan* that was approved by the ODEQ on July 22, 2013.

A disposal plan for contaminated soil would be developed by Jordan Cove once the Project engineering design is finalized. The disposal plan will be submitted to the ODEQ for pre-approval prior to the work. Additional details on the management and regulatory requirements of existing contaminants are provided in Jordan Cove's *Framework Contaminated Media Management Plan.*[57]

Jordan Cove completed a data gap investigation in 2018 to delineate existing petroleum and other contaminants at the former mill site in compliance with the terms and conditions of the No Further Action determination granted by ODEQ in 2006. Based on the analytical results from the data gap investigation, concentrations of PAHs, metals, and/or petroleum hydrocarbons exceeded RBCs for soil. Specific contaminants include naphthalene (46.8 and 92 mg/kg); oil (6,130, 6,190, 14,000, and 61,500 mg/kg); benzo(a)pyrene (2.27 mg/kg); diesel (27,660 mg/kg); and chromium (743 mg/kg). Jordan Cove is in the process of consulting with the ODEQ regarding potential required subsequent remedial mitigation efforts to reduce the concentration of contaminants in soil or eliminate exposure pathways in relation to the Project. Such remedial action(s) would comply with the requirements and recommendations of the No Further Action determination and ODEQ review and approval.

Soils and/or sediments containing residual contamination must be managed and/or disposed in accordance with ODEQ rules. Per guidance from the ODEQ, Jordan Cove would provide prior notice to the ODEQ when grading or ground disturbance activities are planned to occur on the LNG terminal site. In addition, a permanent disposal plan for the boiler ash material would be prepared by Jordan Cove and submitted to the ODEQ for approval prior to site development activities.

Jordan Cove has prepared a *Framework Contaminated Media Management Plan* that includes general measures to be implemented in the event that unanticipated soil contamination is discovered during construction of the Jordan Cove LNG Project but does not include specific monitoring and sampling protocols for handling potential or suspected contamination that might

[57] Included in Resource Report 7, Appendix O.7, as part of Jordan Cove's September 2017 application to the FERC.

be encountered. If Jordan Cove's Environmental, Health and Safety Division determines that additional action is necessary, Jordan Cove would implement the following measures:

- contact a qualified consultant and/or testing laboratory to assist with the determination of the extent and nature of the contamination;
- devise a plan for additional site-specific investigations as necessary;
- conduct site-specific testing and/or laboratory analysis to determine the extent and nature of contamination;
- notify all applicable environmental authorities as required by law, including the ODEQ;
- devise a site-specific plan depending on the nature and extent of the contamination encountered for continuation of construction, which may involve evaluation avoidance options as necessary to support the construction of the proposed facilities;
- devise a strategy or plan for handling wastes in an appropriate manner including waste characterization, hauling, manifesting, and disposal necessary to support continuing construction;
- devise a plan for site stabilization and backfilling; and
- complete all required and necessary agency follow-ups and reporting.

Spills or leaks of fuels, lubricants, or coolant from construction equipment could contaminate soils. The soil and sand on the Project site have high infiltration capacity, and comprise a shallow groundwater (10 feet or less) system with high aquifer transmissivity. A spill, if it occurred, would spread quickly; however, the effects of contamination would typically be minor because of the low frequency of spills and leaks. During construction, Jordan Cove would implement its water quality management plan that includes a SPCC Plan. This plan describes spill prevention practices, spill handling and emergency notification procedures, and training requirements that would be implemented during construction of the Project. The SPCC Plan addresses the unique soil and subsurface conditions of the Project site, including the high permeability, shallow groundwater, and rapid transmissivity. With the implementation of the SPCC Plan and ODEQ requirements, construction of the Project is not anticipated to spread existing contamination or cause additional soil contamination.

4.2.1.3 LNG-Specific Topics

Potentially Contaminated Bay Sediments

The Port developed a sampling and analysis program (SAP; SHN 2006a) that details the sediment collection and testing program conducted on the material that would be dredged during construction of the access channel. The sediment sampling and analysis program followed the Dredged Material Evaluation Framework (DMEF) Tier IIB approach for physical and chemical evaluation of the proposed dredged material and only included physical analysis of materials. As described below, chemical analyses were not required based on grain size.

The results of the grain size distribution based on COE-approved methods (COE et al. 1998) indicated the average percent of sand in sediment samples was over 99 percent. The results of the total volatile solids (TVS) analysis indicated that the average percent TVS in the sediments was approximately 0.7 percent. DMEF Tier IIA states, "If the results of grain size analysis are at least

80 percent sand and TVS is less than 5 percent, the proposed dredging material qualifies for unconfined, aquatic disposal based on exclusionary status." Therefore, the Port's report concluded that further characterization was not considered necessary.

In addition to the access channel, proposed dredging would take place at four locations along/adjacent to the Coos Bay Navigation Channel (i.e., dredge areas 1, 2, 3, and 4). For dredge areas 1 through 4, historical boring logs from the Federal Navigation Channel were evaluated to provide a dredged sediment characterization. Subsurface exploration within the Federal Navigation Channel was performed by GRI in 2005 and 2007 (GRI 2005 and 2007b). More recently, geotechnical site investigations were carried out by GRI in 2011 and 2017. Additional analyses for submittal to the Portland Sediment Evaluation Team (PSET) are underway. A detailed discussion of dredging and material disposal methods is provided in the *Dredged Material Management Plan.*[58]

Jordan Cove has conducted extensive investigations regarding soil contaminants in close coordination with the Portland Sediment Evaluation Team (PSET) at the west portion of the Kentuck mitigation site beginning in 2010. Jordan Cove has submitted four SAPs and three sediment characterization reports for the western portion of the site to the COE from September 2010 to November 2014. These studies document that chemical analysis of samples for VOCs, SVOCs, PAHs, PCBs, metals, dioxins, furans, and butyltin compounds did not detect any contaminants above applicable screening levels and that the material is suitable for its intended use in the Kentuck project site without restriction, with the exception of the golf course irrigation pond. According to the sampling results documented in the November 13, 2014 sediment characterization report, mercury is present at levels above clean fill screening criteria in sediments contained in the golf course irrigation pond. Although oil-range hydrocarbons are also present at this location, these were not detected above applicable screening levels. Affected soil in the Kentuck project site would be excavated and removed to a permitted disposal facility in accordance with an ODEQ work plan that would be approved prior to the removal action.

Jordan Cove prepared a sediment characterization report (GRI 2018) for the east portion of the Kentuck site to characterize material at the former Kentuck Golf Course that would be partially excavated and/or partially overlain by imported material to create a wetlands mitigation site. Sampling and analyses were performed for this portion of the Kentuck site in November 2017. Soil/sediment samples were collected from 10 locations within the intertidal channel and floodplain and analyzed for metals, VOCs, PAHs, SVOCs, PCBs (e.g., Aroclors), and pesticides. With the exception of the detection of the pesticide aldrin above the marine screening level in one area (sample S-27), the sampling and analyses completed show the proposed plan for Kentuck to be consistent with regulatory guidance and applicable screening levels. To address the S-27 area, Jordan Cove proposes to excavate 6 inches below the proposed final grade and replace to design grade with clean imported sand. This excavation would be completed laterally beyond S-27 to a point halfway to the nearest adjacent sample points. The excavated material from the S-27 area would be incorporated into an on-site constructed bermed area with a clean imported sand cap or transported offsite to an approved permitted disposal facility.

[58] Included in Resource Report 7, Appendix N.7, as part of Jordan Cove's September 2017 application to the FERC.

Shoreline along the Waterway for LNG Carrier Marine Traffic

Jordan Cove conducted two studies to evaluate shoreline impacts during the transit of LNG vessels in the waterway to and from the LNG terminal (Moffatt & Nichol 2017a, 2017b). The *Vessel Wakes Impacts Memo* (Moffat & Nichol 2017a) evaluates shoreline erosion within Coos Bay resulting from vessel transit. The study concluded that the proposed LNG terminal combined with the associated changes in the size and speed of vessels expected to utilize the proposed channels would not result in increased shoreline impacts (such as increased erosion) due to ship-generated waves. A rock apron has been proposed to arrest slope migration, or equilibration, before it can progress to a condition that could potentially negatively impact Pile Dike 7.3. Construction of the Pile Dike rock apron is expected to produce a localized, temporary increase in turbidity; however, the long-term effect of the rock apron would improve shoreline stability including accounting for the effects of marine traffic. The *Propeller Wash Analysis Memo* (Moffat & Nichol 2017b) evaluates potential impacts of propeller wash on scour in the slip, access channel, MOF, and at the pile dike areas. An area of potential scour due to propeller wash is located along the eastern side of the slip and access channel, where the maximum bottom propeller wash scour depth is estimated to be nearly 0.5 foot. Jordan Cove would provide slope protection (i.e., armor rip rap as described in section 2.4.1.5) for the west and north sides of the slip, and scour protection would be provided at the base/toe of the bulkhead walls. These measures would provide adequate slope and bulkhead protection to prevent associated scour.

4.2.2 Pacific Connector Pipeline Project

4.2.2.1 General Impacts

Soils along the proposed pipeline route were identified using NRCS surveys for Coos, Douglas, Jackson, and Klamath Counties (NRCS 2004; SCS 1985, 1989, 1993); and NRCS State Soil Geographic Database (STATSGO) and Soil Survey Geographic Database (SSURGO) soil classifications (NRCS 2017). The Forest Service soil resource inventories of the Umpqua, Rogue River, and Winema National Forests were used to assess soil resources in the National Forests (Forest Service 1976, 1977, and 1979). Information in the Forest Service surveys was supplemented by STATSGO and SSURGO data where available.

According to the NRCS Land Resource Regions and Major Land Resource Areas (MLRAs) (NRCS 2006), the pipeline route would cross four MLRAs:

- the Sitka Spruce Belt including the Pacific Coast and Coos Bay area in Coos County;
- the North Pacific Coast Range, Foothills, and Valleys including Coos County and portions of Douglas County;
- the Siskiyou-Trinity Area including portions of Douglas and Jackson Counties, the Umpqua National Forest, and portions of the Rogue River-Siskiyou National Forest; and
- the Klamath and Shasta Valleys and Basins in the southern part of Klamath County.

Soil associations crossed by the pipeline are shown in table G-1 in appendix G by MP, including the mileage percentage of the entire pipeline length. The Medco-McNull-McMullun and Vermisa-Vannoy-Josephine-Beekman soil associations are crossed by 15.7 and 12.9 percent of the pipeline length, respectively. The remaining soil associations are crossed by less than 10 percent of the pipeline length.

Detailed descriptions of all soil associations crossed by the Project and their characteristics are provided in appendix G of this EIS. The remainder of this discussion focuses on the sensitive soils characteristics present along the pipeline route as shown in table 4.2.2.1-1. It is noted that the soil characteristics studies for the Pacific Connector pipeline and the Jordan Cove LNG Project are different in approach. Pacific Connector primarily relies on soils data available from the NRCS databases; and Jordan Cove uses preliminary geotechnical study data as well as NRCS data.

To provide the highest level of detail in quantifying the soil properties and impacts, analysis was based on the characteristics of the individual soil mapping units crossed within each soil association. Major soil characteristics and limitations for the pipeline and aboveground facilities are discussed below. Table 4.2.2.1-1 provides a summary of soil limitations that could be encountered by the pipeline route.

Rows and columns may not add correctly due to rounding. Acres rounded to nearest whole acre, miles to nearest tenth of a mile (values below 1 or 0.1, respectively, are shown as "<1"/ "<0.1").

a/ Numerical values shown are miles crossed by construction, including construction right-of-way and TEWAs. Acres affected shown in parenthesis. Soil data from NRCS 2004; SCS (1985, 1989, 1993); Forest Service 1976, 1977, and 1979. NRCS State Soil Geographic Database (STATSGO and SSURGO) soil classifications (NRCS 2017).

b/ Soils with NRCS rating of high or severe.

c/ Soils with NRCS wind erodibility groups 1 and 2.

d/ Soils with slopes greater than 30 percent.

e/ Soils with greater than 25 percent cobbles and/or stones within pipeline trench depth.

f/ Soils with a restrictive soil layer (bedrock or cemented layer) within 60 inches of the soil surface.

g/ Soils with an NRCS rating of high or severe for the Haul Roads, Log Landings, and Soil Rutting category.

h/ Combined rating for soils with high or severe erosion potential, steep slopes, large stones, shallow soils, saline/sodic conditions, clayey soils (greater than 40 percent), and soil map units with dominant amounts of rock outcrop. The Reclamation/Sensitivity type does not include data related to the revegetation sensitivity studies on federally-managed lands (NSR 2015).

i/ Soils with dominant map unit included on either the state or county list of farmland of importance (includes prime farmland, unique farmland, and farmland of statewide or local importance).

j/ In an effort to maintain milepost continuity while adjusting the pipeline route, milepost equations have been incorporated into the alignment. This allows the mileposts, for the most part, to remain unchanged. However, the ending milepost no longer reflects the actual length of the proposed pipeline.

4.2.2.2 Project-Specific Soil Limitations

Prime Farmland

The pipeline alignment crosses approximately 69 miles (30 percent of the pipeline) of soils where the dominant map unit in the MLRA is classified on either the NRCS state or county list of prime farmland or "farmland of statewide importance."[59] These designations were previously described in section 4.2. Permanent impacts on prime farmland soils from the proposed pipeline would be associated with the aboveground facilities, as discussed in section 4.2.2.3 below. Pacific Connector would implement mitigation measures in areas where existing agricultural land uses would be affected (approximated 43 miles of the pipeline route) to minimize impacts on prime farmland and crop yields, such as topsoil salvaging, scarification, and subsequent testing to ensure that potential compaction is remediated. Topsoil salvage is achieved by mechanically segregating topsoil from subsoil to an approved depth and width along the pipeline right-of-way. Topsoil segregation would be performed over the trench line and spoil storage areas in croplands, hayfields, pastures, and areas specified by landowners. Areas where topsoil salvaging and segregation would occur are shown by MP in table 4.2.2.2-1 to minimize potential impact to soil and agricultural productivity.

TOTAL			**43.22**

Note: For a description of topsoil segregation and effects on wetlands, see section 4.3. (Up to the top 12 inches of topsoil would be segregated from the area disturbed by trenching in wetlands, except in areas where standing water or saturated soils are present.) Topsoil would not be segregated on federal lands as discussed in section 4.2.3.

Erosion Potential

The pipeline route would cross about 94.3 miles (41 percent of pipeline length) of soils with a high or severe water erosion potential and 14.4 miles (6.3 percent of the pipeline length) of soils with a high wind erosion potential (NRCS wind erodibility groups 1 and 2).

Impacts on soils from erosion would be minimized by following the Pacific Connector's Plan and Procedures and their Project-specific ECRP. Pacific Connector would implement specific water erosion prevention measures such as covering temporary storage piles; covering, seeding and mulching of soil and vegetation piles; and installation of sediment barriers, interceptor ditches or berms, or other measures where necessary, to filter water and divert flow away from sensitive areas. With these measures, significant water erosion would not occur. Pacific Connector would implement reseeding efforts, apply mulch, and water for dust control to minimize potential erosion by wind on the disturbed soils during construction. In addition, as described in section 4.1 of this

EIS, an extensive geotechnical review was conducted to ensure that the route avoided known or potential areas of mass soil movement. This effort required minor reroutes in numerous areas along the alignment to ensure the safety and integrity of the pipeline.

Temporary erosion control measures would be installed immediately after clearing and prior to grading (i.e., the initial soil disturbance). Near waterbodies and wetlands, the EIs would determine in the field the extent of temporary erosion control measures (i.e., sediment barriers) that would need to be installed prior to clearing activities to minimize the potential for runoff to enter a wetland or waterbody. All erosion control devices would be routinely inspected and any damaged or temporarily removed structures would be replaced at the end of each working day. Temporary erosion control measures would be maintained until successful revegetation has been achieved.

Sediment barriers would be used to confine sediment to the construction right-of-way and would be constructed of either silt fence or straw bales. Sediment barriers would generally be placed as follows:

- at the base of slopes adjacent to road, wetland and waterbody crossings where sediment could flow from the construction right-of-way onto the road surface or into the wetland or waterbody;
- adjacent to wetland and waterbody crossings, as necessary, to prevent sediment flow in the wetland or waterbody consistent with the requirements of the FERC's *Procedures* (which Pacific Connector's *Procedures* were based upon); and
- on the downslope side of the right-of-way where it traverses steep side slopes (greater than or equal to 30 percent).

Pacific Connector would install temporary slope breakers to reduce runoff velocity, concentrate flow, and to divert water off the construction right-of-way to avoid excessive erosion. Temporary slope breakers may be constructed of materials such as soil, silt fence, staked straw bales, straw wattles, or sand bags. If it becomes necessary to delay final cleanup, including final grading and installation of permanent erosion control measures, beyond 20 days (10 days in residential areas) after the trench is backfilled in a specific area, Pacific Connector would apply mulch on all disturbed slopes before seeding.

Trench breakers would be installed in the trench and keyed into trench walls on slopes prior to backfilling to slow the flow of subsurface water along the trench to prevent erosion of trench backfill materials. A permanent slope breaker and a trench breaker would be installed at the base of slopes near the boundary between the wetland and adjacent upland areas.

Waterbody crossings would be stabilized and temporary sediment barriers installed within 24 hours of completion of backfilling in accordance with Pacific Connector's *Procedures*. Pacific Connector would install erosion control fabric (such as jute or excelsior) on streambanks and steep slopes at the time of recontouring. The erosion control fabric would be designed for the proposed use and would be approved by the EI, and authorized agency representative on federal lands.

Permanent slope breakers (waterbars) would be installed across the right-of-way on steep slopes (greater or equal to 30 percent). The purpose of these structures is to minimize erosion by reducing runoff velocities, by shortening slope lengths, preventing concentrated flow, and by diverting water off the construction right-of-way. Slope breakers are also intended to prevent sediment deposition into sensitive resources.

Compaction Potential

The proposed pipeline alignment would cross a total of 178.7 miles (78.1 percent of the total pipeline length) of soils that are highly susceptible to compaction. Soils in this sensitive group were determined based on the NRCS rating of high or severe for the Haul Roads, Log Landings, and Soil Rutting categories. Soils in this group are rated based on Unified soil texture classification, rock fragments on or below the surface depth to a restrictive layer, depth to a water table and slope. However, most soils are susceptible to compaction depending on the number of passes of heavy equipment and the moisture content of the soils at the time of construction. Unmitigated soil compaction can result in long-term reductions of soil productivity and increased erosion from increased surface runoff.

Pacific Connector would minimize soil compaction, rutting, and structural damage to wet soils and soils with poor drainage by employing BMPs such as the use of low-ground-weight construction equipment, or operating normal equipment on timber riprap, prefabricated equipment mats, or terra mats. In addition, Pacific Connector would not conduct construction activities during extremely wet weather conditions. During forest clearing activities, the potential for soil compaction would be minimized where cable and helicopter logging methods are used. Where log skidding occurs, several practices would be employed as described in Section 2.3 of Pacific Connector's ***Right-of-Way*** *Clearing Plan for Federal Lands*,[60] where feasible, to minimize the potential for soil compaction.

As described in Pacific Connector's ECRP, regrading, recontouring, scarifying, and final cleanup activities after pipeline construction would mitigate potential soil compaction in all areas of pipeline construction. However, these measures alone would not be sufficient to entirely address soil compaction, and additional measures including subsoil ripping and decompaction with hydraulic excavators would also be necessary to fully address soil compaction. Mitigating compaction promotes infiltration, reduces surface water runoff, minimizes erosion, and enhances revegetation efforts. Pacific Connector would test for soil compaction in agricultural areas (e.g., active croplands, hayfields, and pastures), residential areas, and on NFS and BLM lands. Soil compaction mitigation on federal lands is more specifically discussed in section 4.3.2.

Potentially Contaminated Soils and Groundwater

A review of the ODEQ's ECSI database (ODEQ 2017a, 2017b, 2017c, and 2017d) and EPA's (2017) EnviroMapper - Facility Detail Report revealed that there are 116 sites with either cleaned-up, potential, or confirmed soil and/or groundwater contamination within 0.25 mile of the pipeline route as listed in table G-2 in appendix G. Based on a review of these sites, the sites listed in appendix G have the potential to encounter contaminated soil or groundwater during construction. During the review of these sites, the following issues were considered: sites that are closed might have residual contamination and contaminated soils might be carried by the wind to adjacent areas.

The sites listed below are close to the proposed pipeline infrastructure and construction areas, and database listings were insufficient to reach a conclusion regarding the potential for encountering

[60] This plan was included in Pacific Connector's application to the FERC as Appendix U to the POD.

associated contaminated soil or groundwater during Project construction. As a result, **we recommend that**:

- **<u>Prior to the end of the draft EIS comment period</u>, Pacific Connector shall consult with the ODEQ regarding existing soil and groundwater contamination at the sites listed in appendix G, and file the results of this consultation, along with any proposed site-specific soil or groundwater handling, management, and disposal procedures.**

During construction, contamination from accidental spills or leaks of fuels, lubricants, and coolant from construction equipment could adversely impact soils. To minimize impacts, Pacific Connector would implement measures contained in its SPCC Plan, which specifies cleanup procedures in the event of inadvertent spills during Project construction. Pacific Connector has developed a *Contaminated Substances Discovery Plan*[61] that specifies the measures that would be implemented if unanticipated contaminated soil or groundwater are encountered during construction. Some of the measures outlined in that plan specify that all construction work in the immediate vicinity of areas where hazardous or unknown wastes are encountered would be halted; that all construction, oversight, and observing personnel would be evacuated to a road or other accessible up-wind location until the types and levels of potential contamination can be verified, and that if an immediate or imminent threat to human health or the environment exists, one of Pacific Connector's emergency response contractors identified in the SPCC Plan or the National Response Team would be notified and mobilized. Pacific Connector would update the *Contaminated Substances Discovery Plan* to be consistent with the latest information regarding contaminated sites in proximity to the pipeline alignment prior to construction.

4.2.2.3 Pipeline-Specific Topics

Soil Limitations

<u>Reclamation Sensitivity</u>

The pipeline alignment would cross a total of 148.7 miles (64.8 percent of the pipeline length) of soils that are rated as having reclamation sensitivity or poor revegetation potential (NSR 2014). These soils may have a combination of characteristics that could require additional measures or BMPs to reduce erosion and sedimentation potential. Restoration of these soils may require adaptive seed mixtures and implementation of revegetation practices (i.e., fertilization, mulching, monitoring) to enhance revegetation success. Section 10.0 of Pacific Connector's ECRP includes a detailed description of soil restoration procedures and requirements. Pacific Connector would implement revegetation procedures, such as topsoil segregation, recontouring, scarification, soil replacement, seedbed preparation, fertilization, seed mixtures, seeding timing, seeding methods, and supplemental plantings to ensure revegetation success. Information contained in the BLM/Forest Service *Technical Memorandum Soil Risk and Sensitivity Assessment on BLM and National Forest System Lands* (NSR 2015a) would be used to identify and treat areas on BLM and Forest Service lands where specific and focused soils remediation measures may be required to minimize potential erosion and accomplish vegetation objectives (see section 4.2.3).

Pacific Connector would work with individual landowners to address restoration of active agricultural and residential landscaping, if affected by pipeline construction. In active agricultural

[61] The *Contaminated Substances Discovery Plan* was included in Pacific Connector's application to the FERC as Appendix E to the POD.

areas, Pacific Connector would restore the lands in compliance with the *Plan* and *Procedures*, and would also compensate the landowner for any additional restoration measures (e.g., replanting crops) that the landowner preforms. In residential areas, Pacific Connector would use contractors familiar with local horticultural and lawn establishment procedures for reclamation work or would compensate the landowner if the landowner conducts that restoration work; Pacific Connector would still be responsible for ensuring the restoration efforts are successful.

Seedbed preparation would be conducted, where necessary, immediately prior to seeding to prepare a firm seedbed conducive to proper seed placement and moisture retention. Seedbed preparation would also be performed to break up surface crusts and to eliminate weeds which may have developed between initial reclamation and seeding. A seedbed would be prepared in disturbed areas, where necessary, to a depth of up to four inches using appropriate equipment to provide a seedbed that is firm, yet rough. A rough seedbed is conducive to capturing or lodging seed when broadcasted or hydroseeded, and it reduces runoff and erosion potential. The rough seedbed would retain soil moisture for seedling germination and establishment.

In most areas, final right-of-way cleanup procedures are sufficient because they leave a surface smooth enough to accommodate a drill seeder pulled by a farm tractor and rough enough to catch broadcasted seed and trap moisture and runoff. Where residential and cropland areas are disturbed, more intensive ground and seedbed preparations may be required including rock collection, grading, and soil preparation/amending. The EI would be responsible for determining where seedbed preparation measures are required prior to seeding.

Pacific Connector has consulted with the NRCS and land management agencies regarding recommended seed mixtures for the Project area. The seed mixtures developed for the Pacific Connector Pipeline Project are based on these agency recommendations and are provided in the ECRP. During right-of-way negotiations, private landowners may also request other seed mixtures than those proposed in the ECRP. These specific landowner requested/specified seed mixtures would be documented in landowner right-of-way agreements.

Disturbed areas would be seeded within six working days of final grading, weather and soil conditions permitting. If final grading occurs more than 20 days after pipe installation and backfilling, Pacific Connector would apply mulch on all disturbed areas prior to seeding. Seeding would proceed in accordance with the ECRP.

Restrictive Layer

Soils that are rated as having a restrictive layer are shallow soils that have a lithic, paralithic, or other restrictive soil layer within 60 inches of the soil surface. The pipeline alignment would cross a total of about 144.6 miles (63.1 percent of the pipeline length) of soils with a restrictive layer. These soils have thin profiles, restrictive root zones and hold less available water for plant growth. Shallow and hard bedrock can also restrict trenching, requiring special equipment (rock hammers/saws) or blasting in some areas to efficiently excavate the trench to required design depths. Excavation of bedrock or cemented layers may require additional measures to provide suitable pipe bedding materials. Soils in this group are also included in the soils that have reclamation sensitivity. Section 4.1 of this EIS discusses shallow soils, rock lithology, potential blasting locations, rock removal, and disposal.

Large Stones

Soils with more than 25 percent cobbles and stones in the soil profile can present problems with surface reclamation because they hold less available water for plant growth and generally require broadcast seeding methods. Further, the introduction of stones or rocks from subsoils to surface soil layers during trenching or blasting can adversely affect agricultural productivity and agricultural equipment operation.

The pipeline route would cross a total of 73.2 miles (31.9 percent of the pipeline length) of soils containing cobbles and stones. Pacific Connector has developed measures that would reduce impacts on restoration and revegetation caused by rocks, cobbles, and stones near the soil surface. In agricultural and residential areas, topsoil would be segregated except on federal lands as discussed in section 4.2.3. A rock picker would be used to remove large fragments.

Rocks excavated from the trench would be kept separate from topsoil during construction and during surface preparation as part of restoration. Pacific Connector has identified rock disposal sites. These sites are listed in table 4.1.2.4-1. Large rocks and boulders would also be used as OHV barriers along the right-of-way and at road crossings to control unauthorized OHV access to the right-of-way both during construction and operation. Additionally, large rocks and boulders would be piled in upland areas along the right-of-way to create habitat diversity features where approved by the EI or Pacific Connector's authorized representative and the landowner or land management agency.

Aboveground Facilities

Pacific Connector's aboveground facilities would be located within or immediately adjacent to the pipeline construction right-of-way. Each facility would be fenced and graveled immediately after construction. Permanent impacts on soils would occur at aboveground facilities that would be graded and graveled or where facilities would be constructed. Soil limiting characteristics at aboveground facilities are listed on table 4.2.2.3-1. Soils at specific aboveground facilities are described below. Section 10.0 of Pacific Connector's ECRP includes a detailed description of erosion control and soil reclamation procedures and requirements.

MS = meter station, MLV = mainline block valve, CT = communication tower. Soil data from NRCS (2004); SCS (1985, 1989, 1993); Forest Service (1976, 1977, and 1979). NRCS State Soil Geographic Database (STATSGO and SSURGO) soil classifications (NRCS 2017).

a/ Area of pipeline construction and operation right-of-way disturbance. Acreages rounded to nearest whole acre; values less than 1 are reported as <1.

b/ Soils with NRCS water erosion rating of high or severe; and/or soils with NRCS wind erodibility groups 1 and 2.

c/ Soils with slopes greater than 30 percent.

d/ Soils with greater than 25 percent cobbles and/or stones within pipeline trench depth.

e/ Soils with a restrictive soil layer (bedrock or cemented layer) within 60 inches of the soil surface.

f/ Soils with an NRCS rating of high or severe for the Haul Roads, Log Landings, and Soil Rutting category.

g/ Combined rating for soils with high or severe erosion potential, steep slopes, large stones, shallow soils, saline/sodic conditions, clayey soils (greater than 40 percent), and soil map units with dominant amounts of rock outcrop. The Reclamation/Sensitivity type does not include data related to the revegetation sensitivity studies on federally managed lands (NSR 2015).

h/ Soils with dominant map unit included on either the state or county list of farmland of importance (includes prime farmland, unique farmland, and farmland of statewide or local importance).

i/ These aboveground facilities would be located entirely within the proposed Jordan Cove LNG terminal. This soil association has been previously disturbed and would be graded and built up during construction of the Jordan Cove LNG terminal prior to construction of the Pacific Connector pipeline.

Jordan Cove Meter Station

The Jordan Cove Meter Station (at MP 0.0) would be within the South Dunes site, on the North Spit, in Coos County. This area was formerly the location of the Menasha-Weyerhaeuser mill (operated between 1961 and 2003), which is now dismantled. Petroleum hydrocarbons (e.g., fuel, fuel oil, lubricants, solvents, and hydraulic oil constituents) are present in subsurface soils and groundwater from past mill operations/practices in the area of the South Dunes site. In addition, transite/asbestos siding and other debris from the Weyerhaeuser Company mill demolition are present in surficial soils. The meter station would occupy approximately 1 acre on the Bullards-Nehalem-Dune Land soil association. There are no known soil limitations that would affect the construction and use of this parcel for a meter station. The meter station site would be graded and its elevation built up by Jordan Cove from soils excavated and dredged from the LNG terminal access channel and marine slip. The Jordan Cove Meter Station would also contain MLV#1, a receiver, and a communication tower.

The Jordan Cove Meter Station location and pipeline alignment are in the general area of potential debris/fill; however, the TEWA usage has been reduced in size, and the debris/fill material would not be disturbed as the TEWA would be used only for staging equipment or materials. To protect human health and ensure worker safety, Pacific Connector or qualified contractor personnel would collect representative samples of the debris/fill in the excavation zone prior to construction for the meter station and pipeline alignment and surrounding materials for laboratory analysis for contaminants of concern listed above. Based on the results of laboratory analysis, any contaminated material would be removed and properly disposed of in accordance with appropriate federal and state regulations. Where the removed fill must be stockpiled pending characterization and ODEQ approval, Pacific Connector would take precautions to avoid mitigation of existing contamination (e.g., appropriate liner for storage area, berms). Clean backfill would be utilized to backfill excavations. This approach is consistent with ODEQ recommendations for this general area (ODEQ - No Further Action Determination Letter, Former Weyerhaeuser Containerboard Mill North Bend, Coos County, Oregon Tax Lots #25S-13W-4-100, 25S-13W-3-200, and the LNG terminal [Ingram Yard portion of 25S-13W-0-200 ECSI Site ID No. 1083]).[62] Lastly, Pacific Connector would mandate pipeline contractor training that would include this site's status and history, and instruct that site excavation and disturbance is to be limited. Documentation of all analytical results and disposal records would be filed with the FERC following construction of the meter station.

Klamath Compressor Station

The Klamath Compressor Station would be located at MP 228.8 in Klamath County. The site would also include the Klamath-Beaver and Klamath-Eagle meter stations, MLV #17, a launcher/receiver, and a communication tower. The compressor station would occupy a 21.4-acre site within the Fordney-Calimus Poman soil association. The two dominant mapped soil units (i.e., Fordney loamy fine sand and Calimus loam) are considered prime farmland if irrigated; however, the site is not irrigated or otherwise in agricultural use. Fordney loamy fine sand has a high wind erosion hazard; therefore, periodic watering may be necessary to minimize fugitive dust during construction clearing and grading activities until the site has been stabilized with gravel.

[62] Included in Jordan Cove's Resource Report 7, Appendix G.7, in their September 2017 application to the FERC.

Gas Control Communication Towers

Pacific Connector would install a series of communication towers for gas control and system monitoring at 8 locations. As discussed above, one new communication tower would be erected within the Klamath Compressor Station and the Jordan Cove Meter Station. No soils would be disturbed where an existing tower would be utilized. Pacific Connector expects to erect new communication towers adjacent to existing facilities at three locations: Flounce Rock, Robinson Butte, and Stukel Mountain. Construction of the new towers would disturb about 0.2 acre at each location. Information on the soil characteristics for the new tower locations is provided in table 4.2.2.3-1. Pacific Connector would minimize erosion by following its ECRP. Because the communication towers are industrial facilities, the presence of stones, restrictive layers, and poor revegetation potential would not be environmentally adverse factors in the construction and operation of the towers.

Launchers/Receivers and Mainline Block Valves

Seventeen MLVs would be installed along the pipeline according to USDOT spacing requirements (49 CFR Part 192 Section 192.179). Potential impacts from the MLVs are accounted for within the proposed pipeline because these facilities would be located entirely within the construction right-of-way. However, because these small (less than a tenth of an acre) sites would contain aboveground facilities, they would permanently affect soils. Six of the MLV locations would be on soils designated as prime farmland, with five of these locations (MLVs 5, 8, 15, 16, and 17) within existing cropland/pastures rangeland. Construction and operation of the launchers/receivers and MLVs would take a total of about one-third of an acre out of agricultural production, excluding acres that were already discussed under the meter stations. Loss of agricultural production would be a factor considered in compensation to landowners negotiated by Pacific Connector while obtaining easement agreements.

Temporary Storage Yards

Pacific Connector has identified 36 potential, privately-owned contractor and pipe storage yards in the general area of the proposed route. These yards would be used for pipe offloading, office trailers, fabrication, equipment storage, material staging and employee parking. Although it is unlikely that all 36 yards would be utilized, numerous sites are identified and evaluated given that some sites could become unavailable at the time of construction. Most (28) of the yards are located in existing industrial areas or sites that have been previously disturbed by filling, grading, and gravelling activities, and therefore the soils resources at these locations have been substantially altered from natural conditions. Of the remaining storage yards, two have been partially disturbed (i.e., Coquille Park and Rogue Aggregates). Only six storage yards have not been disturbed previously. These include four storage yards that are currently used for agriculture (i.e., Roth, Riddle Pasture, Klamath Falls North of Cross Road East, and Klamath Falls North of Cross Road West). The remaining undisturbed storage yards (i.e., Klamath Amuchastegui Building, and Klamath Falls Industrial Oil) are undeveloped land in industrial parks.

Soil associations, mapping units, and sensitive soil characteristics are listed for each of the storage yards in table 4.2.2.3-2.

TABLE 4.2.2.3-2

Contractor and Pipe Storage Yards with Sensitive Soil Characteristics (Pastures, Fields and Vacant Lots)

Name	County	Section, Township, Range	Acres a/	Description	Soil Association – Soil Mapping Units and Sensitive Soil Characteristics b/
Coquille Park	Coos	Section 35, T. 27 S., R. 13 W.	3.3	Sturdivant Park, adjacent to rail siding	Soil Association: Waldport (OR0797) Soil Mapping Units: (Coos County): 40 & 41 Sensitive Soil Characteristics: 8, 10, 11, 12
Roth	Douglas	Section 29, T. 28 S., R 5 W.	3.8	Pasture, adjacent to rail siding, connect to Pipeline right-of-way	Soil Association: Ruch-Medford-Takilma (OR059) Soil Mapping Units: (Douglas County): 81A & 189F Sensitive Soil Characteristics: Philomath-Dixonville complex soil: 1, 4, 5, 8, 9 Foehlin soil: 8, 12
Riddle Pasture	Douglas	Section 45, T. 30 S., R. 6 W.	7.3	Vacant field adjacent to industrial sites and rail siding	Soil Association: Ruch-Medford-Takilma (OR058) Soil Mapping Units (Douglas County): 14A &14C Sensitive Soil Characteristics: 1, 3
Rogue Aggregates	Jackson	Section 20, T. 36 S., R. 2 W.	38.9	Pasture/undeveloped land within active aggregate quarry and processing facility and undeveloped land includes rail siding	Soil Association: Ruch-Medford-Takilma (OR059) Soil Mapping Units (Jackson County): 10B, 31A, 55A, 133A Sensitive Soil Characteristics: 1
Klamath Amuchastegui Building	Klamath	Section 10, T. 39 S., R. 9 E.	25.5	Existing commercial site and undeveloped industrial lots adjacent to rail siding	Soil Association: Fordney-Calimus-Poman (OR059) Soil Mapping Units (Klamath): 19A, 90 Sensitive Soil Characteristics:1, 5
Klamath Falls Industrial Oil	Klamath	Sections 8, 9 & 10, T.39 S., R. 9 E.	39.5	Undeveloped Industrial Lots adjacent to highway, rail and rail sidings	Soil Association: Malin-Laki-Henley (OR008) Soil Mapping Units (Klamath): 7C, 18A, 74D Sensitive Soil Characteristics: 1, 4
Klamath Falls North of Cross Road East	Klamath	Section 1, T. 40 S., R.9 E.	7.0	Farmland, adjacent to rail siding	Soil Association: Fordney-Calimus-Poman (OR059) Soil Mapping Units (Klamath): 58A Sensitive Soil Characteristics: 1, 4
Klamath Falls North of Cross Road West	Klamath	Section 1, T. 40 S., R.9 E.	37.0	Agricultural Field	Soil Association: Fordney-Calimus-Poman (OR059) Soil Mapping Units (Klamath): 58A Sensitive Soil Characteristics: 1, 4

a Acreages are rounded to nearest tenth acre.
b/ Sensitive Soil Characteristics:
1 – All soils within this mapping unit (based on SSURGO geographic databases) are considered prime farmland soil or farmland of statewide importance.
2 – These soils are positioned on floodplains and stream terraces and have soil components within the mapping unit that may be poorly drained and have either seasonal high water tables at or near the surface and have surface soils that are susceptible to compaction impacts and some that are susceptible to occasional or rare flooding.
3 – These soils have low strength and are susceptible to compaction especially if wet.
4 – Shallow to bedrock or duripan
5 – Seasonal high water table

Pacific Connector would use appropriate erosion control measures to minimize potential impacts at the yards. After the pipeline is constructed, the temporary yards would be restored to their previous condition and use.

The Coquille Yard is identified as a TEWA intended for use as a contractor yard for staging pipe, equipment, or other construction supplies and materials. Based on historical information, contaminated soil at the site was removed and treated in a soil treatment area and the site was encapsulated with fill dirt from ODOT in 1995. In 1998, the ODEQ recommended no further action for the site. Pacific Connector has identified this yard for staging of pipe, equipment or other construction supplies and materials and the use would be surface use only. Minor surface grading would be limited to pushing berms as needed to support pipe joints. This limited use of the site is not expected to result in effects on the encapsulated area or in potential effects on human health, worker safety, or the environment. However, Pacific Connector would consult with the ODEQ prior to use of the site to confirm that the intended use is consistent with the protections required for this property. In addition, Pacific Connector would include pipeline contractor training regarding this site's status and history and would require that site excavation and disturbance be limited.

Access Roads

Most access roads for the pipeline would be existing federal (BLM and Forest Service), state, county, and private roads that intersect the proposed pipeline alignment. Where needed, Pacific Connector proposes to modify existing roads and construct new roads to ensure construction and operation access. Approximately 3.8 acres of soils would be disturbed to construct 10 TARs, and approximately 2.16 acres of soils would be permanently affected to construct or reconstruct 15 PARs. The TARs would be constructed using appropriate BMPs to minimize potential impacts and would be designed and constructed for their intended use. All TARs would be reclaimed (i.e., regraded, scarified, and replanted) upon completion of construction according to the landowner or agency requirements. Soils along PARs would be permanently compacted and unvegetated.

4.2.3 Environmental Consequences on Federal Lands

The causes and extent of environmental effects on soil resources from the proposed Project are described above. The Forest Service has determined that these effects will, in some areas and for some activities will exceed allowable thresholds for detrimental soil conditions established by the applicable forest plans. Therefore, the Forest Service has proposed plan amendments and compensatory mitigation actions to make provision for the proposed project.

The BLM has not established detrimental soil condition thresholds within the applicable Resource Management Plans and therefore has not proposed similar plan amendments.

4.2.3.1 Environmental Consequences on National Forest Lands

The Project may cause soil mixing, displacement, and compaction on the backfilled trench and the spoils side of the corridor, steep slopes in some locations, and rocky soils where subsoil ripping would not effectively be restored to a condition with less than 15 percent increase in bulk density. As a result, an estimated 30 to 70 percent of the project area would likely have detrimental soil conditions from mixing, displacement, or compaction. Complete rehabilitation would also require recovery of the soil biology, which requires restoration of the soil organic matter and time. Some surface erosion is likely to occur; however, 85 to 95 percent of surface erosion can be prevented or trapped on-site by application of measures in the ECRP. Any surface erosion that does occur is expected to be minor, and within the range of natural variability for watersheds in southwest Oregon (see appendix F.4).

The Project may cause sediment transport from construction clearing and use of roads by the project. As part of the Project mitigation, road sediment reduction projects are aimed at reducing the chronic contributions of fine-grained sediment from road surfaces and fill failures to stream systems. As described in chapter 2, table 2.1.5-1, mitigation activities include decommissioning of 93.9 miles of Forest Service roads. Proposed road decommissioning would increase infiltration of precipitation, reduce surface runoff, and reduce sediment production from road-related surface erosion in the watershed where the impacts from the Project occur. Sediment reduction would also include closure of about 1.2 miles of Forest Service roads, reducing fine-grained sediments by eliminating traffic impacts.

LRMPs for the Umpqua, Rogue River, and Winema National Forests have standards and guidelines that establish thresholds for detrimental soils conditions as shown in table 4.2.3.1-1.

TABLE 4.2.3.1-1

Thresholds for Detrimental Soil Conditions on NFS Lands

Rows and columns may not add correctly due to rounding. Acres rounded to nearest whole acre (values below 1 are shown as "<1").
a/ Total Project Acres is all acres within the right-of-way. This includes cleared and uncleared areas.
b/ Cleared Acres are the construction corridor and TEWAs.
c/ Threshold Acres Allowed is the threshold from the standards and guidelines times the Total Project Acres.
d/ Projected Acres in Detrimental Conditions is estimated at 30 percent (minimum) to 70 percent (maximum) of the Cleared Acres.

Detrimental soil conditions are measured upon completion of a project after restoration and rehabilitation work is completed. Detrimental soil conditions are defined in each national forest LRMP, but generally include:

- compaction, which is defined as an increase in bulk density of 15 percent when compared to adjacent undisturbed soils for all soils except volcanic ash or pumice. For volcanic ash soils, compaction is defined as a 20 percent increase in bulk density when compared to adjacent undisturbed soils;
- displacement or mixing, which is the horizontal removal by mechanical means of 50 percent or more of the topsoil or "A" horizons, or mixing of these layers with less fertile subsurface mineral layers such that the continuity of the horizons is lost; and
- detrimental puddling, which is the physical change to soil structure that results when traffic ruts and molds a soil to a depth of 6 inches or more.

Precise estimates of detrimental soil conditions likely to exist at completion of a project are impossible to make. For the purposes of this assessment, 30-70 percent of the pipeline project area may be in a detrimental soil condition upon completion of all soil restoration and rehabilitation efforts. Table 4.3.2.2-1 provides an estimate of predicted detrimental soil conditions. Where projected acres exceed the threshold, an amendment of the affected LRMP is necessary to make provision for the Pacific Connector Pipeline Project.

The impacts of detrimental soil conditions include:

- a possible reduction in soil productivity from mixing or displacement of nutrient-bearing soil layers; and
- a potential increase in runoff and erosion from decreased infiltration of compacted soils.

See section 4.3.4 for measures that would be applied on federal lands to address these issues.

Amendments of Forest Plans Related to Thresholds for Detrimental Soil Conditions

Where detrimental soil conditions exceed the threshold established in an LRMP, an amendment of the LRMP is necessary for the Project to proceed. The following amendments of National Forest LRMPs are proposed to waive limitations on detrimental soil condition thresholds to make provision for the Project. Additional discussion of forest-specific management direction related to soil conditions is provided in section 4.7.3.

UNF-3. Project-Specific Amendment to Waive Limitations on Detrimental Soil Conditions Within the Pacific Connector Right-of-Way in All Management Areas[63]

For planning purposes, soil impacts are considered long term. Soil compaction and displacement would be confined to the project area, but predicting how much would be affected is an estimate based on professional judgment and the nature of corridor construction. See section 4.3.2.3 for a discussion of environmental consequences.

The Project would likely result in a detrimental soil condition on 30 to 70 percent of the project area on the Umpqua National Forest (165 acres) due to displacement and compaction. Approximately 11 of those acres would likely be in Riparian Reserves. Compaction can largely be addressed by subsoil ripping, but displacement would be unavoidable because of the nature of the Project. Existing LRMP standards and guidelines allow up to 20 percent of the project corridor (about 33 acres of the corridor on the Umpqua National Forest) to be in a degraded soil condition upon completion of a project. The Pacific Connector Pipeline Project would exceed these thresholds by about 8 to 71 acres on the Umpqua National Forest. These impacts would be spread over four separate fifth-field watersheds. See section 4.7.3 and appendix F.4, Aquatic Conservation Strategy Assessment, for a watershed-specific evaluation. Amendment of the Umpqua National Forest LRMP to waive limitations on detrimental soil conditions is not expected to prevent attainment of Aquatic Conservation Strategy objectives (section 4.7.3 and appendix F.4). See section 4.7.3 for a discussion of this amendment in the context of the Umpqua National Forest LRMP.

[63] Forest-Wide Soils Standard and Guideline #1 (Umpqua LRMP IV-67)

RRNF–6. Project-Specific Amendment to Waive Limitations on Detrimental Soil Conditions Within the Pacific Connector Right-of-Way in All Management Areas[64]

The Pacific Connector Pipeline Project would likely result in a degraded soil condition on an estimated 30 to 70 percent of the pipeline right-of-way on NFS lands in the Rogue River National Forest (all in the Little Butte Creek Watershed) due to displacement and compaction (Orton 2009). Compaction can largely be addressed by subsoil ripping, but displacement would be unavoidable because of the nature of the project. Existing LRMP standards and guidelines allow up to 10 percent or 28 acres of the pipeline corridor to be in a degraded soil condition on completion of a project. Thus, the pipeline project would likely exceed this threshold by about 34 to 117 additional acres or 0.07 to 0.2 percent of the 57,234 acres (NFS lands only) within the Little Butte Creek Watershed upon completion. About 2 to 6 acres of degraded soil conditions above LRMP thresholds may be in Riparian Reserves. See section 4.7.3 and appendix F.4, Aquatic Conservation Strategy, for a watershed-specific evaluation of consequences. Amendment of the Rogue River National Forest LRMP to waive limitations on detrimental soil conditions is not expected to prevent attainment of Aquatic Conservation Strategy objectives (section 4.7.3 and appendix F.4). See section 4.7.3 for a discussion of this amendment in the context of the Rogue River National Forest LRMP.

WNF-4 and WNF-5: Project-Specific Amendment to Waive Limitations on Detrimental Soil Conditions within the Pacific Connector Right-of-Way in All Management Areas[65]

These standards and guidelines of the Winema National Forest LRMP restrict the amount of an area that may be in a degraded soil condition as a result of a management activity. They are considered together here because the assessment is the same for both standards.

The Pacific Connector Pipeline Project would likely result in a degraded soil condition on an estimated 30 to 70 percent project right-of-way on NFS lands in the Winema National Forest (all in the Spencer Creek Watershed) due to displacement and compaction (Orton 2009). Compaction can largely be addressed by subsoil ripping, but displacement would be unavoidable because of the nature of the project. Existing LRMP standards and guidelines allow up to 10 percent (1.5 acres) of the project corridor in Management Area 8 Riparian Areas or 20 percent (17 acres) in the pipeline corridor outside of Management Area 8 to be in a degraded soil condition on completion of a project. Thus, the pipeline project would likely exceed this threshold by an estimated 5 to 38 additional acres or 0.03 to 0.16 percent within the Spencer Creek watershed upon completion. See section 4.7.3 and appendix F.4, for a watershed-specific evaluation of consequences. Amendment of the Winema National Forest LRMP to waive limitations on detrimental soil conditions is not expected to prevent attainment of Aquatic Conservation Strategy objectives (section 4.7.3 and appendix F.4). See section 4.7.3 for a discussion of this amendment in the context of the Winema National Forest LRMP.

Cumulative Impacts, All Units

Cumulatively, on the Umpqua, Rogue River, and Winema National Forests, detrimental soil conditions within the pipeline project area are expected to range between about 135 and 317 acres

[64] Standards and guidelines in the Rogue River National Forest LRMP (pp. 4-41, 4-83, 4-97, 4-123, 4-177, 4-307)
[65] Winema National Forest LRMP Management Direction for Riparian Areas page 4-73 (WNF-4) and 4-137 (WNF-5).

(table 4.3.3.3-1), or about 47 to 226 acres over the combined LRMP threshold for the pipeline project of 91 acres. Assuming an even distribution over the 30.6-mile NFS part of the pipeline project area, this equals about 2 to 8 acres of detrimental soil conditions above the LRMP thresholds for each mile of pipeline, spread over six separate fifth-

Mitigation also includes storm-proofing of 11.4 miles of Forest Service roads would reduce sediment from roads by increasing the resistance of a road to failure during high-intensity rainfall events. Storm-proofing strategies include improving drainage, reducing diversion potential at culverts, outsloping road surfaces and replacing culverts with hardened low water fords. Road sediment reduction activities would result in approximately 207 total acres (assuming a typical 16-foot wide roadway) of long-term sediment mitigation on federal lands.

Road stabilization and culvert replacement of 11 sites on NFS lands would reduce road-related sediment by stabilizing or removing failing cut and fill slopes. Culvert replacement reduces sediment by replacing undersized or failing culverts with culverts that are appropriate to pass debris at higher flows. This reduces the probability of fill failure associated with plugged culverts.

The locations of the road sediment reduction activities are listed in table 4.2.3.1-2.

TABLE 4.2.3.1-2

Mitigation Projects to Address LMP Amendments on NFS Lands

Unit	Watershed	Mitigation Group	Project Type	Project Name	Quantity	Unit

a/ Mileages are rounded to nearest tenth of a mile.

4.2.3.2 Soil Risk and Sensitivity Assessment

At the request of the BLM and Forest Service, Pacific Connector identified areas on BLM and NFS lands along the proposed Project where there is a low vegetation recovery potential. These soils included combined characteristics including high or severe erosion potential, steep slopes, large stones, shallow soils, saline/sodic conditions, clayey soils (greater than 40 percent), and soil map units with dominant amounts of rock outcrop. Certain types of disturbed soils where residual soil compaction exists in subsurface soil layers, topsoil has eroded, soil horizons have been mixed, and/or topsoil has been removed, can lead to conditions where revegetation can be very difficult, no matter what mitigation methods are employed.

In order to specifically identify areas of revegetation concern where more rigorous mitigation might be required, a Soil Risk and Sensitivity Assessment was performed for the BLM and Forest Service in 2015. The intent of the assessment was to identify the areas where additional soil decompaction, erosion control, or other types of site-specific and focused remediation measures may be required on BLM and NFS lands to minimize erosion potential and/or accomplish agency revegetation objectives. Soil risk and sensitivity factors were identified by a BLM/Forest Service team including four criteria in the assessment of the risk element; plant mortality, soil erosion, slope rating and aspect; and three levels of sensitivity, primarily based on qualitative values related to management objectives.

As depicted in table 4.2.3.2-1, approximately 83 percent of the Project area, or about 1,143 acres, is rated as Level 1 – very low or Level 2 – low for combined risk and sensitivity. These are locations where revegetation measures are expected to be successful with decompaction and other standard methods described in the ECRP. Approximately 18 percent of the Project area, or about 237 acres, is rated as Level 3 – moderate or Level 4 – high for combined risk and sensitivity where more aggressive erosion controls and/or soil remediation are likely to be needed.

TABLE 4.2.3.2-1

	Total	**328**	**814**	**183**	**54**	**<1**

Note: Rows and columns may not sum correctly due to rounding. Acres rounded to nearest whole acre (values below 1 are shown as "<1").

Areas rated as Level 3 – moderate (about 183 acres or 13 percent of the Project) had either high risk or high sensitivity but not both, or were ranked as moderate for both criteria. Areas that ranked as Level 4 – high (about 54 acres or 4 percent of the Project) had both high sensitivity and high risk and would be considered high priority areas for aggressive soil remediation. Less than one acre was ranked Level 5 – very high and considered to have a very high priority for aggressive restoration measures.

Areas ranked a Level 3 – moderate to 5 – very high (237 acres total) would be recommended for more site-specific validation of the risk criteria used in this assessment to confirm that specific locations merit consideration of the more aggressive soil remediation measures listed below:

- a 2- to 3-inch organic mulch surface application (80 percent coverage) of woodchips, logging slash, and/or straw;
- adaptive seed mixes and vegetation to better fit site conditions;
- deep subsoil decompaction with hydraulic excavators that leave constructed corridor mounded and rough with maximum water infiltration so that water cannot flow downhill for any appreciable distance;
- more aggressive use of constructed surface water runoff dispersion structures such as closely placed and more pronounced slope dips and water bars, etc.;
- more aggressive use of constructed surface runoff entrapments such as silt fencing, sediment settling basins, or straw bale structures, etc.;
- more aggressive placement (100 percent coverage) and depth (3 to 4 inches) of ground cover using woodchips, logging slash, straw bales, wattles, etc.; and
- priority monitoring of results as needed to measure success or make future recommendations.

4.2.4 Conclusion

Constructing the Project would result in both short-term and long-term permanent impacts on soils, including soils characterized for reclamation sensitivity. However, based on the applicants' proposed construction and operations procedures, methods, and plans to address known and unanticipated soil contamination, and the implementation of impact minimization and mitigation measures, we conclude that constructing and operating the Project would not significantly affect soils.

4.3 WATER RESOURCES AND WETLANDS

4.3.1 Groundwater

4.3.1.1 Jordan Cove LNG Project

The Jordan Cove LNG Project area is underlain by the unconfined Dune-Sand Aquifer. This aquifer is located within unconsolidated deposits of sand and gravel, which may also contain variable quantities of silt and clay (USGS 2009b). The Dune-Sand Aquifer is generally 100 feet thick (USGS 1992). The aquifer extends to a depth of -160 feet below sea level. Groundwater has been found within about 8 to 10 feet depth at the terminal and fluctuates with the tides and seasonal precipitation. Because the terminal site is bordered on three sides by saltwater bodies, saltwater intrudes into the aquifer and influences groundwater quality (GSI 2017). Iron concentration is also an existing groundwater concern in the area.

High concentrations of iron in shallow groundwater arise from leaching that occurs as rainfall percolates through vegetative litter (such as leaves and pine needles) and into the underlying dunal sands (GSI 2017). Once the percolating water reaches the water table, the iron remains dissolved in the shallow groundwater and can migrate deeper into the aquifer at and near the CBNBWB production wells, which are all screened at depths of 50 feet and greater. Historically, the CBNBWB has observed higher iron concentrations in water from some of its production wells at the northern end of the west wellfield. As part of its wellfield management plan, pumping from these wells was terminated indefinitely to reduce the downward migration of high-iron groundwater from the shallow portion of the aquifer in that area. CBNBWB would not use those wells to meet the Jordan Cove LNG Project's water supply needs.

Information maintained by the OWRD indicates that there are four groundwater wells permitted for industrial use and fire protection by the Roseburg Forest Products located within or near the disturbance area. Additionally, the CBNBWB maintains 18 non-potable, groundwater withdrawal wells north of the terminal site. The closest CBNBWB well is about 3,500 feet north of the terminal site.

A review of EPA's sole source aquifer (SSA) mapping revealed that the closest SSA is approximately 40 miles north-northeast of the Jordan Cove LNG Project.[66] Additionally, a review of ODEQ data showed that the site would not overlie any Groundwater Management Areas where groundwater contamination from non-point source activities warrants state intervention.

Impacts and Mitigation

Jordan Cove would obtain water from the CBNBWB to construct and operate the Jordan Cove LNG Project. As shown in table 4.3.1.1-1, Jordan Cove estimates that it would need a total of about 667 million gallons of water for construction and operation of the Jordan Cove LNG Project.

[66] EPA defines an SSA area as one that supplies at least 50 percent of the drinking water consumed in the area overlying the aquifer. EPA guidelines also stipulate that these areas can have no alternative drinking water source(s) that could physically, legally, and economically supply all those who depend upon the aquifer from drinking water (EPA 2013).

TABLE 4.3.1.1-1

Projected Water Usage for the Proposed Jordan Cove LNG Project

Construction			
Activity	**Total (million gallons)**	**Peak Use (thousand gallons per month)**	**Potable (Y/N)**
General Construction Activities	11.3	382.0	N
Grading Activities	488.4	21,861.0	N
LNG Tank Hydro	60.0	30,000.0	N
Drinking Water	1.7	57.0	Y
Concrete Batch Plant	7.2	275.0	Y
Workforce Housing	26.9	1,102.0	Y
TOTAL	**595.5**		
Operation			
Source of Operation- Phase Water Demand	**Annual Water Demand (million gallons)**	**Average Instantaneous Flowrate (gallons per minute)**	**Potable (Y/N)**
Process Water Makeup	36.3	69	Y
Quench Water	15.8	30	Y
Plant Water	15.8	30	Y
Buildings	3.7	7	Y
TOTAL	**71.5**		

Constructing and operating the Jordan Cove LNG Project could affect groundwater, because of the shallow depth to groundwater and the permeability of the overlying sands and gravels across the site. Site stabilization, excavation, pile driving, and the installation of permanent aboveground facilities could all affect groundwater. In addition to the permanent modification of site topography which could affect underlying groundwater characteristics (quantity, flow, and quality); an inadvertent release of equipment-related fluids, such as lubricating oil, gasoline, and diesel fuel, could affect groundwater. Installing piles to support the Jordan Cove LNG Project could create vertical conduits further affecting underlying groundwater characteristics. Additionally, these conduits could also transmit contaminants.

Three of four Roseburg Forest Products wells would be buried to create a construction staging area and would be permanently abandoned in accordance with state regulations. Jordan Cove would drill new wells to the east to replace the buried wells. The fourth well would remain in place. We conclude that neither construction nor operation of the Project would impact the CBNBWB wells to the north due to the distance of the wells from the Project (the closest CBNBWB well is about 3,500 feet north of the terminal).

The excavation and grading required to create the marine slip could cause local groundwater elevations to shift as a result of the change in topography; however, this change would be minor and localized. Creating the marine slip would also shift the seawater interface inland, but it would not affect the water supply wells.

Based on the depth to groundwater, dewatering would be required during construction of the marine slip. The anticipated method for dewatering is the use of well-points, which consist of a closely spaced series of small-diameter shallow wells connected to a dewatering pump via a common headermain (i.e., a pipe that context to the dewatering pump). The contractor would determine the most appropriate method for dewatering excavations and obtain appropriate permits prior to construction. All water associated with dewatering would be allowed to infiltrate elsewhere onsite and return to the groundwater table. Water associated with construction dewatering would not be directly discharged to waterbodies until either filtered or directed to a settling pond before discharge in accordance with Jordan Cove's ESCP and their *Plan* and *Procedures*. A monitoring program would be conducted prior to, during, and after construction to monitor potential impacts on ground and surface waters. Dewatering would have temporary, localized effects on groundwater movement, but flow patterns would return to normal soon after construction.

An inadvertent equipment-related fluid spill could adversely affect groundwater quality. The significance of the effect would vary depending on fluid, quantity spilled, and location of the spill. To prevent and reduce the potential of a spill and the resulting impact on groundwater, Jordan Cove would implement measures as described in its SPCC Plan.[67] These measures include refueling procedures; spill response procedures, spill response materials, and training; countermeasures/contingency plan; and hazardous liquids storage, and disposal. Spill-related impacts during operation of the Jordan Cove LNG Project would mainly be associated with fuel storage, facilities use, equipment refueling, and equipment maintenance, which would be prevented or minimized with the implementation of Jordan Cove's SPCC Plan.

The terminal site would have a system of curbs, drains, and basins to collect and contain any spills of LNG during operation. In the unlikely event that LNG is spilled, the cryogenic liquid would vaporize rapidly upon contact with the warm air and water. Because LNG is not soluble in water and would completely vaporize shortly after being spilled, the LNG could not mix with or contaminate groundwater.

During operation, the LNG terminal would cover about 100 acres with impervious surface materials, such as asphalt, concrete, and compacted gravel. The conversion of pervious surface to impervious surface can typically cause a decrease in the local recharge of shallow groundwater (by converting infiltration to runoff); however, Jordan Cove would capture most runoff for infiltration into the ground on-site with only high flows expected to run off directly to the bay. Additionally, in comparison to the total 12,480-acre area of the Dune-Sand Aquifer, this 0.8 percent area reduction would not likely result in an adverse effect on the level of groundwater in the area. Through use of the measures discussed above, we conclude that impacts on groundwater resources at the Jordan Cove LNG Project would be minimized to the extent practicable and would not be significant.

Five domestic supply wells in the vicinity of the Kentuck project were evaluated for their vulnerability to saltwater intrusion caused by inundation of the former golf course area as part of the Project wetland mitigation. Of the five wells, two were determined to be moderately to highly vulnerable to Project impacts, and a third was found to have low to moderate vulnerability. Jordan Cove has initiated discussions with the landowners regarding mitigation strategies to offset potential effects on these wells, including well replacement, and other means of settlement.

[67] The preliminary SPCC Plan was included in Jordan Cove's September 2017 application to the FERC as Appendix F.2 to Resource Report 2. The preliminary Spill Plan provides general content but would be updated prior to the start of construction to final detail.

4.3.1.2 Pacific Connector Pipeline Project

The Pacific Connector pipeline (and associated facilities) would be located above four general aquifer types: unconsolidated-deposit; pre-Miocene rock; volcanic and sedimentary rock; and Pliocene and younger basaltic rock.

Unconsolidated-deposit Aquifers – The pipeline would overlie unconsolidated-deposit aquifers for approximately 7.6 miles in and around Coos Bay (between MPs 3.0 and 23.4), 3.1 miles in Douglas County between MPs 55.3 and 69.7, and 23.0 miles in the Klamath Basin between MPs 191.9 and 214.9. These aquifers consist primarily of sand and gravel and are the most productive and widespread aquifers in Oregon. These unconsolidated-deposit aquifers typically provide freshwater for most public-supply, domestic, commercial, and industrial purposes (USGS 1994).

Pre-Miocene Rock Aquifers – The majority of the pipeline route between MPs 23.5 and 155.8 would overlie aquifers in pre-Miocene rocks. These aquifers consist of undifferentiated volcanic rocks, undifferentiated consolidated sedimentary rocks, and undifferentiated igneous and metamorphic rocks principally in the mountainous areas crossed by the pipeline. Within and west of the Cascade Range, the consolidated sedimentary rocks are of marine origin and commonly yield salt water. At depth, the salt water can contaminate overlying freshwater aquifers. Permeability of the aquifers varies greatly. Water from wells completed in these aquifers is used mostly for domestic and agricultural (livestock watering) supplies (USGS 1994).

Volcanic and Sedimentary Rock Aquifers – Northeast of Medford, the pipeline route enters a groundwater area of volcanic and sedimentary rock aquifers for about 8.2 miles between MPs 134.2 and 156.9. These aquifers consist of a variety of volcanic and sedimentary rocks that generally yield fresh water but locally can yield salt water. About 30 percent of the fresh groundwater withdrawals are used for public supply, about 20 percent are used for domestic and commercial, and about 50 percent are used for agricultural (primarily irrigation) purposes (USGS 1994).

Pliocene and Younger Basaltic-rock Aquifers – In the Klamath Basin, between MPs 191.9 and 228.8, the pipeline route passes through an area of Pliocene and younger basaltic-rock aquifers for about 51 miles while also passing in and out of unconsolidated deposit aquifers. Pliocene and younger basaltic-rock aquifers yield fresh water that is used mostly for agricultural (primarily irrigation) purposes (USGS 1994).

Depth to groundwater varies throughout the Project area. Approximately 26 miles (or 13 percent) of the pipeline route would cross areas of shallow groundwater where the water table ranges from zero to 6 feet bgs. Approximately 16 of those 26 pipeline miles would be in areas that have seasonally high groundwater (fall through spring) and the remaining 10 pipeline miles, primarily in the Klamath Basin, would be located in areas with shallow groundwater year-round.

Groundwater-fed springs and seeps were identified along the pipeline route during wetland surveys and by review of aerial photos. Additional springs and seeps may be identified by landowners during easement negotiations and through contact with adjacent property owners. The owners would be asked to identify springs and seeps and their uses. For springs and seeps located within

200 feet of the construction disturbance, Pacific Connector would implement its *Groundwater Supply Monitoring and Mitigation Plan*.[68]

No EPA-designated SSAs would be crossed by the Pacific Connector pipeline. The nearest EPA-designated SSA is located approximately 40 miles to the north.

The 1996 federal Safe Drinking Water Act (SDWA) requires Source Water Assessments for all public water systems that have at least 15 hookups, or serve more than 25 people year-round. About 80 percent of Oregonians get their drinking water from public water systems. The Oregon Health Authority and the ODEQ Drinking Water Protection Program jointly manage the SDWA assessment requirements. ODEQ maintains the Drinking Water Protection database[69], which includes public drinking water source areas for groundwater and surface water, as well as the locations of public water system intakes and public groundwater wells. ODEQ has identified and established wellhead protection areas (WHPAs) to protect public drinking water sources. The SDWA defines a WHPA within the recharge area of a well as the surface and subsurface area surrounding a water well or well field, supplying a public water system, through which contaminants are reasonably likely to move toward and reach such a water well or well field. The pipeline would cross six WHPAs as shown in table 4.3.1.2-1 (ODEQ 2017e). One pipe yard is located within the Klamath Auction Cafeteria WHPA, and one rock source and disposal site (Rum Rye/MP 160.41) is located within the Medford Water Commission WHPA.

TABLE 4.3.1.2-1

Wellhead Protection Areas Crossed by the Pacific Connector Pipeline Project

Starting Milepost	Ending Milepost	County	Public Groundwater Source Area	Public Drinking Water System ID
6.38R	6.74R	Coos	Kentuck Golf Course	4190858
195.09	196.29	Klamath	Production Metal Forming, Inc	4195058
197.43	197.77	Klamath	Green Diamond Resources Services LLC	4193994
198.45	199.62	Klamath	Collins Products LLC	4193995
199.26	199.66	Klamath	Columbia Plywood Corp	4194403
200.54	201.12	Klamath	Crossroads Mobile Home Park	4100446

There are also numerous private wells located along the pipeline route that are exempt from water rights permitting and the locations are not known. To identify these unmapped wells, Pacific Connector would ask the property owners to identify their wells and the water use. For wells located within 200 feet of the construction disturbance, Pacific Connector would implement its *Groundwater Supply Monitoring and Mitigation Plan*. Table 4.3.1.2-2 lists the seven private wells within 200 feet of the construction work area for which location information was available (OWRD 2017).

[68] Included in Pacific Connector's application to the FERC as Appendix F.2 of Resource Report 2.
[69] According to the ODEQ water quality mapping and GIS data page, for security reasons, the agency restricts access to the GIS layers with latitude/longitude readings of wells, springs and intakes (ODEQ 2017e).

TABLE 4.3.1.2-2

Private Wells Within 200 Feet of Construction Work Space for the Pacific Connector Pipeline Project

Milepost	Permit Number	Use	Distance to Construction Area (feet)
190.8	10354	Irrigation	85

b/ Well located 55 feet from Millington 1 Yard

Impacts and Mitigation

Construction activities such as; grading, trenching, dewatering, and backfilling could cause minor fluctuations in shallow groundwater levels, increase turbidity within shallow groundwater and alter the flow path of springs and seeps.

As described previously, approximately 26 miles of the pipeline route would cross areas where groundwater can be found at or very near the surface. In areas with a high groundwater table where standard dewatering may be insufficient, Pacific Connector may use “push-pull” or “float” techniques to install the pipeline. While the installation of trench breakers and trench dewatering by pumps to an upland area may be feasible for small areas of seasonally high groundwater, we note that some of these shallow groundwater areas could extend over 1.6 miles (see table H-4 in appendix H). For longer stretches of the pipeline route, trench dewatering through a well point pumping system with a groundwater treatment plan (such as controlled discharging to a straw bale structure or filter bag) may be required. Dewatering may locally lower the groundwater table and alter flow paths; however, these impacts would be temporary, and the dewatering typically occurs over a few days. If there are wells, seeps, or springs near the dewatering activities, they would be monitored for effects.

Near-surface soil compaction caused by heavy construction vehicles could reduce a soil’s ability to absorb water, which would affect infiltration/groundwater recharge rates and could affect underlying groundwater flow and quality. To minimize these impacts excavated topsoil and subsoils would be segregated within wetlands, agricultural areas, and at the request of landowners, and returned as closely as practical to their original soil horizon and slope position. Following construction, restoration of compacted soils would include regrading, recontouring, scarifying (or ripping), and final cleanup activities. Decompacting soils would restore water infiltration, reduce surface water runoff, minimize erosion, and support revegetation efforts.

There are 116 sites with cleaned-up, potential, or confirmed soil and/or groundwater contamination within 0.25 mile of the pipeline route where there is the potential to encounter contaminated soil or groundwater during construction. The potential to encounter previously contaminated soils and groundwater is evaluated and discussed in the Contaminated Soils and Groundwater section under section 4.2.2.3.

A spill or inadvertent release of equipment-related fluids could adversely affect underlying groundwater quality and use. To minimize the potential for a spill or inadvertent release, Pacific Connector would implement numerous measures as described in its SPCC Plan.[70] These measures include, but are not limited to:

- regular inspection of containers and tanks;
- use of secondary containment of fuel storage tanks and hazardous materials containers 55-gallons or greater;
- implementation of emergency response procedures, including spill reporting procedures; and
- use of standard procedures for excavation and off-site disposal of any soils contaminated by spillage.

Prior to construction, Pacific Connector would include in the SPCC Plan the types and quantities of hazardous materials that would be stored or used during construction. Project personnel would be trained and prepared to demonstrate their ability to implement the SPCC Plan to federal, state, or local inspectors.

In addition to the SPCC Plan, Pacific Connector would implement the measures described in its *Contaminated Substances Discovery Plan*[71] to address an unanticipated discovery of contaminants during construction. As described previously, this plan outlines practices to protect human health and worker safety and measures that would be taken to prevent further contamination.

As described in section 4.1, Pacific Connector has identified numerous locations where blasting may be required for pipeline installation. Blasting could temporarily increase turbidity in groundwater. Pacific Connector has developed a *Blasting Plan*[72] to minimize potential adverse impacts on the environment, nearby water sources, structures, or utilities. As stated in the *Blasting Plan*, licensed blasting contractors would conduct the blasting activities in accordance with all applicable federal, state, and local regulations. Pacific Connector would obtain all necessary permits if blasting is required.

Constructing the Project could affect springs, seeps, and wells. Depending on the location of a well, spring or seep relative to the pipeline, the flow of the feature could be temporarily or permanently affected. These resources could be redirected and experience changes in quantity and quality. To minimize potential impacts, prior to construction, Pacific Connector would implement the measures described in its *Groundwater Supply Monitoring and Mitigation Plan.* Landowners would be supplied with documentation that explains the proposed pipeline construction methods, and outlines the pre-construction field investigation for the identification and monitoring of groundwater supplies. Pre-construction surveys would be conducted to confirm the presence and locations of all groundwater supplies for landowners within and adjacent to construction workspace. Pacific Connector would conduct post-construction sampling if requested by the landowner or in disputed situations to determine the effects of construction, if any, on the

[70] The SPCC Plan was included in Pacific Connector's September 2017 application to the FERC as Appendix B.2 to Resource Report 2.
[71] Included in Pacific Connector's September 2017 application to the FERC as Appendix E of the POD.
[72] The *Blasting Plan* was included in Pacific Connector's September 2017 application to the FERC as Appendix C of the POD.

groundwater supply. The landowner would be provided with a point of contact with Pacific Connector to report potential problems with wells, springs, and seeps believed to be the result of construction. If a groundwater supply is affected by the Project, Pacific Connector would work with the landowner to provide a temporary supply of water; if determined necessary, Pacific Connector would provide a permanent water supply to replace affected groundwater supplies. Mitigation measures would be coordinated with the individual landowner to meet the landowner's specific needs and be specific to each property.

Operation of the aboveground pipeline facilities would include connections to fixed belowground pipes. Pacific Connector would conduct monitoring in accordance with the DOT requirements during operations to minimize the potential of corrosion and leaks that could affect groundwater. Additionally, Pacific Connector would implement BMPs as detailed in the ECRP and SPCC Plan to avoid, minimize, and mitigate the spill of any hazardous substances that could affect shallow groundwater and/or unconsolidated aquifers.

4.3.1.3 Conclusion

The construction of the Project would temporarily affect groundwater. However, based on the characteristics of underlying groundwater, the applicant's proposed construction and operations procedures and methods, and their implementation of impact minimization and mitigation measures, we conclude that constructing and operating the Project would not significantly affect groundwater resources.

4.3.2 Surface Water

The surface waters in the Project area include marine waters along the shipping route within 3 nautical miles of the coast, Coos Bay, and adjoining surface waters, and streams crossed by or near Project facilities extending from Coos Bay about 229 miles to the connecting point of the proposed pipeline in Klamath County in eastern Oregon. State and federal laws and regulations that will affect Project actions related to surface waters are discussed in chapter 1. Waters having special status relative to some of these laws and regulations are discussed below. The discussion is separated into two sections, the first dealing with effects on waters from actions relating to the development and operation of the Jordan Cove LNG Project and the second addressing actions related to the development and operation of the Pacific Connector pipeline.

4.3.2.1 Jordan Cove LNG Project

The Jordan Cove LNG Project would be located in Coos Bay, Oregon. Coos Bay is a major coastal estuary with a surface area of about 12,380 acres at mean high water. Coos Bay is fed by about 30 tributaries, including the Coos River, Millicoma River, Catching Slough, Isthmus Slough, Pony Slough, South Slough, North Slough, Kentuck Slough, and Haynes Inlet. The estimated average annual discharge at the mouth of Coos Bay is 2.2 million acre-feet of fresh water (Roye 1979). The Coos Bay watershed covers an area of approximately 739 square miles of Oregon's southern coastal range and is included in the larger South Coast Watershed Basin (ODEQ 2012b).

The existing Federal Navigational Channel is used by recreational, fishing, and major transport vessels to access multiple locations within Coos Bay from the open ocean and coastal marine waters. Four areas adjacent to the Federal Navigation Channel would be modified (see chapter 2 of this EIS) and used by LNG carriers transiting to the Jordan Cove LNG Project. Between the existing navigation channel and the terminal marine slip, Jordan Cove would create a new access channel. The Oregon Institute of Marine Biology (OIMB) sampled physical oceanographic data in Coos Bay, near the proposed location of the terminal access channel, from August 2009 through December 2010 (Shanks et al. 2010, 2011). The OIMB data set included salinity, temperature, and Chlorophyll a. The OIMB data show there is little variation exhibited in salinity during the tidal cycle, but slightly lower salinity levels occur during low tides and slightly higher salinity levels during high tides. In contrast, temperatures are markedly higher during low tides than high tides. In effect, the results of the OIMB sampling program indicate that there is a great amount of seasonal, but only moderate daily, variability in the physical oceanographic data of the waters of Coos Bay near the Jordan Cove LNG Project.

Impact and Mitigation

The potential impacts and mitigation associated with the construction of the Jordan Cove LNG Project and LNG carrier traffic are related primarily to Project-related dredging, stormwater management, carrier travel, and carrier water use. The effects are related to increases in turbidity, suspended and deposited sediment, bottom and shoreline erosion, toxic substance releases, and water temperature changes.

Jordan Cove would not use surface water sources during construction[73] or operation of the terminal, and all waters discharged from the site would be treated prior to release, including decant water[74] returning from on-land dredge deposits. Permits would be obtained for all wastewater discharges as required by ODEQ. A more detailed presentation of water supply needs for both construction and operation is provided in section 4.3.1.1 and table 4.3.1.1-1.

There are no process water discharges anticipated from the liquefaction process. There would be some wastewater discharges from the oil-water separators that would be directed to the industrial wastewater pipeline. There are no anticipated changes to water quality in Coos Bay from the release of wastewater from the Jordan Cove LNG Project.

The ODEQ's Integrated Report includes Coos Bay on the Section 303(d) list of waterbodies not meeting the criteria for shellfish growing since 2004, due to elevated fecal coliform measurements. Coos Bay is listed as Category 5, water quality limited, and a Total Maximum Daily Load (TMDL) is needed (ODEQ 2012c). Wastewater generated during construction and operation of the Jordan Cove LNG Project would be treated by the City of North Bend's wastewater treatment system via a new sewer line, and therefore the Project is not likely to add fecal coliform to Coos Bay.

<u>Turbidity and Sedimentation</u>

Dredging and construction activities at the Jordan Cove LNG Project would result in temporary increases in turbidity and sedimentation in Coos Bay. Details on marine facility construction, including dredging activities, are provided in chapter 2 of this EIS. Dredging activity, primarily associated with slip, access channel, temporary material barge berth, MOF, and marine waterway modifications would be the major sources of turbidity and suspended sediment in Coos Bay. The

[73] Water from Coos Bay would be included with estuarine dredged bottom sediment transported to land storage areas; no reduction in Coos Bay water volume would occur from this water use.
[74] Water that is included with dredge bottom material from the bay that goes to on-land deposition areas will be held until sediment settles before it is returned to the access slip or adjacent bay areas. ESCP procedures will be implemented to meet turbidity discharge standards.

construction of the marine slip would have most of the slip dredging separated from the bay by an earthen berm and would not affect bay turbidity. Other sources of turbidity would include a dike rock pile apron, Trans-Pacific Parkway/U.S. 101 intersection widening, and various construction-related tailing lines placements.

All work in the bay would be done during the ODFW recommended in-water window between October 1 to February 15. Within the access channel, dredging would be conducted using a hydraulic (e.g., suction) dredge with a cutterhead or mechanical (e.g., clamshell) dredge. The applicant has indicated that the hydraulic cutter suction dredge is their preferred dredging method (due to the lower turbidity that would be generation) and would be used as the primary method; however, the mechanical dredge would need to be used in certain locations due to the presence of buried woody debris or other materials in the substrates that could not be removed using hydraulic methods (e.g., the mechanical dredging methods would be used in parts of the access channel near the shoreline and along the proposed modifications to the marine waterway).

Jordan Cove commissioned modeling efforts to estimate the range of turbidity and suspended sediment that would result from Project-related dredging (Moffatt and Nichol 2006a, 2017c). The models were developed based on a sediment analysis conducted at the site of the dredging and took into consideration wind, tidal currents, and seasonal flows. Moffatt & Nichol (2006a) indicated that constructing the access channel via mechanical dredging would result in a maximum concentration of turbidity of 600 to 6,000 mg/l depending on tidal velocity, decreasing substantially farther away from the site. The latest model (i.e., Moffat & Nichol 2017c) addresses suspended sediment concentrations from the proposed dredging operations. Constructing the slip and access channel would result in suspended sediment that would exceed about 20 mg/l over background levels within about 0.2 to 0.3 mile of the dredging site and exceed about 500 mg/l within about 0.1 mile with either dredging method (clamshell or cutter suction dredge) (Moffat & Nichol 2017c). Moffat & Nichol (2006a) noted maximum concentrations outside of the specific dredge location would only occur for about 2 hours or less over the daily tidal cycle with the plume moving upstream or downstream of the dredge site on flood or ebb tide, respectively. Moffatt & Nichol (2006a) indicated that due to this limited period of elevated suspended sediment in any site-specific area of the plume, other than the actual dredge area, average daily turbidity levels would remain near background values for the mechanical dredge at the slip during active dredging.

Turbidity models for both construction and maintenance of the four Marine Waterway Modifications areas were developed using the three possible dredging methods. Generally, suspended sediment levels would be similar to those modeled for the access channel, but distribution of sediment plumes would be more extensive. The cutter suction dredge would generally have lower concentrations of sediment than other options, but the overall maximum distribution of areas over background suspended sediment (about 20 mg/l) would be similar, averaging about 1.2 miles[75] from the specific active dredging site of the four channel expansion areas with any dredging methods. Turbidity levels and distribution would be similar for both construction or maintenance dredging. Overall levels of peak concentration dependent on method used, with cutter suction the lowest and hopper dredge the highest. Areas of high concentrations, over about 500 mg/l, would generally extend about 0.1 mile from dredge site for cutter suction and clamshell dredges and 1.0 mile for hopper dredge. Based on the Moffat & Nichol (2006a) model

[75] Plume distance noted includes total spread both upstream and downstream of dredge site.

of the access channel dredging, it would be expected that these peak levels would be short lived at any specific location. Given that, as noted above, tides would move the location of the sediment plume, higher concentrations in any location, other than near actual dredge location, would only last about 2 hours.

The model of the Eelgrass Mitigation site (Moffat & Nichol 2017c) assumed an excavator would be used, which would result in a confined area of elevated suspended sediment extending less than 0.1 mile from point of dredging. The more limited effect of tidal flow over the area would help confine the distribution of the elevated sediment plume. These elevated levels would be short term and highly localized to the nearshore area.

As noted above, sedimentation and turbidity would be higher during clamshell dredging than during hydraulic dredging operation. Clamshell dredging is also proposed for maintenance dredging of the slip and access channel, and potential effects are discussed below. Construction and maintenance dredging at the four marine waterway modification areas would be done via hydraulic dredging (cutter suction or hopper) or clamshell dredging, or a combination of these. Hydraulic placement of materials at the upland sites (e.g., APCO Sites 1 and 2, and Kentuck project site) is the preferred method for dredging including material transport with temporary subtidal dredge material transport pipelines (see *Dredged Material Management Plan).*[76]

As discussed above, the modeling conducted by Moffatt and Nichol (2017d) was done to determine the potential effects of all proposed actions including slip and access channel excavation, marine waterway modifications, and Eelgrass Mitigation site dredging on flow hydraulics in the bay. Construction in these areas would produce no or negligible impacts on overall tidal flow, tidal range, current velocity, and circulation in Coos Bay. Additionally, the result of the tidal flow circulation modeling and analysis predicts that there would be localized velocity reduction as well as localized small increases in velocity in portions of the bay. These would include slight velocity increases near the pile dikes at the eastern corner of the access channel. The deepening of the channel near the mouth of the bay (NRI 1 channel deepening area) at the entrance turn also appears to have resulted in locally increased currents to the north in Log-Spiral Bay. However, the model did not include effects of ocean waves that influence current velocity in this outer region of Coos Bay. Overall the effects of Project actions on the Coos Bay tidal prism were unsubstantial, and effects on tidal current velocity changes were also negligible except for a few localized areas.

Using available information on Coos Bay characteristics and the output from the hydrodynamic model, the MIKE-21 sediment transport simulation model was used to determine Project channel modification effects on the rate of sedimentation in the bay (Moffat and Nichols 2017e). The model found that overall sedimentation shoaling rates in the navigation channel within the bay would not change, although there were some local changes associated with project-related actions including a slight increase in deposition by the constructed MOF and some erosion sedimentation on the western side of the slip. While some changes in sedimentation were predicted near the two northernmost pile dikes, the projected changes in this area and rest of the bay from the Project actions were within the natural range of sedimentation rate variability.

[76] Included as Appendix N.7 of Resource Report 7 as part of Jordan Cove's September 2017 application to the FERC.

Based on the turbidity modeling conducted for both construction and maintenance dredging, the effects of maintenance dredging and disposal are predicted to be localized and relatively short term. Effects of maintenance dredging on suspended sediment concentrations and distribution in the slip, access channel, and Federal Navigation Channel would be similar to those discussed for the respective type of dredging methods used (Moffat & Nichol 2017c). However, the duration would be shorter for maintenance as less material would be removed than during construction.

Propeller wash from LNG carriers and tug boats associated with the Project, as well as ship wakes (waves) breaking on shore, could increase erosion along the shoreline and resuspend loose sediment along the shallow shoreline area, resulting in temporary increases of turbidity and sedimentation in the bay, both of which would affect water quality. The effects of these actions relating to sediment, bottom disturbance, and wave actions on marine aquatic resources are discussed in section 4.5 of this EIS.

Jordan Cove developed two models to assess propeller wash effect along the channel (Moffat & Nichol 2008; CHE 2011). The Moffat & Nichol (2008) model indicated propeller wash–induced bottom velocity along most of the main channel would be similar to the maximum velocity of peak tides (about 4 fps) whereas the CHE (2011) model indicated higher bottom velocities (13 fps) but in a very narrow range (about 80 feet wide). Both models, however, indicated that along most of the route, because the bottom of the channel consists of coarse materials (sand and sandstone), bottom material suspension would be limited and would settle rapidly, and elevated turbidity would be unlikely to occur. Moffat & Nichol (2008) estimated that near the docking location (about 0.5 mile), estimated bottom velocity would increase to about 7 to 8 fps. Some increased bottom scour and locally elevated turbidity may occur in this area, but the effects would be limited in dimension. This disturbance would occur below the intertidal area. CHE (2011) also modeled likely bottom disturbance from existing large vessel transit (assumed 106 round trips [212 channel passages] annually) in the bay and found that bottom velocity from these would be slightly greater than that of the LNG carriers (projected 120 round trips [240 channel passages] annually) so LNG effects on disturbance would be less than existing vessel traffic.

An additional model by Moffat and Nichol (2017g) estimated potential for scour and elevated turbidity while carriers are berthing and unberthing at the access channel and slip. The model assumed the LNG carrier engines and propeller would be used in addition to that of tugs for this action. While berthing had low potential for scour, unberthing, with the use of LNG carrier propeller engagement, could cause high potential for scour in the access channel and slip area. They estimate that maximum bottom velocity could be about 13.6 fps during unberthing, but less than 5.4 fps during berthing in the slip and access channel. They estimated that scour depth, with a substrate consisting of mostly medium size sand, could be up to 0.46 foot in the eastern portion of the access channel. Overall, about 12 acres of bottom could be scoured to a depth over 0.2 foot in general on a periodic basis. The bank areas of the slip would be armored, which would prevent scour there. Likely plumes of turbidity could occur briefly near the slip and access channel primarily near the bottom during the period of unberthing. The turbidity increase would be local and settle once the propellers stopped.

Jordan Cove modeled the likely effects of LNG carrier traffic on shoreline waves (Moffatt and Nichol 2017f). Wave height effects were evaluated from the access channel and slip to the mouth of the navigation channel. Moffat & Nichol estimated that the existing large bulk carriers would cause shoreline wave heights of about 0.3-0.6 foot under existing conditions. The LNG carrier transit wave height would be less under proposed channel changes, about 0.2 to 0.3 foot. These vessels' induced waves would likely occur for about 106 bulk carrier and 120 LNG carrier round trips a year CHE (2011). Tug vessels traveling at the same speed as LNG carriers would have similar wave height, but when tug vessels depart Coos Bay to bring in large vessels they may travel at about 10 knots, resulting in shoreline wave heights of about 0.5 to 0.8 foot. Day-to-day natural wave heights near the more protected bay area near the slip entrance are about 0.3 to 0.4 foot, while under windy conditions, much of Coos Bay's shoreline would have shoreline waves of 0.8 to 0.9 foot, and under severe storms even the area near the slip entrance would have wave height of about 2 feet (CHE 2011). CHE (2011) estimated that, considering the annual frequency of LNG carriers, shoreline sediment transport potential may increase by 5 to 8 percent and, considering natural range of variable wave energy, would be unmeasurable. This model assessment did not, however, consider higher speed tug transit. The tug vessel trips at these higher speeds would be about equal to LNG carrier entries (about 120 channel trips) but may not all be made at speeds as high as 10 knots. Each vessel passage would generate some form of wave for about 15 minutes (CHE 2011), with the peak wave period much less in duration. This compares to a natural wave frequency that would last much longer (e.g., hours or days). The induced waves from these additional vessels, with the possible exception of outgoing tugs, would have an unsubstantial effect on shoreline erosion as they are well within the naturally occurring, wind-generated wave heights (CHE 2011). The NMFS has concerns that higher vessel speeds may adversely increase shoreline erosion and fish stranding, potentially adversely affecting marine habitat. The NMFS recommended that vessel speeds not exceeding 8 knots within Coos Bay would be more protective. The FERC does not have the regulatory ability to dictate operational speeds of LNG carriers or tugs; however, the independent carrier operators would be required to follow all Coast Guard requirements regarding the operation of LNG carriers, including carrier speeds.

Spills or Leaks of Hazardous Materials

Project-related fluids that enter Coos Bay could affect state water quality standards. During construction of the Jordan Cove LNG Project, stormwater runoff could transport sediment and hazardous materials into Coos Bay. The introduction of sediment into Coos Bay would increase turbidity and sedimentation as discussed above and the introduction of hazardous materials would affect local water quality. To minimize stormwater runoff, construction activities would be conducted in compliance with the State of Oregon's General NPDES permit (1200-C). Additionally, stormwater runoff would be managed in accordance with a site-specific SPCC Plan. Stormwater collected in areas that have no potential for contamination would be allowed to flow or be pumped to ditches that ultimately drain to the slip or Coos Bay. Stormwater collected in areas that are potentially contaminated with oil or grease would be pumped or would flow to the oily water collection sumps. Collected stormwater from these sumps would flow to the oil-water separator packages before discharge to the industrial wastewater pipeline. Jordan Cove would apply for a new NPDES permit for this discharge prior to Project initiation. No untreated stormwater collected in areas that are potentially contaminated with oil or grease would be allowed to enter federal or state surface waters.

An inadvertent release of construction equipment–related fluids (fuel storage, equipment refueling, and equipment maintenance) could adversely affect water quality in Coos Bay. As described previously, Jordan Cove has prepared a site-specific SPCC Plan. The purpose of this SPCC Plan is to minimize the potential for accidental releases of hazardous materials and to establish proper protocols for minimization, containment, remediation, and reporting of any releases that might occur. Jordan

Cove's proposed measures to reduce the risk of hazardous material spills and minimize impacts should a spill occur include, but are not limited to:

- establishing training requirements for all employees handling fuels and other hazardous substances;
- providing storage location requirements for all hazardous substances, including chemicals, oils, and fuels, of a minimum of 150 feet from a waterbody or wetland boundary;
- requiring overnight equipment parking or any refueling operations to be located a minimum of 150 feet from a waterbody or a wetland boundary;
- requiring containment or diversionary devices for any container with a capacity of 55 gallons or larger, and providing discharge prevention measures like dikes, retaining walls, curbing, weirs, booms, diversion ponds, retention ponds, and absorbent materials;
- stipulating all secondary containment systems be capable of containing a volume equivalent to the largest container plus sufficient freeboard for precipitation (i.e., 110 percent); and
- providing for inspections to ensure no visible sheen is present on accumulated stormwater in containment systems, and the condition documented, prior to discharge.

While a hazardous material spill has the potential for significant adverse environmental impacts, adherence to the SPCC Plan would greatly reduce the likelihood of such impacts, as well as minimize the resulting impacts should a spill occur. As such, significant adverse impacts on surface water due to contamination from hazardous material spills or releases are not expected to occur.

Numerous commenters expressed concern about the impacts of an LNG spill into Coos Bay. If LNG spilled or leaked, it would turn to vapor when exposed to the warmer atmosphere, and these vapors would rise as they would be lighter than air. LNG is not soluble, would not mix with water, and would not contaminate surface water. Spills or releases of fuel or other oils into surface waters from LNG carriers are more likely to occur during fueling or bunkering at the dock when the materials are being transferred onto the carrier.

In compliance with guidelines outlined by the International Maritime Organization (IMO) under the Marine Environmental Protection Committee, vessels with 400 gross tonnage and above, like LNG carriers, are also required to develop and implement a Shipboard Oil Pollution Emergency Plan, which includes measures to be taken when an oil pollution incident has occurred or a ship is at risk of one. With the implementation each LNG carrier's shipboard oil pollution emergency plan, impacts resulting from the spill of fuel, or oil, or other hazardous liquids would be minimized.

Temperature, Chemical, and Biological Effects

While berthed, LNG carriers would release ballast water and engine cooling water into the marine slip. No wastewater would be discharged from the LNG carriers into the slip. The LNG carriers may arrange with licensed private entities for refueling, provisioning, and collection of sanitary and other waste waters contained within the carrier. The licensed private entities would transport the waste to a permitted treatment facility. Discharges from vessels are subject to regulation by EPA. EPA currently regulates these discharges via the Vessel General Permit.

Once arriving in Coos Bay, LNG carriers at the terminal slip would discharge ballast concurrently with the LNG cargo loading. The amount of ballast water discharged must, at a minimum, be adequate to maintain the LNG carrier in a condition of positive stability and with an adequate operating draft while the LNG cargo is loaded. Each LNG carrier would discharge approximately 9.2 million gallons of ballast water during the loading cycle to compensate for 50 percent of the mass of LNG cargo loaded.[77]

The LNG loading rate is designed to be 10,000 m^3/hr (with a peak capacity of 12,000 m^3/hr), or 4,600 metric tons per hour (t/hr) (5,520 t/hr peak), consequently the ballast water discharge rate would be approximately 20,250 gallons per minute (gpm). The typical ballast water discharge port is approximately 3.5 to 4.2 square meters covered by a screen with 4.5 mm bars, spaced every 20 to 25 mm.

LNG carriers and marine barges utilized for this Project must meet the requirements of the EPA and Coast Guard regulations. Coast Guard regulations (33 CFR 151, subpart D and 46 CFR 162.060 on "Standards for Living Organisms in Ships' Ballast Water Discharged in U.S. Waters; Final Rule" [77 FR 17254 (Mar. 23, 2012)] and Navigation and Vessel Inspection Circular 01 18) provide guidance to the maritime industry and Coast Guard personnel relative to the implementation of Ballast Water Management (BWM) system requirements. These governing regulations apply to all vessels that enter or operate within U.S. waters and are equipped with a ballast water system that has been approved by the Coast Guard and meets the applicable ballast water discharge standards.

The Coast Guard regulations require the same discharge standards as the IMO regulations, but the Coast Guard regulations also contain some requirements pertaining to a ship's operational procedures that are additional to the IMO's regulations (DNV GL 2018). These include the following:

- ballast tanks must be cleaned regularly to remove sediments;
- when retrieved, anchors and chains must be rinsed;
- fouling must be removed from the hull, piping, and tanks on a regular basis;
- a BWM Plan that includes the above in addition to BWM must be maintained (however, there is no requirement that the BWM Plan be approved);
- records of ballast and fouling management must be maintained; and
- a report form must be submitted 24 hours before calling at a U.S. port.

The EPA has additional requirements for periodic sampling, including calibration of sensors, sampling of biological indicators, and sampling of residual biocides.

The Coast Guard requires that vessels equipped with ballast tanks and bound for ports or places in the United States (except for the Great Lakes), regardless of whether the vessel operated outside the Exclusive Economic Zone (EEZ), submit the ships' BWM information to the Coast Guard no

[77] One cubic meter of LNG is 0.46 metric tons (t), which for the maximum size of LNG carrier authorized to call on the LNG terminal (148,000 m^3) would be 68,080 t of LNG per ship. Assuming 1 t of seawater is 1.027 m^3, the amount of seawater ballast discharged (50 percent of the weight of the LNG loaded) would be approximately 34,959 m^3 (approximately 9.2 million gallons).

later than 6 hours after arrival at the port or place of destination, or prior to departure from that port or place of destination, whichever is earlier.

In 2017, the International Convention for the Control and Management of Ships' Ballast Water and Sediments developed measures that must be implemented to minimize the potential for introduction of non-native species through ballast water. These measures have since been adopted by the IMO and are required to be implemented in all ships engaged in international trade. While the open sea exchange of ballast water has been used in the past and reduces the potential for non-native species introductions, on-board ballast water treatment systems are more effective at removing potential non-native species from ballast water. There are two different standards that ships must meet. All new ships must meet the "D-2" performance standard, which establishes the maximum number of viable organisms allowed to be discharged in ballast water. Conformity with the D-2 standard requires ships to utilize on-board ballast water treatment systems. Existing ships that do not currently have on-board ballast water treatment systems must continue to, at a minimum, conduct open sea exchanges of ballast water ("D-1" standard). Eventually, all ships will be required to conform with the D-2 standard. The timetable for conformity with the D-2 standard for existing ships is based on the date of the ship's International Oil Pollution Prevention Certificate renewal survey, which occurs every five years (IMO 2017). Therefore, most ships calling on the Project, estimated to begin in 2023 at the earliest, would be expected to have conformed to D-2 standards.

Any discharge of a pollutant into the navigable waters of the United States requires authorization under the CWA. Although discharges of ballast waters were historically excluded from the CWA, in 2013 the EPA issued a NPDES permit, the General Permit for Discharges Incidental to the Normal Operation of Vessels (VGP). The VGP, effective December 19, 2013, sets numeric effluent limits for ballast water discharges from certain large commercial vessels under a staggered implementation schedule. The standard is expressed as the maximum concentrations of living organisms in ballast water. The permit also includes maximum discharge limitations for biocides and residues.

Coast Guard regulations (46 CFR 162.060) were enacted in June 2012 in an effort to phase out ballast water exchange practices. The ballast water discharge standard (33 CFR 151.2030(a)) requires vessels calling at all U.S. ports to be equipped with a Coast Guard-approved BWM system. This applies to all new ships constructed on or after December 2013. All vessels over 300 gross tons or that have the capacity to discharge 2,113 gallons of ballast water must submit a notice of intent to the EPA requesting authorization under the 2013 VGP.

Discharging ballast water would not substantially affect water quality in Coos Bay. At the point of discharge, the interface with Coos Bay would experience temporary changes in salinity, temperature, pH, and dissolved oxygen. However, these changes to water quality would be highly localized and would quickly dissipate. While open ocean water has generally higher salinity (e.g., 35 practical salinity units [psu]) than typically occurs in Coos Bay (range 16 to 33 psu; Shanks et al. 2010, 2011) due to the high volume of water passing by the loading area, the contribution of ballast water would be only about 0.3 percent of the water passing by the terminal. Therefore, no measurable changes in salinity, other than directly at the discharge port, would occur.

Water temperatures are also unlikely to be significantly altered from release of ballast water. The temperature of the water in Coos Bay undergoes both seasonal and diurnal fluctuations. In

December and March, the ocean and fresh water entering the estuary had similar temperatures, around 50°F. In summer, low stream flows results in a rise of temperatures in the bay, to above 60°F in September at NCM 8 (Roye 1979). Based on LNG carrier design, a significant difference in temperature between ballast water and ambient waters is not anticipated. LNG carriers are constructed with double hulls, which increases the structural integrity of the hull system and provides protection for the cargo tanks in case of an incident. The space between the inner and outer hulls is used for water ballast. Because ballast water is stored in the ship's outer hull below the waterline, discharged water temperatures would not be expected to deviate significantly from ambient water temperatures; rather, it is anticipated that the ballast water would be equilibrated to the surrounding water temperature before being discharged. Therefore, thermal impacts from LNG carrier ballast water discharge would not be anticipated. The pH of the ballast water (reflective of open ocean conditions) may be slightly higher as compared to that of freshwater estuaries; however, this slight variation is not expected to have any impacts on existing marine organisms.

Dissolved oxygen levels are a critical component for the respiration of aquatic organisms. Among other factors, dissolved oxygen levels in water can be influenced by water temperature, water depth, phytoplankton, wind, and current. Typical water column profiles indicate a decrease in dissolved oxygen with an increase in depth. Some factors that often influence this stratification include sunlight attenuation for photosynthetic organisms that can produce oxygen, wind, wave, and current that results in mixing. Water that is collected within the ballast tanks of a ship would lack many of these important influences and could suppress dissolved oxygen levels. However, ballast water that is discharged is not expected to be anoxic (i.e., lacking all oxygen), just lower than what levels would likely be at the surface. In addition, ballast water would be discharged near the bottom of the slip where dissolved oxygen levels may already be lower. Therefore, no significant impacts are likely to occur as a result of discharging ocean water with potentially suppressed dissolved oxygen levels.

Cooling water flows while at the berth are approximately 11,000 cubic meters per hour (m^3/hr; 2.91 million gallons per hour or 48,000 gpm). For a 148,000 m^3 vessel, this would total approximately 69.7 million gallons while at berth (for 24 hours). Although LNG carriers vary in design, generally the intake port for this engine cooling water is approximately the same size and at the same location as the ballast water intake port and approximately 32 feet below the water line, or 5.6 feet from the keel of the LNG carrier. The size may vary but it is generally 3.5 to 4.2 square meters covered by a screen with 4.5 mm bars, spaced every 25 mm. The engines would be running to provide power for standard hoteling activities as well as running the ballast water pumps.

Using the numerical thermal plume dispersal model from EPA (2003) in combination with the Coos Bay hydrodynamic model (Moffat and Nichol 2017d), Jordan Cove modeled possible slip temperature changes resulting from the discharge of engine cooling water by an LNG carrier. The model assessed the temperature effects of eight different combinations of vessel type, ambient temperature, volume discharged, temperature, and velocity of discharge water were run (Moffat and Nichol 2017h). The modeling results showed that for typical ambient flow conditions the estimated water temperature of the discharged water would be up to about 2 to 3 degrees Celsius (°C; 3.6 to 5.4°F) warmer at the discharge port than ambient water. At about 40 to 80 feet from the discharge port (LNG carrier sea chest), temperatures would not exceed 0.3°C (0.54°F) above the ambient temperature (CHE 2011; Moffat and Nichol 2017h). The model results for the steam turbine power vessels typically were in the upper portion of these distance ranges. This temperature difference would decrease further with distance from the point of discharge. The average water temperature increases for the total slip volume for one day when an LNG carrier using the larger volume (steam turbine vessel) is at dock would range from 0.03 to 0.06°F. Tidal mixing would also decrease maximum slip temperature.

Potential effects of temperature increase from elevated cooling water releases would be further reduced from the cold LNG temperature entering the LNG carrier while at the terminal berth. Because of the extreme differential of the temperature of the cargo in the LNG carrier (-260°F) and that of the surrounding bay water (nominally 50°F), there is a constant uptake of heat by the LNG carrier while loading. This heat uptake is affected by LNG cargo that changes states from liquid to vapor daily. The typical LNG carrier sees 0.25 percent of its liquid cargo converted to the gaseous state each 24 hours, which requires heat uptake from the surrounding environment. It is reasonable to assume that 50 percent or more of the heat uptake by the carrier is extracted from the water during the full 24 hours of stay. Considering the volume of water in the Jordan Cove marine slip (an estimated 384 million gallons), tidal mixing in Coos Bay, and vessel hull cooling from the gas, the release of heated water from LNG carrier engine cooling operations would not substantially increase ambient bay water temperatures. In addition, ballast water discharged from the LNG carrier would also comprise some portion of the water withdrawn for cooling and affected by its discharge. The predicted temperature increases from the release of engine cooling water at the edge of the mixing zone (about 40 to 80 feet from the vessel) is only about 0.5°F above ambient temperature and that increase would be reduced farther away from the LNG carrier. We conclude that the thermal effect of LNG carrier operations at the berth would have very minimal impact on background water temperatures.

4.3.2.2 Pacific Connector Pipeline Project

The pipeline, associated workspace, and equipment bridges would be located across 19 Hydrologic Unit Code (HUC) level-5 watersheds (see table 4.3.2.2-1). An additional 5 watersheds would be crossed by the proposed access roads.

TABLE 4.3.2.2-1

a/ Hydrologic Unit Code (USGS 1987).
b/ Total miles of watershed area crossed by the pipeline in each HUC, rounded to nearest tenth of a mile.
c/ There are no waterbodies crossed in these watersheds.

The pipeline would be constructed across or near 352 waterbodies. Of the 352 waterbodies, only about 20 percent (69) are identified as perennial streams. Of the remaining affected waterbodies, 270 are intermittent streams (which includes 99 intermittent ditches[78]), 9 are perennial ponds (including stock ponds, an industrial pond, and excavated depressions), and 4 are estuaries. In Coos County, the Project would affect 52 waterbodies, in Douglas County 94 waterbodies, in Jackson County 91 waterbodies, and in Klamath County 117 waterbodies. A table of waterbody crossings, including the proposed crossing method, is included in appendix H (table H-3).

Pacific Connector proposes to use several different methods to install the pipeline across waterbodies depending on site-specific conditions (see chapter 2). Many of the waterbodies crossed by the pipeline are minor intermittent streams or ditches that are expected to be dry or non-flowing at the time of construction. For all waterbodies without flow at the time of construction, Pacific Connector would utilize standard upland, cross-country construction methods identified in Pacific Connector's ECRP. Waterbody crossing methods are characterized as dry open cut, wet open cut, diverted open cut, direct pipe, bore, and HDD. Most streams would be crossed with dry open-cut methods using dam-and-pump or flume methods which generally allow trenching across streams in the dry, minimizing potential turbidity. HDD crossings are primarily used on the largest streams and estuarine crossings in the Project area (see table 4.3.2.2-2). Only one diverted open-cut crossing would be done (South Umpqua River, table 4.3.2.2-2). No planned wet open-cut crossing, where pipeline trenching occurs with flowing water present, is planned. However, a wet open-cut crossing method may be required if all other crossing methods are attempted and fail. If a wet open-cut crossing method is required, then additional permitting and impact analysis may be required.

[78] "Ditches" include irrigation canals and laterals, roadside ditches, and pasture ditches.

TABLE 4.3.2.2-2

FERC Designated Major Waterbodies Crossed by Pacific Connector Pipeline by County and Fifth-Field Watershed a/

County - Fifth-Field Watershed (Fifth-Field HUC)	Major Waterbody	Approximate Milepost	Water Type	Length of Crossing (feet)	Crossing Type

a/ FERC designated major waterbodies are those greater than 100 feet wide at the water's edge at the time of construction.

Oregon Water Quality Regulations and Standards

Section 303(c) of the CWA requires states to establish, review, and revise water quality standards for all surface waters. To comply with these standards, the ODEQ has developed a classification system to describe the highest beneficial use(s) and associated minimum water quality standards of identified surface waterbodies within the state. The Oregon Water Quality Standards include beneficial use(s), fish use designations, narrative and numeric criteria to support the beneficial use(s), and anti-degradation policies. The purpose of the Anti-degradation Policy is to guide decisions that affect water quality such that unnecessary further degradation from new or increased point and nonpoint sources of pollution is prevented, and to protect, maintain, and enhance existing surface water quality to ensure the full protection of all existing beneficial uses. The state-designated beneficial use classifications for the basins crossed by the proposed Pacific Connector pipeline are similar among the basins. They include beneficial uses such as domestic and irrigation and livestock water use (excluding Coos Bay waters), industrial water, fishing and boating, wildlife and hunting, fish and aquatic life, and in some basins navigation and transportation (e.g., Coos Bay), as well as varied other uses.

Each state is required, under Section 305(b) of the CWA, to submit a report to the EPA describing the status of surface waters in the state biennially. Waterbodies are assessed to determine if their use is "fully supported," "fully supported but threatened," "partially supported," or "not supported" in accordance with the water quality standards. A use is said to be "impaired" when it is not supported or only partially supported. A list of waters that are impaired is required by Section 303(d) of the CWA, and it is provided in the 305(b) report (ODEQ 2016). To restore a waterbody to its use classification, a state may elect to impose restrictions more stringent than those normally required by the NPDES or other permitting programs, or even deny a permit for activities that could adversely affect an "impaired" waterbody.

States are also required to develop TMDLs for the impaired waterbodies. TMDLs describe the amount of each pollutant a waterbody can receive and not violate water quality standards. To comply with EPA requirements, the State of Oregon produced a combined report entitled Oregon's 2012 Integrated Report on Water Quality (Integrated Report).

The GIS coverage for the 2010 Integrated Report was reviewed to determine the locations of the water quality limited waters for Water Quality Assessment Categories 4 and 5 to determine if they are in the vicinity of Project components. Based on the ODEQ 2012 Integrated Report GIS coverage, 31 Category 4 and 5 water quality impaired waterbodies would be crossed by the pipeline and are listed in table H-5 in appendix H (ODEQ 2012c).

- TMDLs for the South Umpqua subbasin were completed in October 2006.
- TMDLs for the Upper Rogue subbasin were completed in December 2008.
- TMDLs for the Upper Klamath River, and Lost River subbasins were approved in December 2010.
- TMDLs for the Coos and Coquille Subbasins are currently in progress.

Pacific Connector proposes to cross 26 impaired waterbodies using dry/diverted open-cut crossing techniques. Conventional boring, DP, or HDD methods would be used to cross 5 of the impaired waterbodies.

Contaminated Surface Water or Sediments

As discussed in chapter 2 as well as sections 4.2 and 4.4 of this EIS, Pacific Connector has BMPs and plans in place to control runoff of any potential hazardous material found at all Project areas including TEWAs, pipe storage sites, hydrostatic test discharge sites, and right-of-way clearing areas. These procedures are intended to prevent unacceptable quantities of material (sediment, toxic substances, oils, concrete water) from entering surface waters. Additionally, sites along the pipeline project route were assessed for their potential to contain hazardous substances.

As discussed in section 4.2, a review of ODEQ's Environmental Cleanup Site Information (ECSI) database and EPA's EnviroMapper - Facility Detail Report indicated there are numerous locations within 0.25 mile of the route (see table 4.2.2.3-2) primarily considered pipeline storage sites with either cleaned-up, potential, or confirmed soil and/or groundwater contamination. As noted in section 4.2, many of these sites have the potential to encounter contaminated soil or groundwater during construction. This includes about 12 considered pipe storage sites and three near (but not on) the pipeline route. The FERC has made recommendations that Pacific Connector consult with the ODEQ regarding existing soil and groundwater contamination at these sites (see section 4.2 for the complete list of sites).

Pacific Connector's SPCC Plan is intended to prevent contamination from pipeline activities. Pacific Connector has developed a *Contaminated Substances Discovery Plan* that specifies the measures that would be implemented if unanticipated contaminated soil, surface water, or groundwater are encountered during construction. Some of the measures outlined in that plan include that all construction work in the immediate vicinity of areas where hazardous or unknown wastes are encountered would be halted. The procedures would greatly reduce the risk of hazardous substance entering water bodies along the route.

Additionally, a site with elevated natural mercury levels was found on the originally proposed pipeline route crossing East Fork Cow Creek (MP 109), and concern was expressed that disturbed soil from the crossing could cause human health risk or enter the adjacent stream. Thomason mining claims near East Fork Cow Creek have been determined to have very low concentrations of naturally occurring mercury mineralization (GeoEngineers 2017k). The pipeline route subsequently was rerouted approximately 2,500 feet from where the elevated mercury samples were taken. GeoEngineers (2017k) stated that the soils underlying the currently proposed crossing of East Fork Cow Creek would likely avoid the elevated mercury areas. The ECRP has a number of temporary and permanent erosion control and equipment-cleaning measures to minimize the potential for sediment or contaminated substances to enter wetlands or waterbodies, further reducing potential mercury contamination concerns at this crossing. Additionally, Pacific Connector would implement various site-specific actions at this crossing as recommended by the Forest Service, including:

- Provide 100 percent post-construction ground cover on all disturbed areas. Wood fiber is the preferred material. In addition, construct water bars at 50-foot intervals.
- Ensure that erosion control measures are in place before the fall rains and monitor for rilling, gullying, and other forms of active erosion and issues improve erosion control measures to preclude sedimentation.
- Inspect the construction corridor for sedimentation after each substantial storm event and, if erosion issues are found, correct them

Drinking Water Source Areas and Public Intakes

As identified in table 4.3.2.2-3, the pipeline would cross or be adjacent to 12 public drinking water source areas (DWSAs) (ODEQ 2012e). In some locations, the pipeline would be located within a particular source area for several miles, but in other locations the pipeline would be located along ridgelines meandering in and out of source areas.

Nationwide Rivers Inventory

The Nationwide Rivers Inventory lists more than 3,400 free-flowing river segments in the United States characterized as possessing one or more "outstandingly remarkable" natural or cultural values judged to be of more than local or regional significance. The proposed pipeline would cross three rivers that are listed on the Nationwide Rivers Inventory (NPS 2013):

- The **North Fork of the Coquille River** listing includes its headwaters in Section 16, T.26S., R.10W. and extends to the confluence with the South Fork Coquille River in Section 5, T.29S., R.12W. This segment was added to the list in 1993 for outstandingly remarkable fish, wildlife, and cultural (prehistoric Indian sites) values. The pipeline would cross this river segment at MP 23.1.
- The **East Fork of the Coquille River** listing extends from its headwaters in Section 18, T.28S., R.8W. to the confluence with the North Fork of the Coquille River in Section 36, T.28S., R.12W. It was added to the list in 1993 for outstandingly remarkable fish, wildlife, boating and fishing. The pipeline would cross this river at MP 29.9.
- The **South Umpqua River** listing includes the reach from Tiller (Section 33, T.30S., R.2W.) downstream to the confluence with the North Umpqua River at River Forks (Sections 31 and 32, T.26S., R.6W.). This reach was added to the list in 1993 for outstanding and remarkable fish and historical values. The pipeline would cross this section of river in two locations, MP 71.3 and MP 94.7.

Impacts and Mitigation

Impacts resulting from the pipeline's construction (see chapter 2 for a description of the pipeline's construction techniques) would be temporary and would affect crossed waterbodies. Construction actions may affect the following parameters:

- turbidity and sedimentation;
- channel and streambank integrity and stability
- in-stream flow
- risk of hazardous material spills and
- waterbody status and water use related to:
  - Oregon Water Quality Regulations and Standards effects
  - contaminated surface water or sediment effects
  - drinking water sources areas and public intakes effects
  - point of diversion effects
  - National Rivers Inventory effects

To minimize potential adverse impacts along the construction right-of-way and at waterbody crossings, Pacific Connector would implement its ECRP during construction, restoration, and operation of its proposed facilities.

Project-specific stream crossing evaluations have been conducted and crossing procedures and mitigative actions would also be implemented. Pacific Connector conducted an initial assessment of crossing conditions of all streams suitable for this analysis (GeoEngineers 2017d, 2018a, 2018b). GeoEngineers (2017d) applied the FWS's Stream Crossing Screening Matrix to all stream crossings that display fluvial characteristics. This assessment was intended to determine where stream crossings may pose a substantial risk of increasing streambank erosion and streambed instability. GeoEngineers, using a combination of field and GIS data, rated the 173 fluvial pipeline stream crossings based on the matrix (GeoEngineers 2018a). Some streams could not be accessed, and evaluation was based on desktop analysis for those streams. The matrix has two axes rating the crossing based on the potential Project effects on the crossing and the relative stream response at the crossing. Each crossing was rated as low, medium, or high for each of the two axes (all stream crossings were placed into one of nine categories, such as Low–Low, Low–Medium, or Medium–High).

No crossing was rated as having both high risk of Project impact potential (i.e., high risk of Project impacts) and high risk of site response potential (high risk of stream and site response). If any crossing had been in this category, Pacific Connector indicated that a site-specific crossing plan would be developed. Should later assessment of the crossings (see below) find that a crossing is in this category, a site-specific plan would be developed prior to construction.

GeoEngineers (2017d, 2018b) grouped the nine risk categories into five categories based on generally similar risk of streams being affected and labeled these as color management categories (Blue, Green, Yellow, Orange, and Red). The assessments included an initial survey and follow-up surveys that resulted in the current assessment of streams into these categories.

After the follow-up surveys, stream crossings with the lowest stream response potential and a low or moderate project impact potential (94 total) were designated as the Blue category and would be crossed using project-typical BMPs. These project-typical BMPs would be applied to all streams while additional BMPs would be applied to the other crossings depending on their rated category of risk. The remaining stream crossings (79) included 68 Yellow and 11 Orange crossings with some greater risk potential at the crossings than Blue crossings. These two categories would have specific additional BMPs applied in addition to the project typical BMPs with the purpose of protecting stream and bank processes following pipeline installation at sites with this category of potential risks. The details of these category specific actions are described in GeoEngineers (2017d, 2018b). After follow-up survey some additional BMPs were added to some of these streams including seven surveyed Orange category crossings (Middle Creek [MP 27.04], Elk Creek [MP 32.40], Tributary to Big Creek [MP 37.35], Upper Rock Creek [MP 44.21], East Fork Cow Creek [MP 109.47], West Fork Trail Creek [MP 118.89], and South Fork Little Butte Creek [MP 162.45]), and had specific crossing plans developed that designate the types of bed and bank restoration that would occur at each of these sites GeoEngineers (2017b, 2018a). Additional specific actions would occur at some streams on federal lands (see section 4.7 and appendix F).

Substrate characteristics and physical habitat features have been or would be determined through pre-construction surveys[79], and the upper 1 foot of existing substrate would be replaced, and other physical conditions matched during reconstruction after pipe installation. Clean spawning gravel would be top dressed as appropriate, and composition would be based on pebble counts or other appropriate methods on a site-specific basis; this would require review and approval by agency staff prior to implementation. Many of these actions would be determined prior to construction based on results of the pre-construction survey (see below) and determined by a qualified EI

[79] Some stream crossings were not accessible and would be surveyed prior to construction once approval and land owner access agreements are obtained.

specifically trained to determine proper restoration actions to implement based on river channel processes or a suitably trained professional. On non-federal lands, this person would have the authority to select appropriate additional BMP construction methods, bank stability actions, revegetation types and methods to help reduce the risk of instability of the crossing and potential for future erosion (GeoEngineers 2017d, 2018a).

A pre-construction survey[80] would be conducted by a technically qualified team on all stream crossings to confirm and clarify conditions developed in the aforementioned matrix analysis. This would include surveys of sites currently not accessible due to property ownership issues. Following these surveys, if significant changes were to occur to parameters of the risk matrix for a crossing, changes would be made to risk level and appropriate final methods of crossing and BMPs made at each stream crossing. If any crossing is moved into the "high" project impact and "high" stream response risk matrix category, a site-specific crossing design would be developed for that site. Following the final surveys, special additional BMPs, as described in GeoEngineers (2017d, 2018a), would be implemented depending on individual site conditions and may include such actions as changes in bank material and bank angle modifications, specific substrate composition used, plants used on the bank, artificial stabilizing bank material, rootwad enhancement, type of bed and bank restoration structure, and various other actions.

The approach described above, which would include more site-specific information and possibly more site-specific designs based on the pre-construction survey, is expected to be suitable for the protection of aquatic resources at waterbody crossings. The final procedures would ultimately need to obtain other permit-process approval (e.g., Section 401 water quality certification) before construction is conducted at specific sites.

As a measure to help ensure crossing actions would not adversely affect stream bank and channel structure, Pacific Connector, as part of their pipeline integrity monitoring, would observe all stream crossings, regardless of risk, annually for the life of the Project and note any obvious signs of channel erosion, pipeline exposure, or major shifts in restoration elements. Where any problems were noted during this annual assessment, a follow-up visit by geo-professionals would occur (GeoEngineers 2018a). On a quarterly basis, over two years after construction at all perennial crossings on federal lands as well as the highest risk sites identified on non-federal lands (Orange category), monitoring of vegetation success, stability of restoration elements, fish passage status, channel migration, erosion, head cutting, and other channel characteristics would be conducted. Additional forms of monitoring (e.g., vegetation, animal browse, and continued channel/restoration status) would occur at varied sites over varied intermittent periods over a 10-year period, with the highest frequency and intensity of monitoring effort at those sites of greatest risk of channel and bank instability. Frequency and type of monitoring may be adjusted based on site-specific conditions. In addition, flow and rainfall events would be recorded to understand the response of sites to flow events. Additional monitoring would occur on streams on federal lands. Remediation of adverse conditions with channel stability or habitat found during the monitoring would occur. Reports of the monitoring would be developed for years 1, 2, 3, 5, 7, and 10 after construction describing observations made and any remedial actions taken.

---

[80] Some stream crossing were not accessible and will be surveyed prior to construction once approval and land owner access agreements are obtained

Construction of New TARs, New PARs, Existing Access Roads (EAR), and TEWAs

Construction of roads and facilities have the potential to contribute sediment to streams. Of the existing roads that would be used for construction, approximately 47 would cross waterbodies. All access roads would use the existing crossing facility (e.g., bridge, culvert, ford), except for one that would use a temporary bridge and another with a temporary culvert. It is possible that other crossings may need to be improved or replaced, once final plans are developed prior to construction. These crossings would have to be reviewed and approved by the applicable agencies prior to their implementation.

Currently, there are 8 TARs and 11 PARs that would be built in the range of coho salmon–bearing watersheds along the proposed route. Of these, 2 PARs would directly cross streams and 4 TARs and 3 PARs would be within 200 feet of streams in these watersheds. There would be about 23 EAR segments that would be improved (e.g., by widening, resurfacing, or brush removal) that are within 200 feet of coho salmon-bearing streams, 7 of which would directly cross streams. While there are additional roads that are near or cross streams in other areas along the Project, their numbers are few, especially where fish would potentially be present. Potential sediment delivery to streams would occur from gravel and dirt roads, either newly built or improved ones. Dube et al. (2004) provided a summary table of distance categories for sediment delivery. The table indicated that where roads directly cross streams all sediment (100 percent) that runs off the road at the crossing would be considered to enter the streams, while potential sediment delivery to streams from road runoff decreases exponentially by distance from a stream. Dube et al. (2004) indicated that, from about 1 to 100 feet from a stream, 35 percent of road runoff would reach a stream; between 100 and 200 feet about 10 percent; and beyond 200 feet, no runoff would be considered to reach a stream. Given the locations of these roads, a total of 4 TARs, 3 PARs, and 21 EAR road segments related to the Project could potentially deliver sediment to streams, either from directly crossing streams or being with 200 feet upslope of them. Such sediment delivery would increase turbidity and fine sediment deposits, especially if BMPs were not properly instituted in these areas.

Several actions would be taken to reduce sediment runoff from roads and stream crossing structures. Where road improvements would be required, Pacific Connector would ensure that existing drainage features (e.g., culverts, ditches, dips, and grade sags) continue to function properly or they would employ suitable substitute measures to ensure that drainage is controlled to prevent off-site erosion or other resource damage. Surfaces of all new PARs would be graveled, thereby decreasing their erosion potential. Further, PARs and TARs would meet land-managing agencies' engineering design and road management standards consistent with the intended use of the road, and all applicable agency BMPs for erosion control would be implemented. All TARs would also be restored to preconstruction conditions following completion of construction.

TEWAs, which are common along the route, many near streams, represent another potential source of elevated sediment runoff. To reduce the chance of sediment entry to streams from TEWAs, Pacific Connector would install BMPs according to their ECRP for all related construction actions. BMPs may include silt fence/straw bale, sediment barriers, temporary slope breakers, or prefabricated construction mats to prevent rutting/compaction impacts and mulch, dust control, and permanent erosion control measures that would further minimize sediment discharges from a site after construction is complete. In forested areas, slash-filter windrows may be constructed on the downhill edge of the construction right-of-way and TEWAs, as directed by the EI.

While some additional sediment may enter streams, several factors would minimize or eliminate these occurrences:

- the relatively small area that would be disturbed from these actions,
- the provisions in the *Transportation Management Plan* that would be followed, and
- the ECRP and BMPs that would be implemented for Project roads, right-of-way clearing, and TEWAs.

The result would be that noticeable adverse effects on stream sediment or water quality are unlikely to occur.

Turbidity and Sedimentation

Turbidity and sedimentation affect water clarity and future substrate characteristics. Increases in both can be detrimental to drinking water quality and adversely affect aquatic organisms by impeding light penetration, benthic organism survival, and quality of substrate for invertebrate production and fish spawning success (see section 4.5). Turbidity in streams is often regulated, and levels allowed are usually designated in state water quality certification permits. To minimize increases in turbidity and suspended sediment at waterbody crossings, Pacific Connector would utilize the dry crossing methods (i.e., flume and dam-and-pump) for most of the flowing waterbodies crossed by the pipeline (as discussed above). The remainder would be crossed by conventional bore, diverted open-cut, HDD, and DP. Turbidity and sedimentation resulting from dry open-cut methods are generally minor and temporary and are associated with (1) installation and removal of the upstream and downstream dams used to isolate the construction area; (2) water leaking through the upstream dam and collecting sediments as it flows across the work area and continues through the downstream dam; (3) movement of in-stream rocks and boulders to allow proper alignment and installation of the flume and dams; and (4) when streamflow is returned to the construction work area after the crossing is complete and the dams and flume are removed. Dry methods have been reported to produce one-seventh the suspended sediment in streams than "wet" methods (Reid et al. 2002). According to Pacific Connector, during construction of Williams Northwest Pipeline's Capacity Replacement Project in Washington State (completed in 2006), a total of 67 waterbodies were crossed using dry open-cut crossing methods (fluming and/or dam and pump). During these crossings, there was only one event where state water quality turbidity limits were exceeded. The exceedance occurred through a failure of the pumps during the night when a monitor was not on site to restart the pump.

Some turbidity would result during instream activities and when the water is diverted to the backfilled areas. GeoEngineers (2017e) evaluated the potential risk of turbidity during construction across waterbodies and assigned waterbodies a score from 1 (low) to 5 (high). Of 299 waterbodies evaluated[81], 110 were scored with a low risk (score of 1 or 2) of turbidity increase over a 24-hour period and 189 were scored with a moderate risk (score of 3 or 4), generally due to soil erosion potential, presence of clay or mud, and/or the presence of steep slope or an incised channel that would require construction of a deep trench.

Monitoring studies of varied dry stream crossing pipeline activities have found moderately elevated suspended sediment near these crossings sites. Reid et al. (2004) measured suspended

[81] Excludes ponds, estuaries, streams and canals crossed using trenchless methods and water bodies in right way not crossed.

sediment downstream from 12 flumed pipeline crossings and 23 dam-and-pump crossings in North American streams. The study estimated that suspended sediment concentrations averaged 99 mg/l for flumed crossings and 23 mg/l at the dam-and-pump crossings. Reid et al. (2002) found that below four separate dam-and-pump crossings, mean suspended sediment was less than 20 mg/l within 30 meters (100 feet) downstream.

For Project area streams, average watershed suspended sediment values within 50 meters downstream of the stream crossings were modeled.[82] During a standard crossing using dam-and-pump or flumed crossing methods, when water diversion and sediment control methods are in place, values would range from 27 to 153 mg/l for flumed crossing and 7 to 35 mg/l with dam-and-pump crossings for the affected watersheds. These values are similar to those found by Reid et al. (2004) noted above. However, values would be much higher should the crossing sediment control method fail, with modeled suspended sediment values ranging from 712 to 4,102 mg/l if wet open cut methods were used during crossing failure. Duration of elevated values from failure would likely be short, less than about 2 to 4 hours for small streams and possibly up to about 6 hours for large stream crossings. While failures of diversion control systems during crossings are uncommon (Reid et al. 2004), they would likely occur at some crossings during construction. Suspended sediment concentrations from any crossing method would decrease to background levels (about 2 mg/l) within about 0.6 to 19 km (approximately 0.4 to 11.8 miles) downstream of a crossing, among the 14 watersheds.

The South Umpqua River diverted open-cut crossing would have similar effects on downstream sediment and turbidity, in the short term, to those from other dry crossings. These effects would mostly end once the diversion is in place as stream construction would occur in the dry. There would be short-term turbidity increases for short distances, lasting for several hours during portions of the installation and removal of the diversion structures for the proposed diverted open-cut crossing. Suspended sediment generated during construction at this crossing would likely be low and limited in distribution and downstream transport distance because of the very coarse pebble substrate at the crossing.

Temporary bridge installation may occasionally add turbidity to streams. Temporary stream crossings may occur outside of the fish in-water work window. Pacific Connector's crossing plans include installing temporary bridges from the bank without entering the water. These may include such items as flat-beds that are typically 30 to 40 feet long, some as long as 90 feet. If such bridges are not considered safe to install from the bank, only the equipment needed to cross the stream to install the bridge would cross the stream. Once installed, no further vehicle passage would occur in the channel. Therefore, while a small number of stream channels may be disturbed during installation causing elevated sediment levels, the limited vehicle traffic and number of such crossing locations would minimize water quality effects from turbidity in location and duration along the proposed route.

Potential effects from turbidity from construction across streams are expected to be temporary and minor for the following reasons:

- all but one crossing of perennial streams would be completed either using dry open-cut crossing methods or methods that avoid impacts altogether;

[82] See Pacific Connector's response to a FERC information request related to Resource Report 2, filed May 4, 2018.

- crossings would be completed during ODFW and NMFS recommended in-water work periods when the flow volumes and velocities will be low;
- most dry open-cut crossings would be completed in less than 48 hours;
- headwater streams are typically dominated by gravel/cobble substrates reducing the potential to generate turbidity during crossings; crossings would be scheduled individually, several days apart, and not completed concurrently;
- erosion control BMPs, as outlined in Pacific Connector's ECRP, would be implemented to minimize the potential for erosion and sedimentation; and
- bridge installation where vehicles enter streams would only occur in limited locations and duration, with most areas spanned by bridges without water entry, and Pacific Connector would follow BMPs and procedures approved by state and applicable federal agencies where temporary bridges would be installed.

The *Turbidity-Nutrients-Metals Water Quality Impact Analysis* (GeoEngineers 2017e) concluded that turbidity may exceed Oregon numerical water quality standards for short distances and short durations downstream from each crossing, either during and shortly after construction (in perennial waterbodies) or after fall rains begin (for intermittent and ephemeral streams). Such exceedances are allowed as part of the narrative turbidity standard if recognized in a CWA Section 401 water quality certification if every practicable means to control turbidity has been used.

Contribution of turbidity or sediment from other crossing methods, including DP, bore, and HDD, would be unlikely. DPs and bores would go under waterbodies and avoid contact with flowing streams. Start and end points would be back from the stream banks so standard BMPs for erosion control would reduce potential for sediment to enter streams from their use.

The details of the HDD crossing are described in chapter 2. Pacific Connector proposes to use the HDD method to cross under two spans of 0.7 and 1.6 miles of Coos Bay, and also the Coos, Rogue, and Klamath Rivers. Generally, an HDD would avoid direct effects on the bay and associated estuarine resources; stream habitat and water quality. However, an HDD requires the use of drilling mud as a lubricant during the process. This fluid is under pressure and there is a possibility of an inadvertent release of drilling mud through a substrata fracture, allowing it to rise to the surface (frac-out). The drilling fluid is typically comprised of inert muds, so an inadvertent release would likely be benign. Drilling mud may accumulate locally and be washed downstream, temporarily increasing rates of turbidity and sedimentation. In addition, inadvertent releases most often occur near the entry and exit locations, which are often landward of the stream or estuarine channels, reducing the likelihood that drilling mud would enter surface waters. Pacific Connector prepared detailed surveys and crossing plans[83] for each of the HDD crossing sites, further reducing the chances of HDD crossing problems. To prevent an inadvertent release or address impacts should one occur, Pacific Connector developed its *Drilling Fluid Contingency Plan for Horizontal Directional Drilling Operations*[84] as discussed in chapter 2.

[83] See Appendix G.2 of Pacific Connector's Resource Report 2.
[84] This plan was attached as Appendix 2.H of Resource Report 2, in Pacific Connector's September 2017 application to the FERC.

Overall, drilling mud releases to any waterbody would be short term and would be diluted from large river water volumes and swift flows. We conclude that an inadvertent release of drilling mud from an HDD would have minor, short-term adverse effects on resources in estuarine channels or rivers.

Trench spoil excavated from within the waterbody would be placed at least 10 feet from the water's edge or in a TEWA and may have the potential to contribute sediment and turbidity to streams. In some waterbodies, native washed streambed boulders, cobbles, and gravels removed from the surface of the trench may be stored within the construction right-of-way in the streambed in areas isolated from streamflow (i.e., within the dammed area for flumes or dam-and-pump crossing). Storing this material in the streambed would minimize handling and help to ensure the material would be available for backfill and streambed restoration. This storage procedure requires a modification from Section V.B.4.a. of the FERC's *Procedures* (which require spoil store more than 10 feet from the edge of waterbody). This modification has been requested as part of the license application (see appendix E). Staging areas and additional spoil storage areas would be located at least 50 feet away from waterbody boundaries, where topographic conditions and other site-specific conditions allow. Where topographic conditions do not allow a 50-foot setback, spoil storage areas would be located at least 10 feet from the water's edge. Sediment control devices, such as silt fences and straw bales, would be placed around the spoil piles to prevent spoil flow back into the waterbody reducing the chance of increasing turbidity.

<u>Channel and Stream Bank Integrity</u>

Constructing the pipeline would modify streambanks, resulting in an increase in the rates of erosion, turbidity, and sedimentation into the crossed waterbody. An increase in soil compaction and vegetation clearing could also potentially increase runoff and subsequent streamflow or peak flows. The extent of these impacts would depend on streambank composition and vegetation stream type, velocity, and sediment particle size.

To minimize these impacts, equipment bridges and mats would be used, as necessary, to provide stable work areas and isolate equipment from waterbodies. TEWAs for spoil storage and pipe staging would be set back from the bank as discussed below, and temporary sediment barriers would be installed around disturbed areas, where necessary, in accordance with Pacific Connector's ECRP.

To restore streambanks on non-federal lands, Pacific Connector would return affected lands to preconstruction contours or shaped to a stable angle (see section 4.3.4 for a discussion of requirements on federal lands). Erosion control measures including fiber fabric or matting would be installed on slopes adjacent to streams. On some banks, depending on site-specific conditions, fiber rolls may also be installed to stabilize bank toes. The streambanks would be seeded, and woody riparian vegetation planted for stabilization according to Pacific Connector's ECRP. Pacific Connector does not anticipate that riprap would be required for streambank stabilization, but if used would be limited to the areas where flow conditions preclude effective vegetation stabilization techniques. Pacific Connector may also implement tree revetments, stream barbs/flow deflectors, toe-rock, and vegetation riprap before using hard bank protection. The NMFS has expressed concern with the potential use of riprap or barb/flow deflectors for this Project and has requested that only bioengineered methods (such as LWD) be used for bank protection or flow control for the Project. This NMFS request may also become a condition within their BO for the Project or a requirement during the NMFS permitting process.

Fluvial erosion represents a potential hazard to the pipeline where streams can expose the pipe as a result of channel migration, avulsion, widening, and/or streambed scour. The pipeline would be designed to ensure it does not become exposed from bed scour or channel migration, which may include increasing the depth of cover to more than the 5-foot minimum to accommodate the potential for long-term channel changes. A channel migration and scour analysis was performed and rated crossings as to their risk of pipe exposure. Those sites considered to have potential risk of pipe exposure were evaluated in more detail including site-specific data and, where deemed necessary, would have additional procedures taken to ensure that likelihood of pipe exposure is eliminated. Ten crossings were identified as Level 2 (listed below on table 4.3.2.2-6), which have large or complex channels with a high potential for migration, avulsion, or scour, and required site-specific additional analyses. From the results of the channel migration and scour analysis, Pacific Connector would design all crossings that were assessed in detail to bury the pipe below the 100-year scour depth or into competent bedrock, whichever is shallower, and, for streams likely to have channel migration, outside and below the 50-year channel migration zone. Additional analysis prior to construction would be needed for sites that were not accessible due to property rights. All crossing sites would have pre- and post-construction surveys conducted to document (by post-construction conditions monitoring) that each crossing has been restored to pre-construction conditions (or better) after project construction. A summary of the survey findings would be filed with the FERC. Crossing of various risk categories would have additional BMPs as described below.

TABLE 4.3.2.2-6

Streams Crossed by the Pacific Connector Pipeline Route That Have a High Potential for Scour or Migration

Watershed	Stream Name	MP	Maximum Scour Depth a/	Other Hazards	Mitigation Measures
Coquille	Middle Park Creek	27.0	10.5 feet	Channel widening	Dry open-cut
Coquille	South Fork Elk Creek	34.5	6.0 feet	Channel widening	Bury in bedrock
S. Umpqua	Olalla Creek	58.8	7.5 feet	Migration	Bury in bedrock
S. Umpqua	Western Crossing of the South Fork Umpqua River	71.3	unknown	unknown	DP
S. Umpqua	North Myrtle Creek	79.1	6.5 feet	Migration	Bury in bedrock
S. Umpqua	South Myrtle Creek	81.2	unknown	Migration	Bury in bedrock
S. Umpqua	Eastern Crossing of the South Fork Umpqua River	94.7	18.0 feet	unknown	Diverted open-cut
Rogue	West Fork Trail Creek	118.9	unknown	unknown	Bury in bedrock
Rogue	Rogue River	122.7	20.5 feet	Channel widening	HDD
Rogue	North Fork Little Butte Creek	145.7	unknown	unknown	Dry open-cut

a/ 100-year flood recurrence

Pacific Connector would follow the procedures described in chapter 2 for placement of sediment cover in streams but has requested a modification, where the existing substrate is not gravel or cobbles and site access is limited, only native materials removed from the stream be used for backfilling. Pacific Connector has provided site-specific modification to our *Procedures* (see appendix E). Any subsequent need to place fill within a stream would require a permit from the COE under Section 404 of the CWA and from the ODSL under the ORS.

In-Stream Flow

Flow changes because of Project actions can have effects on water user's access to water and physical and biological conditions of streams. Flow reductions can partially affect stream temperature as well as aquatic habitat.

Project water withdrawal from waterbodies would occur from two main activities: hydrostatic testing and water needed for project dust control. Pacific Connector estimates between 31 and 65 million gallons of water would be required to test the pipeline during hydrostatic testing (see table 4.3.2.2-7).

Water for hydrostatic testing would be primarily obtained from surface water sources, but some private supply wells or other surface water rights may be drawn upon as well (see table 4.3.2.2-7). If water for hydrostatic testing would be acquired from any source other than a municipality, including surface water sources as noted in table 4.3.2.2-7, Pacific Connector would obtain all necessary appropriations and withdrawal permits, including from the ODWR, prior to use.

Pacific Connector would apply for permission from ODEQ to discharge the hydrostatic test water. Where test water cannot be returned to its withdrawal source, the water would be treated with a mild chlorine treatment and discharged to an upland location (at least 150 feet from streams with no direct discharge features) through a dewatering structure at a rate to prevent scour and erosion and to promote infiltration. Hydrostatic discharge points have been located in upland areas where feasible, and at an appropriate distance from wetlands and waterbodies to promote infiltration and to ensure that sedimentation of wetlands, waterbodies, or other sensitive areas do not occur (identified in table D-3 in appendix D). Pacific Connector's EIs would visually monitor the release of hydrostatic test water and trench dewatering activities to ensure that no erosion or sedimentation occurs. In addition, the EIs would ensure that turbid water is not discharged to waters of the state. If an EI determines that a discharge is occurring from trench dewatering, the receiving water would be visually monitored for turbidity. If a turbidity plume is observed, the trench dewatering operations would be immediately adjusted/reinstalled/maintained to ensure that the discharge of sediment to surface water is stopped and water quality standards are not exceeded. In addition, a total of 32 test header section breaks where water would be discharged are located within the construction right-of-way or TEWAs (identified in table D-3 in appendix D).

TABLE 4.3.2.2-7

Potential Hydrostatic Test Water Quantity and Source Locations

Source: Data response table based on April 12, 2018 design (Pacific Connector Response date May 24, 2018 from Attachment – FERC-PCGP-RR10-1)

To address concerns regarding water withdrawals and hydrostatic testing, Pacific Connector developed a *Hydrostatic Testing Plan*.[85] The plan would be updated in consultation with the BLM and Forest Service, as well as the Center for Lakes and Reservoirs and Aquatic Bioinvasion Research and Policy Institute (Portland State University). The plan includes measures to prevent the transfer of aquatic invasive species and pathogens from one watershed to another. Where possible, test water would be released within the same basin from which it was withdrawn. However, cascading water from one test section to another to minimize water withdrawal requirements may make it impractical to release water within the same basin where the water was withdrawn in all cases. If hydrostatic test source water cannot be returned to the same water basin from where it was withdrawn, Pacific Connector would disinfect the water that would be transferred across water basin boundaries. The hydrostatic test water treatment process would incorporate screening during water withdrawal that would meet NMFS and ODFW criteria to prevent the entrainment of small fish. Water would be discharged according to ODEQ requirements for chlorinated water discharges as noted in the *Hydrostatic Testing Plan*. All discharge locations would be monitored after construction for potential noxious weed establishment and treated if necessary.

Potential effects on stream flow associated with hydrostatic testing include reduced downstream flows, erosion and scouring at release points, and the transfer of aquatic nuisance species through the test water from one water basin to another. Estimates of potential water intake amounts from streams indicate flows below intake would be reduced by less than 10 percent of typical monthly instantaneous flow rates during the month of withdrawal for all but one (at 35 percent of flow) potential locations during withdrawal (duration about 6 to 11 days at each potential location; Ambrose 2018, see also table 4.5.2.3-6 in section 4.5 for withdrawal amounts by stream). Final selection of intake rates and sites would be reviewed by ODFW and OWRD prior to testing, so that potential effects from flow reductions would be unlikely.

While it is not possible to know how much water would be needed for dust suppression on the pipeline construction right-of-way, during dry seasons, Pacific Connector estimates that there would be approximately five 3,000-gallon water trucks per construction spread on a given day. Pacific Connector anticipates using five construction spreads, which would total 75,000 gallons for 25 water trucks per day. While the total amount of water needed is unknown, the amount needed for each truck is relatively small. For example, if filling one truck occurred in 30 minutes of water withdrawal, the rate would be about 1.7 gallons per second or 0.2 cfs. This flow reduction would be a small portion of the flow of perennial streams or rivers that are likely to be used for water supply. Therefore, the overall change in any specific reduction in streamflow from this water use would likely be unsubstantial.

Watering trucks would spray only enough water to control the dust or to reach the optimum soil moisture content to create a surface crust. Runoff should not be generated during this operation. All appropriate permits/approvals would be obtained prior to withdrawal. Table 4.3.2.2-8 lists potential dust control water sources that have been identified by Pacific Connector.

[85] Included as Appendix M to Pacific Connector's POD.

TABLE 4.3.2.2-8

Potential Dust Control Water Sources for the Pacific Connector Pipeline

County	Nearest PM	Source
Coos	16.5	Aqueduct Lake
Coos	37.0	Brewster Lake (WI-602)
Douglas	50.2	Lang Creek Reservoir
Douglas	79.0	Big Lick Reservoir
Jackson	128.5	Indian Lake Reservoir
Jackson	133.4	Eagle Point Irrigation Canal Crossing
Jackson	141.0	Star Ranch Lake
Jackson	144.0	Unnamed Reservoir
Jackson	145.0	Gardener Reservoir
Klamath	228.5	High Line Canal
Klamath	228.7	Capek Reservoir
Klamath	229.4	Low Line Canal

Additionally, Pacific Connector has indicated it may utilize a synthetic product such as Dustlock®, in addition to water, for dust control. Dustlock is a naturally occurring byproduct of the vegetable oil refining process. Dustlock penetrates the bed of the material and bonds to make a barrier that is naturally biodegradable, ensuring that the surrounding ground and water are not contaminated, and minimizing any potential effects on fish and wildlife. However, Pacific Connector would not use Dustlock within 150 feet of riparian areas or wetlands.

For dust control water use Pacific connector would be restricted to water withdrawal from permitted waterbodies where flows would not be adversely affected as they would obtain. If water for dust control would be acquired from any source other than a municipality, including surface water sources as noted in table 4.3.2.2-8, Pacific Connector would obtain all necessary appropriations and withdrawal permits, including from the ODWR, prior to use.

According to the Forest Service, vegetation clearing and management that creates sizable canopy openings can increase water yields and subsequently, waterbody flows (Forest Service 2000). Sizeable canopy openings can result in other factors affecting watershed water storage and runoff amount, peak amount and time of runoff (Forest Service 2008). The relatively small percentage of the watersheds affected by the right-of-way and the total area of the watershed within the transient snow zone would, however, greatly limit this potential effect. Although permanent canopy removal in forested areas along the right-of-way would increase the potential for snow accumulation, the forest clearing within any of the watersheds would be so small as to not have a measurable influence on peak flows.

Surface waters could be affected due to alteration of groundwater flow where the pipeline intersects waterbodies. The hyporheic zone is a region beneath and alongside a stream bed where there is mixing of shallow groundwater and surface water. The flow dynamics and behavior in this zone is recognized to be important for surface water and groundwater interactions, as well as fish spawning, among other processes. Pacific Connector conducted a hyporheic exchange analysis on the waterbodies crossed by the pipeline (GeoEngineers 2017g). The assessment focused on determining if construction has the potential to affect the structure and function of the hyporheic zone, and if so, which stream crossing may be most sensitive to changes in hyporheic zone structure and organization. Historically, pipeline construction has not typically been considered as having a potential effect on hyporheic zone function, presumably because of the nature of the construction process having relatively limited, localized and temporary change to the subsurface conditions under streams and rivers. It is difficult to measure hyporheic exchange without detailed site-specific study, but qualitative observations of bed and bank material, stream gradient, location within a watershed, and morphological features can help indicate whether a stream has an active and functional hyporheic zone. GeoEngineers (2017g) developed weighting factors to assign criteria of high, moderate, and low sensitivity to the crossing locations. The analysis used these qualitative parameters to rank how sensitive a stream crossing may be to potential hyporheic zone alteration.

Fifteen stream crossings were categorized as having a high sensitivity to hyporheic zone alteration, which would suggest a high likelihood of a functioning hyporheic zone, mostly associated with larger waterbodies with greater floodplain widths and instream morphologic features. Two of the 'high' sensitivity crossings, including the Coos River crossing at MP 11.13R and the Rogue River crossing at MP 122.65, would be crossed by HDD rather than open trenching across the stream channel.

A "moderate" sensitivity indicates that the stream crossing displays some indicators that a hyporheic zone is active and functional; approximately 66 crossings fit this category, most of them upper to middle watershed streams. A "low" sensitivity indicates that the stream crossing does not likely support either an extensive or functional hyporheic zone; approximately 123 stream crossings fit into this category. Many of these low scoring stream crossings are bedrock-controlled, are dominated by finer-grained material, or are canals and ditches. Eleven stream crossings were not assigned any point values or ranking due to there being no channel or channel forming processes observed at the crossing location in the field.

Water quality parameters, including water temperature and intragravel dissolved oxygen, might potentially be affected at crossings where hyporheic exchange is extensive and active. Thus, streams with a "high" and "moderate" sensitivity would be the streams where water quality could potentially be compromised due to alteration of the hyporheic zone. Those crossings with a 'low' sensitivity indicate that little hyporheic exchange is currently operating in the stream, and thus would not likely impact water quality. Overall, most of the Pacific Connector pipeline crossings fall into a "low" sensitivity category, where water quality (including water temperature and intragravel dissolved oxygen) is unlikely to be significantly or measurably altered by pipeline construction.

The pipeline construction methods and BMPs described in the GeoEngineers (2017g) report, as well as the site-specific restoration plans for crossings of perennial stream on federal lands (NSR 2014) further reduce the potential for pipeline construction to adversely alter the hyporheic zone. Specifically, the BMPs which are of importance to reduce the potential impacts on the hyporheic zone include the following:

- native material that is removed from the pipeline trench during excavation across stream channels would be used to backfill once the pipe is in place to minimize potential changes to preconstruction permeability; and
- trench plugs would be installed at the base of slopes adjacent to wetlands and waterbodies and where needed to avoid draining of wetlands or affecting the original wetland or waterbody hydrology.

While the potential impact of pipeline construction on hyporheic exchange is considered to be low, Pacific Connector would implement the following measures to further reduce this potential:

- Document streambed stratigraphy prior to construction to aid in site restoration.
- As described in the *Stream Crossing Risk Analysis* and *Stream Crossing Risk Analysis Addendum* (GeoEngineers 2017d, 2018a), implement additional site-specific stream crossing restorations plans, of streams not yet field surveyed, after final pre-construction surveys.
- Segregate actively movable streambed gravels and cobbles from underlying streambed materials (including fractured bedrock; i.e., do not mix actively moveable stream bed material with that below that depth). Replace all removed material to their natural pre-construction depths, including removed gravels/cobbles.
- Below active stream gravels, replace native material in a manner to match upstream and downstream stratigraphy and permeability to the maximum extent practicable.

Blasting could alter the in-channel characteristics and hydrology of the stream, potentially decreasing flows due to increased infiltration where bedrock would be fractured. Where blasting is required in streambeds, Pacific Connector would use the dam-and-pump crossing method so that blasting activities can be completed in the dry. For further discussion on minimizing impacts related to blasting, see the *Blasting Plan* discussed in chapter 2.

Stream Temperature

Several comments received by the Commission expressed concern that the removal of vegetation near waterbodies would result in changes to waterbody temperatures. However, available information on the effects of linear pipeline crossings of streams on water temperature indicates there is little to no change. Water has a very high specific heat capacity. That is, the amount of heat needed to raise its temperature is relatively high. Typically pipeline rights-of-way are narrow, and water would flow quickly through the crossing locations, Smaller, slower moving streams have a longer exposure time, but typically do not support temperature sensitive fish species. In general, streamwater exposure to the lack of shade at pipeline crossings would be temporary and limited (see an expanded discussion in section 4.3.4.2 for federal lands).

Pacific Connector conducted research on the potential for its pipeline crossings to increase stream water temperatures (GeoEngineers 2017d). This analysis also used the Stream Segment Temperature Model (SSTEMP) by Bartholow (2002) to estimate potential temperature effects at 15 pipeline crossing locations (each a 75-to 95-foot-wide clearing) along the whole route (table 4.3.2.2-9). The streams selected varied in size from 2 to 135 feet wide with only eight of these having less than a 10-foot flowing width. Conditions modeled were based on conditions measured during late August 2010. The average modeled temperature increase across a cleared right-of-way for these 15 streams were slight, 0.03°F, and the maximum increase among the streams was 0.3°F.

TABLE 4.3.2.2-9

Predicted Modeled Temperatures at Selected Stream Crossings Along the Pacific Connector Pipeline Route

MP	Watershed	Stream	Width (feet)	Ambient Water Temperature (°F)	Post-Construction Water Temperature (°F)	Temperature Change (°F)

a/ Not crossed with current route

The total amount of riparian vegetation within one site potential tree height that would be reduced during construction and operations is discussed in section 4.5.2 of this EIS. The reduction occurs primarily from construction of the pipeline right-of-way clearing over streams but also includes right-of-way clearing that does not cross streams, and development of TARs, PARs, and TEWAs outside of the right-of-way clearing. This would include loss of about of forest during construction and operations, which would remain as non-forested habitat along the route (see table 4.5.2.3-5 in section 4.5.2 of this EIS). This cleared acreage is spread across the entire pipeline route and includes loss from all sources of construction and operations as well as vegetation that would potentially help shade streams. As discussed below, loss of this vegetation is not likely to have a marked cumulative effect on stream temperature, although some local stream increases may occur.

Potential cumulative watershed temperature increases from project riparian clearing would be unlikely. The number of crossings resulting in riparian shade area cleared in any watershed would be slight. No more than nine perennial streams would be crossed in any one of the 19 watersheds crossed by the pipeline route. Primarily perennial stream clearings are likely to have effects on temperature during the warmest part of the year, because many intermittent streams would be dry during the peak temperature periods (July–September). Thus, peak seasonal temperatures would be unlikely to affect many intermittent streams. Even considering the total number of streams crossed in watersheds, which ranges from 3 to 44 crossings per watershed, most watersheds would have less than 16 crossings (see section 4.5.2.3). The riparian area lost that could affect watershed stream temperature relative to all available riparian areas in the watershed would be slight. About

9 linear stream miles of streambank could be affected along the whole Project route (GeoEngineers 2017f; note this counts both banks separately so stream length affected would be half of this value).

To minimize the potential effects of pipeline construction on stream temperatures by the removal of riparian vegetation, Pacific Connector has incorporated the following measures into its Project design:

- narrowing the construction right-of-way at waterbody crossings to 75 feet where feasible based on site-specific topographic conditions;
- locating TEWAs 50 feet back from waterbody crossings to minimize impacts on riparian vegetation, where feasible;
- replanting the streambanks after construction to stabilize banks and to re-establish a riparian strip across the right-of-way for a minimum width of 25 feet back from the streambanks; and
- replanting riparian areas equal to 1:1 ratio to temporary riparian shading vegetation losses and 2:1 ratio for permanent riparian losses from the 30-foot operational easement clearing.

Based on these measures and the studies summarized above, we conclude that the construction and operation of the pipeline would have no discernible effect on stream temperature.

Spills of Hazardous Materials

An inadvertent release of equipment-related fluids would temporarily impact surface water quality. Equipment fluids such as gas and oil can be toxic to aquatic organisms and can affect downstream water uses including drinking water and crop irrigation. Pacific Connector has developed a SPCC Plan that describes measures to be implemented by Project personnel and contractors to prevent and, if necessary, control any inadvertent spill of hazardous materials.

Waterbody Status and Water Use

The construction and operation of the pipeline route could have effects on the status of special features including the water quality limited conditions and special uses, including water diversions and national river status. Actions described below indicate potential effects on these and Project mitigative actions implemented to aid in maintaining the current conditions and regulatory requirements relative to surface waters.

Oregon Water Quality Regulations and Standards Effects

Studies requested by ODEQ are part of a broad evaluation of potential impacts on water quality, stream channel stability, and riparian zones resulting from pipeline construction and maintenance activities. GeoEngineers conducted studies to help evaluate potential impacts including a stream crossing risk analysis, a hyporheic exchange impacts analysis, and a study of the impact to water quality from additional turbidity, nutrients, and metals caused by pipeline construction activities at stream crossings (GeoEngineers 2013a, 2013b, 2013c, and 2018a). The intent of the evaluations is to help focus management resources on those waterbody crossings to which the pipeline would present the greatest risk of impacting beneficial uses. ODEQ's regulatory authority under the CWA and OAR is provided to maintain beneficial uses through enforcement of water quality standards.

During the ODEQ CWA Section 401 process, Pacific Connector would develop a source-specific implementation plan in accordance with OAR 340-042-0080 for areas with existing TMDLs, and Pacific Connector would be identified as a new nonpoint source. The source-specific implementation plan would be reviewed and approved by ODEQ.

BMPs to minimize sedimentation during construction would be employed on all streams. However, to reduce potential stream channel impacts, including increased erosion/sedimentation, additional site-specific BMPs would be installed at sites considered to be at higher potential risk, as discussed earlier under "Impacts and Mitigation" based on the risk matrix analysis. These additional protections may include such items as additional upslope bank protections, hillslope drainage structures, additional wood instream or on bank, wood armoring, enhanced substrate, or reduction in bank slope to further ensure reduced erosion. The plans to keep riparian stream crossing clearing to a minimum (75 feet wide at most crossings) would also result in less removal of woody riparian vegetation and help temperature-impaired streams. Because of the water quality and stream habitat benefits, the NMFS endorses keeping near stream riparian vegetation clearing to a minimum, as is currently proposed; this NMFS request may become a condition within their BO for the Project or a requirement during the NMFS permitting process. Overall, the small reduction in shade is not likely to change stream temperatures substantially downstream of the pipeline crossing in temperature limited streams. However, removal of vegetation that once shaded the stream could cause slight local and temporary (daily) increases in temperature, in small streams with low flow discharge rates during the warm summer months. However, discernible temperature changes are very unlikely due to the limited exposure time as water passes through the 75-foot-wide clearing and the high specific heat capacity of water.

A potential new nonpoint source of nutrients and/or oxygen-demanding pollutants would be the use of fertilizer for revegetation of disturbed areas. Pacific Connector plans to apply fertilizer to disturbed areas to be reseeded, as needed. Additionally, some BLM districts along the Project route have specific recommendation for slow release fertilizer application in specific soil types in planting holes as part of any reforestation. Fertilizer would only be applied at the recommended rates of the land-managing agencies and, if applied by broadcast spreader, worked into the upper 2 inches of soil as soon as practical (see Pacific Connector's ECRP). Application would need approval by the land-managing agency or landowner. No application would occur within 100 feet of flowing water and would be avoided during heavy rain and windy conditions. Aerial broadcast spreaders would only occur with federal land-managing agency approval. Fertilizer would be added directly to hydroseeding slurry. Fertilizer would be stored away from streams and outside of federal Riparian Reserves. The NMFS has expressed concern that fertilizer application has the potential to enter waters and recommends that no application within 150 feet of waterbodies occur; this NMFS request may become a condition within their BO for the Project or a requirement during the NMFS permitting process. Any monitoring required for nutrients at locations where fertilizer is likely to contribute to run-off to waterbodies will be addressed in the state permit process and be included in a source-specific implementation plan as required by OAR 340-042-0080.

Drinking Water Sources Areas and Public Intakes Effects

Prior to construction, Pacific Connector would consult with all surface water intake operators listed in table 4.3.2.2-5 that are still active and establish a process for advanced notification of instream work. A summary of the consultations will be filed with the FERC prior to construction of the pipeline. In the event of an inadvertent spill, or a disruption of flow and/or a possible introduction of sediments into waters upstream of the intakes, Pacific Connector would notify potable water intake users of the conditions so that necessary precautions could be implemented.

Point of Diversion Effects

Pacific Connector would consult with the landowner if impacts on a water supply's point of diversion cannot be avoided, and prior to construction would work together to identify an alternate location to establish the diversion. Should that landowner determined that there has been an impact on the water supply, Pacific Connector would work with the landowner to ensure a temporary supply of water. In addition, if deemed necessary, Pacific Connector would replace the affected water supply with a replacement, permanent water supply. Mitigation measures would be specific to each property and would be determined during landowner negotiations. Points of diversion (both public and private) beyond 150 feet of the construction work areas are not expected to be affected by the pipeline.

National Rivers Inventory Effects

As noted earlier, the pipeline would cross three rivers that are listed on the Nationwide Rivers Inventory. Pacific Connector has developed specific plans for each of these crossing to maintain the quality of these rivers. For the North Fork of the Coquille River and East Fork of the Coquille River, Pacific Connector has developed a site-specific crossing plan for both rivers using a dry open-cut method to contain disturbed sediments. The western South Umpqua River crossing would use a DP installation process to eliminate an open-cut and minimize impacts by drilling under both the river and I-5 in a single operation. The site-specific crossing plan developed for the eastern South Umpqua River crossing would use a diverted open-cut method to limit water quality impacts by creating a "dry" working area isolated from the river. These procedures would maintain stream conditions and quality, and would not adversely affecting the streams' river status(i..e, the National River Inventory status).

4.3.2.3 Conclusion

Constructing and operating the Project would result in short-term and long-term impacts to surface water resources. However, based on Jordan Cove's proposed dredging and vessel operation methods and its impact minimization and mitigation measures (including its implementation of erosion controls, dredging procedures, construction and stormwater management procedures, and construction timing), as well as Pacific Connector's proposed waterbody crossing and restoration methods and its impact minimization and mitigation measures, we conclude that the Project would result in short-term, localized, construction-related water quality impacts, but would not significantly affect surface water resources.

4.3.3 Wetlands

Wetlands are defined by the *Corps of Engineers Wetland Delineation Manual* (Environmental Laboratory 1987) as those areas that are inundated or saturated by surface or groundwater at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.

Wetlands are regulated at the federal, state, and local level. At the federal level, wetlands may be deemed Waters of the United States (33 CFR 328.3) and may be subject to regulation through Sections 401 and 404 of the CWA. Section 401 of the CWA requires that proposed dredge and fill activities under Section 404 be reviewed and certified by the designated state agency and that the project meets state water quality standards. In this case, the ODEQ has been delegated this authority and is charged with verifying that the project meets state water quality standards. In Oregon, wetlands are also regulated at the state level by the ODSL and at the local level by some city and county land-use ordinances. ODSL administers Oregon's Removal-Fill Law (ORS 196.800) to protect waterways and wetlands (see sections 1.3.6 and 1.5.1 for additional details).

Through the state's notification process, provisions for wetlands are included under the ODF's Forest Practices Act and rules will be addressed, if applicable. Details would be submitted to the ODF in either a written plan or alternate plan to include specific provisions for meeting the Forest Practices Act, including those related to wetlands.

On federally managed land, EO 11990, amended in 42 U.S.C. 4321 *et seq*., requires the federal agencies "to avoid adverse impacts associated with the destruction or modification of wetlands wherever there is a practicable alternative" and to "include all practicable measures to minimize harm to wetlands." Further, the agencies are required to preserve and enhance the natural and beneficial values of wetlands in carrying out their responsibilities.

The *Corps of Engineers Wetlands Delineation Manual* (Environmental Laboratory 1987), the *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Western Mountains, Valleys, and Coast Region* (COE 2010) and the *Regional Supplement to the Corps of Engineers Wetland Delineation Manual: Arid West Region (Version 2.0)* (COE 2008) provide the standards for wetlands determinations. Wetland delineations for the Project were conducted in accordance with these federal regulations and methodologies.

4.3.3.1 Jordan Cove LNG Project

Wetlands identified during surveys of the terminal site and associated sites between 2013 and 2017 are shown in figure 4.3-1.[86] Wetlands identified in the area include estuarine subtidal, estuarine intertidal, palustrine unconsolidated bottom, palustrine aquatic bed, palustrine emergent, palustrine scrub-shrub, and palustrine forested wetlands.

[86] The COE reviewed Jordan Cove's 2013 and 2016 wetland delineation and determinations, and provided Preliminary Jurisdictional Determinations on March 13, 2014, October 28, 2014, and March 16, 2017. Requests for Preliminary Jurisdictional Determinations for delineations conducted in 2017 have been submitted to the COE. Additionally, because it has been several years since the Preliminary Jurisdictional Determinations have been issued, Jordan Cove has requested new or revised Jurisdictional Determinations from the COE.

Estuarine intertidal wetlands are intertidal systems that are regularly flooded and have an unconsolidated shore (i.e., tidal mud/sand flats). Vegetation in tidal flats, with the exception of sea grass beds and algal mats, is generally restricted to small areas of accretion in the tidal marsh-mudflat boundary (Seliskar and Gallagher 1983). Estuarine subtidal wetlands occur below mean low tide and are adjacent to tidal mudflats. Subtidal wetlands provide important ecological functions including providing fish and invertebrate shelter during low tides, supporting sea grass communities and acting as nursery areas for some aquatic species (ODFW 2017a). Estuarine wetlands within Coos Bay are characterized by sandy, muddy, or rocky substrates that are regularly inundated by brackish water and influenced by tidal flux, resulting in cycles of saturation and exposure. Plant life is not typically abundant within these types of wetlands, though macro- and microalgae and phytoplankton can be present. Estuarine intertidal and subtidal wetlands occur throughout Coos Bay.

Palustrine unconsolidated bottom wetlands are wetlands have less than 30 percent vegetation cover and a surface with less than 25 percent of the particles smaller than stones. The closely related aquatic bed wetland class has less than 30 percent vegetation cover of plants growing on or below the water's surface for most of the growing season. These wetland types occur along the South Dunes Site and the access/utility corridor.

Palustrine emergent wetlands are freshwater wetlands dominated by erect, rooted, herbaceous wetland plants that generally persist for most of the growing season. Plant species found in emergent wetlands on the Jordan Cove LNG Project area include slough sedge (*Carex obnupta*), Hooker's willow (*Salix hookeriana*), toad rush (*Juncus bufonius*), dagger-leaved rush (*Juncus ensifolius*), tinker's penny (*Hypericum anagalloides*), devil's beggartick (*Bidens frondosa*), knotgrass (*Paspalum distichum*), Yorkshire fog (*Holcus lanatus*), creeping bent-grass (*Agrostis stolonifera*), yellow pond lily (*Nuphar lutea* ssp. *polysepala*), and floating-leaved pondweed (*Potamogeton natans*). Emergent wetlands occur in various portions of the LNG terminal area as well as at the APCO and Kentuck project sites.

Palustrine scrub-shrub wetlands are freshwater wetlands that include areas dominated by woody vegetation less than 20 feet tall and are vegetated with true shrubs, young trees, and trees or shrubs that are small or stunted because of environmental conditions. Species found within scrub-shrub wetlands on the LNG terminal area include Hooker's willow, Sitka willow (*Salix sitchensis*), Douglas spiraea (*Spiraea douglasii*), twinberry (*Lonicera involucrata*), slough sedge, soft rush (*Juncus effusus*), dagger-leaved rush, toad rush, western bent-grass (*Agrostis exarata*), creeping bent-grass, reed canary grass (*Phalaris arundinacea*), northern willowherb (*Epilobium ciliatum*), tall mannagrass (*Glyceria striata* [*G. elata*]), and lowland cudweed (*Gnaphalium palustre*). Scrub-shrub wetlands occur in the various portions of the LNG terminal area, and at the APCO site.

Palustrine forested wetlands are freshwater wetlands that contain woody vegetation that is 20 feet or taller. Coniferous species found in the forested wetlands on the LNG terminal area include shore pine (*Pinus contorta*), Douglas-fir (*Pseudotsuga menziesii*), Sitka spruce (*Picea sitchensis*), western hemlock (*Tsuga heterophylla*) and scattered Port-Orford cedar (*Chamaecyparis lawsoniana*). Shrubs within the forest wetland areas include scotch broom (*Cytisus scoparius*), coyote brush (*Baccharis pilularis*), hairy manzanita (*Arctostaphylos columbiana*), evergreen huckleberry (*Vaccinium ovatum*), salal (*Gaultheria shallon*), wax myrtle (*Morella* [*Myrica*] *californica*) and scattered rhododendron (*Rhododendron macrophyllum*). Herbaceous species include European beachgrass (*Ammophila arenaria*), silver hairgrass (*Aira caryophyllea*), little hairgrass (*A. praecox*), hairy cat's ear (*Hypochaeris radicata*), bracken fern (*Pteridium aquilinum*), sheep sorrel (*Rumex acetosella*), candy-stick (*Allotropa virgata*), and rattlesnake plantain (*Goodyera oblongifolia*). Forested wetlands occur in the north-central portion of the LNG terminal area and at the APCO and Kentuck project sites.

Impacts and Mitigation

Table 4.3.3.1-1 identifies the wetlands located at Jordan Cove's terminal site and associated sites. Approximately 86.1 acres of wetlands would be affected by construction of the proposed Jordan Cove LNG Project and approximately 22.3 acres of wetlands would be permanently lost due to construction and operation of the Project (see table 4.3.3.1-1). Approximately 0.5 acre of this impact would occur to wetlands as a result on non-jurisdictional facilities (e.g., the Trans-Pacific Parkway/U.S. 101 intersection and the industrial wastewater pipeline). The vast majority of impacts are associated with wetlands affected by construction of the ship and access channel and MOF and navigation reliability improvement dredge areas (which would impact 77.4 acres of wetlands).

TABLE 4.3.3.1-1

Wetlands Impacts on the LNG Project Area

Wetland Type	Acres Affected By Construction a/	Acres Affected By Operation

TABLE 4.3.3.1-1 (continued)

Wetlands Impacts on the LNG Project Area

Wetland Type	Acres Affected By Construction a/	Acres Affected By Operation
Temporary Dredge Transfer Line and Loading Area at Eelgrass Mitigation Site f/		
Estuarine b/, c/	1.1	0.0
Subtotal	**1.1**	**0.0**
Ingram Yard g/	0.0	0.0
Port Laydown Site g/	0.0	0.0
Additional Offsite Park & Ride g/	0.0	0.0
Myrtlewood Offsite Park & Ride g/	0.0	0.0
Subtotal	**0.0**	**0.0**
Total Freshwater Wetland Impacts	3.9	3.4 g/
Total Estuarine Wetland Impacts	82.2 b/	18.9
Total All Wetland Impacts	**86.1**	**22.3**

Note that values may not sum correctly due to rounding. Acreages for wetlands are rounded to the nearest tenth of an acre; values below 0.1 acre are noted as <0.1.

a/ Acres affected by construction include acres affected by operation.
b/ Acreage of eelgrass and adjacent estuarine habitats subject to change based on field mapping conducted in late August 2018, which is currently under review.
c/ Impacts to deep subtidal habitat are not expected during operation, because natural recovery of benthic communities within this habitat is expected within a relatively short time frame following construction.; therefore, impacts are recorded as construction-phase only.
d/ APCO Site wetland and estuarine construction impacts are due to temporary bridge pilings.
e/ Wetlands associated with proposed mitigation areas (Panhandle, Lagoon, North Bank upland mitigation sites; Kentuck project site and Eelgrass Mitigation site) are not included in this table. Some correlated impacts to wetlands will occur at the Kentuck project site, but they will be offset by the overall mitigation project. A full accounting of correlated impacts will be included in the 404 permit application submitted to the COE.
f/ There are no wetlands within Ingram Yard, Port Laydown site, or Myrtlewood Offsite Park & Ride.
g/ Total freshwater wetland acreage includes 0.3 acre of operational forested wetland.

To satisfy COE and state permitting, Jordan Cove assessed the function and values of wetlands permanently affected by the Jordan Cove LNG Project to determine high value wetlands. The criteria used to assess wetlands were their water quality and quantity, the value of their fish and wildlife habitat, their native plant communities and species diversity, and their value for recreation and educational purposes. Four wetlands (wetlands 2013-6, 2012-2, Wetland C, and Wetland E), totaling less than two acres, are considered high value wetlands. The COE may also require additional compensatory mitigation for impacts on Aquatic Resources of Special Concern (ARSC), which are defined as “aquatic resources that are unique, difficult to replace, and/or have high ecological function” (COE 2018). ARSCs that may be affected by the Jordan Cove LNG Project may include estuarine wetlands, rocky substrate in tidal waters, and native eelgrass (*Zostera marina*) beds. As identified above, constructing and operating the Jordan Cove LNG Project would temporarily and permanently impact wetlands. In addition to the permanent loss of wetlands, temporary impacts on wetlands include loss of vegetation, and modification of wetland hydrology and soils characteristics. Disturbed wetlands are also susceptible to the introduction of exotic and invasive plant species. Based on assessments evaluating impacts on wetland habitats from dewatering activities, it is expected that groundwater movement and levels would return to pre-disturbance conditions following construction (DEA 2015, 2018a; GSI 2017). A monitoring program would be conducted prior to, during, and after construction to monitor potential impacts on ground and surface waters, as well as wetlands. In addition to impacts on wetlands listed in table 4.3.3.1-1, Henderson Marsh, which is located directly to the west of the terminal, may be affected due to a minor reduction in water entering the marsh due to the construction of the tsunami berm on the west side of the slip.

All impacts associated with mitigation sites are not part of the proposed action and are proposed only as necessary compensation for unavoidable impacts. Approximately 108.7 acres of wetlands (6.0 acres of estuarine wetlands and 102.7 acres of freshwater wetlands and open water) would be temporarily affected at the Kentuck project site in association with wetland restoration and mitigation activities. Potential impacts at the Kentuck project site include a temporary reduction in water quality due to an increase in sedimentation (e.g., resulting from import and grading of dredge material), temporary disturbances to adjacent wildlife, and a temporary impact on vegetation removed during restoration activities at the site. However, these impacts would be part of an overall long-term enhancement of the wetland habitat. Dredging for construction of the Eelgrass Mitigation site could result in approximately 10.3 acres of temporary short-term impacts; potential impacts include a temporary reduction in water quality due to an increase in sedimentation during dredging activities and a temporary loss of benthic organisms. Benthic organisms could re-establish within the area once eelgrass revegetation was complete (see section 4.5 of this EIS).

When unavoidable wetland impacts are proposed, the COE, EPA, and ODSL require that all practicable actions be taken to avoid, minimize, and then compensate for those impacts. The COE would determine the specific type and amount of compensatory mitigation that would be required to offset the loss of wetland acreage and functions that cannot be avoided or minimized as part of the CWA Section 404 permit process and by the ODSL as part of the state Removal-Fill permit process.[87]

Prior to COE authorization, the COE must ensure aquatic resource impact avoidance and minimization have been identified, outlined, and promulgated by an applicant. The COE uses a mitigation sequence to assess the need for aquatic resource impacts. This mitigation sequence contains a primary structure centered on avoidance of aquatic resource impacts, minimization of aquatic resource impacts, restoration of aquatic resource functions and services, and compensation for the loss of aquatic resource impacts that could not be avoided. If, after outlining project aquatic resource avoidance and minimization to the degree practicable, an applicant may mitigate for subsequent aquatic resource impacts. Mitigation for aquatic resource impacts is carried out via the development of a compensatory mitigation plan. A compensatory mitigation plan must be developed to meet the requirements of the 2008 Compensatory Mitigation Rule as outlined in the Final Rule on Compensatory Mitigation for Losses of Aquatic Resources (73 [70] FR 19594-19705 [April 10, 2008]) and in 33 CFR Part 232.4.

A compensatory mitigation plan must replace lost aquatic functions and values, and must contain the following required components:

- goals and objectives;
- site selection criteria;
- site protection instrument;
- baseline environmental information;

[87] The Oregon International Port of Coos Bay received a removal-fill permit from the ODSL to construct the slip and access channel for development of a new terminal (DSL permit 37712-RF). A new application will be submitted to ODSL for the remaining portions of the Jordan Cove Project area not covered by ODSL permit 37712-RF. A permit application that covers the entire Jordan Cove Project area will also be submitted to the COE.

- determination of credit methodology;
- mitigation work plan;
- maintenance plan;
- performance standards;
- monitoring requirements;
- long-term management plan;
- adaptive management plan; and
- financial assurances.

Jordan Cove developed a *Compensatory Wetland Mitigation Plan* to address unavoidable impacts on wetlands and other aquatic resource types.[88] Impacts on freshwater wetland resources would be mitigated via the Kentuck project site. Approximately 9.1 acres of the Kentuck project site would be enhanced and restored to mitigate for permanent impacts on freshwater wetlands (see Table 4 of Jordan Cove's *Compensatory Wetland Mitigation Plan*). Impacts on estuarine wetland and aquatic resources would be mitigated via the Eelgrass Mitigation site and Kentuck project site. Approximately 91.5 acres would be enhanced and restored at the Kentuck project site, and approximately 7.7 acres would be enhanced at the Eelgrass Mitigation site for a total of approximately 99.1 acres of mitigation for permanent impacts on estuarine wetlands and aquatic resources (see Table 4 of Jordan Cove's *Compensatory Wetland Mitigation Plan*). These mitigation plans are still being reviewed by the COE, ODSL, and applicable federal and state agencies. Approval of these mitigation plans by these agencies would be required prior to issuance of federal and state wetland permits. Restoration efforts at the Kentuck project and Eelgrass Mitigation sites would result in some short-term and permanent impacts; however, the *Compensatory Wetland Mitigation Plan* accounts for these impacts and provides mitigation to offset these impacts.

4.3.3.2 Pacific Connector Pipeline Project

Pacific Connector conducted wetland delineations of pipeline related workspaces. For areas where on-site delineation was not possible due to lack of landowner permission, Pacific Connector used USGS topographic maps, NRCS soil surveys, FWS NWI maps, and aerial photography to identify wetland type and boundaries. Wetland types identified along the proposed route included estuarine intertidal flats, estuarine subtidal channels, estuarine emergent, palustrine unconsolidated bottom, palustrine aquatic bed, palustrine emergent, palustrine scrub-shrub, palustrine forested, and riverine.

Along the proposed pipeline route, PEM wetlands, which are commonly disturbed by agricultural and grazing activities, are dominated by hydrophytic pasture grasses such as meadow foxtail (*Alopecurus pratensis*), rough bluegrass (*Poa trivialis*), and various bentgrasses (*Agrostis* spp.). Soft rush and white clover (*Trifolium repens*) are also commonly present in these disturbed wetlands. Within Douglas and Jackson Counties, pennyroyal (*Mentha pulegium*) is also a common dominant species in emergent wetlands. Emergent wetlands dominated by native species are uncommon, but when they occur (primarily within swales and irrigation canals) they generally contain cattail (*Typha latifolia*), small-fruited bulrush (*Scirpus microcarpus*), hardstem bulrush (*Schoenoplectus* [*Scirpus*] *acutus*), manna grass (*Glyceria striata* [*G. elata*]), American

[88] See *Jordan Cove Energy Project Compensatory Wetland Mitigation Plan* filed with the FERC in May 2018.

sloughgrass (*Beckmannia syzigachne*), and various sedges (*Carex* spp.). Vernal pool wetlands, which occur along the proposed pipeline route, are also defined as palustrine emergent wetlands.

Scrub-shrub wetland communities along the proposed pipeline route consist of two primary types: disturbed wetlands associated with grazing or development activities and relatively undisturbed wetlands. Common species within disturbed wetlands tend to support invasive species such as Himalayan blackberry (*Rubus laciniatus*) and sweetbriar rose (*Rosa rubiginosa* [*R. eglanteria*]). Common species in undisturbed wetlands include a mixture of Douglas' spirea, Pacific willow (*Salix lasiandra*), salmonberry (*Rubus spectabilis*), and Pacific ninebark (*Physocarpus capitatus*).

The majority of delineated forested wetlands along the proposed pipeline route contain Oregon ash (*Fraxinus latifolia*). Red alder (*Alnus rubra*) and black cottonwood (*Populus trichocarpa*) are more common along the western part of the pipeline route in Coos and Douglas Counties. Western red-cedar (*Thuja plicata*) and Sitka spruce are common in the coast range forested wetlands. Skunk cabbage (*Lysichiton americanum*) and salmonberry are common in the understory of coast range forested wetlands and lady fern (*Athyrium filix-femina*) and horsetails (*Equisetum* spp.) are often present in the understory in other parts of the pipeline route. Forested wetlands are uncommon along the southeastern portions of the pipeline route, but are generally in swales or depressions. They are dominated by Oregon ash with an understory of Himalayan blackberry, slough sedge, and spreading rush (*Juncus patens*).

Riverine wetlands are freshwater wetland habitats contained within a channel. The riverine wetlands along the proposed pipeline route include species similar to those found in the palustrine emergent, scrub-shrub, and forested wetlands.

Intertidal flats are the predominant estuarine wetland type crossed by the pipeline route. These wetlands are intertidal systems that are regularly flooded and have an unconsolidated shore (i.e., tidal mud/sand flats). Vegetation in estuarine tidal flats, with the exception of sea grass beds and algal mats, is generally restricted to small areas of accretion in the tidal marsh-mudflat boundary (Seliskar and Gallagher 1983). Estuarine subtidal channels occur below mean low tide and are adjacent to tidal mudflats. Subtidal channels provide important ecological functions including providing fish and invertebrate shelter during low tides, supporting sea grass communities and acting as nursery areas for some aquatic species (ODFW 2017a).

Estuarine emergent wetlands, also called estuarine marshes, occur along the outer edges of the tidal mudflats. Vegetation in these wetlands are typically erect, perennial species such as arrow grasses (*Triclochin* spp.), cordgrasses (*Spartina* spp.), bulrushes (*Scirpus* spp.), and alkali grasses (*Puccinellia* spp.).

Impacts and Mitigation

Constructing the pipeline would temporarily and permanently impact wetlands. Clearing wetland vegetation could alter several wetland functions including their ability to provide fish and wildlife habitats, sediment and nutrient trapping, and other water quality functions. Additionally, soil disturbance and removal of vegetation could temporarily affect a wetland's capacity to moderate flood flow, control sediment, or facilitate surface water flow. Removing vegetation could also increase water and soil temperatures and alter species composition within forested and shrub wetlands to a more shade intolerant composition. Digging a trench through an impervious layer of soil in a wetland would alter the hydrologic character of the wetland. Failure to segregate topsoil from the trench could result in altered biological and chemical functions in the wetland soil and could affect the re-establishment of vegetation, recruitment of native vegetation, or success of plantings. Improper operation of equipment or transport of pipe in wetlands could inadvertently rut or compact the soil and affect natural hydrologic patterns of the wetlands and may lead to inhibited seed germination or increase the potential for siltation. Improper sediment controls could lead to sediment deposition in wetlands (including those wetlands located downslope or outside of the right-of-way or construction disturbance footprint), which could lead to the release of chemical and nutrient pollutants from sediments.

The range and intensity of wetland impacts would vary depending on the type of wetland affected. In general, impacts on herbaceous wetlands would be short term, while impacts on scrub-shrub and forested wetlands would be long term. Impacts on herbaceous wetlands would be considered short term because herbaceous vegetation generally regenerates quickly. Scrub-shrub and forested wetlands may take several years to decades to reach functionality similar to pre-construction conditions, depending on the age and complexity of the system. Also, some wetlands would be permanently converted from one type to another (e.g., forested to scrub-shrub and/or herbaceous) as a result of pipeline maintenance activities.

As identified in table 4.3.3.2-1, constructing the pipeline would impact 112.2 acres of wetlands. Of this 112.2 acres, operation of the pipeline would permanently impact approximately 4.9 acres of wetlands. This includes 4.0 acres of long-term impacts on scrub-shrub and forested wetlands and 0.9 acres of wetlands that would be permanently converted to a different wetland type. Tables H-1a and H-1b in appendix H of this EIS list the wetlands crossed by the pipeline by wetland type, ecoregion, subbasin, and fifth-field watershed, and list the acres of impacts that would occur to each of these wetlands.

TABLE 4.3.3.2-1

Summary of Wetland Impacts along the Pacific Connector Pipeline

Wetland Type	Total Acres Affected by Construction	Total Acres Affected by Operation a/, b/
Palustrine unconsolidated bottom and aquatic beds	0.6	0.0
Palustrine emergent wetlands	106.7	0.0
Palustrine forested wetlands	2.6	2.6 (0.7)
Palustrine scrub-shrub wetlands	2.3	2.3 (0.2)
Total Wetland Impact	**112.2**	**4.9 (0.9)**

Note that values may not sum correctly due to rounding. Acreages for wetlands are rounded to the nearest tenth of an acre; values below 0.1 acre are noted as <0.1.

a/ Includes wetlands that would be allowed to restore to preconstruction conditions (i.e., they would not be filled, nor would they be located within the permanent 10-foot-wide operational corridor); however, it could take many decades for conditions within these wetlands to restore to preconstruction conditions.

b/ The numbers in parentheses represent the permanent conversion of forested wetlands within the 30-foot-wide maintenance corridor and scrub-shrub wetlands within the 10-foot-wide maintenance corridor.

The pipeline would cross 18 (fifth-field) watersheds; however, approximately 78 percent (87.3 acres) of the pipeline's total impact on wetlands would occur in two watersheds: the Lake Ewauna Upper Klamath River watershed and the Coos Bay Frontal watershed. The remaining 24.9 acres of wetland impacts would occur primarily in small palustrine emergent wetlands and intermittent drainages where impacts would be temporary and short term. As described previously, to satisfy COE and state permitting, Pacific Connecter assessed the function and values of wetlands to determine which affected wetlands were high value wetlands. Constructing the pipeline would impact approximately 7.1 acres of high value wetlands, with the majority of these impacts (about 4.1 acres) occurring to two palustrine emergent wetlands (Wetland ID EW-33 and EW-35) associated with the floodplain of Salt Creek in Jackson County. As stated above, the COE may also require additional compensatory mitigation for impacts on ARSCs (COE 2018). ARSCs that may be affected by the proposed pipeline include alkali wetlands, mature forested wetlands, vernal pools, and Willamette Valley wet prairie wetlands.

To minimize impacts on wetlands, Pacific Connector would implement the construction and restoration measures contained in its ECRP. Section VI.A.3 of the FERC's *Procedures* requires that the construction right-of-way width be limited to 75 feet across wetlands, while Section VI.B.1.a requires that TEWAs be located at least 50 feet away from wetland boundaries. However, Pacific Connector has submitted modifications for these requirements associated with where the applicant requested a 95-foot-wide construction right-of-way in a wetland or that TEWAs be located less than 50 feet away from a wetland (table E-1 in appendix E). Their justifications for the modifications at specific locations vary, but include reasons such as: 1) necking-down the right-of-way in emergent wetland would require use of TEWAs that would be located 50 feet back from the waterbody, which could result in these work areas being located within forested or shrub wetlands that can have a higher function and value than the disturbed emergent wetland, and 2) where the pipeline traverses disturbed emergent wetlands, such as in agricultural areas (cropland and hayfields), the typical 95-foot-wide construction footprint in uplands will be maintained because these wetlands are degraded systems that are expected to fully recover within one full growing season. Pacific Connector's proposed modifications to FERC's *Plan* and *Procedures* are provided in appendix E, also see discussion in section 2. Based on our *Procedures* and as described in its ECRP, Pacific Connector would implement the following measures in wetlands

- the top 1 foot of topsoil would be segregated from the subsoil in the area disturbed by trenching, except where standing water is present, or soils are saturated or frozen. Immediately after backfilling, the segregated soil would be restored to its original location;
- vegetation would be cut just above ground level to leave the existing root system in place. Tree stump removal and grading would occur directly over the trenchline. Stumps would not be removed from the rest of the right-of-way unless required for safety reasons;
- construction equipment operating would be limited to that needed to clear vegetation, dig trenches, install the pipe, backfill, and restore the right-of-way. Other equipment would use upland access roads to the maximum extent possible. Travel would be restricted across wetlands where topsoil was restored;
- low ground-weight equipment would be used in saturated wetlands or the normal equipment would be operated on prefabricated equipment mats;
- slope breakers and sediment controls would be installed and maintained on slopes greater than 5 percent that are less than 50 feet from a wetland;
- erosion control devices would be installed and maintained as necessary to prevent sedimentation and runoff from entering wetlands;
- trench breakers would be installed, or the bottom of the trench would be sealed as necessary, to maintain the original wetland hydrology;
- appropriate weed-free live seed mixtures would be used for revegetation. No fertilizers would be used in wetlands;

- appropriate native trees and shrubs would be replanted during restoration of wetlands within riparian areas;
- wetlands would be monitored after revegetation for three years after construction or until the revegetation is successful. Revegetation would be considered successful when 80 percent of the type, density, and distribution of species are similar to that of adjacent unaltered wetlands. If revegetation is not successful at the end of three years, Pacific Connector would develop and implement a remedial revegetation plan to actively revegetate the wetland and would continue revegetation efforts until wetland revegetation is successful; and
- vegetation maintenance would not be conducted over the full width of the operational right-of-way within wetlands, but limited to a 10-foot-wide corridor.[89]

The COE and ODSL may require additional mitigation (beyond what is required in this EIS) during their permitting process, which could include creating, restoring, or enhancing wetlands to replace the wetland functions and areas connectivity lost due to Project activities, or purchasing credits from a mitigation bank. ODSL administrative rules (OAR 141-085-0690) include minimum ratios for acres required for compensation that varies by type of mitigation proposed (e.g., restoration is 1 acre for each acre lost, creation is 1.5 for 1, and enhancement is 3 for 1). Pacific Connector has developed a *Compensatory Wetland Mitigation Plan* to mitigate for unavoidable impacts on wetlands affected by construction and operation of the pipeline (see section 4.3.3.1). The adequacy of wetland mitigation, including the scope and location of mitigation, would be determined by the COE.

4.3.3.3 Conclusion

In total the Project would impact a total of about 198 acres of wetlands, about 27 acres of which would be permanently lost. Based on our review of the Project and Jordan Cove and Pacific Connector's implementation of measure to reduce impacts on wetlands, we conclude that constructing and operating the Project would not significantly affect wetlands. Additionally, to mitigate wetlands impacts, Jordan Cove and Pacific Connector have prepared a Compensatory Wetland Mitigation Plan.

4.3.4 Environmental Consequences on Federal Lands

4.3.4.1 Groundwater

Shallow Groundwater

As indicated in section 4.3.1.2, the Pacific Connector Pipeline Project would cross areas where the groundwater is 0-6 feet bgs. The BLM and Forest Service may require that trench dewatering through a well point pumping system with a groundwater treatment plan be used, depending on if the groundwater is emanating from a pressurized or non-pressurized source point. On federal lands, dewatering activities would be coordinated with the BLM or Forest Service.

[89] Additionally, trees may be selectively removed if they are within 15 feet of the pipeline that could compromise the pipeline coating integrity.

Springs, Seeps, and Drains

Pacific Connector surveys have identified a number of springs and seeps, as noted in appendix H of this EIS. Pacific Connector has stated that it would further verify exact locations of springs and seeps during easement negotiations with land managers. Nearby springs and seeps supplied by deeper pressurized groundwater zones would generally not be affected by the trenching activities or trench plugs. Spring and seeps supplied by shallow groundwater, however, may be effected by the pipeline project, particularly if the pipeline is directly up-gradient of a spring or seep location.

The BLM has disclosed that French drains, similar in function to drain tiles, were installed to stabilize Elk Creek Road, which the proposed route would cross six times between MPs 34.02 and 37.15. These crossings are all within BLM lands. Pacific Connector would ensure that any French drains damaged by the pipeline would be repaired before backfilling. If either damage or repair causes a discharge to waterways under federal jurisdiction, a water quality permit would be required under Section 404 of the CWA. All French drains crossed by the Pacific Connector pipeline would be probed prior to right-of-way restoration to check for damage, and a qualified specialist would test for damage and conduct any necessary repairs. Pacific Connector would restore any damaged drains to the same condition that existed prior to construction. In order to identify, monitor, minimize, and mitigate for potential effects to groundwater, Pacific Connector has developed a *Groundwater Supply Monitoring and Mitigation Plan.* Land managers would be supplied with documentation that explains the pipeline construction Project and outlines the pre-construction field investigation for the identification and monitoring of groundwater supplies. Pre-construction surveys would be conducted to confirm the presence and locations of all groundwater supplies within and adjacent to the pipeline right-of-way.

Soil Compaction

Near-surface soil compaction caused by heavy construction vehicles could locally reduce the soil's ability to absorb water, which would increase surface runoff and the potential for ponding. To avoid long-term changes in water table elevation and subsurface hydrology, excavated topsoil and subsoils would be segregated (on non-federal lands) within wetlands, agricultural areas, and at the request of landowners, and returned as closely as practical to their original soil horizon and slope position. Following construction, restoration of compacted soils would include regrading, recontouring, scarifying (or ripping), and final cleanup activities. Decompacting soils would restore water infiltration, reduce surface water runoff, minimize erosion, and support revegetation efforts. The EI would be responsible for conducting soil compaction testing and determining corrective measures on non-federal lands, including localized deep scarification or ripping to an average depth of up to 8 inches where feasible, utilizing appropriate winged-tipped rippers. On federal lands, remediation and corrective measures to address compaction would be consistent with specific requirements of the BLM RMP Best Management Practices (e.g., R-91, TH-18) and Forest Service requirements (see NSR 2015a for details).

Accidental Spills of Hazardous Materials

Pipeline construction necessitates the use of heavy equipment and associated fuels, lubricants, and other potentially hazardous substances that, if spilled, could affect shallow groundwater and/or unconsolidated aquifers, throughout different aquifer layers. Accidental spills or leaks of hazardous materials associated with vehicle fueling, vehicle maintenance, and construction materials storage would present the greatest potential contamination threat to groundwater resources. Soil contamination resulting from these spills or leaks could continue to add pollutants to the groundwater long after a spill occurs. Implementation of proper storage, containment, and handling procedures would minimize the chance of such releases. Pacific Connector will follow the procedures outline in the *SPCC Plan* to minimize the potential of a spill, properly contain a spill in the event that one occurs, and to protect areas of environmental concern.

4.3.4.2 Surface Water

The Pacific Connector pipeline route would cross 19 fifth-field watersheds, and proposed access roads would cross an additional 5 watersheds. Of these, the Pacific Connector would cross NFS land in 6 fifth-field watersheds subject to ACS.

Riparian Reserves and the ACS

The 1994 NWFP set forth detailed requirements that describe how land managers should treat the forest lands within the range of the northern spotted owl (through implementation of the Standards and Guidelines – Attachment A to the 1994 NWFP ROD [Forest Service and BLM 1994a]). Some standards and guidelines apply to all lands and others to a specific land allocation. The 1994 NWFP ROD described the ACS, which was developed to restore and maintain the ecological health of watersheds and aquatic ecosystems contained within them on public lands. The strategy would protect salmon and steelhead habitat on federal lands managed by the Forest Service within the range of the NSO. In August 2016, the BLM issued two RODs for two new RMPs (BLM 2016a and 2016b). These two plans supersede the NWFP on BLM lands. BLM retained a Riparian Reserve allocation but provided new management direction, thus eliminating the ACS requirements on BLM lands. The following discussion is specific to the Forest Service.

To achieve ACS objectives in the 1994 NWFP ROD, the ACS included areas defined as Riparian Reserves and Key Watersheds, specified analytical procedures for evaluating watersheds, and defined a program for watershed restoration. While the ACS focus was primarily on the conservation of anadromous salmon and steelhead, the nine objectives listed for the ACS include maintaining and restoring aquatic systems, floodplains, wetlands, upslope habitats, and riparian zones to support invertebrate and vertebrate species dependent on those habitats.

The existing conditions and range of variability within the fifth-field watersheds that would be crossed by the Pacific Connector pipeline are provided in the watershed analyses that were prepared by the Forest Service having jurisdiction over the NFS lands within the watersheds. Watershed assessments are a necessary component of a monitoring program in order to determine what degraded or impaired areas may exist in the watershed. Table 4.3.4.2-1 lists the fifth-field watersheds subject to ACS that would be crossed by the proposed route.

TABLE 4.3.4.2-1

Fifth-Field Watersheds Crossed by the Pacific Connector Pipeline on Forest Service Lands

Jurisdiction	Watershed (Name)	Approximate Miles Crossed	Watershed Analysis Completed
Forest Service – Umpqua National Forest (NF)	Days Creek-South Umpqua River a/ Elk Creek a/ Upper Cow Creek a/ Trail Creek a/	1.6 2.7 4.5 2.1	2001 1995 a/ 1995 a/ 1995 a/
Forest Service – Rogue River NF	Little Butte Creek	13.7	1997
Forest Service –Winema NF	Spencer Creek	6.1	1995

Note that mileages may not sum correctly due to rounding. Mileages are rounded to the nearest tenth of a unit; values below 0.1 are noted as <0.1.
Source: BLM 2006; Forest Service 2006a
a/ The Elk Creek Watershed Analysis (Forest Service 1996) and the Cow Creek Watershed Analysis (Forest Service 1995a) encompass the Umpqua National Forest lands crossed by the pipeline.

The following subsection discusses acres of impacts to Key Watersheds and the mitigation measures that would be implemented on NFS land to compensate for impacts. Key Watersheds are defined as either Tier 1 or Tier 2. Tier 1 (Aquatic Conservation Emphasis) Key Watersheds contribute directly to conservation of at-risk anadromous salmonids, bull trout, and resident fish species. They also have a high potential of being restored as part of a watershed restoration program. While Tier 2 (other) Key Watersheds may not contain at-risk fish stocks, they are important sources of high-quality water. Riparian Reserves are lands along streams, wetlands, ponds, lakes, reservoirs and unstable and potentially unstable areas where special standards and guidelines direct land use on NFS lands.

Four watersheds that encompass NFS lands that would be crossed by the Pacific Connector pipeline are designated as Key Watersheds: (1) Days Creek-South Umpqua River (Tier 1); (2) Elk Creek-South Umpqua River (Tier 1); (3) Little Butte Creek; and (4) Spencer Creek (Tier 1. Key Watersheds that would be crossed by the Pacific Connector pipeline are listed in table 4.3.4.2-2.

TABLE 4.3.4.2-2

Key Watersheds Crossed by the Proposed Pacific Connector Pipeline

Key Watershed	Jurisdiction	Approximate Miles Crossed	Approximate Construction Disturbance (acres) a/	Approximate Operational Easement (acres) b/
Days Creek-South Umpqua River (Tier 1), MP 82.71-102.59	Umpqua National Forest	1.56	53	10
Elk Creek-South Umpqua River (Tier 1), MP 101.8-109	Umpqua National Forest	2.67	30	16
Little Butte Creek (Tier 1), MP 135.04-168	Rogue River National Forest	13.75	277	83
Spence Creek (Tier 1), MP 168-183.02	Winema National Forest	6.05	92	37
	Total	**24**	**452**	**146**

Note that values may not sum correctly due to rounding. Mileages are rounded to the nearest tenth of a unit; values below 0.1 are noted as <0.1. Acreages are rounded to the nearest whole acre; values less than 1 are noted as <1.
a/ Includes uncleared storage areas.
b/ Assumes 50-foot-wide long-term easement.

The pipeline would not cross any roadless areas and would not require any new roads to be constructed within Tier 1 Watersheds. Although the pipeline would cause temporary disturbance within Tier 1 watersheds, all disturbed areas associated with the pipeline would be restored after construction. No adverse, long-term effects are anticipated to the water resources. The 30-foot operational maintenance corridor along the pipeline centerline would create a long-term vegetation type conversion impact within forested vegetation types, but the vegetation conversion is not expected to measurably alter hydrologic functions. Restoration of all areas disturbed by the Pacific Connector pipeline would include shaping to the approximate original contour to restore drainage patterns, scarification to relieve compaction, and revegetation for stabilization and to restore habitats and land use functions. The compensatory mitigation measures outlined for LSRs and Riparian Reserves on NFS lands would benefit Key Watersheds if the mitigation projects such as road decommissioning occur within these watersheds.

On NFS lands where Riparian Reserves would be affected, up to a 100-foot riparian strip or to the edge of the existing riparian vegetation would be planted to ensure that the "maintain and restore" objectives of the ACS are accomplished for native riparian vegetation.

Impacts on Streams on Federal Lands and Mitigation

Temporary Equipment Crossings

For any temporary equipment crossings on any stream channel (whether intermittent or perennial, wet or dry) on federal lands, equipment crossings must be accomplished using (1) a bridge, (2) a temporary culvert with temporary road fill to be removed after work is completed, or (3) a low water ford with a rock mat. Although the FERC's *Procedures* allow clearing equipment and equipment necessary for installation of the temporary bridges to cross waterbodies prior to bridge installation, Pacific Connector would not allow clearing equipment to cross waterbodies prior to bridge placement. Furthermore, where feasible, Pacific Connector's contractor would attempt to lift, span, and set the bridges from the streambanks. Where it is not feasible to install or safely set the temporary bridges from the streambanks, only the equipment necessary to install the bridge or temporary support pier would cross the waterbody. Any equipment required to enter a waterbody to set a bridge would be inspected to ensure it is clean and free of dirt or hydrocarbons.

No waterbodies or riparian reserves on federal lands would be affected by temporary or permanent access roads.

Water Use During Pipeline Construction

Water withdrawals and releases on federal lands for dust suppression or hydrostatic testing would require site-specific approval from the agency that manages the specific water resources (federal or state). Site-specific approval by the authorized Forest Service officer on NFS lands, and similar authorizations by BLM and Reclamation would be coordinated through the development of the POD to support the Right-of-Way Grant. Withdrawals and releases of hydrostatic test water would be done in accordance with Pacific Connector's *Hydrostatic Test Plan*, included with the POD.

Potential Encounters with Contaminated Sediments

On federal land, hazardous substances, including chemicals, oils, and fuels, would not be stored within 150 feet of a waterbody or wetland boundary. As noted in the ECRP, any variance on federal lands would require prior approval by an authorized agency representative. In instances where it is not possible to maintain the 150-foot distance, the EI would request a variance that would require approval from the authorized agency representative. To reduce impacts from potential encounters with contaminated sediments, Pacific Connector would implement the measures outlined in its *Contaminated Substances Discovery Plan,* which was included as part of its Spill Prevention, Containment, and Countermeasures Plan.

East Fork Cow Creek Crossing

The Forest Service expressed concerns about the potential for naturally occurring mercury to reach the aquatic environment during construction of the pipeline near the historic Thomason claim group (near MP 109). To address this concern, Pacific Connector conducted a mine hazard evaluation and mercury testing study for the proposed 2007 route on the Umpqua National Forest at the crossing of East Fork Cow Creek, which crossed the Thomason claim group (GeoEngineers 2007b).[90] Soil samples were collected along the proposed alignment in an area believed to be outside the zone of mineralization where mercury deposits occur, in the stream system in the vicinity of the East Fork of Cow Creek, and from mine workings in proximity to the Pacific Connector right-of-way in 2007. The samples did not contain concentrations of mercury that exceeded human health risk screening criteria.

Subsequently, Pacific Connector moved its proposed route to the east to avoid a NSO nest site. GeoEngineers (2009)[91] conducted an additional assessment of the relocated route, approximately 3,300 feet upstream and east of the original 2007 crossing to address the continued concerns of the Forest Service regarding the potential for naturally-occurring mercury within the East Fork Cow Creek drainage. That study concluded that the soils underlying the current proposed crossing of East Fork Cow Creek are unlikely to have concentrations of naturally occurring mercury exceeding those measured in samples obtained from the previous 2007 crossing location and most likely will have lower levels than those reported in GeoEngineers' (2007b) mine evaluation.

In addition to the GeoEngineers (2009) report, the Forest Service contracted with a geologist consultant (Broeker 2010)[92] to collect soil and stream sediment samples for analytical testing and reporting of mercury and other naturally occurring minerals along a 2,000-foot section of the proposed pipeline route between MP 109 and the East Fork Cow Creek. The Broeker study also concluded that construction activities along the revised pipeline route are not likely to encounter soils with elevated mercury concentrations.

In order to prevent this naturally occurring mercury from entering the aquatic environment during and after construction, additional erosion control measures and monitoring would be conducted along the pipeline route in the vicinity of the East Fork Cow Creek. If sediments containing high

Bauer and T. Hoyles, filed as stand-alone report with Pacific Connector's June 2013 application to the FERC.
[91] GeoEngineers, Inc., 2 October 2009, *Addendum to Mine Hazards Evaluation and Mercury Testing at the Red Cloud, Mother Lode, Nivinson, and Elkhorn Mining Group*, prepared by A. Bauer and T. Hoyles, filed as stand-alone report with Pacific Connector's June 2013 application to the FERC.
[92] Broeker, L., 3 February 2010, *Potential for Natural-Occurring Mercury Mineralization to Enter the Aquatic Environment between MP 109 and East Fork Cow Creek Williams' Pacific Connector Pipeline Project*, filed as a stand-alone report with Pacific Connector's September 2017 application to the FERC.

levels of mercury are encountered in the East Fork Cow Creek drainage during Project construction, Pacific Connector would implement the measures outlined in its *Contaminated Substances Discovery Plan*.[93]

Hyporheic Exchange at South Fork Little Butte Creek

The Forest Service has expressed concern that the crossing of South Fork Little Butte Creek would go through basalt and andesite bedrock, and therefore a site-specific crossing would need to address the potential for groundwater interception and flow at and near the crossing. A site-specific drawing for Little Butte Creek located on NFS land was included in Appendix 2E of Resource Report 2 with Pacific Connector's September 2017 application to the FERC. The crossing would need to address the potential for groundwater interception and flow at and near the crossing since it is a critical coho stream which flows through andesite and basalt. The *Stream Crossing Hyporheic Analysis* (GeoEngineers 2013c; 2017g) determined that South Fork Little Butte Creek crossing had high hyporheic sensitivity. Therefore, BMPs would be implemented to mitigate for this possible effect.

Given the potential for disruption of hyporheic processes at crossings with a "high" sensitivity ranking, in addition to the pre-construction survey, a qualified geotechnical professional would be on-site to observe trenching/excavation associated with pipeline installation to document subsurface conditions, including the presence of fractured bedrock or the low probability of the presence of lava tubes. The geotechnical professional would make recommendations for backfill composition, including the use of trench plugs or other mitigation measures, to ensure that disruption to groundwater pathways are minimized. These recommendations would be pre-approved by an authorized Forest Service representative.

Stream Temperature Assessment

Project-specific temperature modeling was conducted on federal lands stream crossings. Temperature modeling, using Stream Segment Temperature Model (SSTEMP) (Bartholow 2002), was conducted at the perennial stream crossings on BLM lands at Middle Creek Deep Creek and Big Creek, and NFS lands at multiple crossing on the East Fork Cow Creek in 2009 and again in 2013 to reflect new pipeline alignment and lower flow conditions (NSR 2009, 2015b,c). During 2013, temperature data recorders were placed at selected locations relative to each crossing during the warmest low-flow summer period to help validate the model. Flows in 2013 represented drought conditions and were about 33 percent of those modeled in 2009 at MP 109.69 in the East Fork Cow Creek. When compared to measured existing conditions, the SSTEMP model overestimated the lower flowing stream's actual existing stream temperature slightly (about 0.2 to 0.4°F) (NSR 2015b,c), indicating the inherent uncertainty in modeling stream temperatures in very small stream channels, and the potential to overestimate temperature changes in small streams.

Model analysis of right-of-way clearing effects predicted slight temperature increases on the BLM channel crossings in Middle Creek and a small tributary to Big Creek (NSR 2014), with these limited temperature changes likely due to relatively higher flows (Middle Creek), cooler air temperatures and relative channel orientations (NSR 2015b). During the drought conditions of 2013, modeled 7-day maximum stream temperature just below in the multiple East Fork Cow

[93] Appendix E of the POD filed as a stand-alone report in Pacific Connector's September 2017 application to the FERC.

Creek crossings showed potential temperature increases of 1.2°F to 4.2°F under the rare drought flow conditions that occurred in 2013 (NSR 2015c). Measured stream volumes ranged from 0.045 cubic feet per second to 0.115 cubic feet per second with modeled total vegetation removal in the whole 75-foot right-of-way for post-construction shade levels ranging from 1.2 to 3.7 percent. Under the drought conditions of 2013 (high temperature and low flow), modeled results suggest temperatures may exceed the TMDL thresholds (0.1°C or 0.18°F at the point of maximum impact) or ODEQ Core Cold-Water Habitat temperature criteria of 16°C (61°F) in small perennial channels in the East Fork Cow Creek. This occurrence likely overestimates temperature changes that would most often occur, because of the drought conditions that occurred in 2013 and potential to overestimate of temperature in low-flow channels from the SSTEMP model as noted above. The 2014 analysis showed larger temperature increases than those reported in NSR (2009) primarily due to much lower flows during 2013.

Although exposure to solar radiation may cause temperature increases, temperatures downstream from limited stream-side forested clearings have often been found to cool rapidly once the stream re-enters forested regions (Zwieniecki and Newton 1999). Other studies have noted downstream cooling below timber harvest areas as well, but the extent of this cooling is not entirely clear and varies by stream (Moore et al. 2005; Poole 2001). Although there is some debate on the magnitude of cooling provided by riparian vegetation and the extent to which stream temperatures return to non-cleared temperature levels after exiting a cleared area, studies emphasize that riparian buffers assist in maintaining water temperatures (Correll 1997; Gomi et al. 2006). Generally, changes in temperature, especially in small streams, may recover quickly from cooler surrounding conditions downstream (e.g., streambed cooling, evaporation, hyporheic inflows, shade). This was validated by stream temperature data recorded on the Umpqua National Forest in 2013. The updated temperature assessment prepared for the Forest Service at this location (NSR 2014) incorporated field measurements of existing conditions on the Umpqua National Forest that showed decreasing stream temperatures of as much as -7.6°F per 100 feet with an overall average over 2,040 feet of the East Fork Cow Creek of -0.1°F per 100 feet (NSR 2015c). The presence of numerous small wetlands adjacent to the stream channel provide evidence of likely groundwater interactions. Most of this 2,040-foot reach also has substantial shade, suggesting the retention of shading structures, or at least partial shade, may greatly reduce increases in stream temperature. The 2014 assessment also supports the NSR (2009) finding that potential temperature increases are partially offset by cooling from groundwater interactions in the stream channel.

Observations of these streams suggest that LWD and low-growing willows, huckleberries, and other brush species can provide effective shade for small, narrow channels. Blann et al. (2002) noted that riparian grasses and forbs supply as much shade as wooded buffers for streams less than 8 feet (2.5 meters) wide. In many cases during pipeline crossing construction, low-growing brush outside of the immediate crossing construction area could be retained minimizing shade loss. In the mainstem of the East Fork Cow Creek, LWD provides significant shade that helps maintain cooler water temperatures. As described in the ECRP and waterbody crossing requirements for the project, all LWD and boulders removed from the crossing area would be replaced during site restoration and low-growing brush would be retained where possible (NSR 2015). Many of the channels crossed by the Pacific Connector pipeline on federal lands are very small, and could easily be shaded by the placement of LWD and willow plantings. Where site-specific modeling on NFS perennial stream crossings suggests temperature increases over natural pre-project levels, a plan would be prepared to reestablish pre-crossing shade conditions using items such as willows, boulders, and LWD.

With the retention of existing shading brush on small channels, the placement of LWD, and the replanting of willows and other brush species, downstream temperatures are expected to be comparable to the existing condition and to remain below ODEQ thresholds on the East Fork Cow Creek. Additionally, any temperature increases in small streams would likely be masked by the assimilative capacity of larger streams at the stream network scale (NSR 2009).

During the ODEQ CWA Section 401 process, Pacific Connector would develop a source-specific implementation plan in accordance with OAR 340-042-0080 for areas with existing TMDLs and Pacific Connector would be identified as a new nonpoint source. For perennial stream crossings on federal lands, this plan would incorporate the requirements of the site-specific restoration plans (NSR 2015b, c). The source-specific implementation plan would outline mitigation for predicted thermal impacts (GeoEngineers 2013i). This mitigation would have as its goal restoring shade along affected stream channels and nearby channels within the same fourth-field HUCs. Mitigation for construction-related impacts would occur to the extent allowed by landowners on the affected streambanks. This mitigation would incorporate riparian revegetation required by the Forest Service for impacts to riparian reserves on NFS lands. The length of channel banks planted by Pacific Connector would be determined prior to pipeline construction once a clear understanding of landowner wishes regarding streambank planting are known. Contiguous lengths of streambank planting would be preferred over planting on multiple small parcels, particularly for mitigation of permanent impacts. Mitigation ratios of 1:1 for construction-phase impacts or 2:1 for permanent impacts would be applied as outlined in ODEQ's September 2011 letter. Prior to construction, Pacific Connector would also provide the implementation plan to FERC.

Where TMDL thermal load allocations have not yet been established, ODEQ's 401 Water Quality Certification would require the development of a Water Protection Plan, consistent with the source specific implementation plan, and a mitigation plan to address project impacts on thermal loading.

On NFS lands, the Forest Service has requested that the riparian vegetation strip be extended up to 100 feet on either side of waterbodies in Riparian Reserves. Pacific Connector has agreed to implement this measure on both NFS lands and BLM lands. The riparian strip would generally be replanted with species such as willow cuttings and dogwood to provide a quick cover for shading and streambank stability. Quick cover plantings may be shorter in height than vegetation removed during constructions, thus providing less shade. Plantings/seeding would be done with native vegetation of a local source. The riparian strip would be maintained to allow an herbaceous cover 10 feet in width centered over the pipeline to facilitate corrosion and leak surveys. The remaining area of the construction right-of-way within the riparian strip would be replanted with trees that would provide greater height and stream shading over time.

<u>Restoration</u>

Near-surface soil compaction caused by heavy construction vehicles could locally reduce the soil's ability to absorb water, which would increase surface runoff and the potential for ponding. To avoid long-term changes in water table elevation and subsurface hydrology, excavated topsoil and subsoils would be segregated within wetlands, agricultural areas, and at the request of landowners, and returned as closely as practical to their original soil horizon and slope position. Following construction, restoration of compacted soils would include regrading, recontouring, scarifying (or ripping), and final clean-up activities. Decompacting soils would restore water infiltration, reduce surface water runoff, minimize erosion, and support revegetation efforts. Pacific Connector would test for soil compaction in agricultural (e.g., active croplands, hayfields, and pastures), residential areas, and on federal lands. The EI would be responsible for conducting soil compaction testing and determining corrective measures on non-federal lands, including localized deep scarification or ripping to an average depth of up to 8 inches where feasible, utilizing appropriate winged-tipped rippers. On federal lands, remediation and corrective measures to address compaction will be consistent with specific requirements of the BLM, Forest Service, and Reclamation (see NSR 2015a for details). In response to a Forest Service request, Pacific Connector would stabilize intermittent stream crossings (whether flowing or not) on NFS lands with temporary sediment barriers and reseed as described for other waterbodies. Streambanks and stream beds would be revegetated with native species and "armored" as needed with LWD and boulders to ensure stability. Channel breakers would be installed on each side of the trench to ensure that subsurface flows are not captured by the pipeline trench.

As discussed in section 4.3.2, Pacific Connector has requested a modification to the FERC's *Procedures* requirement that the upper 1 foot of the trench to be backfilled with clean gravel or native cobbles in all waterbodies that contain cold water fisheries. Pacific Connector has requested that for instances where the existing substrate is not gravel or cobbles, and site access is limited and would require unreasonable efforts to transport clean gravel to the waterbody, that only native materials removed from the stream be used for backfill.

For crossings of perennial streams on BLM and NFS lands, the site-specific restoration plans included as a supplement to appendix F.4 (NSR 2014)[94] will be used as directed by BLM and Forest Service monitors in conjunction with FERC's EIs. These restoration plans have been designed to ensure that restoration and revegetation of these crossings are consistent with ACS objectives as described in the relevant Forest Service land management plans.

All disturbed areas on federal lands would be monitored following construction to verify successful revegetation and to implement corrective action. Pacific Connector would also adhere to its mitigation plan (developed to mitigate for impacts to all riparian and upland habitats), which would be followed in areas with severe to soil erosion potential. Throughout operation of the pipeline, Pacific Connector would continue to monitor and maintain the right-of-way. The Forest Service, in consultation with Pacific Connector, has prepared a list of mitigation actions to address unavoidable impacts on NFS lands.

4.3.4.3 Wetlands

The Pacific Connector pipeline would cross approximately 0.2 mile of wetlands on federally managed land, affecting a total of approximately 2.2 acres (see table H-1a in appendix H). Permanent wetland vegetation conversion on federally managed lands would occur in approximately 0.2 acre of wetlands as a result of vegetation management on the operational right-of-way. This 0.2 acre of permanent conversion would occur to three wetlands: palustrine forested wetland CW010 located on lands managed by the BLM Coos Bay District, palustrine forested

[94] These site-specific restoration plans for BLM and Forest Service stream crossings are also incorporated into the Wetland and Waterbody Crossing Plan that is part of the POD.

wetland AW309 located on lands managed by the BLM Medford District, and palustrine scrub-shrub/emergent wetland GW-14/FS-HF-CWWW-111-001 (i.e., a tributary to East Fork Cow Creek) managed by the Forest Service (on the Umpqua National Forest).

There would be no permanent wetland loss or wetland impacts on federally managed land due to the construction of aboveground facilities. Impacts resulting from use of existing roads would be minimized through the implementation of Pacific Connector's ECRP and the mitigation measures described above for the pipeline on all lands.

In order to prevent or limit the spread of invasive species and noxious weeds into wetlands on federally managed lands, Pacific Connector would inspect all construction equipment prior to transporting equipment to the construction right-of-way to ensure that it is clean and free of potential weed seed. Because of the contiguous pattern of NFS lands crossed by the pipeline, equipment would be inspected and cleaned at cleaning stations located at the borders of each National Forest, prior to clearing and grading activities, in addition to being cleaned at cleaning stations associated with any mapped infestation of noxious weed of priority A and T and selected B listed weeds within each National Forest (see section 4.4 for more details regarding noxious weeds). Because the BLM lands crossed by the pipeline are not contiguous but are instead spread out in a checkerboard pattern, Pacific Connector feels that is not practical to set up inspection and cleaning stations at each entry point. Instead, Pacific Connector proposed that where BLM lands are contiguous to NFS lands, the cleaning stations would be located to include the adjacent BLM lands. The location of any additional cleaning stations required in areas where BLM- or Reclamation-managed lands are not contiguous with NFS lands would be coordinated with the agency of jurisdiction. Additional measures to prevent the spread of invasive weed and wildlife species into wetlands and waterbodies are addressed within sections 4.4 and 4.5 of this EIS.

Measures to avoid or minimize impacts on wetlands that would be implemented on federally managed lands, in addition to those described above for the entire pipeline, include the following:

- Where straw is to be used on federally managed lands during seeding operations, the authorized officer for the agency of jurisdiction may inspect and approve straw material to verify that the straw is weed-free. Any gravel or rock used on federal lands would be from weed-free sources as well, and approved by the authorized representative for the agency of jurisdiction.
- Hazardous materials, fuels, and oils would not be stored in a wetland/Riparian Reserve or within 150 feet of a wetland/Riparian Reserve. Storage of hazardous materials on NFS lands would not occur without prior authorization from the BLM, Forest Service or Reclamation.
- During revegetation efforts, specific mixtures specified by the agency with jurisdiction would be used on federally managed lands. No fertilizers would be used during the revegetation of wetlands.

Based on available information, with the implementation of appropriate plans, the use of additional BMPs, and mitigation, substantial effects to waterbodies on federal lands are not expected.

4.4 UPLAND VEGETATION

The vegetation affected by construction and operation of the Project represents arguably the largest and most permanent impact, particularly the forested vegetation. Forests in the Project area support multiple interacting layers of organisms that include plants, animals, fungi, and bacteria. Old-growth forests provide vital habitat for many native species of plants and wildlife, including many federally listed threatened or endangered species, as well as providing a variety of environmental services. Old-growth trees occupied about half of the forest area in Oregon when the first comprehensive forest surveys were made in the 1930s and 1940s. By 1992, only about 20.5 percent of the forest area was old growth (Bolsinger and Waddell 1993). These resources have particular value based on their contribution to other organisms and the fact that much of this habitat has been lost.

In the following sections, we describe the vegetation communities that may be affected by construction and operation of the proposed terminal and pipeline. We also discuss the ways in which construction and operation would affect these resources.

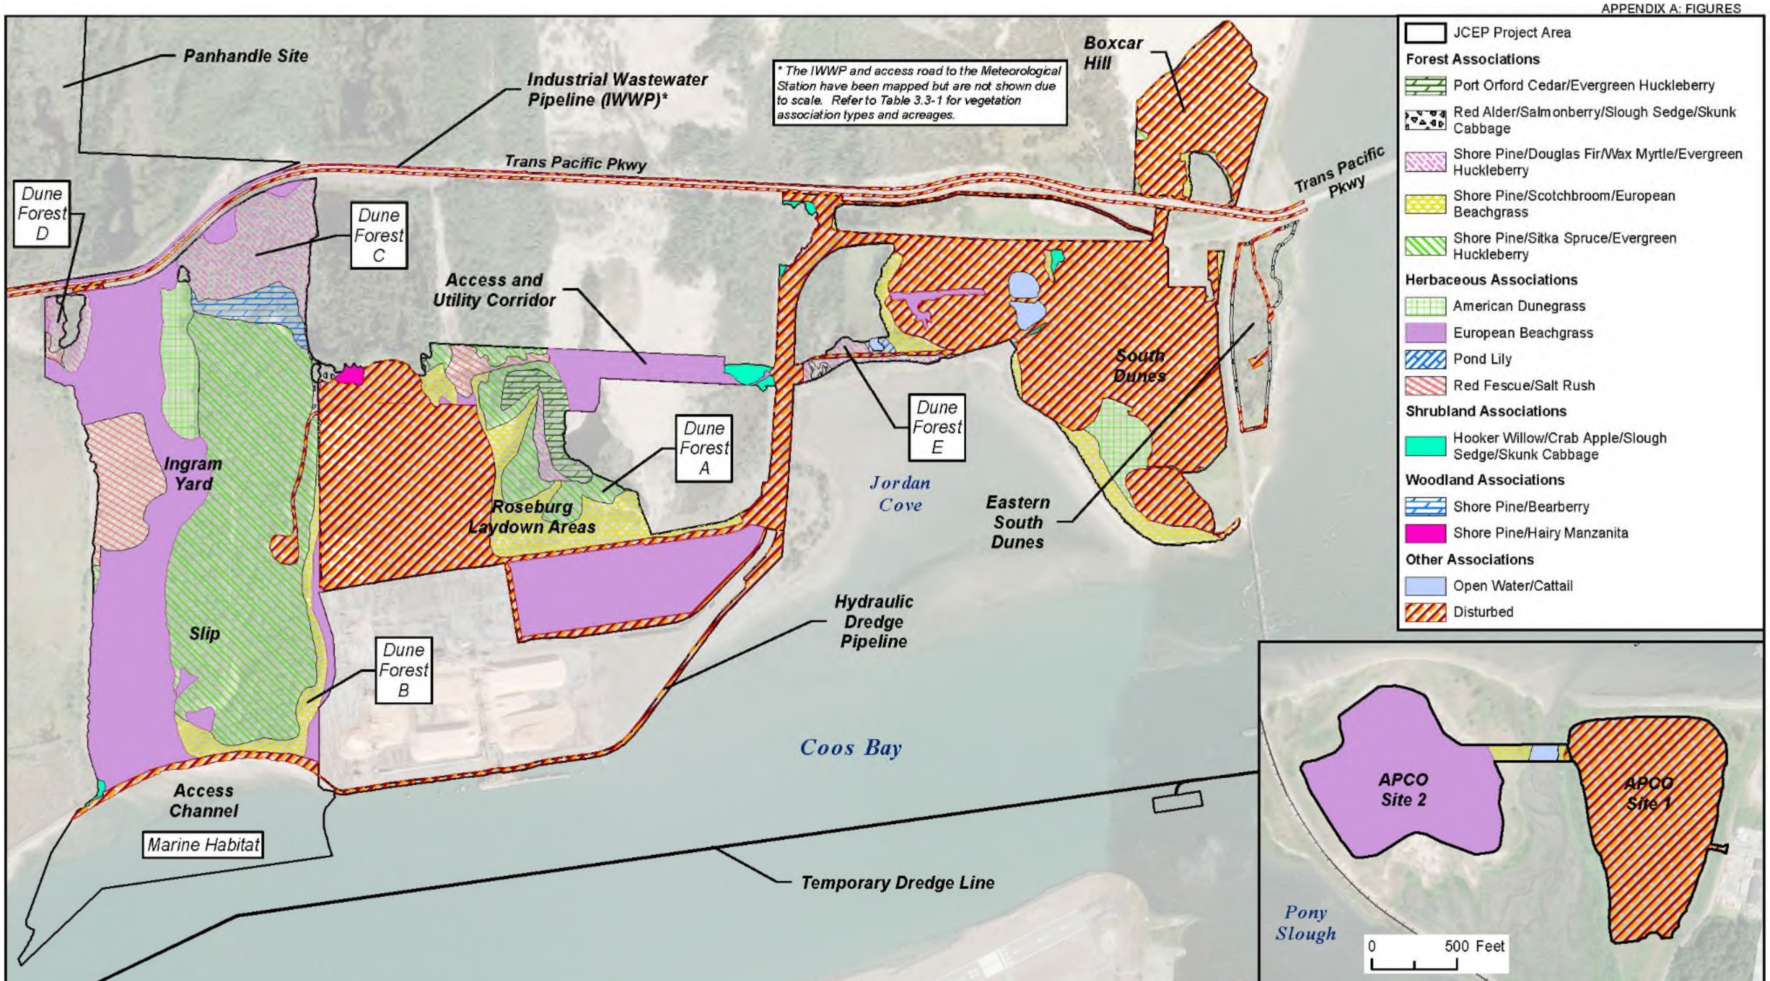
4.4.1 Jordan Cove LNG Project

As depicted in figures 4.4-1a and 4.4-1b, vegetation within the Jordan Cove LNG Project area includes forest, woodland, shrubland, and herbaceous vegetation types (as described in Christy et al. 1998). In addition, multiple areas consisting of disturbed vegetation are located within the area affected by the Project.

4.4.1.1 Forest Vegetation

Forested vegetation is defined as areas where tree species comprise at least 60 percent of the vegetation cover and canopy cover is generally 60 to 100 percent. Forested vegetation within the Jordan Cove LNG Project area varies in age and is dominated by coniferous species with scattered hardwoods. Five forested vegetation types occur within the Jordan Cove LNG Project area, as described below. Generally, the forested vegetation in this area is referred to as dune forest. Five different dune forests have been identified within the Jordan Cove LNG Project area (Dune Forest A through Dune Forest E, see figure 4.4-1a).

The Shore Pine–Douglas-Fir/Wax Myrtle-Evergreen Huckleberry vegetation type typically occurs near previously developed areas such as roads, fill sites, or industrial sites. It occurs most frequently on warm, dry ridges, and slopes on the dunes; primarily with south to west facing aspects (Christy et al. 1998). This vegetation type is characteristic of younger forest sites north of Jordan Cove and occurs in areas where dune stabilization has been achieved through recruitment of vegetation, most notably European beachgrass (*Ammophila arenaria*) and Scotch broom (*Cytisus scoparius*). This vegetation type has an open overstory dominated by shore pine (*Pinus contorta*) with scattered Douglas-fir (*Pseudotsuga menziesii*). The shrub layer is dominated by Scotch broom and coyote bush (*Baccharis pilularis*), with scattered hairy manzanita (*Arctostaphylos columbiana*), wax myrtle (*Morella* [*Myrica*] *californica*), and evergreen huckleberry (*Vaccinium ovatum*). Dominant herbaceous species include non-native species, including European beachgrass, silver hairgrass (*Aira caryophyllea*), little hairgrass (*A. praecox*), hairy cat's ear (*Hypochaeris radicata*), and sheep sorrel (*Rumex acetosella*), as well as native bracken fern (*Pteridium aquilinum*). This vegetation type can be found in portions of Dune Forests A, B, and C where adjacent landscapes have been altered by human or natural influences.



Associations used are based on the USDA Publication National Vegetation Classification System (NVCS).

Source: SHN Engineers, David Evans and Associates, Inc.

Figure 4.4-1a

Vegetation Associations

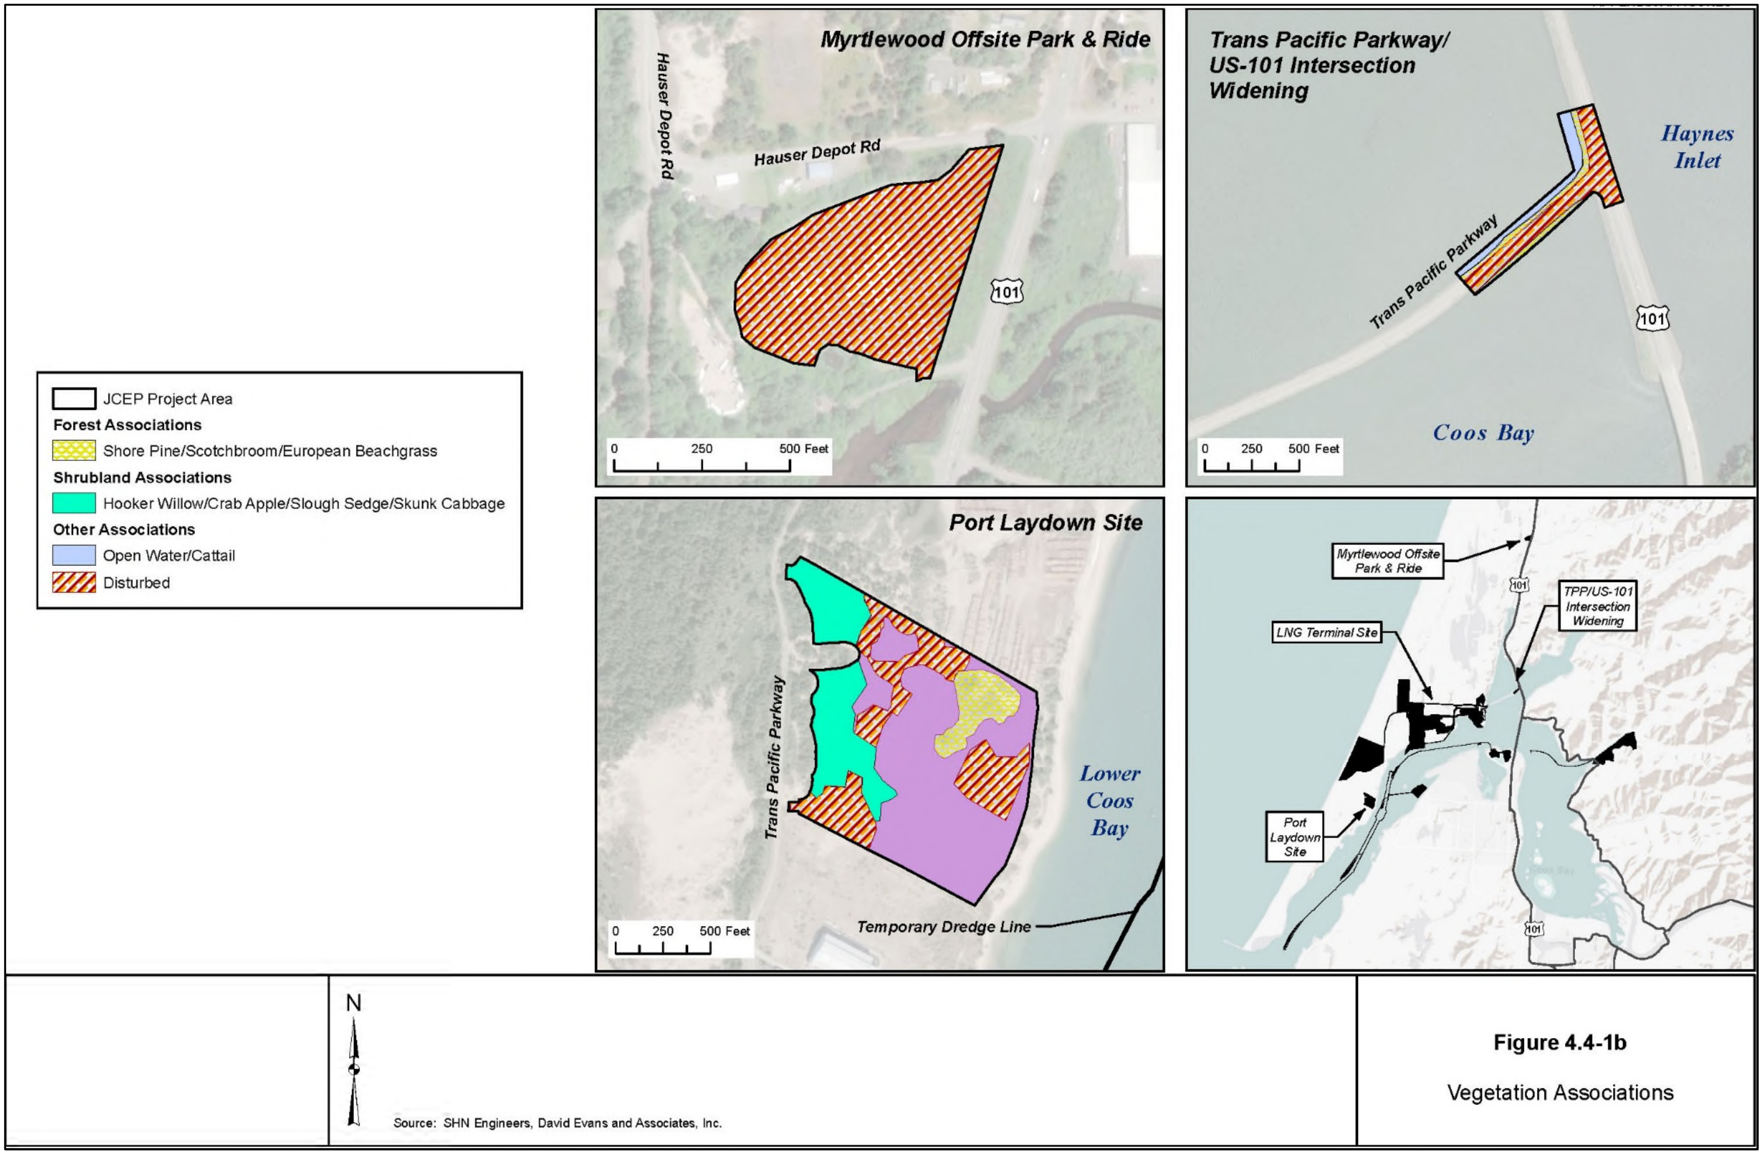


Figure 4.4-1b

Vegetation Associations

The Shore Pine-Sitka Spruce/Evergreen Huckleberry vegetation type is common in more successionally mature forests. Stands are generally dominated by shore pine and Douglas-fir, but also include Sitka spruce (*Picea sitchensis*), western hemlock (*Tsuga heterophylla*), and scattered Port Orford cedar (*Chamaecyparis lawsoniana*). The dense shrub understory in this vegetation type is dominated by evergreen huckleberry, salal (*Gaultheria shallon*), and wax myrtle, with scattered Pacific rhododendron (*Rhododendron macrophyllum*) also present. The herbaceous layer varies from sparse to moderately covered with candy-stick (*Allotropa virgata*), rattlesnake plantain (*Goodyera oblongifolia*), and bracken fern along edges or gaps in the overstory. Dune Forest B occurs in this vegetation type.

The Port Orford Cedar/Evergreen-Huckleberry vegetation type is dominated by Port Orford cedar and is considered unique because it is being decimated throughout its limited range by the Port Orford cedar root rot disease which is caused by the fungal root rot *Phytopthora lateralis* (Christy et al. 1998). A small area of well-developed Port Orford cedar/evergreen huckleberry vegetation is located upslope from the southwestern shore of Jordan Lake. Port Orford cedar observed at this location includes two trees upslope from the existing access trail that travels from the Roseburg Forest Products facility to Jordan Lake. Additionally, 23 Port Orford cedars were observed at sites located adjacent to Jordan Lake, in areas that would be preserved as part of the Jordan Cove LNG Project. This vegetation type can be found in portions of Dune Forest A.

The Red Alder/Salmonberry/Slough Sedge-Skunk Cabbage vegetation type occurs in wetland vegetation adjacent to upland forested vegetation, and in low flat areas adjacent to inundated wetlands. In this vegetation type, the overstory consists entirely of red alder (*Alnus rubra*) around wet areas, but transitions to shore pine in adjacent areas. Canopy cover varies from moderate (i.e., more than 50 percent canopy cover) to closed. Scattered clusters of dense shrubs, including salmonberry (*Rubus spectabilis*) and Hooker's willow (*Salix hookeriana*), are located in the understory. Herbaceous coverage is generally found in wet areas and consists almost entirely of slough sedge, with scattered skunk cabbage (*Lysichiton americanus*). This vegetation type occurs in Dune Forest E and adjacent to Dune Forest B.

Although the Shore Pine/Scotch Broom/European Beachgrass vegetation type contains shore pine, it is also described as a shrubland due to the high density of shrubby species, including Scotch broom. This vegetation type is relatively widespread throughout the Jordan Cove LNG Project site and is associated with roads and other disturbed areas. The overstory is generally open, averaging less than 50 percent cover of shore pine. Scotch broom cover varies from moderately to very dense in areas that lack a substantial canopy cover. Dominant herbaceous species include European beachgrass, red fescue (*Festuca rubra*), tall fescue (*Schedonorus arundinaceus* [*Festuca arundinacea*]), silver hairgrass, hairy cat's ear, and sheep sorrel. This vegetation type occurs west of the South Dunes site, north of the Roseburg Forest Products property, along previous road cuts for the Trans-Pacific Parkway, and along the edges of the shore pine-Sitka spruce/evergreen huckleberry community at the Port Laydown, Boxcar Hill, and APCO sites.

4.4.1.2 Woodland Vegetation

Woodland vegetation includes areas of open tree stands with cover generally varying from 25 percent to 60 percent. They occur on all aspects of dry, well drained, partially stabilized dune ridges, slopes, and flats between the sand and the forest edge (Christy et al. 1998). Two woodland vegetation types occur within the Jordan Cove LNG Project site.

The overstory of the shore pine/bearberry (*Arctostaphylos uva-ursi*) woodland vegetation type consists entirely of shore pine. The shrub layer is dominated by the low growing shrub bearberry with hairy manzanita in scattered patches. The understory is comprised almost entirely of moss and lichen species except for scattered little hairgrass, hairy cat's ear, and shrub starts. This vegetation type is restricted to a thin band adjacent to the coastline and is easily damaged by human disturbances. Shore pine/bearberry vegetation is scattered throughout the LNG terminal site, with the most substantial occurrence between Dune Forests B and C.

The overstory of the shore pine/hairy manzanita woodland vegetation type is moderately open and is dominated by shore pine with scattered Douglas-fir trees. The shrub layer varies from moderate to dense in areas where the canopy is patchy. Hairy manzanita is the dominant shrub species with scattered evergreen huckleberry and bearberry along edges. A small area of this vegetation type can be found along the eastern boundary of Dune Forest B along the access and utility corridor.

4.4.1.3 Shrubland Vegetation

Shrubland vegetation types generally consist of greater than 25 percent cover of shrubs more than 0.5 meter tall and generally less than 25 percent tree cover. A single shrubland vegetation type was identified within the Jordan Cove LNG Project area.

The overstory within the Hooker Willow/Crabapple/Slough Sedge-Skunk Cabbage vegetation type is dominated by Hooker willow, Sitka willow (*Salix sitchensis*), and Douglas spiraea (*Spiraea douglasii*), with scattered twinberry (*Lonicera involucrata*). Evergreen trees are mostly absent but may include scattered shore pine and Sitka spruce. Slough sedge is the most abundant herbaceous species. Other herbaceous species include common rush (*Juncus effusus*), dagger-leaved rush (*Juncus ensifolius*), toad rush (*J. bufonius*), western bent-grass (*Agrostis exarata*), creeping bent-grass (*A. stolonifera*), reed canarygrass (*Phalaris arundinacea)*, northern willowherb (*Epilobium ciliatum*), tall mannagrass (*Glyceria striata* [*G. elata*]), and lowland cudweed (*Gnaphalium palustre*). This vegetation type occurs throughout the wetland areas west of Jordan Cove Road, in the access and utility corridor, and at the South Dunes site.

4.4.1.4 Herbaceous Vegetation

Herbaceous vegetation types are communities with less than 25 percent shrub cover and greater than 25 percent herbaceous cover. Five herbaceous vegetation types occur within the Jordan Cove LNG Project area.

Dominant species within the European beachgrass vegetation type include European beachgrass, red fescue, silver burweed (*Ambrosia chamissonis*), sand pea (*Lathyrus japonicus*), seashore lupine (*Lupinus littoralis*), beach silvertop (*Glehnia littoralis*), and beach evening primrose (*Camissonia cheiranthifolia*). This vegetation type occurs where the terminal marine slip would be located. It was also observed in patches north of Jordan Lake where the access/utility corridor is proposed and at the Port Laydown site and is the dominant vegetation type at the APCO Site 2.

The Red Fescue/Salt Rush vegetation type is generally found in grasslands on sand or fill material. Red fescue is the dominant species in this association. Scattered red fescue was observed on fill west of the South Dunes site and on sand north of the Roseburg Forest Products export facility. At the South Dunes site, in an area surrounded by scattered red fescue, a portion of a small dune was dominated by salt rush (*Juncus lesuerii*). Red fescue/salt rush was also observed at sites where sand burial by wind driven forces limits species diversity, including the western part of the LNG terminal site.

The American dunegrass vegetation type includes dune lands with the single dominant species American dunegrass (*Leymus mollis*). It can be found on beaches and in foredunes, and to a lesser extent on open deflation plains and in upper estuaries. Continual sand burial and inputs of salt spray seem necessary for American dunegrass to thrive. Scattered American dunegrass was observed west of Dune Forest B, in the LNG terminal grassland vegetation east of Henderson Marsh on previous fill deposits, and the western half of APCO Site 1.

Dominant species in the Pond Lily vegetation type include yellow pond lily (*Nuphar lutea* ssp. *polysepala),* floating water-pennywort *(Hydrocotyle ranunculoides)*, floating-leaved pondweed (*Potamogeton natans*), parrotfeather (*Myriophyllum aquaticum*), water shield (*Brasenia schreberi*), and common bladderwort (*Utricularia macrorhiza*). Pond lily vegetation has been observed in deep freshwater wetlands located at the LNG terminal site.

The Common Cattail/Open-Water vegetation type includes wetland fringe sites observed adjacent to open bodies of water. Open water and areas dominated by common cattails can be found surrounding the existing sludge ponds at the South Dunes site as well as around wetlands observed south of the Trans-Pacific Parkway in the eastern portion of the LNG terminal site.

Disturbed vegetation occurs in previously human-disturbed areas, where extensive grading and gravel and dredge spoils deposition has occurred. These areas often contain non-native upland shrubs with small patches of young coastal forest dominated by shore pine, and herbaceous communities dominated by European beachgrass. Disturbed vegetation within the Jordan Cove LNG Project site typically consists of ruderal shrub, such as Scotch broom, and herbaceous vegetation. Dominant herbaceous species include silver hairgrass, hairy cat's ear, bracken fern sheep sorrel, red fescue, and seashore lupine. Disturbed vegetation is common in many areas of the Jordan Cove LNG Project site including the South Dunes site, the Port Laydown site, and the APCO Site 1.

4.4.1.5 General Impacts on Vegetation

Table 4.4.1.5-1 identifies the amount of vegetation affected by construction and operation of the Jordan Cove LNG Project. Constructing the Jordan Cove Project would result in 499 acres of vegetation clearing, which includes the permanent clearing of 168 acres of vegetation. Construction of the Kentuck project and Eelgrass Mitigation sites would result in an additional 127 acres of vegetation clearing not included in table 4.4.1.5-1.

Approximately 73 acres of forested vegetation, 59 acres of which consists of the shore pine-Sitka spruce/evergreen huckleberry vegetation type, would be permanently affected. All of Dune Forests A and B, the majority of Dune Forest C, and portions of Dune Forest D and E would be permanently affected. The clearing of dune forest vegetation during construction would affect the vegetation at the newly exposed edge of the coniferous forest by changing the micro-climate factors (wind, light, salt spray, organisms that prefer edges). The vegetation found within the forest interior would be exposed to the environmental elements experienced by a forest edge, which could lead to a change in species composition.

TABLE 4.4.1.5-1

Impacts on Vegetation Type from the Jordan Cove LNG Project a/

Vegetation Type	Land Cleared during Construction (acres) b/, c/	Land Permanently Cleared due to Operations (acres) b/
Jordan Cove LNG Project Facilities		
Forested Vegetation	75	71
Woodland Vegetation	<1	<1
Shrubland Vegetation	1	<1
Herbaceous Vegetation	72	64
Disturbed Vegetation	24	21
Total Impacts from Project Facilities	***172***	***157***
Temporary Construction Areas d/		
Forested Vegetation	58	2
Woodland Vegetation	4	0
Shrubland Vegetation	8	<1
Herbaceous Vegetation	71	<1
Disturbed Vegetation	186	9
Total Impacts from Temporary Construction Areas	***327***	***11***
Grand Total for All Impacts		
Impact Grand Total	**499**	**168**

See table 2.3.1-1 in chapter 2 for the acreage of each individual Project component.

a/ Table does not include impacts on unvegetated upland areas or impacts on estuarine vegetation (impacts on estuarine vegetation is discussed in section 4.3).

b/ Values may not sum exactly due to rounding of significant digits. Acreages are rounded to the nearest whole acre; acreages less than 1 acre are reported as <1.

c/ Values include land permanently cleared due to operations.

d/ Temporary Construction Facilities include the Ingram Yard perimeter, North Ingram Yard, IWWP, Hydraulic Dredge Pipeline, Roseburg site laydown areas, APCO Sites, Boxcar Hill, Port Laydown site, South Dunes site, Workforce Housing Facility, parking, and Laydown area, the Trans-Pacific Parkway/U.S. Highway 101 Intersection Widening, the Additional Park & Ride site, and the Myrtlewood Off-site Park & Ride.

4.4.1.6 Noxious Weeds and Invasive Species

Noxious weeds and invasive plant species are non-native or introduced species that are able to exclude and out-compete desirable native species, and thereby decrease overall species diversity. Noxious weeds often invade and persist in areas after the vegetation and ground have been disturbed and can hinder restoration. Noxious weeds can adversely affect an area either when invasive plants become established or when an existing species' population size increases. Invasive or noxious plants can negatively affect native vegetation by competing for resources such as water and light, changing the community composition, eliminating or reducing native plants, or changing the vegetation structure. The changes in community composition or vegetation structure can reduce native plant populations and can also negatively affect wildlife habitat. Additionally, the movement of equipment to and from construction work areas can also increase the spread of noxious weeds and invasive species. In general, grasslands, riparian areas, and relatively dry or open forests, are more susceptible to invasion than are dense, moist forests, high montane areas, and serpentine areas that have relatively closed canopy cover or have extreme climate or soils that are tolerated by fewer invasive plant species.

Noxious weeds are classified by the Oregon State Weed Board (OSWB) as any plant that is injurious to public health, agriculture, recreation, wildlife, or any public or private property. The ODA Noxious Weed Control Program and the Oregon State Weed Board (OSWB) maintain the State Noxious Weed List. There are three categories of listed noxious weeds under the ODA Noxious

Weed Control Classification System (i.e., A Listed, B Listed, and List T weeds[95]). Species listed in the Noxious Weed Policy and Classification System that have been documented or could occur within the LNG terminal area are summarized in table 4.4.1.6-1.

TABLE 4.4.1.6-1

Noxious Weeds and Invasive Aquatic Species Documented or with Potential to Occur in the Jordan Cove LNG Project Area

Common Name	Scientific Name	LNG Terminal a/	Boxcar Hill	APCO Sites	Kentuck Project Site	Port Laydown
"A" List Weeds						
cordgrass (T)	*Spartina angelica, S. alterniflora, S. densiflora, S. patens*	D				
"B" List Weeds						
bull thistle	*Cirsium vulgare*	L			L	
butterfly bush	*Buddleja davidii*	L		L	L	D
Canada thistle	*Cirsium arvense*	D	D	L	D	D
English ivy	*Hedera helix*	D	D	L	L	
field bindweed (T) (morning glory)	*Convolvulus arvensis*	L		L		
French broom	*Cytisus monspessulana*	L		L		
gorse (T)	*Ulex europaeus*	D				
Himalayan blackberry	*Rubus armeniacus (R. discolor, R. procerus, R. fruticosa)*	D	D	D	D	
Jubata grass (Pampas grass)	*Cortaderia jubata*	D			L	
meadow knapweed	*Centaurea moncktonii*				L	
parrot feather	*Myriophyllum aquaticum*	D				
poison hemlock	*Conium maculatum*	D			D	
Scotch broom	*Cytisus scoparius*	D	D	D	D	D

"D" – indicates species has been documented at the Project site.
"L" – indicates species is likely to occur at the Project site.
"(T)" – indicates target species designated for removal and control in Oregon
a/ Includes LNG terminal, access and utility corridor, South Dunes site, and Roseburg Laydown area.

To avoid introducing or spreading invasive species, Jordan Cove would follow the recommendations outlined in the Oregon Invasive Species Council (OISC) Action Plan for 2017-2019, BLM's multi-state EIS Northwest Area Noxious Weed Control Program (BLM 1985) and its supplements, the BLM's *Final Vegetation Treatments on Bureau of Land Management Lands in 17 Western States Programmatic Environmental Report* (2007), and the BLM's *Final North Spit Plan* (2005). These documents focus on detection, containment, and/or reduction of invasive plant infestations with an integrated pest management approach (e.g., chemical, mechanical, manual, and/or biological) as well as implementation of measures to avoid the introduction and spread of noxious weeds.

[95] A Listed – Weeds of known economic importance which occur in small enough infestations to make eradication or containment possible; or are not known to occur in Oregon but are present in neighboring states making future occurrence in Oregon seem imminent.
B Listed – Weeds of economic importance which are regionally abundant, but which may have limited distribution in some counties in Oregon.
T List – Priority noxious weeds designated as target species that will be the focus of prevention and control by the Noxious Weed Control Program and for which the ODA will develop and implement statewide management plans. Species selected from either the "A" or "B" list.

Jordan Cove would conduct a pre-construction survey of the Project area to identify noxious species listed by the ODA that persist despite recent and previous control efforts. Following the survey, Jordan Cove would employ standard removal practices (BLM 1985) for the weed species identified on the Project area. Methods for removal that would not aid in the dispersal of these species would be used and would include the use of integrated BMPs such as fire, mechanical or manual removal, and herbicide application, as appropriate. Treated areas would be restored by spreading native seeds and planting native plants.

Jordan Cove would also use herbaceous and native dune seed mixes to limit germination of noxious weeds during the stabilization and restoration of the site during and following construction. Once the site is stabilized and in operation, Jordan Cove would check the site for noxious weed infestations and control measures would be implemented that are consistent with ODA, OISC, and BLM noxious weed control plans and policies, as applicable.

4.4.1.7 Vegetative Pathogens

Port Orford cedar root rot disease is caused by the fungus *Phytophthora lateralis*. The disease was first discovered in Port Orford cedar's natural range in 1952 and since has spread throughout its range. Port Orford cedar root rot disease affects both seedlings and mature trees. The spores live in the soil and are spread through contact with contaminated soil or via free water. The disease is primarily spread through soil disturbance and moving water. Spread of the disease over long distances occurs from contaminated equipment and livestock.

Jordan Cove would take precautions during construction to minimize the introduction or spread of Port Orford cedar root rot disease from contaminated earth moving equipment. To ensure adequate conservation measures to address Port Orford cedar root rot disease are in place and implemented, Jordan Cove would follow the measures and recommendations found in the Forest Service and BLM's Final Supplemental EIS regarding the management of Port Orford cedar in southwest Oregon (Forest Service and BLM 2004).

4.4.2 Pacific Connector Pipeline Project

Vegetation types that would be crossed by the pipeline include forests and woodlands, shrublands, grasslands, wetland, and agricultural (see table 4.4.2-1). Wetland vegetation types found along the pipeline route are discussed in section 4.3.

TABLE 4.4.2-1

Vegetation Types Crossed by the Pacific Connector Pipeline Project a/

General Vegetation Type	Mapped Vegetation Category	Late Successional or Old-Growth Forest Crossed (miles)	Mid-Seral Forest Crossed (miles)	Clearcut/ Regenerating Forest Crossed (miles)	Total Miles b/	Percent of Total Vegetation

General: Mileages may not sum correctly due to rounding. Mileages are rounded to nearest tenth of a mile; values less than 0.1 are shown as "<0.1".)

a/ Table does not include impacts on unvegetated areas (e.g., urban, industrial, beaches, roads, open water).

b/ Total miles crossed include the 0.9 mile of pipeline that would not disturb vegetation because of the HDD method and direct pipe method used to install pipeline below six waterbodies: Coos Estuary (2 crossings), Coos River, South Umpqua River, Rogue River, and Klamath River.

4.4.2.1 Forest and Woodland Vegetation

Forests vegetation found along the Pacific Connector pipeline route were assigned an age class using available GIS data (BLM 2016c; Moeur et al. 2005, 2006, and 2011; Davis et al. 2015).[97] Age classes were categorized within various age ranges: clearcut (0-5 years), regenerating (5-40 years), mid-seral (40-80 years), as well as LSOG (80+ years).

- Clearcut/Regenerating forest:
  - Clearcut forest includes areas that were harvested within the past five years but presently are non-stocked. This age class generally has a canopy cover of less than 10 percent (Moeur et al. 2005).
  - Regenerating forest generally includes areas with canopy cover greater than 10 percent and tree size less than 10 inches diameter at breast height (dbh; Moeur et al. 2005). This category was further refined to identify early regenerating forest (harvested within the last 10 to 15 years) and regenerating forest for interior forest analyses described later in this section.
- Mid-seral forest includes stands within the current harvest rotation and generally includes small single- and multi-storied trees with canopy cover greater than 10 percent and tree size between 10 and 20 inches dbh (Moeur et al. 2005).
- LSOG:
  - Late successional forest includes forest stands greater than 80 years old. This age range is consistent with definitions used in the NWFP and as described in Moeur et al. (2005) and Davis et al. (2015). This age class generally includes medium and large single- or multi-storied trees with canopy cover greater than 10 percent and average tree size between 20 and 30 inches dbh.
  - Old-growth forest includes forest stands greater than 175 years and dominated by coniferous forest. This correlates well with Moeur et al. (2005), Franklin et al. (1981, 1986), and Franklin and Spies (1991) descriptions that consider primary size and canopy structure characteristics of old-growth Douglas-fir to develop between 175 and 250. This age class generally includes large, multi-storied stands with canopy cover greater than 10 percent and average tree dbh greater than 30 inches (Moeur et al. 2005). Mature deciduous-dominated forests were also included in this forest age classification.

The following text describes dominant vegetation communities in the Project area, lists the common species, and discusses the general distribution:

The Douglas-fir–Western Hemlock–Western Redcedar Forest type occurs at low to middle elevations and has a multi-storied canopy dominated by Douglas-fir, with western hemlock, western redcedar (*Thuja plicata*), and grand fir (*Abies grandis*) as co-dominants. In addition, Pacific yew (*Taxus brevifolia*) may be present in the subcanopy (Kagan et al. 1999). Port Orford cedar can also be a dominant tree species within Douglas-fir–Western hemlock–Western redcedar forest types within the pipeline Project area (Johnson and O'Neil 2001). Within riparian areas, and non-conifer dominated stands, bigleaf maple (*Acer macrophyllum*) and red alder are common. Large stature shrubs, such as vine maple (*Acer circinatum*), Pacific rhododendron, and evergreen

[97] Age class was also reviewed by BLM and Forest Service biologists on their respective lands between 2007 and 2008, with specific focus on verifying/classifying late seral forest stands, as well as by Siskiyou BioSurvey LLC.

and red huckleberry (*Vaccinium ovatum* and *V. parvifolium*), are frequently present. Ferns dominate the rich and diverse herbaceous layer. It is located within Coos and Douglas Counties.

The Douglas-Fir–Mixed Deciduous Forest type is a low to mid-elevation conifer and mixed deciduous forest found primarily in southwestern Oregon. The upper tree layer always contains Douglas-fir, with the sub-canopy consisting of a mix of shade tolerant conifers and deciduous trees including: tanoak (*Notholithocarpus densiflorus*), Pacific madrone (*Arbutus menziesii*), golden chinquapin (*Chrysolepis chrysophylla*), and Pacific dogwood (*Cornus nuttallii*). Indicative shrubs of this cover type include dwarf Oregon-grape (*Mahonia nervosa*), pacific blackberry (*Rubus ursinus*), oceanspray (*Holodiscus discolor*), California hazelnut (*Corylus cornuta*), and others (Kagan et al. 1999). This forest type is found within Douglas, Jackson, and Klamath Counties.

The Alder–Cottonwood Forest type is found along the margin of flowing streams in the foothills and mountains throughout much of Oregon. It is prevalent along high gradient stream systems that flood frequently and deposit bed-load sand and gravel. Black cottonwood (*Populus balsamifera* ssp. *trichocarpa*) is always present in the overstory of this forest type. West of the Cascade crest, other dominant species in the overstory include red alder and big leaf maple, and conifers could include Douglas-fir, western hemlock, western redcedar, and Port Orford cedar. East of the Cascade crest, the other dominant species is typically white alder (*Alnus rhombifolia*), with other deciduous trees present including mountain alder (*Alnus incana* ssp. *tenuifolia*), Pacific willow (*Salix lucida* ssp. *lasiandra*), non-native black locust (*Robinia pseudoacacia*), and quaking aspen (*Populus tremuloides*). Associated conifers east of the Cascades include ponderosa pine (*Pinus ponderosa*), Douglas-fir, Engelmann spruce (*Picea engelmannii*), and lodgepole pine (Kagan et al. 1999). It is found within Coos, Douglas, Jackson, and Klamath Counties.

The Mixed Conifer/Mixed Deciduous Forest type is generally composed of co-dominant conifer (e.g., Douglas-fir) and deciduous (e.g., red alder and/or bigleaf maple) trees in a single-layered canopy forest (Kagan et al. 1999). Port Orford cedar may also be the dominant tree species within this forest type (Johnson and O'Neil 2001). This forest type is found in low- to mid-elevations (Kagan et al. 1999) within Coos County.

The Shasta Red Fir–Mountain Hemlock Forest type is a mid-to-upper elevation conifer forest mostly found above 4,000 feet. Overstory species generally include Shasta red fir (*Abies magnifica* var. *shastensis*), mountain hemlock (*Tsuga mertenxiana*), white fir (*Abies concolor*), and lodgepole pine. It often is a closed, multi-story canopy with dense understory of shrubs, forbs, and ferns, including dwarf bramble (*Rubus lasiococcus*), Oregon boxwood (*Paxistima myrsinites*), pinemat manzanita (*Arctostaphylos nevadensis*), and Sadler's oak (*Quercus sadleriana;* Kagan et al. 1999). It is found within Jackson and Klamath Counties.

The Douglas-fir–White Fir/Tanoak–Madrone Mixed Forest type is a multi-layered forest of mixed conifer and mixed deciduous species. It always contains Douglas-fir, with other co-dominants (e.g., white fir, incense cedar (*Calocedrus* [*Libocedrus*] *decurrens*), sugar pine [*Pinus lambertiana*] and western white pine [*Pinus monticola*]). Subcanopy layers contain shade-tolerant trees, including tanoak, Pacific madrone, golden chinquapin, Pacific dogwood, and California laurel (*Umbellularia californica*). Shrub and herb layers are generally well represented. This forest type is found at low to mid elevations (Kagan et al. 1999) within Jackson County.

The Douglas-fir Dominant-Mixed Conifer Forest type typically consists of a single-layer forest canopy, although stand structure can be diverse in undisturbed late seral stands. There is a wide range of canopy closure based on management practice, disturbance history, and microsite. Douglas-fir is dominant, with a variety of coniferous trees including, white fir, incense cedar, western white pine, ponderosa pine, and sugar pine. Understory vegetation is usually diverse and rich in species. This forest type is found at mid elevations (Kagan et al. 1999) within Coos, Douglas, Jackson, and Klamath Counties.

Ponderosa pine and white oak (*Quercus garryana*) are the dominant overstory species within the Ponderosa Pine/White Oak Forest and Woodland type. Shrub cover is typically sparse, but herbaceous and grass species tend to be abundant. This forest type is found at low elevations (Kagan et al. 1999) within Jackson and Klamath Counties.

Ponderosa pine is exclusively the overstory tree at low elevations within the Ponderosa Pine Forest and Woodland type. White fir, grand fir, western larch, incense cedar, Douglas-fir, subalpine fir, and Engelmann spruce are common at higher elevations. Understory and regeneration layers reflect similar composition as overstory. Lower elevations have fewer shrubs, with shrubs increasing in diversity and abundance with elevation and improved soil moisture conditions. This forest type is found at low to middle elevations (Kagan et al. 1999) within Jackson and Klamath Counties.

The Oregon White Oak Forest type contains deciduous woodland/forest dominated by Oregon white oak. Other canopy trees can be Douglas-fir and ponderosa pine in upland settings, and Oregon ash (*Fraxinus latifolia*), black cottonwood, and bigleaf maple on valley floors. The subcanopy often consists of California black oak (*Quercus kelloggii*). Understory typically contains tall deciduous shrubs and smaller stature deciduous trees. This forest type is a highly desirable wildlife habitat that has been decreasing as a result of fire suppression. It is found at low elevations (Kagan et al. 1999). This forest type can require more than 100 years to reach full productivity and function as wildlife habitat, and these types of wildlife habitats are limited within the region (see section 4.5). It is found within Douglas and Jackson \Counties.

The Grass-shrub-sapling or Regenerating Young Forest type is characteristic of successional conditions following timber harvest, which can include ground scarification and slash/large woody debris, a variety of shrubs and forbs typical of the area, and then conifer saplings which form a continuous canopy above the shrub layer (Kagan et al. 1999). It is found within Coos, Douglas, Jackson, and Klamath Counties.

The Western Juniper Woodland type is dominated by western juniper (*Juniperus occidentalis*) and has an open canopy (less than 30 percent crown closure) and single story, short stature (6 to 20 feet tall) trees. Understory vegetation is dominated by sagebrush species, such as big sagebrush (*Artemisia tridentata*), rigid sagebrush (*Artemisia rigida*), and low sagebrush (*Artemisia arbuscula*), as well as mountain mahogany (*Cercocarpus ledifolius*), bitterbrush (*Purshia tridentata*), and rabbitbrush (*Ericameria* ssp; *Chrysothamnus* spp.). Grasses characterize the herbaceous layer. This woodland type is found at a wide range of elevations (Kagan et al. 1999) within Klamath County.

The Ponderosa Pine/Western Juniper and Woodland type is typically found in the foothill margins bordering upland conifer types and sagebrush dominant lowlands. This forest type has a two-story canopy with widely spaced overstory ponderosa pine and a subcanopy of western juniper. Canopy cover is generally between 10 and 50 percent. The understory is dominated by a shrub layer, including big sagebrush, low sagebrush, rabbitbrush, mountain mahogany, and bitterbrush, and is interspersed with non-native grasses (typically in areas that are overgrazed) and native bunchgrasses (Kagan et al. 1999). It is found within Klamath County.

Late Successional and Old-growth Forest

Many of the forested and woodland vegetation types discussed above include areas that contain late-successional and mature old-growth vegetation (i.e., old-growth forests). Historic logging practices within the Pacific Northwest have dramatically reduced the size and health of old-growth forests. There is no single definition of old growth and multiple definitions have been used, depending on the forest type (deciduous or evergreen) being considered and the agency/organization managing the land. The NWFP defines old growth as "(a) forest stand usually at least 180 to 220 years old with moderate to high canopy closure; a multilayered, multi species canopy dominated by large overstory trees; high incidence of large trees, some with broken tops and other indications of old and decaying wood (decadence); numerous large snags; and heavy accumulations of wood, including large logs on the ground" (FEMAT 1993). In addition, old-growth forests typically contain moderate-to-high accumulations of nonvascular vegetation such as fungi, lichens, and bryophytes (Forest Service and BLM 1994b).

LSOG forests west of the Cascade Range typically consist of old large overstory trees, such as Douglas-fir and western hemlock, multiple tree canopy levels, shade-tolerant tree species in the understory, large course woody debris and snags, a lush understory shrub layer, and infrequent stand replacement fire events (BLM 2008a, ODFW 2016a). The drier LSOG forests of eastern and southwest Oregon generally contain widely spaced or small groups of large overstory trees, such as ponderosa pine, with a more open grassy understory maintained by frequent low-intensity fire (BLM 2008a).

LSOG forests provide vital habitat for many native plant and animal species, including many federally-listed threatened or endangered species (Forest Service and BLM 1994b). Bird species that are obligates of old-growth forests include the federally threatened northern spotted owl and marbled murrelet (see section 4.6). LSOG forests have been greatly reduced in size and connectivity, which impacts plant and wildlife species adapted to LSOG conditions and/or wildlife species with limited ability to travel over long distances to find new suitable areas (ODFW 2016a). Additionally, many of the species supported by LSOG forests require large patches of older or mature forests to survive and may be sensitive to changes in the seral stage of the forest (ODFW 2016a). LSOG forests also provide a variety of other environmental services, including clean water, carbon sequestration, and a variety of recreational opportunities (BLM 2008a). Additionally, the complexity of LSOG forests increases the resiliency of these forest to disturbance (BLM 2008a). The loss of LSOG forests since 1850 in the Coast Range, West Cascades, and Klamath Mountains ecoregions of Oregon is estimated to be almost 90 percent (ODFW 2016a).

4.4.2.2 Shrubland Vegetation

The Sagebrush Steppe vegetation type is a mosaic of grasses (mostly introduced) and shrubs that include sagebrush subspecies, such as Wyoming (*Artemisia tridentata* ssp. *wyomingensis*), basin (*A. tridentata* ssp. *tridentata*), and mountain (*A. tridentata* ssp. *vaseyana*). Other shrubs include low, silver, and three-tip sagebrush, and rabbitbrush. A variety of bunchgrasses are scattered with the shrubs, although overgrazing has limited their presence (Kagan et al. 1999). Sagebrush steppe vegetation is a valuable natural resource and many species of wildlife (including ungulates, birds, reptiles, and invertebrates) rely on sagebrush steppe vegetation (Monsen and Shaw 2000; FWS 2014a). Vast areas of sagebrush steppe vegetation have been altered or lost through grazing, agriculture or other development, conversion to non-native annual or perennial grasslands through artificial seeding or invasion of annual grasses, and wildfire; and sagebrush steppe is now considered one of the most imperiled ecosystems in the United States (Monsen and Shaw 2000; FWS 2014a). Sagebrush steppe is found within Klamath County.

The Shrublands vegetation type consists of a mosaic of grasses and shrubs. It may include sagebrush but is not dominated by this species and species composition can vary greatly based on location along the pipeline. Common shrubs may include rabbitbrush (*Ericameria nauseosa* and *Chrysothamnus viscidiflorus*), bitterbrush, and manazanita (*Arctostaphylos* spp.) east of the Cascades. West of the Cascades native shrubs may include salmonberry (*Rubus spectabilis*), thimbleberry (*Rubus parviflorus*), as well as non-native shrubs including Scotch broom. It typically occurs within revegetated utility corridors and transitional areas, such as reclaimed industrial sites. It is located within Coos, Douglas, Jackson, and Klamath counties.

4.4.2.3 Herbaceous Vegetation

Grasslands (west of Cascades) are found at lower elevations and contain less than 30 percent tree or shrub cover and is generally used for livestock grazing. Native-dominated sites consist primarily of bunchgrasses, with mosses, lichens, and native forbs occurring throughout. Native westside grasslands (i.e., native prairie) have largely been disturbed through grazing activities and are typically vegetated with a mix of native and non-native perennial and annual grasses and forbs. Patches of native remnant prairie still occur, but their distribution is limited. It is found within Coos, Douglas, and Jackson Counties.

Grasslands (east of Cascades) contain a mosaic of various bunchgrasses, typically dominated by Idaho fescue (*Festuca idahoensis*). Other co-dominant grass species include bluebunch wheatgrass (*Pseudoroegneria spicata*), junegrass (*Koeleria* spp.), Sandberg bluegrass (*Poa secunda*), and western needlegrass (*Achnatherum occidentale*). In heavily grazed stands, cheatgrass (*Bromus tectorum*) and bottlebrush squirreltail (*Elymus elymoides* ssp. *elymoides*) can be dominant. This vegetation type is found at low to middle elevations (Kagan et al. 1999) within Klamath County.

Agricultural vegetation includes crop land, orchards, hay fields, and managed pastures. These areas consist of lands that have been cleared of native vegetation and modified for growing crops.

4.4.2.4 General Impacts on Vegetation

Constructing the pipeline would temporarily and permanently impact approximately 4,186 acres of vegetation (table 4.4.2.4-1). Operating the pipeline would permanently impact approximately 782 acres of vegetation (table 4.4.2.4-2). Permanent impacts would occur in association with aboveground facilities, new permanent access roads, and areas of road improvements. In these locations, vegetation would be removed during construction and the areas would not be revegetated during restoration. Permanent impacts would also occur within the 30-foot-wide operational right-of-way maintenance corridor. While this corridor would be revegetated following construction, it would be maintained in an herbaceous and/or low-growing shrub state during the life of the pipeline. Finally, the clearing of mature forested vegetation is also a permanent impact because restoration to preconstruction conditions would not happen during the life of the Project.

As indicated in tables 4.4.2.4-1 and 4.4.2.4-2, constructing and operating the pipeline would require the temporary and permanent clearing of vegetation, including clearing of unique or sensitive vegetation (i.e., LSOG forest, native prairie grasslands, and sagebrush steppe). Removal of vegetation would increase the potential for soil erosion, edge effects, and introduction and spread of noxious weeds and invasive species, and would reduce the amount of available wildlife habitat. The degree of impact depends on the type and amount of vegetation affected, the rate of vegetation regeneration following construction, and the frequency of vegetation maintenance conducted within the 30-foot-wide maintenance corridor within the operational pipeline easement. Additionally, site-specific conditions, such as grazing, precipitation, soil type, and presence of noxious weeds and invasive plants, would influence the length of time required to achieve successful revegetation. Clearing of agricultural and grassland areas would be considered a short-term impact because revegetation of these areas would typically occur within three growing seasons. Clearing of forested and shrubland areas would be considered a long-term impact because affected areas would not resemble adjacent undisturbed areas for many years to many decades; and, as stated above, clearing of mature forests (e.g., LSOG forest) would be considered a permanent impact.

Additional long-term impacts would include the cutting of danger trees or hazard trees, which are defined as trees located outside approved construction areas that are at risk of falling on workers or vehicles and thus would need to be removed. The removal of these trees would result in an additional long-term impact to adjacent vegetation. The extent or existence of danger trees would be identified, to the extent possible, following creation of the construction right-of-way, TEWAs, new access roads, and on roads that have not triggered land-managing agency danger tree removal due to limited road use. Pacific Connector would compensate the respective land manager/owner for any merchantable danger trees that are felled. Danger trees are discussed further in section 4.7.2.5 of this EIS.

TABLE 4.4.2.4-1

General: Rows and columns may not sum correctly due to rounding. Acres rounded to nearest whole acre (values below 1 are shown as "<1").

a/ "L-O" = Late Successional and Old-Growth; M-S = Mid-Seral; "C-R" = Clearcut or Regenerating

b/ Road improvements will affect approximately 22.52 acres along the margins of existing access roads; all acres of disturbance have been included in vegetation type "roads."

c/ Construction disturbance associated with aboveground facilities (mainline block valves and meter stations) is included in construction right-of-way and/or TEWA acres of disturbance. Approximately 1.61 acres associated with communication towers is not included in this table (previously disturbed sites).

d/ Approximately 658 acres of construction-related disturbance to LSOG forests would occur on lands managed by the BLM and Forest Service.

General: Rows and columns may not sum correctly due to rounding. Acres rounded to nearest whole acre (values below 1 are shown as "<1").

a/ Acres disturbed were evaluated using GIS; footprints for each component (aboveground facilities, 50-foot-wide permanent easement, and 30-foot-wide maintenance corridor) were overlaid on the digitized vegetation coverage.

b/ "L-O" = Late Successional and Old-Growth; "M-S" = Mid-Seral; "C-R" = Clearcut or Regenerating Young Forest.

c/ Shaded cells identify acres of vegetation type within the defined area but are not included in the overall Project total because: 1) only the 30-foot-wide Maintenance Corridor included within the 50-foot-wide Permanent Easement is expected to be affected during operations and maintenance activities, and 2) no additional maintenance would occur on access roads improved for construction of the Project.

d/ Aboveground facilities include block valve assemblies (BVAs), the Jordan Cove, Clarks Branch, and Klamath meter stations, and the Klamath Compressor Station.

e/ Total by Vegetation Type includes the 30-foot-wide maintenance corridor and permanent access roads, and only aboveground facilities with a meter station or compression station (mainline block valves are located within the 30-foot-wide maintenance corridor).

Acres of impacts only include impacts on vegetated areas; therefore, impacts in this table may not reflect impact values reported in other sections of this EIS. Shaded cells identify acres of vegetation type within the defined area but are not included in the overall Project total because: 1) only the 30-foot-wide Maintenance Corridor included within the 50-foot-wide Permanent Easement is expected to be affected during operations and maintenance activities, and 2) no additional maintenance would occur on access roads improved for construction of the Project.

The Pacific Connector Pipeline Project would impact approximately 133 acres of sagebrush steppe habitat. Impacts on sagebrush steppe would be long term because big sagebrush only regenerates from seed and may take 20 years or more to become reestablished (West 1988). Constructing and operating the pipeline would also impact approximately 773 acres of LSOG forests, 800 acres of mid-seral forest, and 1,177 acres of clearcut/regenerating forests.

Throughout our environmental review of this Project, we have received comments not only from the public, but from the tribes, and federal and state resource agencies expressing concern about impacts on forests, specifically "old-growth" forests. Since implementation of the Northwest Forest Plan (NWFP) in 1994, periodic monitoring of the amount, distribution, and spatial arrangement of LSOG forest within the range of the NWFP has been conducted. Based on monitoring conducted in 2012, there was approximately 6,460,900 acres of LSOG forests within the NWFP boundary in the four physiographic provinces in Oregon (Coast Range, Western Cascades, Eastern Cascades and Klamath) crossed by the pipeline (Davis et al. 2015). The impacts to 773 acres of LSOG forests from construction and operation of the Project would represents a loss of only 0.01 percent of the remaining LSOG forest in the four physiographic provinces crossed by the pipeline. As stated above, LSOG forests provide vital habitat for many native species of plants and wildlife, including many federally-listed threatened or endangered species, as well as providing a variety of environmental services (Forest Service and BLM 1994b; BLM 2008a). The loss of this forest vegetation would reduce the amount of habitat available to species dependent on LSOG vegetation and would potentially alter existing vegetation composition and soil and hydrologic characteristics and the ecosystem services provided by LSOG forests.

Additionally, constructing the pipeline would result in forest fragmentation and edge effects. The pipeline would fragment or "break-up" large tracts of contiguous forest and further the fragmentation of tracts broken up previously due to other forest practices (timber harvest, access roads), and other development (urban growth, agricultural development, utility corridors). Fragmentation reduces forest size and can reduce the size and increase the spatial isolation of local plant populations, including rare or endangered species (Jules et al. 1999). Fragmented forests also affect wildlife movement and its ability to successfully function as wildlife habitat (see section 4.5).

Fragmentation also results in new forest "edges" which play a crucial role in ecosystem interactions and landscape function, including the distribution of plants and animals, fire spread, vegetation structure, and wildlife habitat. New forest edges would affect microclimate factors such as wind, humidity, and light, and can lead to a change in species composition within the adjacent forest or increase invasion by invasive species. Compared to the forest interior, vegetation edges receive more direct solar radiation during the day, lose more light and heat at night, and experience less humidity. Increased solar radiation (e.g., light and heat) and wind can desiccate vegetation by increasing evapotranspiration, which can affect which species survive along the edge (typically favoring shade intolerant species) and can impact soil characteristics. The orientation of a fragment's edge can affect the extent and magnitude of edge effects because the amount of solar radiation that falls on the newly created edge would depend on the direction it faces, its latitude, time of year and time of day, and height of trees in the area that would cast shadows on the new edge (Chen et al. 1995). Because these values constantly change temporally and spatially, the edge effects would also constantly change along the pipeline, as tree shadows would extend different distances across the right-of-way depending on the time of year or aspect of the edge. This would result as some areas would be in shade at one point in the year (reducing edge effects) and in sunlight during another portion of the year (increasing edge effects).[98]

Harper et al. (2005) reported that the mean distance of edge influence could occur up to 300 feet (approximately 100 meters); however, the study also found that the development of a sidewall of dense vegetation along the new edge can affect the overall mean distance of edge effects.. This may reduce the depth of penetration of energy and matter into the forest, shortening the length of the gradient (distance) while the magnitude of edge influence remains strong (Harper et al. 2005). In general, the greater distances were not found in the North American sites, where the influence associated with maintained clearings was less than 150 feet; however, these studies were done in boreal forests (Harper et al. 2015) which may not be directly applicable to the temperate old-growth forests in the Pacific Northwest. A study on edge influence in old-growth Douglas-fir forests in the Pacific Northwest found that the edge influence on microclimatic variables (air temperature, soil temperature, relative humidity, short-wave radiation, and wind speed) extended between 98 feet (30 meters) to more than 785 feet (240 meters) depending on the microclimatic variable (Chen et al. 1995). Additionally, Jules et al. (1999) found that the depth of edge influence on forest understory species in the Klamath ecoregion ranged from 0 feet to more than 197 feet (60 meters) depending on the species. In younger coniferous forests or mixed forests with deciduous species, edge effects compared to interior forests have been much less pronounced (Heithecker and Halpern 2007; Harper and Macdonald 2002).

Although any vegetation type can be fragmented, of the vegetation types crossed by the pipeline, forested and woodland vegetation and their associated species are likely the most sensitive to fragmentation. Existing patch size, patch isolation, and edge characteristic (i.e., the contrast or the relative difference among adjacent patches) of coniferous and/or mixed forest patches of different age classes were evaluated along the pipeline's centerline to determine the acreage of interior forests that would be fragmented and experience new edge effects. Based on this assessment, approximately 430 acres of interior forest would be affected by construction of the pipeline, while between 1,752 and 3,504 acres would be indirectly affected (i.e., would be within 50 to 100 meters of newly created edges). This includes effects on approximately 185 acres of LSOG forests, 126 acres of mid-seral forests, and 119 acres of regenerating forests, and indirect effects on approximately 1,449 acres of LSOG forest, 1,010 acres of mid-seral forests, and 1,046 acres of regenerating forests.

To minimize forest fragmentation and edge effects, Douglas-fir or western hemlock would be planted during restoration of temporary work areas, including TEWAs, in the pipeline right-of-way (except in the 30-foot-wide maintenance corridor centered on the pipe), where conifers would be removed during construction activities. By revegetating the area, the edge along the fragment would be reduced, thereby reducing the effects of fragmentation and edge effects. If 12-inch- tall Douglas-firs and western hemlocks are planted during restoration and they are not harvested later,

[98] For example, assume the 95-foot-wide pipeline construction corridor is oriented northwest to southeast at 135 degrees from north. At a location in the vicinity of the pipeline (longitude=123.0 degrees West, latitude=42.5 degrees North) on June 21, the sun would be shining from the east (azimuth ≈91.5 degrees) at 0815 (Pacific Standard Time [PST]) with solar altitude of ≈ 37.6 degrees. A tree 100 feet tall on the southwest-facing edge of the right-of-way would cast a shadow 130 feet which, given the angle and width of the right-of-way, would fall short of reaching the opposite side (northeast-facing edge) by about 5 feet. On May 21, however, the sun in the same position would have cast a shadow of about 170 feet at 0745 (PST) and on July 21 at 0800 (PST) the shadow would extend about 160 feet. In both instances, the edge opposite the eastern sun would be in shadow.

trees of both species could, depending on site conditions, range between about 20 and 120 feet tall in 50 years at the end of the Project's operational life. Douglas-fir and western hemlock planted adjacent to edges of clearcut and/or early regenerating stands (assuming conifers from 1 to 10 feet tall at the time of construction) would modify edges of the seral stands from hard, to soft, to no edge as they grow. As the replanted trees grow, edge contrasts would decrease, as would effects on forest interiors, because taller trees would reduce direct solar radiation and increase soil moisture and humidity along the edges of stand interiors (Chen et al. 1993; Heithecker and Halpern 2007).

The Project's proposed vegetation clearing in forested vegetation has the potential to exacerbate the rate of windthrow in adjacent forest stands. Long-term forest stand degradation due to windthrow could potentially occur in local areas along the proposed right-of-way where the route is exposed to strong winds, especially where it runs perpendicular to the direction of the prevailing wind.

UCSAs would not be cleared of vegetation during construction but would be located in areas of woodlands and dense, mature forest. Within UCSAs located in forests and woodlands, some damage to understory vegetation and minor damage to trees would occur. Trees that are damaged at the time of construction could die over time (e.g., from severed roots, damage to lateral or anchoring roots, broken tops, or damage to more than 50 percent of the circumference of the tree). In these cases, the impact would be long term, i.e., the death of a tree would be considered a long-term or permanent impact. Vegetation disturbance would generally depend on the site-specific vegetation characteristics, with younger regenerating forests being potentially more susceptible to damage such as limb breakage. To protect trees within UCSAs, Pacific Connector would implement the measures outlined in its *Leave Tree Protection Plan*.[99] After construction, Pacific Connector would assess potential tree damage within the UCSAs and would appropriately compensate the landowner for damage.

Pacific Connector would implement numerous measures to minimize impacts on vegetation and ensure successful revegetation of disturbed areas. These measures include those found in the ECRP, *Leave Tree Protection Plan*, *Integrated Pest Management Plan*, *Fire Prevention and Suppression Plan*, and the *SPCC Plan* (see the POD, appendix F.10). These measures would be applied to all lands crossed by the pipeline route. However, as part of their ROW grant, the Forest Service and BLM would require additional measures to minimize and mitigate impacts on vegetation, including LSOG forests, on federal lands. Measures specific to federally managed lands are addressed below in section 4.4.3.3, as well as in the *BLM and Forest Service Compensatory Mitigation Plan and Amendment* (appendix F.2) and *Late Successional Reserves Crossed by the PGCP Project* (appendix F.3).

4.4.2.5 Noxious Weeds and Invasive Species

Section 4.4.1.6 describes and defines what noxious weeds and other invasive plant species are, as well as the general effects that they can have to a system. List "T" (i.e., target species) noxious weeds that have the potential of occurring in the area of the pipeline are listed in table 4.4.2.5-1.

[99] This plan was included as Appendix P to Pacific Connector's POD.

TABLE 4.4.2.5-1

Oregon Target Weeds (List T) Suspected within or Near the Proposed Pacific Connector Pipeline Work Area a/

Noxious Weed Common and Scientific Name	Known or Suspected Occurrences County b/	Forest Service Region 6 c/	BLM Districts c/	ODA Noxious Weed Class d/
Garlic mustard *Alliaria petiolata*	Jackson (L)		MD - D	B

Saltcedar *Tamarix ramosissima*	Jackson (L) Klamath (L)		LV - D	B
Gorse *Ulex europaeus*	Coos (W) Douglas (L)	RRS – D UMP – D	CB – D, MD – D, RO - D	B

a/ Source: ODA 2018a; Forest Service 2005b and 2017b; BLM 2017

b/ Letter in parenthesis indicates distribution within the county, if provided (ODA 2018a). L = Limited, W = Widespread, and H = Historic. No letter indicates county not listed on the ODA (2018a) species fact sheet

c/ Forest Service and BLM District Codes: UPM–Umpqua NF, RRS – Rogue River Siskiyou NF, FW – Fremont-Winema NF, CB–Coos Bay BLM, LV – Lakeview BLM, MD–Medford BLM, RO - Roseburg BLM. "D" indicates that it is documented in National Forest Service or BLM District but not necessarily within county crossed by the Pacific Connector pipeline.

d/ Oregon Noxious Weed List: List "A" weeds occur in small enough infestations to make eradication or containment possible or is not known to occur in Oregon but is present in neighboring states making occurrence in Oregon seem imminent. List "B" weeds are regionally abundant but may have limited distribution in some counties. List "T" weeds are selected from the "A" or "B" lists and are designated as a target species

e/ BLM District indicated that this species is found in the listed county (BLM 2017a).

In addition to the List T weeds, other weed species (e.g., non-List T species) that are also of concern could occur along the pipeline route.[100]

All Oregon State-listed noxious weeds (List A, B, and T species) documented along the pipeline route are listed in table 4.4.2.5-2. Five List T weeds, spotted knapweed, rush skeletonweed, Dalmatian toadflax, tansy ragwort, and gorse, were documented.

TABLE 4.4.2.5-2

Summary of Noxious Weeds found within the Vicinity of the Pacific Connector Pipeline Route during Surveys a/

Common Name *Scientific Name*	**ODA Noxious Weed Class**	**ODA Target "T" Weed**
Velvetleaf *Abutilon theophrasti*	B	No
Biddy-biddy *Acaena novae-zelandiae*	B	No
False brome *Brachypodium sylvaticum*	B	No
Butterfly bush *Buddleja davidii*	B	No
Musk thistle *Carduus nutans*	B	No
Meadow knapweed *Centaurea moncktonii*	B	No
Yellow starthistle *Centaurea solstitialis*	B	No
Spotted knapweed *Centaurea stoebe* (*C. maculosa*)	B	Yes
Rush skeletonweed *Chondrilla juncea*	B	Yes
Canada thistle *Cirsium arvense*	B	No
Bull thistle *Cirsium vulgare*	B	No
Houndstongue *Cynoglossum officinale*	B	No
Scotch broom *Cytisus scoparius*	B	No
Cutleaf teasel *Dipsacus laciniatus*	B	No
French broom *Genista monspessulana*	B	No
English ivy *Hedera helix*	B	No
St. Johnswort *Hypericum perforatum*	B	No
Perennial peavine *Lathyrus latifolius*	B	No
Dalmation toadflax *Linaria dalmatica (L. genista)*	B	Yes
Purple loosestrife *Lythrum salicaria*	B	No
Scotch thistle *Onopordum acanthium*	B	No
Japanese knotweed *Polygonum cuspidatum* (*Fallopia japonica*)	B	No
Sulphur cinquefoil *Potentilla recta*	B	No
Himalayan blackberry *Rubus armeniacus (R. discolor, R. procerus, R. fruticosa)*	B	No
Tansy ragwort *Senecio jacobaea*	B	Yes
Medusahead rye *Tainiatherum caput-medusae*	B	No
Gorse *Ulex europaeus*	B	Yes

a/ Documented within 100 feet of the pipeline project route.

Pacific Connector's ECRP includes measures to control noxious weeds, soil pests, and forest pathogens. In addition, Pacific Connector developed an *Integrated Pest Management Plan,*[101] in consultation with the ODA (Butler 2017), BLM, and the Forest Service, to minimize the potential spread and infestation of weeds. This plan, applicable to all land ownerships, includes requirements for surveys to be conducted prior to construction to determine the presence of noxious weeds; determining where management or pretreatment may be necessary prior to construction to prevent the spread of noxious weeds; cleaning of construction equipment prior to moving it onto the construction right-of-way; and cleaning of vegetation clearing and grading

[100] All Oregon State noxious weeds that could potentially occur along the pipeline project (including List A and B species) are included in Table C.3-4 of Appendix C.3 in Resource Report 3 in Pacific Connector's September 2017 application to the FERC.
[101] See Appendix N to the POD submitted to the FERC January 23, 2018.

equipment if it passes through areas where weeds have been identified. Additionally, disturbed areas would be replanted with appropriate seed mixes to prevent noxious weed germination. After construction, the right-of-way would be monitored and any noxious weed infestations would be controlled. Pacific Connector would also investigate noxious weed issues raised by landowners during operation of the pipeline.

To minimize the spread of noxious weeds, construction equipment would be power washed, if necessary, as determined by the EI. In addition, initial inspections of all company and construction contractor vehicles would be performed prior to being allowed on the construction right-of-way. The EI or Pacific Connector's authorized representative would be responsible for performing inspections and registering or tagging the equipment prior to being transported or moved to the right-of-way. Any equipment used within areas where noxious weeds are present (specifically those that are classified as priority A and T as well as selected B listed weeds) would be cleaned by hand, blown down with air, or pressure washed prior to leaving the site. Equipment cleaning on the right-of-way would occur in a cleaning station approved by the EI. Infested areas and cleaning stations would be mapped to ensure that these areas are monitored during construction and to ensure that weeds at these areas are controlled and not spread.

After construction, Pacific Connector would monitor the right-of-way for infestations of noxious weeds, in compliance with its *Integrated Pest Management Plan*. Targeted weed monitoring would occur in the areas where noxious weeds were identified prior to construction and were previously mapped to ensure that potential infestations do not reestablish and/or spread. Monitoring would also occur in areas along the right-of-way where equipment cleaning stations, hydrostatic dewatering sites, and other temporary project disturbances were located to ensure that infestation at these locations do not occur. If infestations occur along the right-of-way, Pacific Connector would make an assessment of the source of the infestation, the potential for the infestation to spread, and develop a treatment plan to control the infestation. Where infestations occur on federal lands, this assessment and treatment plan would be developed cooperatively with these agencies. The treatment plan would be developed using integrated weed management principles, and if herbicides are used, all applicable approvals would be obtained prior to their use including landowner approvals. Only herbicides that are approved for use on the affected lands (private, state, or federal) would be used. Herbicide treatments would not be conducted during precipitation events or when precipitation is expected within 24 hours to minimize the risk of these chemicals moving beyond the treated areas or into waterbodies. If weeds targeted for herbicide treatments are in the vicinity of sensitive sites, proper buffers would be used in order to prevent the spread of herbicides to these areas. Pacific Connector would consult with the ODA Noxious Weed Control Program or local County Weed Programs for additional support regarding noxious weed control issues that may occur during the pipeline operations. Pacific Connector would conduct follow-up inspections of all disturbed areas until revegetation is successful. If additional infestations or other invasive/noxious weed species are found, then these would be controlled and monitored as well.

4.4.2.6 Vegetation Pathogens

In Oregon, the Forest Service and ODF conduct annual aerial surveys of all forested land to determine insect and disease activity status. These surveys indicated the following insect and/or disease activity within 0.5 mile of the pipeline route: Douglas-fir beetle, fir engraver, flatheaded borer, mountain pine beetle (ponderosa and sugar pine), western pine beetle, needle cast (lodgepole pine, ponderosa pine, and Swiss), and Port Orford cedar root disease.[102] Within the pipeline Project area, the flatheaded borer, western pine beetle, and fir engraver are most prevalent. Other diseases that may occur or have potential to occur are annosus root and butt rot, laminated root rot, dwarf mistletoe, sudden oak death, and the black stain root disease. As indicated in table 4.4.2.6-1, multiple infestations of insect parasites and tree pathogens already exist along the pipeline route.

TABLE 4.4.2.6-1

Summary of Known Infestations of Insect Parasites and Tree Diseases Along the Pacific Connector Pipeline Route a/

Tree Insect or Disease	Land Ownership	Number of Incidences Along Pipeline Route	Approximate Mileposts (MP) of Right-of-Way Affected
Douglas-fir Beetle	BLM/Private/Forest Service	7	MP 32.1-32.2; MP 48.0; MP 98.4 – 102.2
Fir Engraver	BLM/Private/Forest Service	18	MP 48.3; MP 82.0 – 84.5; MP 103.9 – 113.7; MP 152.3-177.7
Flatheaded Borer	BLM/Private/Forest Service	27	MP 30.5 – 40.9; MP 50.8 – 51.1; MP 104.4 – 158.1
Laminated Root Rot	Forest Service	1	MP 154.2 – 154.5
Mountain Pine Beetle	BLM/Private/Forest Service	9	MP 112.3; MP 159.5 – 173.8; MP 224.2 – 224.9
Needle Cast	BLM/Private/Forest Service	7	MP 6.7R – 22.0; MP 161.5 – 168.7
Pine Engraver	Private	1	126.8
Port Orford Cedar Root Disease	Private	4	MP 23.1; MP 30.4 – 30.9; MP 39.65
Western Pine Beetle	BLM/Private/Forest Service	13	MP 96.9 – 97.0; MP 116.6 – 127.1; MP 139.9 – 154.0

Mileages rounded to nearest tenth of a mile.
a/ Summarized from Table 1-2 in the *Integrated Pest Management Plan* (Appendix N to the POD).
Source Data: ODF 2004 through 2017 aerial GIS data.

The introduction and/or spread of insects and diseases from construction equipment, activities, and personnel can adversely affect vegetation. Impacts include loss, reduced species fitness and diversity, and changes to habitat characteristics and subsequent wildlife use. To minimize the introduction and spread of insects and disease, Pacific Connector would implement measures described in its *Integrated Pest Management Plan*. Pacific Connector would identify/verify areas infested with forest pathogens during timber cruises prior to construction and implement minimization measures, including but not limited to cleaning equipment and vehicles upon entering/departing infested areas, applying sporax/borax on freshly cut stumps and wounds to reduce spread of root rot, and utilizing standard logging practices that minimize or prevent damage to standing trees adjacent to the pipeline.

4.4.2.7 Fire Regimes

Fires play a substantial role in shaping the composition and structure of vegetative communities. The pipeline would pass through numerous fire regimes. Table 4.4.2.7-1 lists the mean fire return interval (i.e., mean fire frequency in the area) as well as the total acres that have burned between 2000 and 2015 (based on existing fire data) for the fifth field watersheds crossed by the pipeline. The most notable recent fire event in the region is the Stouts Creek fire, which burned 26,452 acres in and around the pipeline project area in 2015 in the Days Creek-South Umpqua River and Elk

[102] Table C.3-3 in Appendix C.3 of Pacific Connector's Resource Report 3 lists the location (by MP when known) of each identified pathogen near the pipeline route.

Creek watersheds (Northwest Interagency Coordination Center 2015). Approximately 10.7 miles (227 acres) of the pipeline crosses the area burned by the Stouts Creek fire, generally between MP 95.5 through MP 108.8.

TABLE 4.4.2.7-1

Historic Average Fire Frequency and Extent of Acreage Burned in Watersheds Crossed by the Proposed Pacific Connector Pipeline

Ecoregion	HUC – Fifth-Field Watershed	Mean Fire Return Interval a/	Total Acres Burned (2000–2015) b/
Coast Range	Coos Bay-Frontal Pacific Ocean	126-150 Years	0
	Coquille River	81-90 Years	0
	North Fork Coquille River	151-200 Years	0
	East Fork Coquille River	126-150 Years	0
	Middle Fork Coquille River	61-70 Years	827
Klamath Mountains	Olalla Creek-Lookingglass Creek	21-25 Years	0
	Clark Branch-South Umpqua River	26-30 Years	56
	Myrtle Creek	61-70 Years	0
	Days Creek-South Umpqua River	46-50 Years	17,753
	Lower Cow Creek	41-45 Years	11,551
	Upper Cow Creek	41-45 Years	897
	Elk Creek	36-40 Years	13,504
	Trail Creek	26-30 Years	835
	Shady Cove-Rogue River	21-25 Years	48,677
	Bear Creek	21-25 Years	2,379
	Gold Hill-Rogue River	21-25 Years	1,870
	Big Butte Creek	26-30 Years	986
	Little Butte Creek	26-30 Years	3,644
Eastern Cascades Slopes and Foothills	Spencer Creek	31-35 Years	0
	John C Boyle Reservoir-Klamath River	26-30 Years	5,529
	Lake Ewauna-Klamath River	61-70 Years	26
	Mills Creek-Lost River	91-100 Years	13

a/ Data from LANDFIRE (2017).

b/ Data from BLM_Fire_History shapefile (BLM 2017b). Acres rounded to nearest whole acre.

The use of heavy equipment to construct the pipeline would increase the potential for a wildfire. Specifically, prescribed burning of slash, mowing, welding, refueling with flammable liquids, and parking vehicles with hot mufflers or tailpipes on tall dry grass would increase the risk of wildfires. A wildfire would result in additional loss of vegetation.

Certain activities associated with construction and operation of the Pacific Connector project (such as prescribed burning of slash, mowing, welding, refueling with flammable liquids, and parking vehicles with hot mufflers or tailpipes on tall dry grass) could increase the risk of wildland fires, especially if these activities occur within the fire season. Even small fires, created during these activities, could have far-reaching consequences on vegetative communities. For example, large forest fires could occur if small, low-intensity surface fires, ignited within the herbaceous or low-shrub cover maintained along the permanent right-of-way, spread to ladder fuels near forest edges, allowing access to the forest's canopy. This could trigger a high intensity crown fire that could spread to adjacent areas, away from the pipeline's route. If fire frequencies were to increase due to Project activities, vegetative communities could shift over time to a species composition more adapted to higher fire frequencies. It is also possible that the cleared right-of-way could serve as a fire break for large crown fires, thereby reducing the extent of a fire's spread; however, as discussed above, the presence of the cleared right-of-way could also increase the risk of crown fires occurring in the first place.

4.4.3 Environmental Consequences on Federal Lands

The Pacific Connector pipeline route would cross lands managed by federal agencies including the Forest Service, BLM, and Reclamation. The pipeline would pass through portions of federal land designations that are intended to protect vegetation or habitats: such as Riparian Reserves and LSRs. These federal land designations, as well as the effects that the pipeline would have on these areas, are addressed in section 4.7.

4.4.3.1 BLM – Forest Operations Inventory

The BLM tracks vegetation, land management treatments, and disturbance within each district during operations inventories. These data and/or attributes are then transferred to a GIS coverage called the Forest Operations Inventory (FOI). The FOI describes and classifies forest cover (vegetation), site class, denudation cause, dominant species, understory species, treatments, age class, and stand condition (BLM 2016c).

Table I-6 in appendix I lists the acres of impact that would occur to FOIs from both construction and operation of the pipeline. As shown in table I-6, there would be approximately 893 acres of impact during construction of the pipeline to FOIs, which includes about 285 acres on the Coos Bay District (approximately 238 acres of conifer forest, 7 acres of hardwood forest, 31 acres of mixed conifer and hardwood forest, and 9 acres of non-forest/other), 316 acres on the Roseburg District (approximately 273 acres of conifer forest, 37 acres of mixed conifer and hardwood forest, and 7 acres of non-forest/other), 274 acres on the Medford District (approximately 107 acres of conifer forest, 34 acres of hardwood forest, 83 acres of mixed conifer and hardwood forest, and 50 acres of non-forest/other), and 18 acres on the Lakeview District (all conifer forest).

4.4.3.2 Forest Service – Plant Series and Plant Association Groups

The Forest Service classifies potential vegetation based on plant series, and plant association groups (PAGs). Plant series are based on the climax dominant trees of a stand (e.g., the Douglas-fir series). Plant series can be subdivided into PAGs, which are described primarily by the presence or absence of plant species, as well as the abundance of a species based on environmental variables, including soil, aspect, slope, slope position, and moisture. Not all of the three National Forests crossed by the Pacific Connector pipeline route have identified PAGs or plant series, and these unidentified areas are noted as "not in series" (Forest Service 1996a). Table I-7 lists the acres of impact that would occur on PAGs and plant series from both construction and operation of the pipeline. As shown in table I-7, there would be approximately 585 acres of impacts during construction of the pipeline on PAGs and plant series, which includes about 211 acres on the Umpqua National Forest, 276 acres on the Rogue River-Siskiyou National Forest, and 98 acres on the Fremont-Winema National Forest. White fir and Douglas-fir series would be the most heavily affected PAGs.

The following describes the seven plant series that would be crossed by the pipeline, based on GIS coverage.

Douglas-Fir Series

Douglas-fir occurs in all PAG series within elevations ranging from sea level to 5,600 feet. Usually overstory presence of Douglas-fir indicates recent ground disturbance while presence and dominance in the understory can indicate hot, dry conditions, which is characteristic of the Douglas-fir Series. Many other tree species may be present that are also tolerant of drought-like conditions, such as ponderosa pine, incense cedar, and canyon live oak (*Quercus chrysolepis*). Within Umpqua National Forest, the following shrubs/plant associations may occur within the Douglas-fir Series: poison oak (*Toxicodendron diversilobum*), canyon live oak, chinquapin, salal, and species associated with ultramafic parent materials. Potentially canyon live oak and Douglas-fir may occur on the Rogue River-Siskiyou National Forest.

Mountain Hemlock Series

In Southwest Oregon, mountain hemlock occurs at high elevations, ranging from approximately 3,950 feet to 6,690 feet in the Cascades, with cold temperatures and moderate precipitation. Associated parent material is highly variable, although pumice, andesite, and basalt are the most common. Mountain hemlock and Shasta red fir are dominant tree species in the overstory, with western white pine and Douglas-fir occasionally occurring. Within the Rogue River-Siskiyou National Forest, the Mountain Hemlock Series may be associated with grouse huckleberry (*Vacccinium scoparium*) in deep soils at higher elevations, Pacific rhododendron at lower elevations and warmer conditions, and/or with the wildflower sidebells pyrola (*Pyrola secunda*). Mountain Hemlock Series has also been documented in the Fremont-Winema National Forest.

Shasta Red Fir Series

The Shasta Red Fir Series is representative of a variety of California red fir found in southwest Oregon and northern California generally at higher elevations (4,000 to 6,900 feet) where the climate is cool and moist. Shasta red fir is typically the dominant tree in the overstory, although on warmer sites, white fir is present and, on cooler sites, mountain hemlock is present. Within the Rogue River-Siskiyou National Forest, the mountain sweet-root (*Osmorhiza berteroi*)/Shasta Red Fir Series association, which is typically located at sites with lower precipitation, may potentially be found. In the Winema National Forest, the Shasta Red Fir series is found within the Cascade Province of Southwest Oregon.

White Fir Series

This species is most abundant in southwest Oregon and will occur on a variety of sites and therefore is not specific to slope, aspect, soil type, or elevation. White Fir Series generally occurs on cool sites, with an average rainfall varying between 45 inches in drier areas of the Cascades to 102 inches near the coast. As a result of frequent disturbances, other early seral species become the dominant overstory tree in the White Fir Series, such as Douglas-fir and Shasta red fir, which are present within the Rogue River-Siskiyou National Forest. Also, dwarf Oregon-grape is common and widespread within the Series and may occur within the area crossed by the pipeline. Based on GIS coverage, white fir-Shasta red fir is crossed on the Winema National Forest.

Grand Fir Series

No specific description has been created for this series. However, based on GIS coverage, grand fir trees may be dominant within stands located in the Umpqua National Forest, with a canyon live oak association.

Jeffrey Pine Series

This species is scattered throughout Jackson and Douglas Counties and usually occurs on dry, ultramafic parent material, mainly serpentine and peridotite with high exposed gravel, surface rock, and bedrock components. As a result of the serpentine/periodotite parent material, this series is associated with many unique and rare species. This series is found within a wide elevational range, from 1,200 feet to 6,000 feet; however, most occurrences are concentrated near 2,000 feet. It can occur on all aspects and slope positions although it is most common on the southerly aspect and mid-slope position. Often Douglas-fir and incense cedar are associated with the Jeffrey Pine Series, which has an open canopy characteristic. Within the Umpqua National Forest, Jeffrey pine has the potential to occur with high grass understory coverage.

Western Hemlock Series

This plant series is known to occur in drier conditions on Umpqua National Forest, and the associations crossed by the pipeline are salal, Oregon-grape, and rhododendron. The series is associated with low to moderate elevations. Because of the frequent disturbances in southwest Oregon, the overstory of this series is generally dominated by Douglas-fir with the understory predominately western hemlock; however, within the western hemlock/salal-dwarf Oregon-grape association, both western hemlock and Douglas-fir are present in the overstory.

Lodgepole Pine Series

This plant series is widely distributed throughout forested areas of eastern Oregon, where distribution is apparently tied directly to ash and pumice deposits, mostly from Mt. Mazama. Within the area crossed by the pipeline, this series occurs within the Fremont-Winema National Forest and is associated with huckleberry (*Vaccinium* spp.) and forbs within elevations between 5,000 and 5,700 feet on lower slopes and bottoms, and shrub (cool-xeric zone) at upper elevations in well-drained soils. This series tends to dominate sites that are too wet or too dry for its competitors (ponderosa pine, white fir-grand fir, Shasta red fir, or mountain hemlock).

4.4.3.3 Measures Implemented on Federally Managed Lands

Listed below are the avoidance and minimization measures that would be implemented on federally managed lands, in addition to those described above:

- Disturbed areas would be replanted to prevent noxious weed germination, and disturbed areas would be revegetated with seed mixes described in the ECRP.
- The authorized officer for the BLM or Forest Service may inspect and approve straw material used on federal lands to verify that it is certified noxious weed free. Gravel/rock used on federal lands would be from weed-free sources as well, and approved by the agencies' authorized representative.
- Pacific Connector has agreed to plant the easement with native trees/shrubs described in the ECRP. Affected riparian areas would be replanted extending 100 feet from the streambanks on federal lands. All plantings proposed for federally administered lands must be approved by each agency's authorized representative.
- The Forest Service and Pacific Connector are currently working together to develop projects that could be implemented in order to provide compensatory mitigation for environmental impacts on Forest Service lands, as well as ensure that the Pacific Connector pipeline is consistent with the objectives of LMPs.

4.4.3.4 Noxious Weeds

Pacific Connector developed an *Integrated Pest Management Plan*, in consultation with the ODA (Butler 2017), BLM, and Forest Service, to minimize the potential spread and infestation of weeds. This plan, applicable to both public and private lands, includes requirements for surveys to be conducted prior to construction to determine the presence of noxious weeds; determining where management or pretreatment may be necessary prior to construction to prevent the spread of noxious weeds; cleaning of construction equipment prior to moving it onto the construction right-of-way; and cleaning of vegetation clearing and grading equipment if it passes through areas where weeds have been identified.

The BLM objective for weeds is Early Detection Rapid Response (EDRR) in order to avoid introduction or spread of noxious weeds, and to contain and/or reduce noxious weed infestations using an integrated pest management approach (e.g., chemical, mechanical, manual, and/or biological), as outlined in the BLM's multi-state Northwest Area Noxious Weed Control Program EIS (BLM 1985) and its supplements, as well as the BLM's (2010a) *Vegetation Treatments Using Herbicides on Bureau of Land Management Lands in Oregon*. The BLM is concerned with the impacts of weeds on special areas, including LSRs (see section 4.7), and seeks to eliminate or control weeds that adversely affect those areas. The BLM surveys for noxious weed infestations, reports them to the ODA, and coordinates with them to reduce infestations while using methods that do not conflict with the objectives of each BLM District's RMP.

The Forest Service's objective for invasive plants and noxious weeds is similar to BLM's objectives (described above). Control of noxious weeds by the Forest Service is coordinated with state, county, and private organizations through weed control districts or coordinated resource management agreements. On NFS lands, preventive management is critical to an effective control program. The agency utilizes management direction provided in the *Pacific Northwest Region Invasive Plant Program: Preventing and Managing Invasive Plants Final Environmental Impact Statement* (Forest Service 2005b). Noxious weeds classified as target species that occur on federally managed lands are listed in table 4.4.1.6-1.

In order to prevent or limit the spread of invasive species and noxious weeds, all construction equipment would be inspected to ensure that it is clean and free of potential weed seed or propagules, prior to transporting equipment to the construction right-of-way. In addition, equipment used in areas of priority A and T listed weeds, as well as selected B listed weeds, would be cleaned by hand, blown down with air, or pressure washed prior to leaving the site, as determined necessary by the EI based on the specific weed infestation, level of infestation, and stage of growth of the weed. Because of the contiguous pattern of NFS lands crossed by the pipeline, equipment that could serve as a vector for invasive species would be inspected and cleaned at cleaning stations located at the borders of each National Forest, prior to clearing and grading activities. Because the BLM lands crossed by the Project are not contiguous and are spread out in a checkerboard pattern, it is not practical to set up inspection and cleaning stations at each entry point. However, where BLM lands are contiguous to NFS lands, cleaning stations would be located to include the adjacent BLM lands. Additionally, equipment would be inspected and cleaned at cleaning stations located adjacent to mapped noxious weed infestation areas that were identified during preconstruction surveys on federal lands and where a treatment plan has been developed in consultation with the agency authorized representative.

Additionally, equipment would be inspected and cleaned at stations located adjacent to mapped noxious weed infestation areas that were identified during pre-construction surveys on federally-managed lands. The cleaning stations would be located and approved by the EIs and authorized agency representative; these locations would also be mapped for future monitoring efforts to determine if potential infestations occur at these sites and, if they do, to ensure that appropriate control treatments are applied. The BLM has indicated that cleaning of equipment should occur when leaving noxious weed sites prior to entering BLM-managed lands regardless of land continuity. Also, monitoring efforts for weed species would be similar to those described above (for all lands), except that Pacific Connector has proposed to conduct monitoring on federally managed lands annually for a period of at least three to five years. However, the BLM and Forest Service have indicated that they would require that monitoring on federally managed lands be conducted every three to five years for the life of the Project, and that this would be a condition of the Right-of-Way Grant. Therefore, **we recommend that:**

- **<u>Prior to construction</u>, Pacific Connector should file a revised *Integrated Pest Management Plan* with the Secretary, for review and written approval by the Director of the OEP, that specifies that construction equipment would be cleaned after leaving areas of noxious weed infestations and prior to entering BLM-managed lands regardless of contiguous land owner. The revised plan should also address BLM and Forest Service requirements related to monitoring of invasive plant species on federally managed lands, and documentation that the revised plan was found acceptable by the BLM and Forest Service.**

4.4.3.5 Vegetative Pathogens

The existing conditions related to known occurrences of insects or pathogens are identical to the discussion presented in section 4.4.2. Insects or pathogens that have the potential to occur within the area that would be affected by the Project include Douglas-fir beetle, fir engraver, flatheaded borer, mountain pine beetle (ponderosa and sugar pine), western pine beetle, needle cast (lodgepole pine, ponderosa pine, and Swiss), Port Orford cedar root disease, annosus root and butt rot, laminated root rot, dwarf mistletoe, sudden oak death, and the black stain root disease (see section 4.4.2). The effects that could occur as well as the measures that would be implemented for the prevention of infestation by insects or pathogens on federally managed lands would be similar to those discussed in section 4.4.2, with the addition of the following:

- *Douglas-fir beetle*—No Douglas-fir down wood, 12 inches or larger in diameter, would be left in areas on NFS lands where there are known infestations of Douglas-fir beetle.
- *Port Orford cedar root disease*—All equipment entering NFS lands would comply with all Forest Service *P. lateralis* mitigation requirements. The Forest Service (Region 6) and BLM prepared management objectives for affected federally managed lands in 2004 to help control the spread of the fungus. The objectives focus on maintaining disease-free watersheds, preventing spread through sanitation, seasonal restrictions for activities, and reestablishing Port Orford cedar using resistant and non-resistant seedlings.
- *All pathogens*—Directional tree falling would be required on all NFS lands, including areas with no known insect/disease occurrence, to prevent residual tree damage/injury and disease infection.

4.4.3.6 Wild-Harvesting of Non-Timber Forest Products

Wild-harvesting is the act of gathering food, decorative, or medicinal botanical products that grow naturally on lands not normally associated with agriculture. The non-timber forest products harvested near the pipeline route are of three categories: floral greens, edibles, and medicinals. Some of the more common of these are salal, evergreen huckleberry, swordfern (*Polystichum munitum*), and pinemat manzanita (Forest Service 2017b). This harvesting of non-timber forest products is widespread on public lands in the Pacific Northwest and can occur year-round (OPB 2006).

The Forest Service and BLM grant permits to wild-harvest for both recreational and commercial uses. Some recreational and commercial harvesters could be temporarily displaced during pipeline construction. Additionally, some of the forest products typically harvested would be removed during vegetation clearing for the Pacific Connector pipeline. However, the pipeline right-of-way and roads would also create new access into forested areas. As a result, it is possible that wild harvesting could increase as a result of the operation of the pipeline project.

4.4.4 Conclusion

Constructing the Jordan Cove LNG Project would result in about 499 acres of impacts on vegetation, including 168 acres of permanent vegetation loss. Constructing the Pacific Connector Pipeline Project would impact approximately 4,186 acres of vegetation; this amount includes a total of approximately 133 acres of sagebrush steppe and 2,750 acres of forested lands, including 773 acres of LSOG forests.

Most of the vegetation types affected by the Project are common and widespread in the vicinity of the Project. Although constructing and operating the Project would result in the loss of 773 acres of LSOG forests, this represents only a small percentage of remaining LSOG forests in Oregon. Additionally, measures listed in section 4.4.3.3, as well as in the *BLM and Forest Service Compensatory Mitigation Plan and Amendment* (appendix F.2) and *Late Successional Reserves Crossed by the PGCP Project* (appendix F.3) would minimize or mitigate impacts to LSOG forests. Therefore, based on the types and amounts of vegetation that would be affected by the Project, the measures that would be implemented to avoid, minimize, and mitigate the resulting impacts, and the presence of similar vegetation in the affected watersheds, we conclude that constructing and operating the Project would not significantly affect vegetation.

4.5 WILDLIFE AND AQUATIC RESOURCES

4.5.1 Terrestrial Wildlife

The Project would affect suitable habitat for a number of wildlife species associated with the coastal, mid-coastal, interior foothills, and mountain terrains in southern Oregon. The types of wildlife habitat affected by the Project and the wildlife species potentially located in those habitats are described below. Endangered and threatened species and other special status species are addressed in section 4.6.

4.5.1.1 Jordan Cove LNG Project

Wildlife Habitats

Characterizations of wildlife habitats potentially affected by construction of the Project are based on resource agency consultations, on-the-ground surveys, and published reports. In accordance with its Fish and Wildlife Habitat Mitigation Policy, the ODFW has established the following six classifications for habitats, based on dominant plant, soil, and water associations of value to the support and use of fish and wildlife:

- Category 1 – irreplaceable[103], essential habitat[104] that is limited;[105]
- Category 2 – essential habitat that is limited;
- Category 3 – essential habitat, or important[106] habitat that is limited;
- Category 4 – important habitat;
- Category 5 – habitat having a high potential to become essential or important habitat; and
- Category 6 – habitat that has a low potential to become essential or important habitat.

Below we discuss the habitats found in the Jordan Cove terminal tract, their vegetation cover, associated wildlife, and ODFW habitat categories.

<u>Upland Habitats</u>

Uplands on the North Spit contain coastal dune forest, riparian forest, shrubs, grasslands (herbaceous), and unvegetated sand dunes (see section 4.4 for more details and descriptions). Dominant overstory for coastal dune forest include Douglas-fir, western hemlock, shore pine, Sitka spruce, and Port Orford cedar, with an understory including evergreen huckleberry, salal, bearberry, rhododendron, California wax myrtle, and manzanita. Shore pine and Sitka spruce forests constitute the habitat with the greatest structural complexity on the North Spit and support the greatest diversity of wildlife species. The trees, snags, and downed logs in coastal dune forests

[103] "Irreplaceable" means that successful in-kind habitat mitigation to replace lost habitat quantity and/or quality is not feasible within an acceptable period of time or location, or involves an unacceptable level of risk or uncertainty, depending on the habitat under consideration and the fish and wildlife species or populations that are affected. "Acceptable", for the purpose of this definition, means in a reasonable time frame to benefit the affected fish and wildlife species (OAR 635-415-0025).

[104] "Essential Habitat" means any habitat condition or set of habitat conditions that, if diminished in quality or quantity, would result in depletion of a fish or wildlife species (OAR 635-415-0025).

[105] "Limited habitat" means an amount insufficient or barely sufficient to sustain fish and wildlife populations over time (OAR 635-415-0025).

[106] "Important Habitat" means any habitat recognized as a contributor to sustaining fish and wildlife populations on a physiographic province basis over time (OAR 635-415-0025).

provide important breeding, foraging, and cover habitat for a variety of wildlife species: upland amphibians seek cover in downed logs, and many bird species, including raptors, woodpeckers, and songbirds, nest and forage in these habitats.

Coastal dune forest and riparian forest habitats are classified as Category 3 because they are "essential to wildlife" but are "not limited" (as defined by Oregon under OAR 635-415-0025). Species that depend on these habitat types include the Pacific marten (*Martes caurina*) (or coastal marten, addressed in section 4.6), bats, and some songbirds.

Herbaceous, herbaceous shrub, and shrub upland habitat types are all classified as Category 4 because they are not essential or limited, but they are still important to wildlife. The vast majority of these habitats lie on dredge spoils covered by weedy herbaceous and shrub species. Shrub species present within these habitats include young shore pine and invasive species such as Scotch broom and Himalayan blackberry. Herbaceous vegetation in these habitat types includes native species such as seashore lupine, small-head clover, and beach strawberry, together with invasive species such as European beachgrass, colonial bentgrass, and sweet vernal grass. These habitats have been extensively degraded historically, and only provide habitat for generalist species such as deer, small mammals, and a limited suite of songbirds (DEA 2014).

Open Water/ Wetland Habitats

Open water and wetland habitats on the LNG terminal site are composed of several freshwater lakes, ponds, forested and shrub wetlands, and emergent wetlands and marshes, together with the Coos Bay estuary and its associated shoreline, including mudflats. Habitats found in this environment support a rich terrestrial wildlife community, including mammals, birds, reptiles, and invertebrates; aquatic species found in these habitats are discussed below in section 4.5.2. Terrestrial wildlife species that use open water and wetland habitats (inland, estuarine, or marine) on the North Spit are generally specialized or are strongly associated with one habitat type. However, there are dozens of species that may occur in the area affected by the Project that are very well adapted to utilizing one, two, or all three of these open water and wetland habitats, as seasonal conditions warrant. Resident and migrant shorebirds congregate on the tidally inundated mudflats along the shore of Coos Bay, to forage on the invertebrates in the shallow waters and exposed mudflats, especially during low tides. Raptors known to use open water and shoreline habitats include the bald eagle (*Haliaeetus leucocephalus*), osprey (*Pandion haliaetus*), northern harrier (*Circus cyaneus*), and peregrine falcon (*Falco peregrinus*). Mammals that also forage in wetlands and near shore environments include, but are not limited to, raccoon (*Procyon lotor*), mink (*Neovison vison*), and striped skunk (*Mephitis mephitis)*.

Forested, scrub-shrub, and emergent wetlands are classified as Category 2, because they are essential for wildlife, and limited, but not irreplaceable. The access channel contains open water habitat in Coos Bay (see figure 4.5-2 in section 4.5.2). This area consists of salt marsh, eelgrass, intertidal, and subtidal habitats. Open water habitat contains both Category 2 and Category 3 habitat classifications.

Developed Habitat

Developed areas include portions of the LNG terminal site that have been substantially disturbed by previous development and industrial use, including land use activities such as demolished mill foundations/concrete pads, unvegetated cut slopes, rocked yards, paved roads, parking lots, gravel roads, concrete laydown areas, log deck storage areas, and sandy roadside areas. Developed lands have limited potential to become important or essential wildlife habitat, and therefore are classified as Category 6.

Terrestrial Animals in the Project Area

Terrestrial wildlife that may occupy the area affected by the Jordan Cove LNG Project includes mammals, birds, amphibians, reptiles, and invertebrates. Approximately 178 species of amphibians, reptiles, birds, and mammals were recorded in uplands on or adjacent to the Jordan Cove Project site (i.e., the LNG terminal facility) during surveys conducted from 2005 to 2017 in support of the Project.

Mammals

Fifty-eight mammal species are known to occur on the North Spit (BLM 2005). This includes large mammals, such as mountain lion (*Puma concolor*), Roosevelt elk (*Cervus elaphus roosevelti*), American black bear (*Ursus americanus*), and black-tailed deer (*Odocoileus hemionus*). Wildlife surveys conducted for Jordan Cove in 2005, 2006, and 2012 documented 11 mammal species in the terminal tract (LBJ 2006; SHN 2013b): American beaver (*Castor canadensis*), Roosevelt elk, Virginia opossum (*Didelphis virginiana*), North American porcupine (*Erethizon dorsatum*), mountain lion, Townsend's chipmunk (*Neotamias townsendi*), black-tailed deer, harbor seal (*Phoca vitulina*), raccoon, Douglas' squirrel (*Tamiasciurus douglasii*), and American black bear. Nine species of bats are known to occur on the North Spit (BLM 2005). While bat-specific surveys were not completed by Jordan Cove, the mosaic of habitat types in the area suggests bat presence is potentially high. Unidentified bats were observed in one of the buildings on the Roseburg Forest Products property on July 21, 2005.

Birds

Migratory birds, which include all native birds in the U.S., with the exception of upland game birds, are protected under the MBTA, as described in section 1.5.1.10. Additionally, EO 13186 was enacted, in part, to ensure that the environmental analysis of a federal action evaluates the effects of that action on migratory birds, and the federal agency and its project proponents avoid, minimize effects, conserve species, and restore and enhance migratory bird habitat. EO 13186 states that emphasis should be placed on species of concern, priority habitat, and key risk factors. In March 2011, FERC and FWS finalized an MOU to implement EO 13186. Conservation of migratory bird habitats, avoiding or minimizing take of migratory birds, and developing effective mitigation measures to restore or enhance habitats on lands affected by energy projects are included as obligatory elements in the MOU. The MOU also places emphasis on, but is not exclusive to, birds of conservation concern (BCC; FWS 2008).

The Jordan Cove LNG Project is located in the Pacific Flyway path for migratory birds and is in Bird Conservation Region (BCR) 5 as defined by FWS (2008) (note that the Pacific Connector Pipeline Project is also in BCR 9 as well, as discussed in section 4.5.1.2). Birds that are known or that likely occur along the waterway and in the LNG terminal site include seabirds, shorebirds, waterfowl, passerines (songbirds), wading birds, and raptors. The number of bird species documented on or near the North Spit of Coos Bay is 277: the BLM has documented 275 avian species in this area (BLM 2005), while LBJ Enterprises (2006) documented 151 avian species during surveys of the LNG terminal tract, including two additional species not documented by the BLM. BCC that potentially occur in the area affected by the Project are listed in table 4.5.1.1-1.

Federally- or state-listed species that are also BCC are not included below, as they are discussed in more detail in sections 4.6.1 and 4.6.2.

TABLE 4.5.1.1-1

Birds of Conservation Concern in the Project Area, Timing of Potential Occurrence, and Expected Habitat

Common Name	Scientific Name	Timing of Potential Occurrence	Expected Habitat
Allen's hummingbird	*Selasphorus sasin*	Summer	Chaparral, thickets, brushy hillsides, open coniferous woodlands, and gardens near coast
Bald eagle	*Haliaeetus leucocephalus*	year-round	Near large bodies of water
Black oystercatcher	*Haematopus bachmani*	year round	Coastal beaches, bays, and estuaries
Black swift	*Cypseloides niger*	Migration	Forages over forests and open areas
Caspian tern	*Sterna caspia*	Migration	Coastal areas
Hudsonian godwit	*Limosa haemastica*	Rare	Marshes, beaches, flooded fields, and tidal mudflats
Lesser yellowlegs	*Tringa flavipes*	Migration	Marshes, ponds, wet meadows, lakes and mudflats
Long-billed curlew	*Numenius americanus*	Winter	Fields, dry prairies, mudflats
Little willow flycatcher	*Empidonax traillii brewsteri*	Summer	Low brushy vegetation in wet areas
Marbled godwit	*Limosa fedoa* (ssp. *beringiae* only)	Winter	Beaches, mudflats, shallow pools
Olive-sided flycatcher	*Contopus cooperi*	Summer	Coniferous forests
Oregon vesper sparrow	*Pooecetes gramineus* (ssp. *affinis* only)	Very unlikely to occur in vicinity of Project	Open fields and pastures
Peregrine falcon	*Falco peregrinus*	winter/year-round	Open habitats, nests on cliffs
Purple finch	*Carpodacus purpureus*	Year-round	Wooded areas
Red knot	*Calidris canutus*	Migration	Beaches and mudflats
Rufous hummingbird	*Selasphorus rufus*	summer/migration	Coniferous forests
Short-billed dowitcher	*Limnodromus griseus*	Winter	Beaches, mudflats, shallow ponds
Western grebe	*Aechmophorus occidentalis*	Winter	Marshes, lakes, and bays
Whimbrel	*Numenius phaeopus*	Migration	Coastal marshes, beaches, rocky shores

Sources: FWS (2008); Sibley (2000); NatureServe (2009, 2013)

Seabirds

Thirteen seabird species breed along Oregon's coast, with offshore rocks and islands providing critical nesting habitat and important rest-over locations. Seabirds depend on relatively undisturbed coastal nesting habitats and on the rich coastal waters for food (Oregon Ocean Resources Management Task Force 1991). Foraging habitat can differ by species; some species such as the sooty shearwater (*Puffinus griseus*) and the northern fulmar (*Fulmarus glacialis*) are found primarily along the mid and outer shelf, while California gull (*Larus californicus*) and western gull (*Larus occidentalis*) occur only in the nearshore (Oregon Ocean Resources Management Task Force 1991). Foraging sea birds can be encountered along the LNG carrier transit route, at the terminal site, and in adjacent Coos Bay water.

Shorebirds

Coos Bay is an important area for shorebirds between San Francisco Bay and British Columbia. Key areas for migrating shorebirds include Coos Bay and the beaches and deflation plains in the Oregon Dunes National Recreation Area (ODNRA). Coos Bay's extensive eelgrass beds, productive sloughs, intertidal algal flats, and substantial tidal marshes provide valuable habitat for thousands of shorebirds. Foraging habitat for shorebirds includes inter-tidal mudflats, rocky inter-tidal areas, estuaries, salt marshes, and beaches; salt marshes are used for resting and preening. The vast majority of shorebirds are migratory and non-breeders in Coos Bay. An important exception is the western snowy plover (*Charadrius alexandrinus nivosus*), which nests on the North Spit (this species is discussed in more detail in section 4.6). Shorebirds are most likely to be encountered along the beaches of the North Spit, and in the bay along tidal mudflats, salt marshes, and other exposed estuarine habitat.

Waterfowl

Waterfowl habitat varies from ocean surf to fields and open meadows to upland streams (FWS 2007a). The southern Oregon coast provides wintering and migratory habitat for waterfowl of the Pacific Flyway. Coos Bay is recognized as an important migration and wintering waterfowl location. Waterfowl are most likely to be encountered in Coos Bay and the immediate near shore habitat.

Passerines (Songbirds)

Breeding and foraging habitat for migratory passerines is associated with terrestrial and wetland habitat in Coos Bay. Important habitat includes coastal scrub-shrub, coastal dune forest and palustrine wetlands. In the case of swallows, human-made structures can be important structures for nesting colonies. Passerines are likely to occur in all habitats at the terminal site.

Neotropical migrants (birds that breed in North America and overwinter in the tropics) were observed during surveys of the waterway and LNG terminal. These are largely forest-nesting species. Examples of neotropical migrants detected at the LNG terminal site include olive-sided flycatcher (*Contopus cooperi*), Wilson's warbler (*Wilsonia pusilla*), orange-crowned warbler (*Vermivora celata*), and Swainson's thrush (*Catharus ustulatus*).

Wading Birds

Several wading bird species are resident in the Coos Bay area and the North Spit. Wading birds are typically colonial when nesting and therefore are sensitive to anthropogenic disturbance at breeding sites. Wading birds hunt in a variety of habitat types from fields and meadows to palustrine and estuarine wetlands. Wading birds are likely to occur in the shoreline habitats at the terminal site.

At least two historic great blue heron (*Ardea herodias*) rookeries occur close to the Jordan Cove LNG terminal site area. One rookery is located about 2,000 feet to the east of the LNG terminal site and about 300 feet from Jordan Cove Road (on both sides of Trans-Pacific Parkway) (LBJ 2006). The other historical rookery is located adjacent to the LNG terminal site on the south side of Henderson Marsh (BLM 2006a). No evidence of great blue heron breeding in the area was observed during the 2005, 2006, 2012, or 2013 surveys.

Raptors

Raptors are abundant year-round residents in Coos Bay. Fourteen species of raptor are known to occur on the North Spit (BLM 2005), and surveys conducted by LBJ (2006) detected both peregrine falcons and bald eagles near the Jordan Cove site. Coos Bay and the North Spit provide a mosaic of terrestrial, coastal, and nearshore habitat types with abundant prey for raptors. White-tailed kites (*Elanus leucurus*) were observed during 2005 surveys near Henderson Marsh. Osprey, falcons, and eagles may occur in the nearshore habitats along the waterway for LNG carrier transit and at the terminal site. Ospreys are relatively common near river estuaries and bays and nest on human-made structures including the Roseburg Forest Products facility lights. Falcons are likely to be associated with salt marsh and tidal mudflats where shorebirds are abundant.

Amphibians and Reptiles

Eleven species of amphibians (8 salamanders, 3 frogs) are known to occur on the North Spit (BLM 2005). Despite the presence of invasive non-native bullfrogs (*Lithobates catesbeianus*), two native amphibian species were observed in suitable habitat during the wildlife surveys conducted in 2005, 2006, and 2012 for the LNG terminal (LBJ 2006; SHN 2013b). The northern red-legged frog (*Rana aurora*) and northwestern salamander (*Ambystoma gracile*) are present in some wetlands within the terminal tract.

Ten species of reptiles are known to occur on the North Spit (BLM 2005), including the western pond turtle (*Actinemys marmorata*). However, the western pond turtle was not observed during wildlife surveys of the Jordan Cove LNG terminal area (LBJ 2006; SHN 2013b). Reptiles observed during Project surveys in 2005, 2006 and 2012 included the northern alligator lizard (*Elgaria coerulea*) and northwestern garter snake (*Thamnophis ordinoides*) (LBJ 2006; SHN 2013b).

Invertebrates

Inland sand dunes at the North Spit are used extensively by certain species of terrestrial insects, primarily beetles, centipedes, and millipedes. Flying insects are also common throughout the site and are fed upon heavily by barn swallows (*Hirundo rustica*) (BLM 2005).

Effects on Wildlife Habitat and Terrestrial Wildlife Species from Construction and Operation of the Jordan Cove LNG Project

Effects on Habitats

The area affected by the construction of the LNG terminal and associated facilities (including the Workforce Housing Facility, Ingram Yard, laydown areas, etc.) is presented by temporary and permanent acres of disturbance by habitat type in table 4.5.1.1-2. Temporary disturbances to upland habitat would be restored in consultation with landowners and to the extent possible using non-invasive native plant species. Permanent disturbance to habitat results in these areas being converted to a developed habitat type that would be occupied by Project facilities during operations.

a/ Access and Utility Corridor includes all temporary construction and permanent access roads and facilities and utilities, as well as the Fire Department (non-jurisdictional).

b/ APCO Sites 1 and 2 includes off-loading transfer platform and temporary dredge pipeline option.

c/ Ingram Yard Site includes all permanent LNG Terminal facilities. e.g., LNG tanks and liquefaction equipment, compressors, etc., and any other temporary construction facilities located on Ingram Yard.

d/ Meteorological Station includes access road.

e/ South Dunes Site includes Workforce Housing Facility, metering station, administrative building, and SORSC (non-jurisdictional), and temporary areas around the border.

f/ Temporary Construction Sites includes construction laydown/staging and off-site park & rides, i.e. Roseburg laydown site, Port laydown site, Boxcar Hill, Mill Casino, and Myrtlewood and Hydraulic Dredge Pipeline/Access Road from Jordan Cove Road to MOF.

g/ The acres disturbed as listed in this table includes vegetated and unvegetated upland and wetland habitats (excluding mitigation sites) and thus may differ from the total acreage disturbed as listed in other sections of this EIS, such as the vegetation section.

The primary effect on wildlife from construction and operation of the LNG terminal would be habitat modification or habitat loss. The natural habitats most important to wildlife that would be affected include forested dunes and open water/wetlands. Jordan Cove has indicated that upland habitat values lost to the construction of the LNG terminal and related facilities would be mitigated through the Panhandle, Lagoon, and North Bank mitigation sites. More details on these upland mitigation sites will be provided in a *Wildlife Habitat Mitigation Plan* that will be provided by the applicant as an appendix to their *Comprehensive Mitigation Plan*. Jordan Cove has indicated that estuarine habitat values lost to the construction of the LNG terminal and related facilities would be replaced in-kind at the eelgrass and Kentuck mitigation sites. Standard measures to avoid or minimize effects on wildlife, such as those presented in the ECRP and *Integrated Pest Management*

Plan, would also apply to actions taken at mitigation sites. These upland and estuarine mitigation sites include:

- The Panhandle site is approximately 133 acres and is located north of Trans-Pacific Parkway. The Panhandle site is part of a larger natural area that extends north into the ODNRA. It contains coastal dune forest, herbaceous, shrub, unvegetated sand, wetlands, and open water habitat types. The Panhandle site is home to a known population of northern red-legged frog and unique wetland types. Scotch broom would be removed at this site to promote ecological uplift.
- More than 100 acres of the 320-acre Lagoon site is proposed as mitigation. The Lagoon site is located adjacent to the meteorological station and contains shrub, herbaceous shrub, herbaceous, emergent wetland, and scrub-shrub wetland habitat types. Existing overhead power lines would be buried at the site.
- The North Bank site is approximately 156 acres and is located on the north bank of the Coquille River adjacent to the Bandon Marsh National Wildlife Refuge (NWR). It contains conifer forest, stabilized sand dunes, and scrub-shrub wetland habitat types. Forestry activities and weed control are proposed at the site that promote progress towards a mature forest setting.
- Eelgrass (Habitat Category 2) would be replaced by constructing an eelgrass mitigation site across the bay from the LNG terminal site, south of the runway for the Southwest Oregon Regional Airport;
- Estuarine resources (Habitat Category 2), including intertidal sand/mudflats, salt marsh, and shallow subtidal, would be mitigated by the construction of mudflat estuarine wetlands in the Kentuck project site; and
- Additional freshwater wetland resources (Habitat Category 2) disturbed by the construction of the LNG terminal would be mitigated out-of-kind at the Kentuck project site and in accordance with ODSL wetland mitigation requirements (OAR Chapter 141, Division 85 and Division 90) on neighboring North Spit property owned by Jordan Cove.

Effects on Terrestrial Wildlife Species

General Effects Applicable to All Terrestrial Wildlife

Constructing the project would temporarily and permanently affect wildlife. Impacts would include mortality if less mobile individuals are unable to avoid equipment or vehicles or cannot flee away from an oil or fuel spill. More mobile species would likely be displaced from the terminal area during active construction to adjacent similar habitats. Wildlife near the LNG terminal would also be disturbed by construction activities and noise and may move farther away.

An increased human presence and the resulting trash/waste could attract predators. However, the Project site would be kept clear of construction debris and food wastes. Covered, animal-proof receptacles would be provided in eating and break areas, parking lots, and at appropriate locations around the construction site. During construction, the site would be cleaned on a daily basis to remove any food or other debris left by construction workers. During operations, the Project site would be regularly inspected to ensure that no garbage is allowed to accumulate.

Noise associated with construction of the Project could also affect wildlife. Construction-related noise could affect animal behavior, foraging, or breeding patterns, and cause wildlife species to move away from the noise or relocate in order to avoid the disturbance. Noise from construction of the LNG terminal should be similar to typical commercial construction programs, which have noise levels averaging between 47 to 57 A-weighted decibels (dBA) when measured 2,000 feet away (H&K 1994). Noise from construction of the terminal is discussed in detail in section 4.12.2.4. Construction of the terminal would occur over a period of about five years. Noise associated with construction would be intermittent and may be operated on two 10-hour shifts, 6 days per week, with the potential to increase to a 24/7 schedule if required. Given the high level of current activity on the North Spit, including existing industrial operations and vehicle and rail traffic,[107] and the temporary nature of Jordan Cove's construction activities, Project-related construction noise is not expected to adversely affect wildlife in the region.

Operating the Project would also affect wildlife. For example, an LNG carrier in transit in the waterway could strike seabirds or shorebirds, an oil or fuel leak from a ship could affect both aquatic wildlife and terrestrial wildlife near the surface of the water and along the shorelines of the navigation channel, or vessel traffic may cause shoreline erosion. Jordan Cove would encourage LNG carrier operators to implement measures that would reduce the potential for oil or fuel spills. LNG carriers have a double hull that would keep fuel and oil onboard, thereby reducing the potential for a spill. Furthermore, each LNG carrier would maintain a shipboard oil pollution emergency plan. Further details on the potential effects of a spill are discussed in section 4.5.2.1. Studies conducted by Jordan Cove have shown that LNG carriers transiting at slow speeds in the Coos Bay navigation channel suggests that waves created by the vessels would be within the normal magnitude of waves that naturally occur in the bay and that any increase in shoreline erosion would be minor (section 4.5.2.1).[108]

Light being emitted from the LNG terminal facility could cause wildlife to alter their behavior to either avoid areas of artificial light or be attracted to those areas. Lighting at the LNG terminal would likely include a mixture of low-power fluorescent lighting and higher intensity security lighting that would primarily be located on shore, in and adjacent to the slip. When an LNG carrier is not in the berth, the lighting would be reduced to that required for security. Other industrial facilities on the North Spit (Roseburg, Southport, DB Western) already have night lighting. Jordan Cove has proposed including hooded or cut-off fixtures in its lighting plan to reduce glare and reduce light pollution to night skies. Because Jordan Cove has not prepared and filed a lighting plan, **we recommend that:**

- **Prior to construction, Jordan Cove should file with the Secretary, for review and written approval by the Director of OEP, its lighting plan. The plan should include measures that will reduce lighting to the minimal levels necessary to ensure safe operation of the LNG facilities and any other measures that will be implemented to minimize lighting impacts on fish and wildlife. Along with its lighting plan, Jordan Cove should file documentation that the plan was developed in consultation with the**

[107] Current ambient noise levels measured at the BLM boat ramp parking lot on the North Spit about 2 miles south of the Jordan Cove terminal site ranged from 40.8 to 47.6 dBA. See section 4.12.2.4 of this EIS.

[108] See *Technical Report – Draft, Volume 2 – Jordan Cove Energy Project and Pacific Connector Gas Pipeline, Coastal Engineering Modeling and Analysis*, filed by Jordan Cove as Appendix I.2 in Resource Report 2 included with its September 2017 application to the FERC.

FWS, NMFS, and ODFW. This lighting plan should also be in compliance with the lighting recommendations found in section 4.13.

Operational noise from the Jordan Cove Project could have long-term effects on wildlife on the North Spit. We predict that operational noise from the LNG terminal would have an equivalent sound level (L_{eq}) of 49 dBA and day-night sound level (L_{dn}) of 55 dBA when measured about 0.7 miles away, at the nearby ODNRA. This compares to current ambient L_{dn} noise levels of about 55 dBA at this location (see section 4.12.2.4 of this EIS). During operation, the ODNRA would experience a noise level of 58 dBA L_{dn} (a 3 dB increase). A small portion of the ODNRA would be subjected to day-night sound levels as high as 65 dBA. The Jordan Cove Project would result in a 3 decibel (dB) or greater increase over ambient at this recreation area. We conclude that operational noise from the terminal may affect some wildlife depending on their proximity to the terminal and each species' tolerance for increased noise.

Special status species that could be affected by the Jordan Cove Project, and relevant mitigation of those effects, are discussed in section 4.6.

Effects on Mammals

The construction and operation of the LNG terminal would reduce the amount of habitat available for big game species, and vehicle traffic related to the Project would increase the potential for collisions. However, due to the amount of previous disturbance at the site, and existing industrial activities in the area, we conclude that the Project would not significantly affect mammal species that currently occupy the North Spit.

Breeding and roosting sites for bats at the LNG terminal tract are limited due to the absence of typical bat habitat such as cliffs, rock outcrops, bridges, caves, and mines. Dune forest habitat is available on the LNG terminal site for those bat species that roost under bark. Removal of dune forest habitat would remove bat roosting habitat and likely displace individuals into nearby dune forest habitat (such as the ODNRA immediately north of the LNG terminal site). A meteorological station on the North Spit would pose a collision risk for bats, especially if guy-lines are required for operation. As with other mammals, we conclude that the Project would not significantly affect bat species.

Effects on Birds

Migratory bird species would likely experience disturbance due to the construction and operation of the Jordan Cove Project. Effects on birds would most likely be related to modification of habitat. However, areas affected by the Jordan Cove Project are relatively small in comparison to the total habitat available in Coos Bay, and in the larger BCR 5. Effects on migratory birds from both jurisdictional and non-jurisdictional facilities are included in this analysis.

Nesting habitat for migratory birds occurs in areas that would be cleared for the LNG terminal and related facilities. The Project would alter and disturb breeding and non-breeding habitat and could affect prey populations. The removal of coastal dune forest, grasslands (herbaceous), and shrublands (herbaceous shrubs and shrubs) could affect nesting and foraging opportunities for songbirds and raptors that occupy upland habitats. The effect of the construction of the slip and access channel, pile dike rock apron, and MOF on wetlands would be the permanent loss of intertidal, shallow subtidal, and eelgrass. These are all habitats utilized by seabirds, waterfowl, wading birds, and shorebirds. The loss of wetland habitat would be offset by the creation of in-kind mitigation areas proposed by Jordan Cove at the Kentuck project and eelgrass mitigation site. Table 4.5.1.1-2 presents the acreage of upland and wetland habitat disturbed during construction.

The great blue heron rookery located 300 feet from the Jordan Cove Road would be subject to potential disturbance from noise from construction traffic using Jordan Cove Road. The rookery is currently subject to noise from truck traffic delivering chips to the Roseburg wood chip export facility. Similarly, the historic rookery on the south side of Henderson Marsh could be affected by construction noise if the rookery was active during site construction. Jordan Cove would conduct spring status assessments annually of both great blue heron rookeries, as reuse by this species could occur. If biologists from other agencies (such as ODFW and BLM) conduct rookery surveys on the North Spit, Jordan Cove may use the results of these agency surveys. If either rookery becomes active, Jordan Cove, in consultation with ODFW, would develop an appropriate mitigation plan.

During operation of the Project, birds would be at risk of colliding with terminal facilities, including the LNG storage tanks and meteorological station. This risk is expected to be low given the visibility of most facilities, but could increase during storms, dense fog, at night, or at other times with reduced visibility. The meteorological station would be less visible than the terminal facilities and storage tanks and would likely pose a greater collision risk for birds that utilize beach and dunes habitat than the other facilities. If guy-lines would be required for operation of the meteorological station, they would be outfitted with bird deterrent measures to reduce the likelihood of bird strikes.

The facilities would be well lit at night, which could attract birds. There is some evidence that high intensity continuous anti-collision lights on structures may result in an increased number of bird strikes, especially at night or during fog and overcast conditions. The number of strikes can apparently be reduced by strobe or blinking the anti-collision lights. The LNG storage tanks would not be illuminated with high-intensity lighting. The intensity and number of lights would be limited to what is required for security and operations. Use of low-intensity lighting should reduce the likelihood of adverse effects on birds from collision with the LNG storage tanks compared to use of high intensity lighting.

Similar to lighting, birds can be drawn to the terminal flares. For example, some 7,500 songbirds were killed in September 2013 when they flew into the 30-meter-tall flare at the Canaport LNG import terminal in Saint John, New Brunswick, Canada (CBC News 2013). The flares at the LNG terminal are unlikely to have a similar adverse effect on birds due to design features. These flares would be lower in height and only be used for temporary periods, such as during start-up and shutdown, maintenance, and in response to unplanned pressure changes in the system to maintain safe operations. Jordan Cove can also implement measures through a lighting plan that would minimize effects on birds from terminal lighting. However, Jordan Cove would not develop its final lighting plan until final design. We have recommended above that Jordan Cove produce a final lighting plan prior to construction, for our review and approval that outlines measures to be implemented to ensure that facility lighting would not have major effects on birds and other wildlife.

Birds would also be at risk of colliding with LNG carriers in the waterway during operation of the terminal. Although the annual ship traffic would increase due to the Project, LNG carriers in the navigation channel would be traveling slowly and escorted by tugboats, and operate in compliance with Coast Guard as well as Oregon State requirements. Therefore, we conclude that LNG carrier marine traffic in the waterway would not significantly affect birds.

Jordan Cove proposes to implement various measures to avoid, minimize, and in some instances mitigate, effects on birds and their local habitats. All vegetation clearing at the LNG terminal would be conducted prior to March 1 or after August 31 to ensure most nesting birds have fledged. If construction activities must occur during the nesting season, Jordan Cove would conduct focused pre-construction surveys to determine if there are active migratory bird nests present that need to be avoided. The surveys would be conducted within the construction limits and within 100 feet (200 feet for raptors) of the construction limits. If active nests are encountered within the limits of the survey, construction and vegetation removal activities would be halted in the immediate vicinity (to approximately 20 feet away) until a qualified biologist has determined that the individuals have fledged from the nest (evacuated) or that the nest has failed from natural causes. If no active nests are encountered within the limits of the survey, construction and vegetation removal would proceed. Empty or abandoned nests would be removed; permits are not required (except for eagles and listed species) to remove an empty or abandoned nest or to remove or alter the structure the nest is built in or on (FWS 2003a, 2013a). Jordan Cove would coordinate with the FWS prior to proceeding with construction, and any consultation exchange with the FWS would be provided to the FERC. Further description of avoidance, minimization, and mitigation measures is provided in the draft *Migratory Bird Conservation Plan* filed with FERC on August 31, 2018.

Structures associated with the Project would be monitored to discourage use by avian predator species. Frequent inspections would ensure that nests are not being constructed and all nests found would be removed immediately, before birds could lay eggs. It is anticipated that there would be sufficient inspections and other activities mandated by safety and security requirements to keep the structures nest free. However, in the unlikely event that a nest becomes established and it is not discovered until eggs or young birds are present, the disposition of the nest would be handled in accordance with the provisions of the MBTA in consultation with the FWS. The FWS would require a special use permit if an active nest is encountered that would need to be removed, relocated, or transferred to a rehabilitation center. The Commission requires that all necessary permits be obtained prior to construction, including a Migratory Bird Special Use permit under 50 CFR section 21.27 if needed.

Additionally, in August 2018 both Jordan Cove and Pacific Connector jointly filed a draft *Migratory Bird Conservation Plan*. Both companies continue to consult with the FWS to finalize the plan and to prioritize conservation of migratory birds during construction and operation of all facilities. Therefore, we conclude that the Project would not significantly affect birds.

Effects on Amphibians and Reptiles

Potential Project-related effects on amphibians and reptiles would include mortality from construction if they were not able to avoid equipment or traffic, and habitat loss. Fill activity in wetlands would reduce available habitat for some amphibians and reptiles. Removal of dune forest for the Project would reduce habitat for the clouded salamander (*Aneides ferreus*), should this species occur in these areas. Jordan Lake and nearby wetlands on the east side of the terminal tract may offer suitable breeding habitat for the western toad (*Anaxyrus boreas*), although the species was not found during surveys of the site.

Jordan Cove proposed to mitigate potential effects on amphibians and by conducting pre-construction surveys for the western pond turtle, northern red-legged frog, and clouded salamander. Individuals located in the construction area would be captured and transported to suitable nearby habitats, as agreed to by the ODFW.

4.5.1.2 Pacific Connector Pipeline

Wildlife Habitats

Wildlife associations with habitats in the area that would be affected by the Pacific Connector Pipeline Project include the following (adapted from Johnson and O'Neil 2001):

- close association: a species is known to depend on a specific habitat for part or all of its life history requirements (feeding and reproduction) implying that the species has an essential need for a particular habitat for its maintenance and viability;
- general association: a highly adaptable species that is supported by a number of habitats that provide for its maintenance and viability; and
- present: a species that occasionally uses a habitat that provides marginal support for its maintenance and viability.

Sixteen wildlife habitat types (Johnson and O'Neil 2001) coincide with one or more of the vegetation types described for the Pacific Connector pipeline area in Section 4.4.1.2. Wildlife species associations with these habitat types provide a basis for evaluating Project effects on biodiversity and in some cases, on individual species. Two additional wildlife habitat types are not specifically addressed in Johnson and O'Neil (2001) but are well represented in the area affected by the Project: Grass-Shrub-Sapling or Regenerating Young Forest and Roads. Table 4.5.1.2-1 lists the miles of each of these habitat types crossed. Westside Lowland Conifer-Hardwood Forest and Southwest Oregon Mixed Conifer-Hardwood Forest are the most abundant habitats crossed, with 60.1 and 47.1 miles crossed, respectively.

Specialized habitat features also occur within the area affected by the pipeline project. Such features include cliffs that provide nesting for peregrine falcons and possibly other raptors. Snags provide roosting locations for several bat species, and nesting locations for cavity-nesting birds. LWD is present, which could be used by reptiles and amphibians.

TABLE 4.5.1.2-1

Wildlife Habitat Types Crossed by the Pacific Connector Pipeline and Wildlife Species Associated with Habitats

General Habitat Type	Mapped Habitat Type	Late Successional or Old-Growth Forest Crossed a/,f/ (miles)	Mid-Seral Forest Crossed b/,f/ (miles)	Clearcut/ Regenerating Forest Crossed c/,f/ (miles)	Total Miles	Percent of Total Project Mileage per Habitat Type	Number of Species Associated d/

Note: Mileages rounded to nearest tenth of a mile; values less than 0.1 miles shown as "<0.1". Rows/columns may not sum correctly due to rounding.

a/ Late Successional (80 to 175 years) and Old-Growth Forest (175 + years).
b/ Mid-Seral Forest (40 to 80 years).
c/ Clearcut (0 to 5 years) and Regenerating Forest (5 to 40 years).
d/ Numbers of species associated with each habitat type crossed by the Pacific Connector Project were summarized from Pacific Connector's Environmental Resource Report 3, Appendix 3D, Table 3D-1.
e/ Following wetland regulation protocols, construction of the pipeline would initially affect 112.2 acres of wetlands. See section 4.3 for results of jurisdictional wetland delineation and discussion of Project effects on wetlands.
f/ Cells with no data result from the fact that non-forested habitat types did not identify seral stage; thus, miles are identified only in the "total miles" column.
g/ Distances in parentheses indicate crossing through recently burned Southwest Oregon Mixed Conifer-Hardwood Forest.

Grasslands and/or meadows provide habitats for animals that are adapted to areas dominated with perennial bunchgrasses and forbs. A wide variety of species use grasslands and meadows, including songbirds, amphibians, and reptiles. We estimate that the pipeline route would cross about 16.3 miles of grasslands (see table 4.5.1.2-1). Wetlands provide habitat for migrating and breeding waterfowl, shorebirds, waterbirds, songbirds, mammals, amphibians, and reptiles (ODFW 2006b). Riparian zones (including forested wetlands) support high species diversity (Johnson and O'Neil 2001). In total, the pipeline route would cross about 6 miles of wetlands and riparian habitats.[109]

The pipeline route would cross about 142 miles of woodlands and forest habitats. Deciduous hardwood species, such as oak and tanoak, occur in the area affected by the pipeline project. Mixed coniferous and deciduous forests, deciduous-dominated riparian areas, and oak woodlands are found most often in Douglas and Jackson Counties. In Coos County, many of the historical deciduous woodlands have been reduced as a result of conifer plantings and changes in fire frequency and intensity, as well as conversion to agricultural and residential uses. A wide variety of species use deciduous and young conifer forest habitats, including songbirds, reptiles, and small mammals.

Mature (greater than 40 years old), late successional (80 to 175 years old), and old-growth (greater than 175 years old) forests are unique, important habitat elements. Tree species common in mature to old-growth forests are western hemlock, Douglas-fir, western redcedar, Sitka spruce, red alder, and bigleaf maple (Chappell et al. 2001). Bird species that are obligates of old-growth forests include the federally threatened NSO and MAMU (further discussed in section 4.6). Old-growth forests are most common along the pipeline route in the Klamath Mountains (see section 4.4).

Terrestrial Animals in the Project Area

The areas crossed by the Pacific Connector pipeline route provide diverse habitats for wildlife, including forests, shrublands, and grasslands. These habitats support an array of wildlife species. Overall, 47 amphibian and reptile, 281 bird, and 108 mammal species are known or suspected to occur in the area affected by the Project.

Mammals

Based on their distributions in southwestern Oregon and habitat associations described by Johnson and O'Neil (2001), 108 species of mammals may be present in habitats that coincide with and/or are adjacent to the Pacific Connector pipeline. The most numerous groups likely to occur are rodents (46 species, such as Baird's shrew, coast mole, least chipmunk, and Douglas' squirrel), carnivores (19 species, such as coyote, gray fox, black bear, and mink), and bats (13 species; see subsection below). Mammal species with special state or federal status are discussed in section 4.6.

The highest diversity of mammals can be expected in the Johnson and O'Neil (2001) Agriculture, Pastures, and Mixed Environs habitat and Eastside and Westside Riparian-Wetlands habitat (78 species, respectively). Mammalian species diversity is also relatively high in Westside Lowland Conifer-Hardwood-Forest (66 species), Southwest Oregon Mixed Conifer-Hardwood Forest

[109] Following wetland regulation protocols, construction of the pipeline would initially impact 112.2 acres of wetlands. See section 4.3 for results of jurisdictional wetland delineation and discussion of Project effects on wetlands.

(65species), Westside Oak and Dry Douglas-Fir Forest and Woodlands (65), Montane Mixed Conifer Forest (64 species), as well as in Developed-Urban and Mixed Environs (64 species). The lowest species diversity of mammals is expected in Bays and Estuaries (12).

Wild Horses

The BLM and the Forest Service manage wild horses to ensure healthy herds and healthy rangelands in Oregon. The Pokegama Herd Management Area (HMA) is in the southwestern corner of Klamath County and the southeast corner of Jackson County, on both private and BLM lands in the Lakeview District. While the pipeline does not cross it, the HMA is in the general vicinity of the Project. From 1972 to 2002, the average number of horses in the HMA was 42.7, but the population has ranged from 23 to 55 horses over that time. Relative to other wild horse herds (which increase about 22 percent per year), the Pokegama herd has a low yearly increase of 4 to 5 percent. This may be due to illegal removal or mountain lion predation (BLM 2002).

Bats

A total of 15 species of bat occur in Oregon; 13 of the species potentially occur in the area affected by the Project. All of the species except for little brown myotis, big brown bat, and Brazilian free-tailed bat have some special status, whether identified by the State as sensitive, the FWS as a Species of Concern, or by the BLM or the Forest Service as a Sensitive Species. Special status species are discussed in section 4.6; special status bats are listed in table I-3 of appendix I. Uses of different habitats that may occur along the pipeline route vary between little brown myotis, big brown bat, and Brazilian free-tailed bat (table 4.5.1.2-2).

TABLE 4.5.1.2-2

Non-Special Status Bat Species and Associated Habitats Likely to Occur In the Project Area

Species	Distribution in Southern Oregon	Habitat Types	Foraging Habitat
Little brown myotis *Myotis lucifugus carissima*	Yearlong throughout Oregon	Associated with all habitats described in table 4.5.1.2-1	Forages for insects in scattered trees, along edges of dense timber, near water in shrub-grassland
Big brown bat *Eptesicus fuscus*	Yearlong throughout Oregon	Associated with all habitats described in table 4.5.1.2-1	Forages for insects over forest canopy, along roads/edges through trees, forest clearing
Brazilian free-tailed bat *Tadarida brasiliensis mexicana*	Non-migratory southern Oregon only	Westside Lowland Conifer-Hardwood Forest, Southwest Oregon Mixed Conifer-Hardwood Forest, Ponderosa Pine Forest and Woodlands, Westside Oak and Dry Douglas-fir Forest and Woodlands, Western Juniper and Mountain Mahogany Woodlands, Shrub-steppe, Westside Grasslands, Westside Riparian-Wetlands, Herbaceous Wetlands, Agriculture, Pastures, and Mixed Environs, Urban and Mixed Environs, Open Water - Lakes, Rivers, and Streams	Forages for insects in heated buildings or outside during warm spells during winter. During other periods, will forage almost anywhere from valley bottoms to Cascade / Siskiyou Mtn. crest, foraging long distances, e.g., 30+ miles round trip per night

Sources: Maser and Cross (1981), Verts and Carraway (1998), Johnson and O'Neil (2001), Weller (2008), ODFW (2013a)

All of the bat species consume insects, and most are associated with tree-dominated habitats that occur in the area affected by the pipeline project. Bats have roosts used by nursing females and young, roosts used during daylight, and hibernacula that are used to survive during winter while hibernating or in torpor. White-nose syndrome is a disease of hibernating bats, caused by a fungus that affects skin for the nose, ears, and wings of hibernating bats (USGS 2013b).

White-nose syndrome has spread from the northeastern United States to 28 states and has most recently been identified in the state of Washington in 2016; since 2006 over 6 million insect-eating bats have died from the effects of this disease. ODFW, along with other federal agencies, has been surveying caves for the disease with no positive indications that the disease is presently in Oregon bat populations (ODFW 2017b).

Birds

Based on their distributions in southwestern Oregon, 281 bird species may be present in habitats that would be crossed by the Pacific Connector pipeline (Johnson and O'Neil 2001). The highest diversity of bird species can be expected in habitats associated with agriculture, pastures, and mixed environs (181 species). Many species are also associated with riparian-wetland habitats (156 species), herbaceous wetlands (134 species), bays and estuaries (132 species), and developed-urban and mixed environs (133 species; table 4.5.1.2-1). The fewest number of bird species are associated with sagebrush shrub-steppe (76) and eastside grasslands (80).

Annual breeding bird survey (BBS) counts were used to determine additional potential bird species presence in habitats crossed by the Pacific Connector pipeline. Fewer species have been documented on BBS routes (241 species observed) than the number of species associations of wildlife habitats coinciding with the Pacific Connector Project (281 species expected). The disparity is likely due to several factors: the BBS does not usually document all of the species possibly present at the time of the survey (i.e., nocturnal owls and birds that do not sing or call regularly); species reported are present only during the season of the survey; and survey routes may not include or be representative of all habitat types crossed by the pipeline. Regardless, the BBS survey counts can be used as an index of some species' population trends over time.

The Pacific Connector pipeline crosses two BCRs: (1) BCR 5 – Northern Pacific Rainforest, from MP 1.5R to MP 168.15; and (2) BCR 9 – Great Basin, from MP 168.15 to MP 228.81. Bird species diversity and population trends in the region surrounding the Project were evaluated from data collected on 33 BBS routes that have been surveyed within 50 miles of the Project (17 routes in BCR 5, 16 routes in BCR 9). Of the 238 species observed on the BBS routes, 11 species are BCC in BCR 5 (excluding the MAMU, discussed in section 4.6) and 21 species are BCC in BCR 9. BCC in the area affected by the Pacific Connector pipeline are listed in table 4.5.1.2-3.

TABLE 4.5.1.2-3

Birds of Conservation Concern in BCR-5 and BCR-9 that Have Been Observed on BBS Routes within 50 Miles of the Pacific Connector Pipeline Project with Regional and Local Population Trends, and Breeding Dates, if Known

Common Name a/ *Scientific Name*	Regional BCR Trend 1996 to 2015 b/	Local Trend 1997 to 2016 c/	Confirmed Breeding Dates d/ Earliest	Latest
BCR-5, Northern Pacific Rainforest				
pelagic cormorant *Phalacrocorax pelagicus*	No Trend	No Data	22 Mar	26 Jul

tricolored blackbird *Agelaius tricolor*	No Trend	Increasing (p<0.10)	12 Apr	9 Aug
eared grebe *Podiceps nigricollis*	No Trend	Insufficient Data	31 May	23 Aug

a/ BCC species listed by BCR in FWS (2008).
b/ Regional trend analyses available at https://www.mbr-pwrc.usgs.gov/bbs/bbs.html (Sauer et al. 2017).
c/ BBS data retrieved from https://www.pwrc.usgs.gov/bbs/RawData/ (Pardieck et al. 2017). Local population trends in each BCR were estimated from average number observed per BBS route if data were sufficient (average occurrence per route per year ≥1, average number of routes per year with species counted ≥5).
d/ Confirmed breeding dates from Oregon Breeding Bird Atlas (Adamus et al. 2001).
e/ Only applies to streaked horned lark (*Eremophila alpestris strigata)* subspecies not differentiated in data sources.
f/ Only applies to Oregon vesper sparrow (*Pooecetes gramineus affinis)* subspecies not differentiated in data sources.
g/ Sage sparrow was recently split into two species: Bell's sparrow (*Artemisiospiza belli*) and sagebrush sparrow (*Artemisiospiza nevadensis*). Sagebrush sparrows were observed within 50 miles of the pipeline in BCR-9 and are assumed to be BCC in that region.

For BCR 5 regional trends, peregrine falcons and bald eagles are increasing and for the rest of the birds either there is a decreasing trend (4) or no trend (5). For BCR 5 local trends, rufous hummingbird, willow flycatcher, and purple finch are increasing and for the rest of the birds either there is no data or insufficient data (7 birds), or no trend (1 bird). For BCR 9 regional trends, bald eagle, long-billed curlew, and white-headed woodpecker have increasing trends, the sage thrasher and pinyon jay display a decreasing trend, and for the rest of the birds either there is a no trend (13) or no analysis (4). The local trend for BCR 9 is increasing for tricolored blackbird. For the other birds in BCR 9, there are 4 exhibiting no local trend and the rest do not have sufficient data to report a trend.

Many migratory bird species have been observed during the annual Christmas Bird Count (CBC), sponsored by the Audubon Society in the vicinity of the Project. At least 272 bird species (common names are reported and have not been standardized) have been counted at eight locations proximate to the area affected by the Pacific Connector Pipeline Project. While 152 bird species have been reported by both BBS and CBC, 91 species have only been reported by the CBC. The species include various seabirds (auklets, murres, guillemots, jaegers, gulls, albatrosses, shearwaters, and cormorants), waterfowl (scoters, geese, swans), and shorebirds (dowitchers, sandpipers, plovers, turnstones). The local population of common ravens has been increasing during the breeding period in BCR 9 and during winter on CBC count circles near the Pacific Connector pipeline.

Several raptor species are known or suspected to nest, migrate, and seasonally reside in the general vicinity of the pipeline route. Those reported for BBS routes in the region include turkey vulture, osprey, white-tailed kite, bald eagle, northern harrier, sharp-shinned hawk, Cooper's hawk, northern goshawk, red-shouldered hawk, Swainson's hawk, red-tailed hawk, ferruginous hawk, golden eagle, American kestrel, American peregrine falcon, and prairie falcon. Several additional raptor species have only been observed during CBC surveys. Those include rough-legged hawk, gyrfalcon, and merlin. Bald eagles, northern goshawks, and peregrine falcons have nest sites within 3 miles, some much closer to the Project (data from ORBIC 2012 and 2017a; BLM 2017a; Forest Service 2017c; and pipeline surveys for the northern goshawk on Rogue River-Siskiyou National Forest). Other raptor species have been observed, some nesting, along the Project route during surveys focusing on other rare species. Bald eagles, ospreys, sharp-shinned hawks, Cooper' hawks, goshawks, golden eagles, red-shouldered hawks, red-tailed hawks, peregrine falcons, and turkey vultures have been reported during surveys in 2007 and 2008 but nest sites were not included in the documentation. Some of these raptor species have probably nested in the Project vicinity in the past.

There are also several species of owls that have been documented on BBS routes and are likely to occur in the areas crossed by the pipeline. They include barn owl (*Tyto alba*), western screech owl (*Otus kennicottii*), great horned owl (*Bubo virginianus*), northern pygmy-owl (*Glaucidium gnoma*), barred owl (*Strix varia*), great gray owl (*Strix nebulosa*), short-eared owl (*Asio flammeus*), and NSO. Owls seen only during the winter CBC surveys include northern saw-whet owls (*Aegolius acadicus*) and burrowing owls (*Athene cunicularia*). Additionally, boreal owl (*Aegolius funereus*), flammulated owl (*Otus flammeolus*), and long-eared owl (*Asio otus*) are expected to occur in habitats crossed by the Pacific Connector pipeline route. The burrowing owl, flammulated owl, and great gray owl have special state or federal status and more information on their occurrence is included in appendix I. The NSO has threatened state and federal status and is discussed in more detail in section 4.6. Great horned owls, western screech owls, NSOs, barred owls, northern pygmy owls, and great gray owls have been reported during surveys in 2007 and 2008 but nest sites were not included in the documentation.

Game Animals

Several species of mammals and birds are considered game animals and are harvested through recreational and/or subsistence hunting. Except for wildlife harvest administered and managed under tribal authorities, hunting is regulated by the ODFW in defined Wildlife Management Units. Big game species that may occur in the areas crossed by the Pacific Connector pipeline route include black-tailed deer, mule deer, Roosevelt elk, Rocky Mountain elk, black bear, and cougar. Demographic data and harvest data for game animals are compiled by ODFW and are available in online reports, listed by animals taken by each hunt unit.

Two subspecies of mule deer occur in the Pacific Connector pipeline area: the larger Rocky Mountain mule deer, usually found east of the Cascade Mountain crest, and the black-tailed deer, generally found west of the Cascades (ODFW 2008). A second species, Columbian white-tailed deer, was state and federally delisted in 2003 and may occur between MPs 56.0 and 61.0, and MPs 65.5 and 66.2, in an area mapped by ODFW as "peripheral big game range" and "impacted habitat" (ODFW 2017c, 2017d). Black-tailed deer are considered management indicator species (MIS) for both the Umpqua and Rogue River National Forests (Forest Service 1990a, 1990b).

In eastern Oregon, mule deer are mainly confined to open woods or isolated mountain ranges, although they once ranged into sagebrush plains in canyons or rimrock. During the winter, a period considered critical for the mule deer, they descend to lower elevations to browse sagebrush, bitterbrush, rabbitbrush, juniper, and mountain-mahogany, which are high in fats (ODFW 2003a, 2011; Csuti et al. 2001). In western Oregon, black-tailed deer are found in forested areas and heavy brush areas at the edges of forests and chaparral thickets. Black-tailed deer prefer early successional stages created by clear-cuts or burns, providing grasses, forbs, and shrubs (ODFW 2008; Csuti et al. 2001). Most black-tailed deer that summer in the high Cascades winter at lower elevations on the west slope, although some wintering may occur east of the Cascade crest (ODFW 2008). Winter loss of black-tailed deer is generally far less than for mule deer, because the snow does not remain on the valley floors for extended periods and a crust does not form on the surface as it does on the east side of the Cascades (ODFW 2008). In Jackson County, black-tailed deer are highly migratory and often move along well-defined migration trails at night during the months between October and March (ODFW 2007a). In Douglas County, Columbian white-tailed deer are most often associated with riparian habitats, although they are known to use a variety of lower elevation habitat types, such as grasslands, grass shrub, oak woodlands, coniferous woodlands, and mixed deciduous and coniferous woodlands (FWS 2003b).

Rocky Mountain elk inhabit most of eastern Oregon and Roosevelt elk occupy most of western Oregon with concentrations in the Cascades and Coast ranges. They are known to make significant movements in response to disturbances from humans and predators, as well as seasonal weather patterns. Rocky Mountain elk is considered an MIS for both the Umpqua and Rogue River National Forests (Forest Service 1990a, 1990b). Note that MIS species are addressed in more detail in section 4.5.1.3

Several herds of elk are known to winter on the western slopes of the Cascades (ODFW 2003b). Summer elk forage consists of a combination of lush forbs, grasses, and shrubs, which is usually attained at higher elevations in wet meadows, springs, and riparian areas in close proximity to forested stands. Forage becomes less abundant and accessible in winter and the nutritional quality declines. Winter range is usually in forested sites, which provide protection against weather as well as lichens and other plants used as forage (ODFW 2003b); however, in Jackson County, winter range also consists of other habitat types such as grassy meadows, recent clearcuts, industrial forestlands, agricultural fields, orchards and urban edges. Most elk range is on BLM and NFS lands (ODFW 2003b); however, in the Pacific Connector pipeline area, most winter range occurs on private lands (table 4.5.1.2-4). Jackson County has the most winter range affected by the Project, followed by Klamath County, then Douglas County.

ODFW delineated digital GIS coverage of deer and elk habitat in Oregon, which include big-game winter management areas in Jackson and Klamath counties in the vicinity of the pipeline (ODFW 2012b, 2012c, and 2017d). The delineated areas do not necessarily represent complete deer and elk winter ranges in each county, but designate areas that provide some level of protection for big-game winter range while allowing development to occur (Milburn 2007). Additionally, our analysis incorporates GIS coverage of big-game winter range on NFS lands, which also includes a few delineated areas in the Umpqua National Forest in Douglas County (Forest Service 2006). BLM Districts defer to winter range delineated by ODFW (Waddell 2017) Harvested small game and furbearer species that occur are beaver, bobcat, gray fox, red fox, marten, mink, muskrat, otter, raccoon, badger, coyote, nutria, opossum, spotted skunk, striped skunk, and weasel (Hiller 2011).

TABLE 4.5.1.2-4

Designated Big Game Winter Range Crossed by the Pacific Connector Pipeline

Klamath County Total	**0.3**	**0.0**	**19.8**	**20.1**
Overall County	**13.7**	**2.1**	**41.9**	**57.7**

Note: Rows/columns may not sum correctly due to rounding. Mileages rounded to the nearest tenth of a mile (values below 0.1 are shown as "<0.1").

a/ Other includes non-federal lands, such as private, county, and state.

b/ Seasonal restrictions are specific to landownership. "Other" designation is stipulated by ODFW.

c/ Sensitive Wildlife Areas coverage (ODFW 2017c) also incorporates Forest Service Deer Winter Range coverage (Trail Creek, Big Butte Creek, and Lake Creek). Occurs in Evans Creek and Rogue ODFW big game management units.

d/ Very Sensitive Wildlife Area coverage (ODFW 2017c) also incorporates BLM Deer (Camel Hump, BFRA Salt Creek, Little Butte Creek South) and Elk (Camel Hump, BFRA Salt Creek) Winter Management Area coverages, as well as Forest Service Deer Winter Range coverages (Big Butte Creek, Lake Creek). Occurs in Rogue ODFW big game management units.

e/ Deer Low/Medium Density Winter Range coverage (ODFW 2012b) includes the ODFW Keno big game management unit.

f/ Deer Low/Medium Density Winter Range (ODFW 2012a) incorporates BLM Deer Winter Management coverages (Stukel, South Bryant). Occurs in Klamath Falls big game management unit.

g/ Elk Winter Range for Eastern Oregon (ODFW 2012c).

Amphibians and Reptiles

Based on their distributions in southwestern Oregon, 23 amphibian species and 24 reptile species may be present in habitats that would be crossed by the Pacific Connector pipeline route (Leonard et al. 1993; Nussbaum et al. 1983). Habitats in the area of the pipeline that support the highest diversity of reptiles and amphibians include Wetlands/Eastside Riparian-Wetlands (38 species), Developed, Urban, and Mixed Environments (37 species), and Mixed Conifer-Hardwood Forest (36 species). One reptile species (western terrestrial garter snake) is potentially found in bays and estuarine habitats. Amphibian and reptile species that could potentially occur near the Project include, but are not limited to, clouded salamander, tailed frog, western toad, western pond turtle, sagebrush lizard, rattlesnake, king snake, western fence lizard, gopher snake, and rubber boa.

Some amphibian species potentially occurring in the area affected by the pipeline project are associated with a variety of habitats and thus are common and widespread with healthy populations, such as the Pacific tree frog and rough-skinned newt. Other species that have been documented, such as the foothill yellow-legged frog (a federal species of concern, state sensitive, BLM and Forest Service sensitive species), are declining (ODFW 2006b; Oregon Conservation Strategy 2016). Amphibians demonstrate close associations with aquatic and riparian habitats, though they may occur in other habitat types if not too distant from water, for example, the ensatina (a lungless salamander), which is found in forests. Amphibians with extremely limited distributions and relatively specific ecological requirements may be more at risk of further population declines (Walls et al. 1992).

Reptiles present along the pipeline project are also associated with a variety of habitats crossed, although not all are as closely associated with water and/or water-dominated features as amphibians.

Invertebrates

Terrestrial invertebrates occur along the Pacific Connector pipeline. Arthropods occur in all habitat types crossed by the pipeline, though terrestrial mollusks (gastropods) are considerably more restricted. With few exceptions, terrestrial mollusks are generally found in moist habitats associated with springs, seeps, decaying wood, moist mature forests, and habitats maintained in the coastal "fog" zone near the ocean. Other invertebrate species would likely be widespread and abundant throughout the area affected by the Project; some examples include *Peromyscopsylla selenis*, earthworm (*Lumbricus variegatus)*, orb weaver spider (family *Araneidae)*, and grass spiders (*Agelenopsis* spp.*)*. Some invertebrates, such as bees (from families such as *Apidae*, *Halictidae*, *Andrenidae*, *Megachilidae*, and *Colletidae*), play an important role in pollination of native plants in the area affected by the Project.

Effects on Wildlife Habitat and Terrestrial Wildlife Species from Construction and Operation of the Pacific Connector Gas Pipeline Facilities

Effects on Habitats

The acres of wildlife habitat types (from Johnson and O'Neil 2001) that would be affected by construction of the Pacific Connector pipeline are listed in table 4.5.1.2-5. Westside Lowland Conifer Forest, Southwest Oregon Mixed Conifer-Hardwood Forest, Shrublands and Grasslands, Agriculture, Pastures, and Mixed Environs, and Urban and Mixed Environs would be the wildlife habitats most affected by construction.

At aboveground facilities, native habitats would be cleared, and on private lands the area would be permanently converted into developed-industrial land. During pipeline operation, a 30-foot-wide corridor, centered over the pipe, would be kept clear of trees. As a result, areas cleared of forest during pipeline construction would be maintained in a shrub/herbaceous state within this 30-foot-wide corridor. The remainder of the temporary pipeline construction right-of-way would be revegetated with native species, although it would take years to many decades for forested and shrub-steppe habitat to regenerate. Other habitats, such as grasslands, within the temporary construction right-of-way would typically be restored within three years. A 10-foot-wide corridor centered on the pipeline may be mowed annually and maintained in an herbaceous state. The remainder of the 30-foot-wide corridor within the permanent easement may be subject to vegetation clearing every three years. The acres of wildlife habitat that would be affected by operation of the Pacific Connector Project are listed in table 4.5.1.2-6.

TABLE 4.5.1.2-5

General: Columns and rows do not necessarily sum correctly due to rounding. Acres rounded to nearest whole acre. Values less than 1 acre shown as "<1".
Acres of disturbance to non-vegetated areas are included in this table for consistency in values reported in this document.

a/ Acres disturbed were evaluated using GIS; footprints for each component (aboveground facilities, permanent easement, and 30-foot maintenance corridor) were overlaid on the digitized vegetation coverage.

b/ The "Late Successional and Old-Growth" category (L-O) describes those forest areas with a majority of trees over 80 years of age. Forests with stands greater than 175 years are considered to have old-growth characteristics.

c/ The "Mid-Seral" category (M-S) describes those forest areas with a majority of trees over 40 years of age but less than 80 years of age.

d/ The "Grass-shrub-sapling or Regenerating Young Forest" category (C-R) describes those forest areas that are either clear-cut (tree age 0-5 years) or regenerating (tree age 5 to 40 years). Forest areas in this category are divided into forest vegetation types based on their potential to become those types of forests.

General: Columns and rows do not necessarily sum correctly due to rounding. Acres rounded to nearest whole acre. Values less than 1 acre shown as "<1".
Acres of disturbance to non-vegetated areas are included in this table for consistency in values reported in this document.

a/ Acres disturbed were evaluated using GIS; footprints for each component (aboveground facilities, permanent easement, and 30-foot maintenance corridor) were overlaid on the digitized vegetation coverage.

b/ The "Late Successional and Old-Growth" category (L-O) describes those forest areas with a majority of trees over 80 years of age. Forests with stands greater than 175 years are considered to have old-growth characteristics.

c/ The "Mid-Seral" category (M-S) describes those forest areas with a majority of trees over 40 years of age but less than 80 years of age.

d/ The "Grass-shrub-sapling or Regenerating Young Forest" category (C-R) describes those forest areas that are either clear-cut (tree age 0-5 years) or regenerating (tree age 5 to 40 years). Forest areas in this category are divided into forest vegetation types based on their potential to become those types of forests.

e/ Subtotal by Habitat Type includes the 30-foot maintenance corridor, permanent access roads, and only aboveground facilities with a meter station or compressor station (mainline block valves located within the 30-foot maintenance corridor).

During construction and restoration, Pacific Connector would implement numerous measures to minimize impacts on vegetation and ensure successful revegetation of disturbed areas (see section 4.4). These measures include those found in the ECRP, *Leave Tree Protection Plan*, *Integrated Pest Management Plan*, *Fire Prevention and Suppression Plan*, and the *SPCC Plan*. These measures would be applied to all lands crossed by the pipeline route; however, federal land-managing agencies may impose additional measures on federal lands. Measures specific to federally managed lands are addressed in the upland vegetation section 4.4.1.3.

Effects on Terrestrial Wildlife Species

General Effects Applicable to All Terrestrial Wildlife

Many species have very specific habitat requirements that may or may not be present in the area affected by the Project and would not be described in the relatively broad habitat types used in this section (habitat types described by Johnson and O'Neil 2001). Consequently, the assumption has been made that if a species' occupied range is known or likely to coincide with the area affected by the Project, and if general habitat types that would be affected by the Pacific Connector pipeline could include more specific habitat components required by that species, then the species could occur and be affected in some way by the Project.

Constructing and operating the Project could cause habitat degradation by spreading noxious weeds, herbicide use, noise, and habitat fragmentation. Wildlife may be affected by construction vehicles traveling to and from construction sites. Species most susceptible to vehicle-related injury and mortality include those that are inconspicuous (salamanders, frogs, snakes, small mammals), those with limited mobility (amphibians), burrowing species (mice and voles, weasels, beaver, frogs and toads, snakes, subterranean mollusks), and wildlife with behavioral activity patterns making them vulnerable, such as deer that are more active at dusk and dawn, and wildlife that may scavenge roadside carrion (Leedy 1975; Bennett 1991; Forman and Alexander 1998; Trombulak and Frissell 2000). Vegetation clearing during operations of the pipeline could also affect wildlife.

Other species are likely to be displaced from habitats that are cleared of vegetation (passerine birds, and tree-dependent/cavity-dependent birds and mammals such as woodpeckers and bats) and from areas adjacent to construction sites (waterfowl, raptors and medium-sized mammals). Populations may also be negatively affected if individuals emigrate from habitats affected by project-related disturbances. Displacement of mobile wildlife would most likely be a short-term effect. Once construction and restoration of the right-of-way is complete, displaced individuals are expected to return to the original area they occupied. If adjacent habitats are at carrying capacity for the species, displaced individuals would cause increased competition for resources, increased susceptibility to predation, or promote disease that may be facilitated by crowding.

Activities associated with constructing the pipeline could decrease individuals' reproductive success by increasing neonate or nest abandonment and possibly by interfering with breeding behaviors, sustenance, and growth of fetuses and/or young, conception rates, and fetal survival. These impacts may affect population growth through diminished rates of survivorship and fecundity.

Both long-term and short-term effects could occur to amphibians and reptiles associated with waterbodies and the riparian areas. Removal of riparian vegetation along stream edges that are crossed by the Project could increase sedimentation input into the waterbody and/or increase water temperatures. Changes in hydrology could also occur in wetlands and waterbodies used for breeding, limiting dispersal or reducing breeding habitat (ODFW 2006b).

Construction of the pipeline through upland forests would require removal of deciduous and coniferous trees and would remove those habitat features over the long-term. It would take decades for trees to grow to their original size in temporary workspaces in cleared forested areas that are restored and revegetated after construction. Former forested habitats in Pacific Connector's 30-foot-wide operational right-of-way would be converted to shrub-sapling dominated or herbaceous cover for an extended period of time (50 years or more). This conversion could benefit some wildlife species that characteristically inhabit shrub or grassland habitats but would be detrimental to wildlife species adapted to forest interiors. Construction through forested areas would also result in the removal of snags and LWD that are used by a variety of wildlife, including cavity nesters and bats.

Construction through existing shrub-dominated areas would mostly result in short-term habitat loss. After restoration and revegetation, grasses and shrubs would be allowed to regenerate across the entire right-of-way. There would be long-term habitat loss in some areas, where shrubs, such as species of sagebrush, would require longer than 5 years to become reestablished. Loss of this habitat type could potentially affect certain species of birds and mammals that utilize shrubs, by reducing forage and nesting opportunities.

Noxious Weeds and Invasive Species

Short- or long-term effects on wildlife habitat would also occur if the pipeline causes the establishment and spread of noxious weeds, as well as other invasive species (animals and microbes) not native to a region. In general, habitats with more bare ground, such as grasslands, riparian areas, relatively dry, open forests, and disturbed areas such as roads are more susceptible to invasive species establishment than are dense, moist forests, high mountain areas, and serpentine areas that have relatively closed plant cover or have extreme climate or soils.

Noxious weeds often out-compete native vegetation. They displace native species by spreading rapidly and utilizing resources (nutrients, water, sunlight) that can eventually lead to a weed-dominated monoculture. Such transformed habitat can be unsuitable to former wildlife inhabitants. Often, as habitat quality degenerates, wildlife diversity declines. For example, purple loosestrife forms dense monocultures that inhibit native vegetation, causing decreasing species' diversity, limit water flows and wildlife access to water, and in some instances can make waterfowl nesting areas unsuitable (Whitson 1996). A summary of noxious weed species found along the pipeline route is provided in table 4.4.1.2-4.

Clearing of vegetation from the linear right-of-way and soil disturbance from right-of-way grading would increase the chance of spreading noxious weeds through the removal of native, established species and soil disturbance, which could encourage the establishment of invasive plants. Equipment moving along the right-of-way could also bring seeds from one place to the next, aiding the spread of these species. Pacific Connector has measures in place to help prevent this as described in the ECRP.[110] Weed surveys would take place prior to vegetation removal, and infested areas would be pretreated through mechanical methods and herbicide spot treatment to minimize the spread of invasive plants. Equipment would also be inspected and cleaned of any

[110] See Appendix I to the POD, which was included in Pacific Connector's application to the FERC.

potential weed seed or propagules (i.e., soil roots or rhizomes). During restoration, disturbed areas would be revegetated with native seed mixtures. Monitoring would typically occur for a period of three to five years (as described in the *Integrated Pest Management Plan* and ECRP) to ensure that no non-native plants establish themselves in lands disturbed by pipeline activities. Due to measures that would be employed before, during, and after construction, the risk of the pipeline causing noxious weeds to spread in the area of the pipeline should be low.

Pacific Connector would mitigate for the spread of noxious weeds, forest pathogens, and soil pests by following the measures outlined in its *Integrated Pest Management Plan*.[111] Further measures for controlling the spread of noxious weeds are contained in its ECRP. See section 4.4.1.2 for more details on invasive plants and mitigation measures.

Invasive insects, mites (e.g., spruce spider mite), and terrestrial mollusks (e.g., the predatory spotted leopard slug) can similarly disperse along a newly created corridor where native vegetation formerly presented barriers to dispersion. In general, invasive exotic wildlife species can adversely affect native species and their populations through various pathways, singly or in combination that include:

- introduction of disease or parasites to native wildlife;
- interbreeding (hybridization) with native wildlife;
- competition for habitat with native wildlife;
- degradation of habitat of native wildlife; and/or
- predation on native wildlife.

The measures outlined in the *Integrated Pest Management Plan* would help decrease the adverse effects of invasive insects.

Invasive animals such as introduced bullfrogs have adversely affected various native frog populations through predation (Hayes and Jennings 1986), including populations of Oregon spotted frogs in Washington (Watson et al. 2000). Bullfrogs prey on and out-compete native frog species. They spread very quickly due to their prolific nature, lack of predators, ability to travel long distances over dry land, and wide habitat and diet preferences. Pacific Connector has developed BMPs to avoid the potential spread of the aquatic invasive species and pathogens of concern during Project hydrostatic testing operations (see the *Hydrostatic Testing Plan*[112]). While bullfrogs are not specifically addressed in the *Hydrostatic Testing Plan*, it is anticipated that the screening/filtering, chlorine treatment, and upland dewatering BMPs would be effective at eliminating the potential spread of bullfrogs and their eggs or tadpoles.

The range of the barred owl has expanded into NSO habitat, and this species competes with NSO for resources and has been known to displace NSO from suitable habitat (Kelley et al. 2003; Kelley and Forsman 2004). Barred owls negatively affect NSO populations, primarily by reducing survival and increasing local territory extinctions (Dugger et al. 2016).

[111] See Appendix N to the POD, which was included in Pacific Connector's application to the FERC.
[112] See Appendix M to the POD, which was included in Pacific Connector's application to the FERC.

Herbicides

Herbicides could affect native plant species, thereby affecting wildlife habitat and potentially the animals themselves. While adverse effects on wildlife tend to be low, some symptoms include breakdown of vital organs, reduction in numbers of healthy offspring, decreased fitness, and direct mortality (Forest Service 2005b). Amphibians can be deformed or killed by some herbicides if these chemicals get into the water. Herbicides tend to form residue on grasses more readily than other vegetation; therefore, wildlife that eats grass, as well as those species above them on the food chain, tend to be most susceptible to the effects of herbicides (Forest Service 2005b).

Pacific Connector would control all ODA A- and T-listed weeds, along with some B-listed weeds (ODA 2017b). To determine if an herbicide is to be used over hand and mechanical weed control methods, Pacific Connector would implement integrated weed management principles following BLM (2010b) and Forest Service (2005c) guidelines (see section 4.4 for more details).

In accordance with Pacific Connector's *Integrated Pest Management Plan*, only specific spots would be treated with herbicides to control noxious weeds. Because agency-approved herbicides are generally of low toxicity to animals when applied per label instructions, adverse effects on wildlife should be low.

Noise

Noise from construction and operation of the Pacific Connector Pipeline Project is discussed in detail in section 4.12.2.2 of this EIS. We estimate that noise from general construction of the pipeline would range from the L_{eq} of about 93 dBA at 50 feet, to 85 dBA at 100 feet, and 72 dBA at 300 feet. Ambient sound levels in much of the Pacific Connector pipeline route area probably would be similar to the Arcata Fish and Wildlife Office's projections (FWS 2006a). Ambient sound is defined as the sound qualities as they might exist currently and might include human-generated sources over the long term. The typical ambient sound level for forest habitats ranges from 25 dB to 44 dB. Considering ambient sound as a base, noise levels associated with some common machines and activities that would be present during pipeline construction are included in table 4.5.1.2-7. Noise from HDD drilling would range from L_{dn}[113] of about 32 to 73 dBA at NSAs, with no noise mitigation. This compares to current ambient L_{dn} levels at these NSAs ranging from about 42 to 66 dBA. Double rotor helicopters may be used for timber clearing along a portion (15.4 miles) of the Pacific Connector pipeline route. This type of helicopter generates noise of about 92 dBA within 700 feet of its area of use. Operation of the Klamath Compressor Station would result in estimated L_{dn} noise of about 51 dBA at an NSA located about 1,230 feet away. Current ambient noise at this residence is an L_{dn} level of about 43 dBA.

TABLE 4.5.1.2-7

Common Sound Levels for Equipment/Activities Potentially Associated with the Pacific Connector Pipeline

Measured Sound Source	Range of Reported dB Values (at Distance Measured 50 feet)	Relative Sound Level a/
Forest Habitats	25 – 44	Ambient
Yelling	70	Low
Chain Saw (various types/conditions)	61 – 93	Low – Very High
Pickup Truck (idle to driving)	55 – 71	Very Low – Moderate
Mowers	68 – 85	Low – High

[113] Appendix B of Pacific Connector's POD filed with the FERC on January 23, 2018.

TABLE 4.5.1.2-7

Common Sound Levels for Equipment/Activities Potentially Associated with the Pacific Connector Pipeline

Measured Sound Source	Range of Reported dB Values (at Distance Measured 50 feet)	Relative Sound Level a/
Log Truck	77 – 97	Moderate - Very High
Dump Truck	84 – 98	High - Very High
Rock Drills	82 – 98	High - Very High
Pumps, Generators, Compressors	87	High
Drill Rig	88	High
General Construction	84 – 96	High – Very High
Track Hoe	91 – 106	Very High – Extreme
Helicopter or Airplane (various types/conditions)	96 – 112	Very High – Extreme
Rock Blast	112 b/	Extreme
Logging Helicopter (Columbia double rotor)	108 – 123	Extreme

a/ A general, subjective ranking of noise levels created by the sources considered when used for analysis of relative noise effects on species.
b/ Blasting required for the Pacific Connector pipeline would be underground and muffled, which should result in a lower dB value at 50 feet.

Noise could potentially affect wildlife in localized areas for a short duration during pipeline construction activities, including clearing and grading the right-of-way, and HDD operations. The average time a given point along the pipeline would be disturbed by construction noise is approximately 8 weeks. This would vary, as the speed at which a crew would be able to work would be affected by terrain, construction methods, weather, and environmental windows. HDD operations may occur 24 hours per day, seven days a week. HDD operations are estimated to last from 20 to 100 days depending on the location.

Distances at which noise would attenuate to ambient levels would depend on local conditions such as tree cover and density, topography, weather (humidity), and wind, all of which can alter background noise conditions. Consequently, short-term effects on wildlife by construction noise would vary along the length of the pipeline route.

Noise would most likely displace wildlife some distance away from noise sources especially if wildlife species are nearby. However, any short-term effects on wildlife by noise would occur simultaneously with human presence and the presence of heavy machinery normally required for pipeline construction. Most likely, any effects on wildlife due to noise could not be separated from those due to all other construction-related activities occurring concurrently. Noise and human presence would move along the construction right-of-way, albeit at a rather slow pace. Therefore, effects on wildlife because of noise would be of short duration and spatially localized.

Research has demonstrated varying short-term reactions of wildlife to noise. Most research has focused on wildlife reaction to more constant noise generated by roads and high-volume traffic (e.g., Forman and Alexander 1998). Some research has recorded wildlife reaction to airplanes, sonic booms, helicopters, artillery, and blasting that could produce similar reactions from noises associated with construction activities for the Pacific Connector Pipeline Project. For example, Golden et al. (1980) provided the following behavioral and physiological reactions of animals to known noise levels ranging between 75 and 105 dB from various disturbances, including aircraft:

- fish demonstrate reduced viability, survival, and/or growth (20 dB for 11 to 12 days);
- ungulates become nervous and/or run (82 to 95 dB) or panic (95 to 105 dB);

- waterfowl flock (80 to 85 dB), move and/or become nervous (85 to 95 dB), or startle (95 to 105 dB); and
- birds scare (85 dB).

Raptors and other forest-dwelling bird species have demonstrated more adverse effects on project-generated sound during nesting and breeding when levels substantially exceed ambient conditions existing prior to a project. For instance, the FWS has determined that sound exceeding ambient nesting conditions by 20 to 25 dB or exceeding 90 dB when added to ambient conditions may be considered take under ESA when evaluating effects on NSO and MAMU (FWS 2006a). Such sound levels could potentially result in egg failure or reduced juvenile survival, malnutrition or starvation of the young, or reducing the growth or likelihood of survival of young. However, these effects may be minimal; Awbrey and Bowles (1990) found that raptors flushed from their nests while incubating did not leave the eggs exposed for more than 10 minutes and concluded that multiple, closely spaced disturbances would be required to cause lethal egg exposure. Some raptors, for example osprey, refuse to be flushed from their nest despite closely approaching helicopters (Poole 1989).

Specific studies to determine effects on wildlife from noise generated from construction of a pipeline have not been conducted. However, it is expected that construction noise in remote areas that are relatively free from noise would have a greater potential to disrupt wildlife. Potential effects on wildlife from some noises generated from construction activities can be evaluated to an extent, such as noise from vehicles and/or increased road traffic, blasting, helicopter timber harvest or pipeline delivery, and aerial fly-overs.

Animals could flee the area because of helicopter disturbance. Pacific Connector has filed an *Air, Noise and Fugitive Dust Control Plan*[114] that describes helicopter noise and potential mitigation. In the case of birds, helicopter noise could cause adult birds to flush leaving eggs exposed to weather and predators. For all animals, helicopter disturbance could have negative energetic effects. Mitigation for helicopter noise includes operational restrictions, such as scheduling restrictions near sensitive areas, maintaining a high altitude and flight paths away from noise sensitive areas whenever possible.

The USDOT (2004) has summarized numerous studies and literature that have reported the effects of noise on wildlife, specifically focusing on noise associated with roads. Overall, existing information suggests that fish are unlikely to be adversely affected by noise levels produced from road traffic; reptiles and amphibians show some barrier effect due to roads (but no clear evidence of a noise effect alone); bird numbers and breeding can be strongly affected by the proximity of roads; large mammals can be repelled by road/vehicle noise; and small mammals do not appear to be adversely affected by road noise.

Blasting may be required for pipeline trench excavation in areas where hard, non-rippable bedrock occurs in the trench profile. Approximately 117 miles of the pipeline alignment is considered to have moderate to high blasting potential, although not all substrate in those areas identified may require blasting to achieve the required trench depth. Blasting activities may involve a single blast or a repetitive blasting sequence. Blasting during trench excavation is discussed in more detail in section 4.1.2.5.

[114] Appendix B of Pacific Connector's POD filed with the FERC on January 23, 2018.

Noise from blasting would be short-term and localized. The noise associated with blasting activities is reported to be in the range of 112 dB within 50 feet of the trench (see table 4.5.1.2-7), and may cause alarm in wildlife (e.g., birds, terrestrial mammals, etc.). With the proposed Best Management Practices and mitigation measures applied to trench blasting, the blasting noise would attenuate to 92 dB within 200 feet and 70 dB within 1,025 feet. Mitigation includes blasting methods, which reduce noise through charge placement and timing of detonation, and physical mitigation such as covering the blast areas with soil or blast mats. Pacific Connector has filed a *Blasting Plan* (Appendix C to the POD) and an *Air, Noise and Fugitive Dust Control Plan* (Appendix B to the POD) that further discusses blasting mitigation methods. Noise from blasting would disturb wildlife individuals near blast areas for short periods of time resulting in temporary changes in foraging or breeding behaviors. We conclude that the Project would not significantly affect terrestrial wildlife.

In 2005, a study was conducted during a 4,000-foot-long HDD crossing of the Nooksack River crossing in Whatcom County, Washington, to determine if drilling noise associated with the HDD (noise levels between 47 and 52 dBA at the study area) had a negative effect on wintering bald eagles. Eagles were observed from November 1, 2005, through April 7, 2006, and results indicated that bald eagles were not negatively affected by HDD rig activity (Edge Environmental, Inc. 2006).

Pacific Connector proposes to cross the Coos, Rogue, and Klamath Rivers, Coos Bay at two separate locations, and a BPA powerline corridor using HDD technology. Pacific Connector would cross the South Umpqua River using DP. Noise studies conducted for the HDD and DP of each proposed crossing determined that, with the use of mitigation measures (such as special vinyl fabric acoustic tents or other barriers), noise levels at the seven crossings are not expected to exceed the Oregon State noise regulations of 55 dBA during the day and 50 dBA at night within 25 feet of an NSA. To ensure adequate mitigation and monitoring, we are recommending Pacific Connector file HDD noise mitigation plans for review and approval prior to construction (see section 4.12.2.4). Noise effects on wildlife from the operation of the drilling equipment from the HDD crossings at Coos, South Umpqua, Rogue, and Klamath Rivers should be negligible.

A minimal increase in ambient noise levels would occur during periodic right-of-way vegetation maintenance activities (i.e., mowing, chainsaws) during operation. The major source of operational noise for the Project would be from the Klamath Compressor Station, which is located in an area surrounded by rural residences, agricultural lands, and rangelands and grasslands. Noise from the compressor station would be long-term but localized to one site. The expected increase in L_{dn} noise levels would range from 0.5 dBA to 7.2 dBA above current ambient noise at the nearby NSAs during normal station operations. In terms of environmental noise effects, an increase to the ambient sound level of 10 dBA typically results in the perception of a doubling of sound. Consequently, the Klamath Compressor Station would have noise effects on the surrounding NSAs because of the very quiet existing ambient conditions. With appropriate mitigation measures, we expect the compressor station to operate below our standard of 55 dBA for all NSAs. This sound level could have localized adverse effects on wildlife near the station.

Habitat Fragmentation and Edge

One manifestation of fragmentation is the amount of edge created through otherwise contiguous habitats. In the context of habitat fragmentation, edge is the portion of habitat (or ecosystem on a larger scale) "near its perimeter, where influences of the surroundings prevent development of interior environmental conditions" (Forman 1995). As compared to interior habitats, edge habitats generally support different species composition, structure, and species' abundance. For example, vertebrate species richness (bird and amphibian) has been positively associated with edges in fragmented Douglas-fir forests (Rosenberg and Raphael 1986), although species benefitted are typically habitat generalists. Edge habitat would no longer favors species that are dependent on forest interior conditions, allowing species that utilize the edge habitat to disperse into the forest interior which can have adverse effects on wildlife and plants through competition for resources, increased predations, spread of disease and insect infestation, and establishment of noxious weeds (Bannerman 1998).

Along with the creation of edge, pipeline construction would further fragment habitat. Habitat fragmentation has already occurred to some extent in the areas crossed by the pipeline route because of existing residential developments, tree harvests, roads, and utility corridors. These sources of habitat fragmentation are expected to increase in the foreseeable future outside of protected areas such as LSRs). Fragmentation can also affect the rate and scope of blowdowns in forested habitats (the effects of blowdowns are discussed in section 4.4).

Because the pipeline is linear, the created patch associated with the new edge would be narrow and elongated unlike edges created by forest practices (Forman and Gordon 1986). Creation of edges by the Project would affect seral stands differently. Douglas-fir or western hemlock would be replanted during restoration of temporary work areas, including TEWAs, in the pipeline right-of-way (except in the 30-foot-wide maintenance corridor centered on the pipe), where conifers would be removed during construction activities. It is anticipated that both temporary and permanently cleared areas in forest habitats would increase the occurrence of windthrow (snapping of branches and uprooting, snapping of boles), which could result in greater effects on forest habitat than just those areas identified for disturbance.

Douglas-fir and western hemlock planted adjacent to edges of clearcut and/or early regenerating stands (assuming conifers from 1 to 10 feet tall at the time of construction) would modify edges with the seral stands from hard to soft to no edge as they grow. In 50 years, which is the operational life of the Project, trees replanted in temporary workspaces outside of the 30-foot-wide maintenance corridor would similarly modify edges of regenerating and mid-seral stands adjacent to the right-of-way, from hard to soft edge characteristics as tree heights increase. As the replanted trees grow, edge contrasts would decrease, as would the effects on forest interiors, because taller trees would reduce direct solar radiation and increase soil moisture and humidity along the edges of stand interiors (Chen et al. 1993; Heithecker and Halpern 2007). During operations, Pacific Connector would use mechanical vegetation management methods or, where access of machinery is infeasible, manual clearing to maintain the existing right-of-way; this vegetation management would increase the edge effect beyond the maintained right-of-way (e.g., light and wind would be able to penetrate farther into previously "interior" forests).

Different species composition and abundance occurs in edge habitats (Forman and Gordon 1986) than in patch interiors, depending on species' tolerances for the variation in microclimatic parameters. Some terrestrial amphibians, for example, have narrow temperature and moisture tolerances (Spotila 1972; Feder 1983). Moist, cool, and stable microclimatic conditions are essential to these species. Loss of canopy cover and coarse wood can affect amphibians' microclimatic conditions. Some wildlife species use right-of-way corridors created by pipelines and other linear utilities. For example, bird species' diversity in powerline corridors through forested vegetation was found to be higher in the corridor than in the adjacent forest (Kroodsma 1984). Often present along the edge are higher levels of flower and fruit production, pollinator, and frugivore densities and seed dispersal. Also, deer and elk use of available browse in corridors or on edges of corridors that are adjacent to hiding and thermal cover have been documented (Hartley et al. 1984; Brusnyk and Westworth 1985). Increased herbivore density in edge habitat provides a food source for predators (Forman 1995); therefore, predator density is expected to increase along the edge.

Few studies have evaluated the establishment of forage in pipeline corridors and utilization by big game. The study conducted in Alberta by Brusnyk and Westworth (1985) focused on forage and browse production on a 17-year-old pipeline right-of-way and on a 2-year-old right-of-way. They compared big game use (moose, deer, and elk) of forage on the two rights-of-way to use in adjacent undisturbed forest ecotones and undisturbed forest. Deer appeared to utilize browse in the 17-year-old corridor but returned to adjacent undisturbed forest, probably utilizing available hiding or thermal cover. Deer utilized the corridors for travel in early winter prior to limiting snow depths. Elk utilized forage on the two-year-old right-of-way primarily where portions were adjacent to forested habitats. The principal conclusion of this study was that pipeline corridors increased local habitat diversity and that diversity—juxtapositions of browse or forage to undisturbed forested habitat—influenced use of the corridors by ungulates. Similarly, studies in Washington and Oregon have shown that elk prefer habitat that is close to cover-forage edges (Rowland et al. 2018).

During right-of-way restoration, Pacific Connector would create habitat diversity features in the right-of-way corridor, such as rock and brush piles, that would provide habitat for a variety of wildlife species including mollusks, amphibians, and small mammals. Such features reduce fragmentation effects of abrupt edge characteristics by creating local irregularities. LWD placed in and/or across the right-of-way may eventually contribute to microsite diversification and provide corridors for some wildlife (e.g., terrestrial mollusks) to travel across an otherwise potential barrier. Such movements would be essential to avoid potential genetic isolation of relatively non-mobile species.

Effects on Mammals

Effects discussed for "General Effects Applicable to All Terrestrial Wildlife" would be relevant to mammals. Because it will not be known where mammals are specifically located, effects can be quantified by acres of disturbance in habitats in which they could occur (see table 4.5.1.2-1). The Project would be cutting a narrow swath out of larger areas of potentially suitable habitat. Because of the low percentage of all available habitat in the area being affected, the Project is not expected to have population-level effects on mammals.

The Pacific Connector Project is not expected to affect the Pokegama wild horse herd, as the Project would not cross through or affect the HMA.

Timber clearing in winter and early spring would coincide with the bat hibernation period. Bats utilizing trees for hibernation would be killed by timber clearing. Timber clearing in spring and early summer would coincide with natal or maternity periods but would not occur between April 1 and July 15 in order to avoid the migratory bird nesting season. Females and young inhabiting roosts in tree cavities would likely be killed if occupied roost trees and/or snags were felled. Likewise, bats utilizing day roosts under loose bark or in snags with cavities could be killed by timber clearing at any time of the year. Young bats would likely be killed if roost trees were felled before they were able to fly. Most bat species, especially Townsend's big-eared bat, are sensitive to disturbance and would abandon disturbed roosts (Csuti et al. 2001; Verts and Carraway 1998; ODFW 2013a). This disturbance and subsequent abandonment would have energetic repercussions, potentially decreasing successful reproduction and survival.

Noise from traffic and other sources is believed to interfere with bats' echolocation (Jones 2008). We estimate that noise from general construction of the pipeline would be about 72 dBA at 300 feet. construction-related traffic and other pipeline construction noise would be limited to daylight hours, except for HDDs, and would mostly avoid periods when bats use echolocation to forage. Consequently, pipeline construction noise would not significantly affect bats. Pipeline construction noise is discussed in more detail in section 4.12.2.2.

Night lighting could act as barriers to bat movements (Kuijper et al. 2008), reduce bat activity in the immediate vicinity (Stone et al. 2009), or have an opposite effect by attracting nocturnal insects (Svensson and Rydell 1998; Rydell and Racey 1993). The Klamath Compressor Station would be equipped with outside lighting to support night work activities. During normal operations, nighttime work or maintenance activities would generally not be scheduled; therefore, these lights would only be used periodically and possibly for short periods during the winter when daylight hours are short.

Pacific Connector would operate 15 new communication towers ranging in height from 40 to 170 feet tall (table 2.1.2.2-2). Of the 15 new towers, 7 would be associated with new project features and Pacific Connector would attempt to co-locate the other 8 towers with existing facilities. It is possible that bats would fly into the communication towers. Placement of 8 towers within existing facility sites is not expected to affect habitat or wildlife more than has already been affected with the original construction and operation of these facilities. New towers would not significantly affect bats, as these towers would not have guy wires or lighting, which would decrease the possibility of collisions but would not entirely eliminate that risk.

Because it will not be known where bat roosts are specifically located, effects on bats are assumed to occur in forested habitat types. Timber clearing is expected to injure or cause mortality to an unknown number of individual bats. Because white-nose syndrome is not known to affect bats in Oregon, the Pacific Connector pipeline is not expected to facilitate spread of this disease. Considering the amount of available forested habitat adjacent to the pipeline, and the dispersed nature in which tree-roosting bats typically roost in the west, construction and operation of the Pacific Connector pipeline would not be expected to significantly effect these bat species.

Effects on Birds

Effects on migratory bird occupied nests, eggs, pre-fledgling young, and potentially adults would be minimized by Pacific Connector's commitment to various seasonal restrictions during construction. Tree felling and brush removal during construction would be conducted outside of the primary migratory bird nesting season, which is April 1 through July 15. The primary migratory bird nesting season is based on data from Adamus et al. (2001) and determined in consultation with FWS as described in the draft *Migratory Bird Conservation Plan*. In addition, tree felling within 0.25 mile of an NSO activity center would occur after September 30 and before March 1, and tree felling within 330 feet of MAMU stands would occur after September 15 but before April 1. Routine vegetation clearing during operations would only be done between August

1 and April 15 of any year, to reduce effects on nesting birds during the primary spring and summer breeding season. Additional restrictions for other migratory birds are listed in the draft *Migratory Bird Conservation Plan* filed with the FERC on August 31, 2018. While these timing restrictions would minimize effects on migratory birds, some mortality could occur outside of the primary nesting season.

If a species' breeding period begins or ends outside of the primary breeding season, the active nest, eggs, or unfledged juvenile birds would be at risk. Numbers of migratory birds, nests, and eggs that might be affected during vegetation clearing and/or construction on spreads 1 through 5 are estimated and summarized in table I-13 in appendix I. Construction spreads 1, 2, and 3 are in BCR 5; spread 4 is mostly in BCR 5 with about 1.5 miles in BCR 9; and spread 5 is in BCR 9.

To estimate the amount of birds and eggs affected, Pacific Connector compiled data for 33 BBS routes within 50 miles of the pipeline. Numbers of birds for species observed each year on a route were divided by the length of the BBS route (birds per mile), averaged each year for routes reporting the species, and averaged for the 20-year period 1997 to 2016. For each species that had a close or general association with habitats affected by the pipeline, the average number of birds per mile was multiplied by miles of habitat affected in each construction spread 1 through 5 (miles of habitat affected are included in table I-13 in appendix I).

Edge habitat created by the pipeline right-of-way is expected to have both positive and negative effects on bird species. Expected positive effects are increased diversity and density of bird species, increased access to a variety of food resources, and increased ground cover favoring ground-nesting species (Rosenberg and Raphael 1986). Potential negative effects include increased brood parasitism, increased nest depredation in grasslands, forests and edge habitats, and lower nesting success (Thomas and Towiell 1982; Burger et al. 1994; Vickery et al. 1994; Marini et al. 1995; Danielson et al. 1997; Brand and George 2000). There have been declines of sagebrush-dependent migratory passerine bird species with loss of sagebrush steppe vegetation and increased fragmentation in remaining sagebrush-dominated habitats (Knick and Rotenberry 1995; Knick et al. 2003). Densities of Brewer's sparrow and sagebrush sparrow, as well as other species dependent on sagebrush for nesting habitat, were greatly reduced near well-field roads and pipelines compared to densities beyond 300 feet (Ingelfinger 2001). Nest parasitism by brown-headed cowbirds is especially likely in fragmented shrub-dominated habitats (Vander Haegen and Walker 1998). Such effects would be facilitated over the long term because maintenance of the 30-foot permanent easement would create areas of early-seral habitat throughout the operational life of the project. These corridor areas would not only provide habitat used by some wildlife species, but would also connect patches of suitable habitat, allowing wildlife to move between one patch and another (Turner et al. 2001).

Corvids, including common ravens and American crows (also jays and magpies), are opportunistic predators and will prey on other species' nests (Marzluff and Neatherlin 2006; Vander Haegen et al. 2002; Luginbuhl et al. 2001). Studies have shown that corvid populations expand and nest predation increases near human developments (Marzluff and Neatherlin 2006) and corvid predation increases in habitats that have been fragmented by humans (Vander Haegen et al. 2002). Potential effects on nesting birds by predatory corvids attracted to the right-of-way would be addressed by ensuring that all construction contractors practice appropriate and responsible trash disposal every day.

Pacific Connector would apply spatial and temporal buffers to known NSO, golden eagle, peregrine falcon, and great gray owl nesting habitat. Pacific Connector would also perform eagle and buteo hawk nest surveys prior to construction or timber clearing, and any occupied nests would be subject to spatial and temporal buffers appropriate for the species. FWS has drafted *Guidelines for Raptor Conservation in the Western United States* (Whittington and Allen 2008). The draft guidelines recommend spatial buffers for nests of breeding raptors during the breeding periods, which vary by location across the western states. Table 4.5.1.2-8 lists the raptor species that have been reported along the Pacific Connector Pipeline Project route by various sources and the recommended spatial buffers during nesting periods (not included in the table). Human disturbances in spatial buffers risk nest abandonment by adults and nest failure (Whittington and Allen 2008). As previously described for migratory birds, timber clearing and project construction during the breeding period would affect raptor nests, eggs, young, and adults; many effects would be avoided or minimized through vegetation clearing timing restrictions during the breeding season, raptor nest surveys, and other conservation measures provided in the draft *Migratory Bird Conservation Plan*.

TABLE 4.5.1.2-8

FWS Recommended Spatial Buffers Surrounding Raptor Nests of Species that May Occur in the Vicinity of the Pacific Connector Pipeline

Common Name	Scientific Name	Spatial Buffer (miles) c/
Hawks, Eagles, Falcons		
Osprey	*Pandion haliaetus*	0.25
Bald Eagle a/	*Haliaeetus leucocephalus*	0.5–1.0 (0.25)
Northern Harrier b/	*Circus cyaneus*	0.25
Sharp-shinned Hawk	*Accipiter striatus*	0.25
Cooper's Hawk	*Accipiter cooperii*	0.25
Northern Goshawk	*Accipiter gentilis*	0.50
Red-shouldered Hawk	*Buteo lineatus*	0.25
Red-tailed Hawk	*Buteo jamaicensis*	0.33
Ferruginous Hawk b/	*Buteo regalis*	1.00
Golden Eagle	*Aquila chrysaetos*	0.50 (0.50)
American Kestrel b/	*Falco sparvarius*	0.125
Peregrine Falcon	*Falco peregrinus*	1.00 (1.50)
Owls		
Western Screech Owl	*Megascops kennicottii*	0.125
Great Horned Owl	*Bubo virginianus*	0.125
Northern Pygmy Owl	*Glaucidium gnoma*	0.25
Burrowing Owl b/	*Athene cunicularia*	0.25

TABLE 4.5.1.2-8

FWS Recommended Spatial Buffers Surrounding Raptor Nests of Species that May Occur in the Vicinity of the Pacific Connector Pipeline

Common Name	Scientific Name	Spatial Buffer (miles) c/
Northern Spotted Owl	*Strix occidentalis caurina*	0.50 (0.25)
Barred Owl	*Strix varia*	0.25
Great Gray Owl	*Strix nebulosa*	0.25 (0.25)
Short-eared Owl b/	*Asio flammeus*	0.25
Northern Saw-whet Owl	*Aegolius acadicus*	0.125

Source: Whittington and Allen (2008)
Note: Includes special status species that are otherwise addressed in section 4.6.
a/ Spatial buffer dependent on line-of-sight to nest.
b/ Species added to table based on occurrence on BBS routes.
c/ Spatial buffers committed to in the Draft Migratory Bird Conservation Plan are in parenthesis. Note that the National Bald Eagle Management Guidelines (FWS 2007b) recommend a 660-foot (200-meter) buffer surrounding nests during the breeding season applied to timber harvest, road construction, chain saw, and yarding operations (assumed similar to timber clearing & pipeline construction).

Pacific Connector would use eight existing communication towers and construct seven new towers (see table 2.1.2.2-2). Communications towers are estimated to kill millions of birds each year, with mortality near guyed towers greater than self-supporting towers (FCC 2006). Also, the majority of bird-tower collisions are reported from towers over 500 feet tall (Gehring 2004). Most bird-tower collisions occur at night, generally during conditions with low visibility, and during the day under foggy conditions. Bird-tower collisions may also increase with lighting on the towers. Research indicates that white strobe lights on towers may create less of a hazard to migratory birds, although these types of lights are not allowed within three nautical miles of an airport (FCC 2006). Additionally, some research has indicated that marking guy-wires to make them more visible may reduce avian mortality (FCC 2006).

Use of eight currently existing towers is not expected to affect habitat or wildlife more than has already been affected with the original construction and operation of these facilities. New towers would not have guy wires or lighting and are either 40 or 170 feet tall, which would decrease the possibility of bird collisions but would not eliminate that risk entirely. Some additional mortality could occur from collision with towers but, given the relatively low height and the fact that towers do not have lighting or guy wires, additional mortality is expected to be minimal.

As described above, the Pacific Connector Project would affect migratory bird nests, eggs, young, and adults from tree clearing occurring outside of the primary migratory bird nesting season. Where vegetation clearing cannot be avoided during the breeding season, Pacific Connector would have qualified biologists perform pre-construction surveys of the area to be disturbed, plus a 20-foot buffer adjacent to areas affected. If nests are encountered, Pacific Connector would work with the FWS to avoid nests as feasible. The FWS would require a special use permit if an active nest is encountered that would need to be removed, relocated, or transferred to a rehabilitation center.

Laws and regulations regarding the treatment of migratory birds, including the MBTA and EO 13186, are described above (see section 1.5.1.10). In accordance with the March 2011 MOU between the FERC and the FWS to implement the policies of EO 13186, a draft *Migratory Bird Conservation Plan* was filed with the FERC on August 31, 2018. The draft *Migratory Bird Conservation Plan* identifies avoidance and minimization strategies, as well as habitat restoration.

With incorporation of the draft and anticipated final *Migratory Bird Conservation Plan,* we conclude that the Project would not significantly affect migratory bird species.

Effects on Game Animals

Numerous studies have shown that both Rocky Mountain and Roosevelt elk are sensitive to human disturbances such as motorized travel on and off roads (Rowland et al. 2000). Roads are generally avoided by elk when they are open but are heavily utilized by elk as travel corridors when closed. During construction of the Pacific Connector pipeline, there would be short-term, localized effects on hunter success rates in the affected hunt units. When construction in a particular hunt unit coincides with hunting seasons, hunter utilization and success in the immediate vicinity would probably be adversely affected for the duration of construction in that area. However, hunter success rates for any species in each affected hunt unit are relatively low despite seemingly extensive hunter efforts (ODFW 2014a).

Where the Pacific Connector pipeline crosses existing roads, the newly created corridor would be potentially accessible from each road and probably more so at points crossed where access roads are adjacent to previously dense and/or forested habitats. The Project would require construction of 15 PARs. Increased hunter success as a result of those access points is likely but any changes in success cannot be predicted or estimated because so little area (the pipeline corridor) in any given hunt unit would be subject to increased hunter access.

After construction, there could potentially be a secondary effect (Comer 1982) on harvest rates because of increased access by hunters using the pipeline right-of-way to access remote areas. Increased public recreation along cleared rights-of-way in the fall hunting season, especially near crossings of existing access points, has been documented elsewhere (Crabtree 1984). Increased public access because of the cleared pipeline right-of-way could increase poaching of game animals and non-game wildlife on a local level. Enforcement of wildlife regulations is the responsibility of the Oregon State Police, Fish and Wildlife Division.

In big game winter management areas in Douglas, Jackson, and Klamath Counties, mature and regenerating forest would be converted to an herbaceous/shrub vegetative cover for the long term, increasing the amount of forage available to big game adjacent to forested stands potentially used for thermal cover (table 4.5.1.2-9). Forested areas would be the most commonly affected, followed by grasslands/shrublands. Temporary disturbance areas that are forested, regenerating, or recently clear-cut stands removed during construction on big game winter range would be replanted with trees after construction of the pipeline, eventually providing similar habitat to that present prior to construction.

TABLE 4.5.1.2-9

Acres of Habitat Types Affected in Big Game Winter Ranges by Construction and Operation of the Pacific Connector Pipeline by Landowner

			Acres of Habitat Affected in Winter Range

Note: Rows/columns may not sum correctly due to rounding. Acres rounded to nearest whole acre. Acreages less than 1 are shown as "<1".

a/ Other terrestrial habitat includes agriculture, developed, and barren. Restoration efforts will allow habitat type to be converted back to original state.

b/ Upland 30-foot Operation/Maintenance Right-of-Way will be maintained in an herbaceous/shrub state less than 6 feet in height. Riparian 30-foot Operation/Maintenance Right-of-Way will be maintained in an herbaceous/shrub state within a 10-foot corridor centered over the pipeline and the additional 10 feet either side of the pipeline will be maintained in an herbaceous/shrub/tree state less than 15 feet in height (see Typical Drawings 3430.34-X-0015, 3430.34-X-0016 and 3430.34-X-0017 in Appendix 1B to Resource Report 1).

c/ Habitat Revegetation: trees planted in forested habitats, including regenerating and clear-cut forest; grasses and shrubs planted in non-forested habitat and 30-foot maintenance corridor (except riparian areas). On private lands, revegetation will occur in consultation with the landowners.

Sources: BLM Deer and Winter Management Areas, Forest Service Deer Winter Range, ODFW 2007 GIS data delineated from County planning maps, ODFW (2012c) Elk Winter Range for Eastern Oregon.

In addition, big game are expected to be displaced from habitats adjacent to construction-related disturbance. In general, deer and elk return to habitats from which they have vacated in some relatively short period of time, which would likely depend on the time of year, available hiding cover, and duration of local disturbances. Following reclamation of the pipeline corridor, big game may utilize the corridor for travel and for foraging, depending on vegetation species planted and rapidity of successful revegetation.

Construction of the Pacific Connector pipeline may coincide with big game calving and fawning times, generally in late spring (May to early June). Calving and/or fawning areas may be close to winter ranges or may be at higher elevations than winter range. During active construction, big game would most likely avoid construction areas and may be adversely affected in one or more ways, including increased energy expense if they escape from disturbances or are displaced to areas of deeper snow accumulation, use of suboptimal habitats that do not provide adequate functions (food, shelter, escape cover), and use of habitats that increase the risk of predation. The expected consequences of these responses would be decreased over-winter survival and decreased calving/fawning success (for example, see Bradshaw et al. 1998).

The BLM, Forest Service, and ODFW recommend the application of seasonal construction restrictions on big-game winter range. Pacific Connector would apply the following ODFW, BLM, and Forest Service recommended seasonal closures for big game winter range (with the exception of big game winter range located in Klamath Basin, where a waiver would be obtained): November 1 to April 15 (BLM - Medford), December 1 to April 30 (Forest Service), and non-federal lands from December 1 to March 31 (private and state). Timber felling and construction activities may occur in ODFW, BLM, and/or Forest Service big game winter ranges in Douglas (Umpqua National Forest), Jackson, and Klamath counties to minimize or avoid effects on migratory birds, NSO, and MAMU.

The ODFW expressed concern that open trenches during construction of the Pacific Connector pipeline could entrap deer and elk. To minimize the potential effect of open trenches on big game in delineated big-game winter and summer range, Pacific Connector would leave breaks at least 5 feet wide at approximately 0.5-mile intervals, and at visible wildlife trails, to serve as routes for big game to cross the construction right-of-way until pipe is ready to be installed (Forman et al. 2003). Alternatively, Pacific Connector would install soft plugs (backfilled trench materials) in the trench after excavation at these distances to provide wildlife passage. Additionally, 20-foot-wide gaps would be left in spoil and topsoil stockpiles at all hard or soft plug locations, and a corresponding gap in the welded pipe string would be left in these locations. Suitable ramps would also be installed from the bottom of the trench to the top to allow any wildlife that enters the trench to escape.

Pacific Connector would install barriers at locations along its pipeline route to discourage unauthorized public access to the right-of-way. These barriers may include boulders, dirt berms, log barriers, signs, and locked gates. Slash from clearing operations would be redistributed on the right-of-way, to improve habitat and to make OHV travel difficult. These barriers should minimize OHV access to the right-of-way and reduce unauthorized hunting or poaching of game animals (see section 4.10.2.5 of this EIS for a further discussion about OHV traffic).

Effects on Amphibians and Reptiles

Effects discussed above under General Effects Applicable to All Terrestrial Wildlife would be relevant to amphibians and reptiles. Because it will not be known where amphibians and reptiles are specifically located, effects are assumed to occur in Wetlands/Eastside Riparian-Wetlands, Developed, Urban, and Mixed Environments, and Mixed Conifer-Hardwood Forest. Some threats to amphibians in habitats crossed by the Project include loss of habitat and its connectivity, changes in hydrology and water quality, predation, and competition with invasive species (ODFW 2006b; Oregon Conservation Strategy 2016). The primary threats to reptiles are habitat loss and fragmentation, predation, and competition with nonnative invasive species, such as turtles, fish, and bullfrogs (ODFW 2006b; Oregon Conservation Strategy 2016). The Pacific Connector Pipeline Project would be cutting a narrow swath out of larger areas of potentially suitable habitat. Because of the low percentage of all available habitat in the area being affected, we conclude that the Project would not significantly affect these species.

Effects on Invertebrates

Effects discussed above under General Effects Applicable to All Terrestrial Wildlife would be relevant to invertebrates. Invertebrates are assumed present in all habitat types crossed by the Pacific Connector Project. Because of the low percentage of all available habitat in the area being affected, we have determined that the Project would not significantly affect these species. Of specific concern to invertebrate pollinators is the use of chemical herbicides to control noxious weeds and other invasive plant species that can often colonize areas disturbed by construction activities. Implementation of Pacific Connector's *Integrated Pest Management Plan*[115] would reduce the likelihood of establishment and spread of noxious weeds from construction activities. Control of noxious weeds helps to preserve native plants that pollinators require for survival; however, some chemicals used to control noxious weeds have been shown to have a detrimental effect on pollinators when used within typical to maximum application rates, such as 2,4-D, glyphosate, and triclopyr (Forest Service 2005b). These three herbicides are included in the Pacific Connector's *Integrated Pest Management Plan* and would likely have adverse effects on pollinators when applied in the immediate vicinity of project disturbances.

4.5.1.3 Environmental Consequences on Federal Lands

Wildlife species present on federal lands crossed by the Pacific Connector pipeline would be similar to those discussed for all land ownerships above in section 4.5.1.2, including mammals, birds, amphibians, reptiles, and invertebrates. Wildlife on federal lands is managed under a variety of directives. Species managed on federal lands include NWFP Survey and Manage species, BLM and Forest Service sensitive species, and federally threatened, endangered, and proposed species. The presence of these species on federal lands and potential effects on these species are discussed in section 4.6.

The Forest Service additionally identifies MIS, which include wildlife monitored during forest plan implementation to assess the effects of management activities on their populations and the populations of other species with similar habitat needs which they may represent (Forest Service Manual [FSM] 2620.5). On the Umpqua National Forest, MIS include NSO, pileated woodpecker, primary cavity excavators (nesters), American marten, Roosevelt elk, Columbian black-tailed deer,

[115] See Appendix N to the POD, which was included in Pacific Connector's application to the FERC.

peregrine falcon, bald eagle, and steelhead (water quality indicator). On the Rogue River National Forest, MIS species include Columbian black-tailed deer, Roosevelt elk, American marten, NSO, pileated woodpecker, and primary cavity excavators (nesters). On the Winema National Forest, MIS include NSO, pileated woodpecker, northern goshawk, three-toed woodpecker or black-backed woodpecker, bald eagle, mule deer, resident trout, and American marten. Potential effects of the pipeline on MIS, and by association wildlife with similar habitat needs, are assessed in the MIS Report (appendix F.6 of this EIS). Additionally, effects on some of these species (Roosevelt elk, Columbian black-tailed deer, peregrine falcons, northern goshawks, mule deer, and bald eagles), including effects on federal lands, are discussed above in section 4.5.1.2.

Federal lands crossed by the pipeline contain 16 of the 17 wildlife habitats affected by the pipeline across all ownership; only the wildlife habitat "Bays and Estuaries" is not affected on federal lands. Wildlife species' associations with these habitats provide a basis for evaluating potential effects on wildlife. The acreage of each wildlife habitat that would be affected on federal land during pipeline construction, and the number of species of herpetofauna (i.e., amphibians and reptiles), birds, and mammals associated with those habitats are shown below in table 4.5.1.3-1. Agriculture and Westside Riparian-Wetlands/Eastside Riparian-Wetlands have the highest number of associated species (290 and 270, respectively), but have very few acres affected. Of all the forest habitats, Southwest Oregon Mixed Conifer-Hardwood Forest would be the most affected by the pipeline (most acres of disturbance) as well as being the forest habitat that supports the greatest number of wildlife species (226 species associated).

TABLE 4.5.1.3-1

Acres of Construction-Related Disturbance to Wildlife Habitat Types by the Pacific Connector Pipeline on Federal Land, and Wildlife Species Associated with Johnson and O'Neil (2001) Habitats

Note: Rows and columns may not sum correctly due to rounding. Acreages rounded to nearest whole acre; values less than 1 acre shown as "<1".

a/ Late Successional (80 to 175 years) and Old-Growth Forest (175 + years).

b/ Mid-Seral Forest (40 to 80 years).

c/ Clearcut (0 to 5 years) and Regenerating Forest (5 to 40 years).

d/ Numbers of species associated with each habitat type crossed by the Pacific Connector pipeline were summarized from Pacific Connector's Environmental Resource Report 3, Appendix 3D, Table 3D-1.

e/ Cells with no data result from the fact that non-forested habitat types did not identify seral stage, thus acres are identified only in the "total acres" column.

Effects on wildlife would be similar on federal lands to those discussed for all land ownerships above in section 4.5.1.2, including direct mortality to individuals unable to move away from construction equipment, noise and visual disturbance during construction, and habitat loss and modification. Less mobile wildlife species that are not able to move away from construction activities during clearing and site preparation could experience direct mortality. More mobile species would likely be displaced from the site during active construction. Wildlife in the vicinity of the pipeline would also be disturbed by construction activities and noise, and may move away from the construction site. However, the primary effect on wildlife from construction and operation of the pipeline would be habitat loss.

The discussion of effects on big game in section 4.5.1.2 under Game Animals includes effects on big game on federal lands. Table 4.5.1.2-4 lists the miles of designated big game winter range crossed by the pipeline within and outside federal lands, and table 4.5.1.2-10 lists the acres of habitat types in big game winter ranges affected by pipeline construction and operation within and outside federal lands.

Seasonal road closures on public lands have been applied to big-game winter range on BLM and NFS lands to minimize the effect of winter stress on deer and elk. Additionally, the BLM, Forest Service, and ODFW recommend the application of seasonal construction restrictions on big-game winter range. The following are recommended seasonal closures for big game winter range: November 1 to April 15 (BLM), December 1 to April 30 (Forest Service), and December 1 to March 31 (private and state). Pacific Connector notes that the numerous seasonal restrictions to protect applicable species pursuant to the ESA and the MBTA would require timber-clearing activities to be conducted outside nesting seasons during the spring and summer months. Therefore, Pacific Connector would be required to complete timber-clearing and other construction activities during recommended seasonal closures for big game winter range and appropriate waivers for recommended seasonal big game closures would be necessary.

Effects on wildlife associated with late-successional and riparian habitat on federal land would be generally similar to those described above wherein direct effects would occur during clearing and pipeline construction if individuals are killed, injured, and/or displaced to other locations where possible mortality increases and/or fecundity decreases. The goal for the LSR and Riparian Reserve Forest Service and BLM land allocations is to encourage healthy late-successional and riparian forests; see appendix F. Direct effects on late-successional and riparian habitat (removal and/or conversion to different vegetation) may indirectly affect wildlife by decreasing the amount of habitat locally available and decreasing the effectiveness of adjacent habitats in providing life-requisite functions for wildlife. That effect would not be able to be mitigated on-site and is assumed to persist through the long term. Effects on species inhabiting other, non-forested habitats in the affected areas in late-successional and riparian habitat on federal land (including LSRs, Riparian Reserves and the Matrix/Harvest Land Base) would be similarly affected, although the amount of time required to restore affected non-forested habitats would be shorter (see section 4.4.2.4). Effects on LSRs and Riparian Reserves on federal lands from construction and operation of the Pacific Connector pipeline are addressed in section 4.7.3 and appendix F.

Loss of snags is expected to be a long-term effect. Estimates of snag density (numbers per acre) that would be affected in the construction right-of-way and TEWAs were made on each of the three National Forests during timber reconnaissance conducted in 2006 and 2007, and verified in 2015 (Chapman 2017). Estimates of snag density by size class (inches dbh) and decay class (hard or soft) are provided in table 4.5.1.3-2. In the areas affected by construction, conifer snags less than 13 inches dbh are generally most dense on each forest, although there are numerous hardwood snags in that size category on the Rogue River National Forest. Most of the smaller snags (less than 13 inches dbh) were observed as hard wood, rather than softened due to decay.

TABLE 4.5.1.3-2

Snag Density Estimates on NFS Lands

National Forest	Tree Type	Decay Class	Estimates of Snag Density a/ (Number per Acre) by Size Category (inches dbh) <13	13-24	25-36	>36
Umpqua	conifer	Hard	5.7	0.7	1.0	0
		Soft	0.1	1.0	1.0	0.5
Rogue River	conifer	Hard	1.7	0.2	0.1	0
		Soft	0	0.5	0.2	0.1
	hardwood	Hard	1.7	0	0	0
		Soft	0	0.1	0	0
Winema	conifer	Hard	3.3	0.2	0.1	0
		Soft	0	0.4	0.1	0

a/ Snag density was verified in 2015 but was prior to Stout's Creek fire that affected acreage in Umpqua National Forest.
Source: Chapman 2017

Although no other portions of the pipeline route have been similarly examined, available data for the BLM districts crossed by the proposed pipeline generally show that snag density is higher on the BLM districts (BLM 2008). It is also assumed that snag densities on the Umpqua National Forest have increased following the 2015 Stout's Creek fire. Nevertheless, loss of snags regardless of decay class is expected to be a long-term effect because recruitment of new snags in the affected areas would take much longer than three years.

The Forest Service will require mitigation to meet their respective land use plans; those mitigation actions are described in table 2.1.5-1. Road decommissioning, fuel breaks, and forest thinning mitigation actions will assist in the recovery of late-seral habitat, reduce habitat fragmentation and edge effects, and enhance resilience of mature forest stands. Proposed snag creation and placement of LWD will mitigate the effect of loss of snag habitat and reduction in the contribution of large down wood due to clearing of forested habitat. Reallocation of matrix lands to LSR will meet the neutral to beneficial standard for new developments that affect LSRs and habitat improvement of meadow habitat within LSRs will mitigate effects on unique habitat. Livestock fencing will be used to protect revegetation efforts associated with construction disturbances.

4.5.1.4 Conclusion

Constructing and operating the Project would have both short- and long-term adverse effects on wildlife habitat and terrestrial wildlife species. We expect that some wildlife individuals would experience displacement or mortality during construction and operation, and some wildlife habitat would be removed or modified temporarily or permanently. However, based on the characteristics of the terrestrial wildlife species and habitat, the applicant's proposed construction and operations procedures and methods, and their implementation of impact minimization and mitigation measures, we conclude that the Project would not significantly affect terrestrial wildlife.

4.5.2 Aquatic Resources

4.5.2.1 Waterway for LNG Carrier Traffic

The waterway for LNG carrier traffic to Jordan Cove's terminal contains a diverse collection of anadromous, estuarine, and marine organisms and associated habitats (figure 4.5-1). The marine environment along the transit route outside of Coos Bay consists of varied habitats used by aquatic organisms including commercial and recreational fish and shellfish and marine mammals. This habitat includes gently sloping nearshore intertidal and subtidal sand area near the Coos Bay mouth and rocky shoreline to the south. Habitats near the mouth of the bay range from sand beaches to rocky shorelines. Offshore, deeper soft bottom habitats extend over 100 feet deep with main pelagic surface water along the ship transit route.

The Coos Bay estuary is described in section 4.3.2.1. Several freshwater streams and sloughs enter the bay, so that its habitats range from marine to estuarine. The bay contains shellfish resources, as well as marine fish. It is a migration corridor for salmon (*Oncorhynchus* spp.) and steelhead (*O. mykiss*) that spawn and rear in the streams that drain into Coos Bay. The bay along the transit route for LNG carrier marine traffic contains mostly sloping beaches with algae and eelgrass beds that supply important habitat for the estuarine organisms. A total of over 14,000 acres of habitat is present in Coos Bay, including some 1,400 acres of eelgrass beds.

Many fish, shellfish, and marine mammal species are common in the waterway leading to the Jordan Cove LNG terminal (see appendix I, table I-1). Most of these aquatic species are mentioned below.

The status and potential project effects of federally listed fish, marine mammals, and turtle species are presented in our pending BA. EFH fish species that are managed under the MSA will be presented in our EFH Assessment that will be attached to our BA. The federally listed species information is summarized in section 4.6, and the EFH assessment is summarized in appendix I.

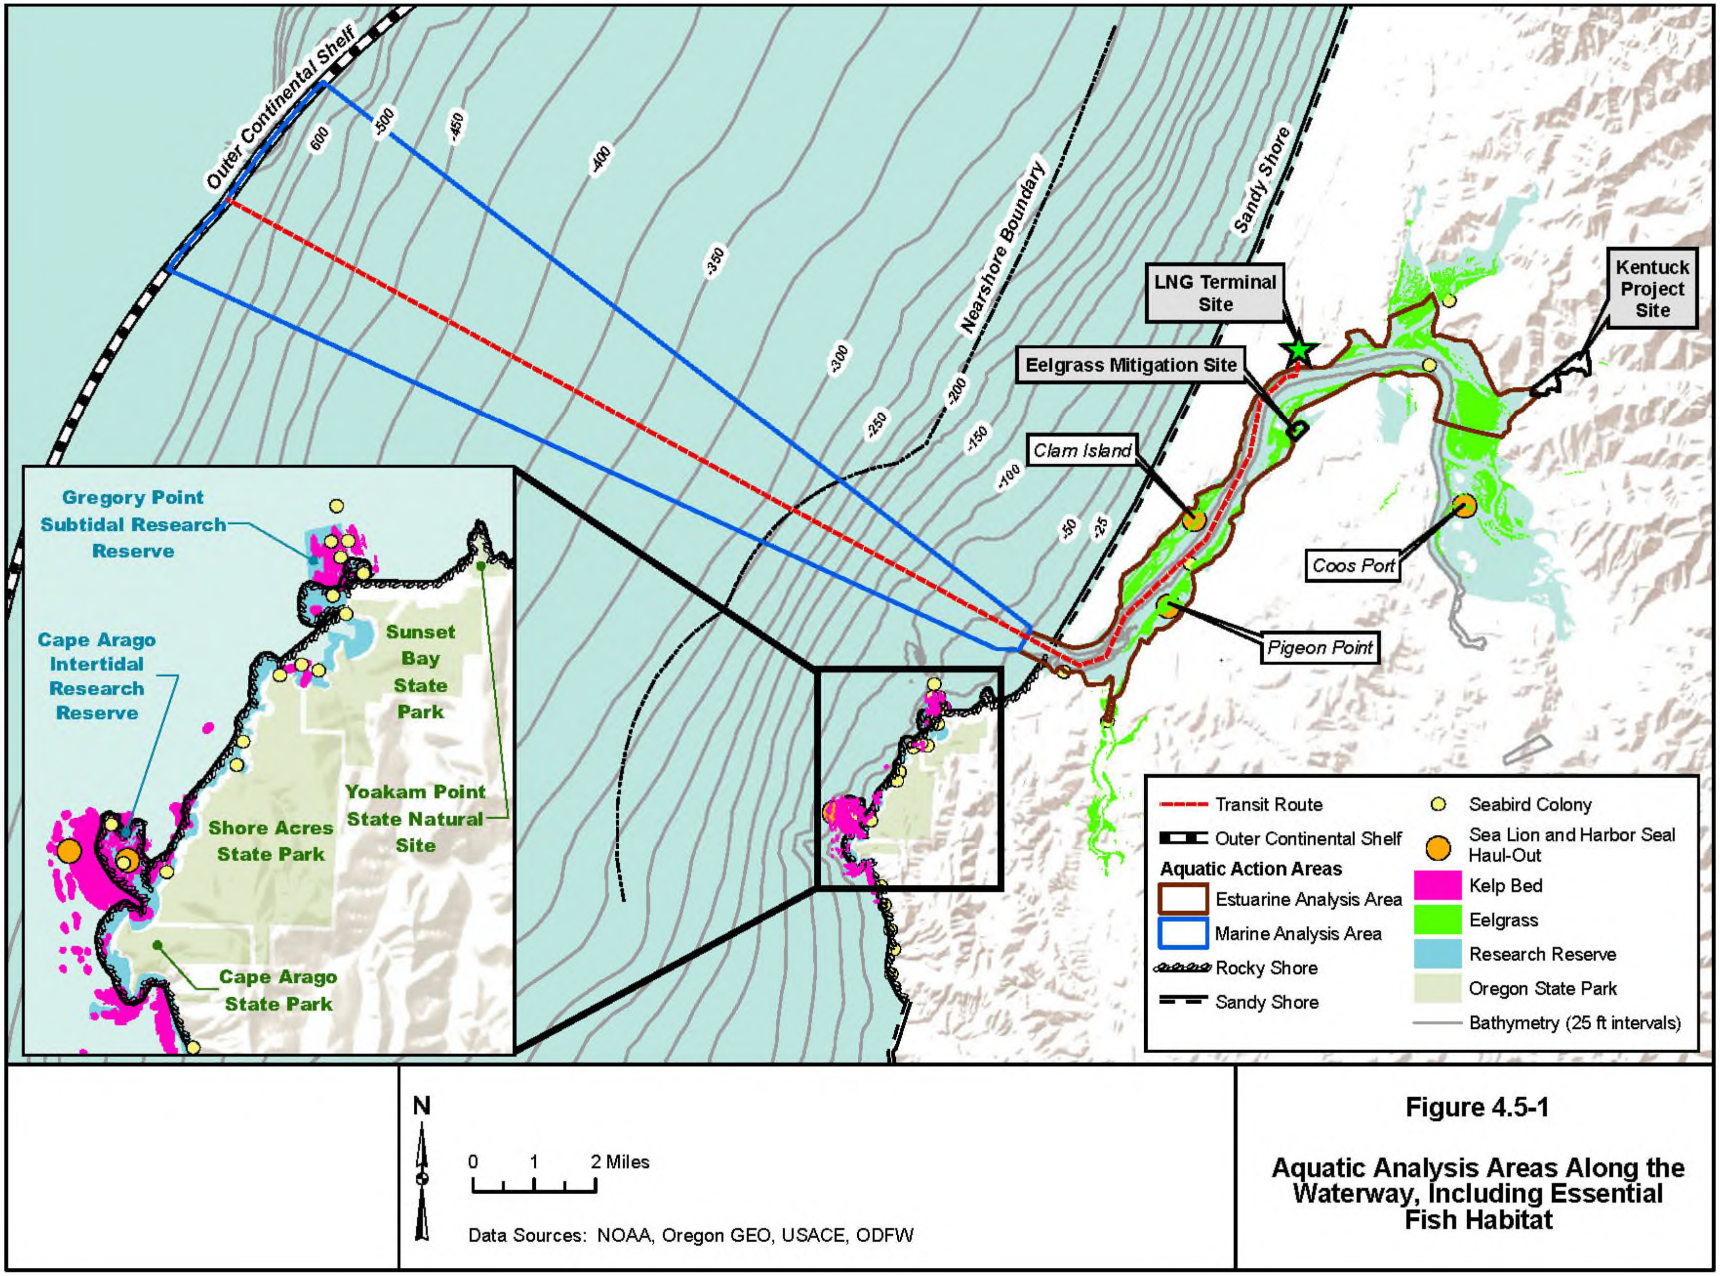

Figure 4.5-1

Aquatic Analysis Areas Along the Waterway, Including Essential Fish Habitat

Marine Fish

Species of groundfish, pelagic, anadromous, and marine species would be present in the waterway for LNG carrier traffic to the terminal, in the nearshore and marine waters outside of the Coos Bay estuary. This includes a variety of rockfish, flatfish, shark, skates, sturgeon, sablefish, cod, and migratory fish such as anchovy and sardine and in the outer regions may rarely include some highly migratory species such as thresher shark (*Alopias* spp.) and tuna.

Marine fish communities in Coos Bay consist of species found in estuarine and marine waters. Their distribution and abundance vary with physical factors such as bottom conditions, slope, current, salinity, and temperature, as well as season, which can affect migration and spawning timing. Some of the more commonly abundant fish include Pacific herring (*Clupea pallasii*), and the non-native American shad (*Alosa sapidissima*). Most fish species are migratory or seasonal, spending only part of their life in these waters. Other common seasonal marine fish species include surfperch (family *Embiotocidae*), lingcod (*Ophiodon elongatus*), rock greenling (*Hexagrammos lagocephalus*), sculpin, surf smelt (*Hypomesus pretiosus*), Pacific herring (*Clupea pallasii*), English sole (*Parophrys vetulus*), black rockfish (*Sebastes melanops*), northern anchovy (*Engraulis mordax*), eulachon (*Thaleichthys pacificus*), longfin smelt (*Spirinchus thaleichthys*), Pacific tomcod (*Microgadus proximus*), sandsole (*Psettichthys melanostictus*), and topsmelt (*Atherinops affinis*). California halibut (*Paralichthys californicus*) is also present in the bay near Jordan Cove. A few common species like kelp greenling (*Hexagrammos decagrammus*) and starry flounder (*Platichthys stellatus*) reside in the bay year-round. The bay from just beyond the LNG terminal site to its mouth is a prime feeding area for many local and seasonal fish species.

Fish abundance varies with salinity. Near NCM 1.5, the sloughs are mostly of high salinity, while farther up the bay, near NCM 15.5, sloughs are generally brackish, of lower salinity. Toward the mouth of the bay, the salinity is higher, especially in the summer, which is when the number of fish increase.

Anadromous Fish

A common group of anadromous fish species found in the waterway for LNG carrier traffic to the terminal includes Chinook salmon (*Oncorhynchus tshawytscha*), coho salmon (*O. kisutch*), chum salmon (*O. keta*), steelhead, coastal cutthroat trout (*O. clarkii clarkii*), Pacific lamprey (*Lampetra tridentata*), river lamprey (*L. ayersi*) , white sturgeon (*Acipenser transmontanus*), green sturgeon (*A. medirostris*), striped bass (*Morone saxatilis*), and American shad (*Alosa sapidissima*). Anadromous is a term describing fish that return from the ocean to the rivers where they were born to spawn. Adult anadromous fish spend a portion of their adult life in the ocean; the amount of time varies among the species. Sexually mature adults migrate or "run" from the ocean and estuaries upstream to fresh water streams to spawn for most salmonid anadromous fish in shallow gravel stretches. Other anadromous stocks noted above have varied spawning habitat uses. After a period, which varies with the species, juveniles migrate downstream to estuaries typically in late winter to summer. Salmon and steelhead undergo smolting (physiological maturation to adjust from fresh to salt water) before entering marine waters as juveniles. Salmon and steelhead and cutthroat typically rear in the ocean for one to five years before returning as adults to their natal streams to spawn, while other anadromous fish (striped bass, American shad, sturgeon, and lamprey) have a range of ocean-rearing periods ranging over multiple years, with striped bass largely confined to the estuary. Salmon typically return to streams in late summer through fall.

Steelhead and sea-run cutthroat trout may return to streams in the summer, fall, winter, or spring depending. Lamprey return from spring to fall to fresh water; striped bass are not native but spawn in the spring over a brief period in Coos River. Salmon species die after spawning but some steelhead and anadromous coastal cutthroat survive to return to the ocean and can spawn again. Steelhead typically remain in freshwater streams after emergence for two to three years before migrating to the ocean, with adults returning to spawn in their fourth or fifth year. Sea-run cutthroat usually remain in fresh water for two to four years before smolting and migrating to saltwater, usually staying in the estuaries or near shore (Behnke 1992).

There are eight native species of coldwater anadromous fisheries in the area affected by the Jordan Cove LNG Project: Chinook salmon, coho salmon, chum salmon, steelhead, coastal cutthroat trout, Pacific lamprey, river lamprey, and green sturgeon. The Oregon Coastal Coho Salmon Evolutionarily Significant Unit (ESU) is present and is listed under the ESA. The North American Green Sturgeon – Southern Distinct Population Segment (DPS), and Southern DPS Pacific eulachon, which are both listed as Threatened under the ESA, may be present or migrate through Coos Bay. The Project effects on these ESA listed fish and their critical habitat are presented in section 4.6 of this EIS.

Shellfish

A large and diverse population of benthic and epibenthic invertebrates is present beyond the entrance to Coos Bay. Clams, crabs, oysters, and shrimp make up important components of these invertebrates in the bay. Some of the most abundant and commercially important of these species include bentnose clams (*Macoma nasuta*), Pacific oyster (*Crassostrea gigas*), Dungeness crab (*Metacarcinus magister*), and ghost shrimp (*Neotrypaea californiensis*). Distribution varies along the route from the LNG terminal to the bay mouth. Principal subtidal clam beds are found in the lower bay and South Slough although the upper bay also has substantial clamming areas. Clam Island, located at the mouth of Coos Bay, has an abundance of recreationally important clams. Some of the highest recreational harvest of clams and crabs occurs at the mouth of Coos Bay with much of the crabbing occurring from the BLM boat ramp, west of the LNG terminal site to the mouth. Razor clams (*Siliqua patula*) are an important commercial and recreational species. In Jordan Cove, ghost shrimp, a commonly harvested bait shrimp, are found in the fine sediment and eel grass beds. Mud shrimp (*Upogebia pugettensis*) are also harvested in this region.

Coos Bay contains one of only three known native Oregon coastal populations of the Olympia oyster (*Ostrea lurida*). Within its native range, this species has significantly diminished from historical levels (National Fish and Wildlife Federation et al. 2010). Efforts have been taken in the bay to restore this species and improvements in bay water quality and sediment have resulted in self-sustaining populations over the last two decades (Groth and Rumrill 2009; Rumrill 2007). A pilot restoration project began in 2010 that resulted in stocking 4 million juvenile Olympic oysters in South Slough. Because of its low abundance and efforts to improve the quality of the Coos Bay environment and its survival, the Olympia oyster is not harvested.

Marine Mammals

Thirty species of marine mammals occur in Oregon, including seven species of baleen whales, nine species of toothed whales, eight species of dolphins and porpoises, five species of pinnipeds (seals and sea lions), and a single species of sea otter (NMFS 2017a).

Steller sea lions (*Eumetopias jubatus*), California sea lions (*Zalophus californianus*), northern elephant seals (*Mirounga angustirostris*), and Pacific harbor seals (*Phoca vitulina*) use haulout sites in the vicinity at Cape Arago, Three Arch Rocks, and Shell Island, along the southwest Oregon Coast. Eight species of whales are federally and state-listed. All marine mammals are protected under the MMPA.

Sea Turtles

Four species of sea turtles have been documented off the coast of Oregon: the green (*Chelonia mydas*), olive ridley (*Lepidochelys olivacea*), leatherback (*Dermochelys coriacea*), and loggerhead sea turtles (*Caretta caretta*).

Effects on Aquatic Habitat and Aquatic Species Along the Waterway for LNG Carrier Transit

The following section discusses transit-related effects of the LNG carriers. Although the regular transit of LNG carriers is a part of the operation of the Project, the carriers and their operation do not fall under the jurisdiction of the Commission; therefore, we can disclose but not require mitigation for these activities. Project-related effects from the LNG facility construction actions (including dredging of areas abutting the Federal Navigation Channel) are presented in section 4.5.2.2.

Vessel Strikes

Jordan Cove anticipates that as many as 120 LNG carriers each year would use the waterway to reach its terminal. In addition, in accordance with the WSR and LOR, there must be three tugboats and additional security ships that assist each LNG carrier in transit along the Coos Bay navigation channel. These vessels have the potential to strike aquatic species, including sea turtles and marine mammals, and seabirds and shorebirds during their transit to and from the Jordan Cove terminal.

In the open ocean prior to entering the Coos Bay Federal Navigation Channel, it is estimated that LNG carriers would travel at speeds of about 12 knots. Jordan Cove has proposed to provide measures supplied by NMFS to vessel operators in order to minimize potential ship strikes to cetaceans, and possibly other listed (sea turtles) and non-listed marine species by LNG carriers in a *Ship-Strike Reduction Plan*. Jordan Cove would provide operators of LNG carriers that would visit the terminal with copies of this plan for avoidance of marine mammals or sea turtles while in transit at sea. Some of the suggested measures would include the following:

- train LNG carrier crews to watch out for and avoid marine mammals and sea turtles;
- keep on board vessels copies of marine species reference guides, such as Marine Mammals of the Pacific Northwest, including Oregon, Washington, British Columbia and South Alaska by Pieter Folkens (2001);
- request LNG carriers to establish navigation policies when marine mammals or sea turtles are sighted, including:
  - maintain a distance of 90 meters or greater.
  - attempt to maintain a parallel course to the animal and avoid abrupt changes in direction until the animal has left the area.

  - reduce speed when pods or assemblages of marine mammals or sea turtles are observed nearby; and
- report sightings of any injured or dead marine mammal or sea turtles to the NMFS, regardless of whether the injury or death was caused by the LNG carrier. If the injury or death were caused by collision with an LNG carrier heading to or from the Jordan Cove terminal, the FERC should be notified within 24 hours of the incident. Information to be provided would include the date and location (latitude/longitude) of the strike, the ship name, and the species, if possible.

LNG carriers would enter the waterway at speeds between 8 and 10 knots, and slow between 4 to 6 knots as they proceed up the Coos Bay navigation channel to the Jordan Cove terminal. As required by the WSR, two tugs would escort each LNG carrier in the navigation channel, and another tug would assist in docking the vessel at the terminal. Use of tugs would allow the LNG carriers to maintain steerage even at these slow speeds.

Most sea turtles, marine mammals, and seabirds and shorebirds would be able to avoid LNG carriers traveling at slow speed through the waterway. Even with the additional LNG carriers in the waterway, the number of ships would still be below historic levels for deep-draft traffic to the Port. Effects on aquatic resources from LNG carriers would be not much greater than the effects of current deep-draft cargo ships visiting the Port. Based on the reduced speed of the LNG carriers and the efforts by Jordan Cove to increase the awareness of vessel operators, we conclude that the incidence of accidental strikes of aquatic species by LNG carriers in transit to and from the Jordan Cove terminal would be low.

Ship Grounding

During scoping some commenters raised the possibility that an LNG carrier waiting offshore to enter Coos Bay, either to avoid another ship coming out of the Port or seeking proper tidal conditions, could lose anchorage or steerage and run aground on the North Spit, like the *New Carrisa* incident of 1999. A ship grounding would have the potential to affect aquatic resources, as oil and fuel could leak from a grounded vessel. However, a Coast Guard investigation found that the *New Carrisa* grounding was caused by the captain's error in not having the ship well anchored.

All LNG carriers visiting the Jordan Cove terminal would have to adhere to Coast Guard regulations, including anchoring procedures offshore, in addition to the measures outlined in the WSA, WSR, and LOR. A pilot would board the LNG carrier to guide it through the Coos Bay navigation channel, and the vessel would be accompanied by tugs and security escort boats to keep it on course. In addition, the geometry of the navigation channel would keep the LNG carrier within its confines, away from the shore.

Shoreline Erosion from Waves and Propeller Wash

Propeller wash from LNG carriers and tugboats transiting the waterway to and from Jordan Cove's terminal could cause shoreline and bottom erosion and displace bottom organisms due to scour. Wakes and waves caused by vessels in the waterway could increase erosion along the shoreline and resuspend loose sediments in the bay. Increased erosion and suspended sediment levels can adversely affect fish eggs and fish survival, benthic community diversity and health, and spawning habitat. At high concentrations, suspended sediments can affect oxygen exchange over the gills, resulting in weakened individuals or mortality. Waves from vessels breaking on the shoreline can also cause fish stranding.

The possible magnitude and effects of the Jordan Cove Project on shoreline erosion were approximated by Jordan Cove through models that assessed effects of waves and propeller wash from LNG carriers in Coos Bay and at the LNG docking area (i.e., Moffat & Nichol 2008; CHE 2011; Moffatt & Nichol 2017f), and the details of the model results on physical conditions in the bay resulting from LNG carrier traffic and docking are presented in section 4.3.

Overall, the models estimated that additional waves generated by the new LNG carrier traffic could increase shoreline sediment transport at the modeled point by 5 to 8 percent over existing conditions (e.g., wind-generated waves plus existing large vessel–generated waves). While both models indicated some additional shore sediment movement could occur from the waves generated by the passage of LNG carriers through Coos Bay, the effects would be small because low magnitude and relative frequency of waves, contributing a small portion of total annual wave energy and sediment transport, and be within the normal magnitude of waves that naturally occur in the bay. Therefore, the total effect would likely be within the range of natural annual variability of wave conditions. Overall, increased sedimentation and disruption of aquatic nearshore habitat from additional tugboat and LNG carrier–generated waves would be unlikely because of the factors discussed in section 4.3.

The effects of propeller wash from LNG carriers and related tugboat vessels on bottom erosion and turbidity likewise would not reach levels to cause substantial disruption to benthic or pelagic resources other than in the immediate access channel and slip area (see section 4.3 for details of modeling results). The bottom velocity caused by the propeller would be similar to the maximum velocity of peak tidal exchange (about 4 fps) along most of the route. Because the disturbance would be relatively similar to what occurs during tidal exchange and confined to the relatively coarse sediment within an 80-foot-wide swath along the 9-mile-long Federal Navigation Channel, the bottom area disturbed would be slight along most of the route. Few organisms would be displaced by physical disturbance or affected by turbidity (see section 4.3 for details); however, as noted below, there are some areas near the entrance to the access channel that would experience bottom erosion and likely benthic disruption as the LNG carrier and tug boat leave after loading.

Mobile organisms would be able to return to the area affected, while some benthic organisms could be permanently displaced. Turbidity would likely be slight due to the coarse characteristics of the navigation channel sediment that is resistant to current induced suspension. The one area that would have marked local bottom scour and increased turbidity would be in the east side of the access channel and slip where bottom scour over about 12 acres may occur during each LNG carrier departure (Moffatt & Nichol 2017g). Overall, some loss of benthic organisms could occur from LNG carrier propeller wash during each transport trip near the slip approach, but the magnitude would be small and likely less than currently occurs under each existing large vessel trip. There would be some additional local bottom disturbance in the docking area. In most cases, this disturbance would likely be much less than estimated because of the conservative assumptions used for the model. While some sessile benthic organisms may be displaced during LNG carrier docking, the limited extent of bottom disturbance and sediment suspension would result in unsubstantial effects on organisms in the slip.

Fish Stranding

Fish stranding can occur when fish become caught in a vessel's wake and are deposited on shore by the wave generated by the vessel's passing. Stranding typically results in mortality unless another wave carries the fish back into the water. A study of strandings (Pearson et al. 2006) suggests that a series of interlinked factors act together to produce stranding during a ship passage. These factors include:

- Water-surface elevation—Low tides are generally more likely to result in strandings than high tides.
- Beach slope—Low-gradient beaches are generally more likely stranding locations than high-gradient ones.
- Wake characteristics—Ship wakes that result in both the greatest drawn-down and run-up on the beach are generally most likely to result in strandings. Wake characteristics are influenced by a number of dynamics including vessel size and hull form ("short and fat" vessels have a greater displacement effect and generate larger wakes than "long and thin" vessels); vessel draught (the smaller the under-keel clearance, the larger the wakes; thus, loaded vessels are more likely to result in strandings than unloaded vessels); vessel speed (fast moving vessels generate larger wakes than slow vessels); and the distance between the passing vessel and the beach (strandings are generally more likely at beaches close to the shipping channel than more distant beaches). Fish strandings were observed because of four types of vessel passages including oil tankers, container ships, car carriers, and bulk carriers (in order of the vessels observed to cause the highest to lowest stranding frequency).
- Various biological factors—For example, the larger the number of subyearling salmon that are present near the shoreline, the more fish that are likely to be stranded; salmon that are larger and relatively strong swimmers are generally less prone to stranding.
- Vessel speed—No stranding has been observed on the Columbia River at speeds less than 8 to 9 knots (about 10 miles per hour).

The factors discussed above can vary simultaneously, making it difficult to predict where and to what degree strandings may occur. A few areas may have the potential to strand fish in Coos Bay. One is the mud flats on the west side of the navigation channel along the Coos Bay and Empire Range that have beach morphology that has been shown to have potential for stranding, especially at low tide. Jordan Cove (Moffat & Nichol 2008) modeled the potential wave height and overall energy from 200 LNG carrier transits a year (combined inbound and outbound). As noted in section 4.3, the wave's height would not exceed that of normal conditions in Coos Bay and vessel-induced waves contribute a small portion of total waves in the bay. In addition, the LNG carriers would be arriving and leaving at high tide, which is a period when gently sloping beaches are mostly covered, and less likely to be dewatered from waves. The maximum vessel speed once inside the navigation channel, about 6 knots, is less than that observed to cause stranding in the Pearson et al. (2006) study. The one exception is near the Coos Bay entrance (first mile), when vessels may be traveling 8 to 10 knots. While waves generated in this portion of the waterway may be larger than farther in the bay, this is an area likely already receiving larger ocean-generated waves, so the vessel-generated waves would be little different than current conditions in this region. Additionally, the presence in Coos Bay of subyearling Chinook salmon, which are the outmigrating fish most likely to be stranded, is limited to the summer months, approximately mid-

June through the end of August. Considering the conditions, including LNG carriers entering and leaving at high slack tide, low velocity in most areas, wave height within normal range, and infrequent occurrence of susceptible fish, it appears unlikely that LNG carrier traffic in the waterway would substantially contribute to fish stranding.

LNG Spills

In a highly unlikely scenario, there could be an accidental spill of LNG from a carrier transiting in the waterway. As explained in section 4.13, in the entire history of LNG carrier transport worldwide, there has never been a major incident resulting in a large LNG spill or fire on water. An LNG spill has an extremely low probability of occurrence and, as described below, would likely affect a small area. As more fully discussed in section 4.13 of this EIS, spilled LNG would not mix in the water column, but would vaporize as warmed by ambient temperature and, if the LNG ignited, a fire could result. The greatest threat to aquatic organisms near an LNG spill would be from changes in water temperature. A spill of LNG would float on the water surface and not mix, but in the process of changing state from solid to liquid would rapidly cool off the upper water layers closest to the LNG spill. As the LNG would vaporize and turn to natural gas, it would be less dense than air and would rise above the water. Aquatic species in the waterway would not be directly affected unless individuals come in direct contact with the LNG. Should an aquatic species directly contact the LNG when it is first released, it could have its flesh frozen because the temperature is very low. The chance of this occurring would be remote because it would require the individual to be near the water surface at the direct point of the LNG spill, before it warms. If an LNG spill from a carrier in the waterway were to ignite, it would cause localized heating of the surface water. Neither the cooling nor heating would likely cause the overall water column to change temperature to the point of affecting aquatic organism beyond the surface layer at the time of initial spill or ignition. Aquatic species, other than possibly the smallest planktonic stages and shellfish, near this spill would be able to detect undesirable temperatures and avoid the LNG spill by swimming away.

The mitigation measures outlined in the WSA, WSR, and LOR would protect public safety and the environment, and ensure that aquatic resources would not be adversely affected by LNG carrier traffic in the waterway to the Jordan Cove terminal.

Fuel or Oil Spills

Fuel (e.g., diesel) used for LNG carrier propulsion could possibly leak or be spilled while en route in the waterway; likewise, oil could be spilled. Adverse effect could occur on marine fish and shellfish from oil spills ranging from direct morality, reduced growth and feeding, and reduced spawning success depending on location magnitude and type of spill. Effect can be compounded when spills intersect the shoreline habitats. These effects can be both short and long term. LNG carriers would have measures aboard to contain fuel or oil spills should they occur, as required under the Coast Guard required hazardous spill response plan for vessels in U.S. waters of 2013 (78 FR 60099). Additionally, LNG carriers are double hulled, which should prevent the escape of fuel or oil, other than spills from the deck. The chance of a spill is low, and any quantities leaked are likely to be small. As reported by Pacific States/British Columbia annual reports (http://oilspilltaskforce.org/documents/), the number of oil spills reported from fishing, recreational, and other harbor marine vessels in Oregon ranged from about 9 to 65 per year, which is infrequent considering that thousands of marine vessels, both recreational and commercial, use Oregon coastal marine waters. Spills or releases of fuel or other oils into surface waters from LNG carriers are more likely to occur during fueling at the dock when the materials are being transferred onto the carrier. As discussed in section 4.3, LNG carriers are required to develop and implement a Shipboard Oil Pollution Emergency Plan, which includes measures to be taken if an oil pollution incident has occurred, or a ship is at risk of one. With the implementation each LNG carrier's Shipboard Oil Pollution Emergency Plan, impacts resulting from the spill of fuel, oil, or other hazardous liquids would be minimized both in occurrence and quantity. We conclude that because fuel or oil leaks from LNG carriers transiting in the waterway to and from the Jordan Cove terminal are not reasonably certain to occur, adverse effects on aquatic resources are not anticipated.

<u>Introduction of Nuisance Species</u>

LNG carrier origin locations are unknown now; they could originate from ports across the Pacific. Operators of commercial vessels have a significant economic interest in maintaining underwater body hull platings in a clean condition. Fouling of bottom platings would result in increased fuel costs for voyages and could reduce the vessel's maximum transit speed. To prevent fouling and the associated economic costs, operators aggressively and conscientiously implement hull plating preservation and maintenance programs. Failure to preserve and maintain hull plating not only raises short-term operation costs but also sets the stage for increased long-term hull maintenance costs. There is a sensitivity to this engineering and economic reality regarding commercial vessels operating at the higher end of the sailing rates schedule, as is the case for LNG carriers.

In addition to the antifouling program measures, fluid dynamics plays a practical role as a barrier to the introduction of invasive species. The amount of water that passes over the hull and through the sea chest is a massively large volume. A sea chest is an opening with associated piping in the hull below the waterline to provide seawater to condensers, pumps, and other associated equipment. The velocity of the seawater, abrasive by nature, along the hull would be expected to "waterblast" off anything that is not affixed to the hull (e.g., a barnacle). The sea chest would have the equivalent of untold multiples of seawater exchange such that an organism would be flushed out with much more velocity and volume of water than the accepted international ballast exchange procedure.

Ballast water may be another source of non-native organisms. Water is held in the ballast tanks and cargo holds of LNG carriers to provide stability and maneuverability during a voyage when vessels are not carrying cargo. Normal ballast exchange requires only three changes of water through the ballast tanks to purge any loading port organisms before arrival at the unloading port. The effects of ballast water exchange, and the measures that would be implemented to minimize or avoid effects from this action, are addressed in section 4.3.

Conclusion

Based on measures and actions that will be in place to eliminate or mitigate potential adverse effects from actions during operation of LNG carrier transit, including waves size and propeller wash, LNG gas or hazardous substance spills or introduction of invasive species to marine resources, we conclude that the Project would not significantly affect marine resources.

4.5.2.2 Jordan Cove LNG Project

Coos Bay contains a variety of habitat for anadromous, marine, and estuarine fish species. A large diverse invertebrate population exists in Coos Bay. Shellfish (predominantly clams, crabs, and shrimp) are of significant economic importance to the Coos Bay area. Of marine mammals in Coos Bay, only the harbor seal, California sea lion, and killer whale have been observed during field surveys at the proposed location of the Jordan Cove access channel. No turtles have been observed or would be expected in the bay. Fish, shellfish, and marine mammals that may occupy Coos Bay are more fully discussed in the section 4.5.2.1.

Juvenile and larval life stages of vertebrate and invertebrate marine organisms are varied in the bay and near the terminal site. Over 35 species of ichthyoplankton have been documented in Coos Bay (Miller and Shanks 2005). There are some seasonal trends, with highest occurrence October through May, but fewer differences by month in the upper bay than near the ocean. Shanks et al. (2010, 2011) sampled zooplankton and ichthyoplankton in Coos Bay near the Jordan Cove terminal. A variety of zooplankton were found to be present in the bay (see table 4.5.2.2-1). Among the potential forage items, copepod adults, larvaceans, harpacticoid copepods, and Daphnia had the highest peak abundance. Overall, larval fish abundance was generally low, with those that spawn primarily in or near estuaries common (surf smelt, sand lance, and staghorn sculpins [*Leptocottus armatus*]). At times, other larval or juvenile fish were relatively abundant including English sole, buffalo sculpin (*Enophrys bison*), anchovy, and pipefish. A total of nine fish species were captured. Primary fish species spawn in winter and early spring, and larval fish were most abundant in winter samples (Shanks et al. 2011). Over 12 taxa of crab and shrimp larvae were also collected, including some recreational and commercially important crab and shrimp species, such as Dungeness crab and ghost shrimp larvae. Major known oyster and shrimp habitat and clamming and crabbing areas in the bay relative to Project activities are shown in figure 4.5-2. These habitat areas are mostly oriented along shoreline and shallow areas of the bay except for crabbing areas which extend into deeper water.

TABLE 4.5.2.2-1

Taxa Groups Collected in Coos Bay Near the Jordan Cove Terminal During 2009–2011

Categories	Specific Taxa
Fish larvae/juvenile	Surf smelt, sand lance, staghorn sculpin, buffalo sculpin, anchovy, pipefish, English sole, gunnel, pricklefish
Crab/Shrimp larvae	Porcelain crabs, pea crabs (*Pinnotheres pisum*), green crab (*Carcinus maenas*) (invasive), xanthid crabs, majid crabs, cancer crabs (e.g., Dungeness, rock crab), Lithodidae, Hippidae, Pagurid (hermit crabs), Callinassa (ghost shrimp), Sergestid shrimp, Pachygrapus crassipes (striped shore crab)
Gastropod and Bivalves larvae	Mytilus (mussels), Clinocardium (cockles), Bivalve juveniles, Gastropod juveniles
Larval Invertebrates	Barnacle nauplii and cyprids, Mytilus larvae, bivalve larvae
Cnidaria/ctenophore	Sea anemone, Hydroids, sea goose berry
Polychaete Worm Larvae	Marine worms
Salmonid Food Prey	Mysids, Amphipods, Isopods, Cumaceans, Copepod adults, Harpacticoid copepods, Calanoid copepods, Daphnia, Larvaceans, larval fish

Source: Shanks et al. (2010, 2011)

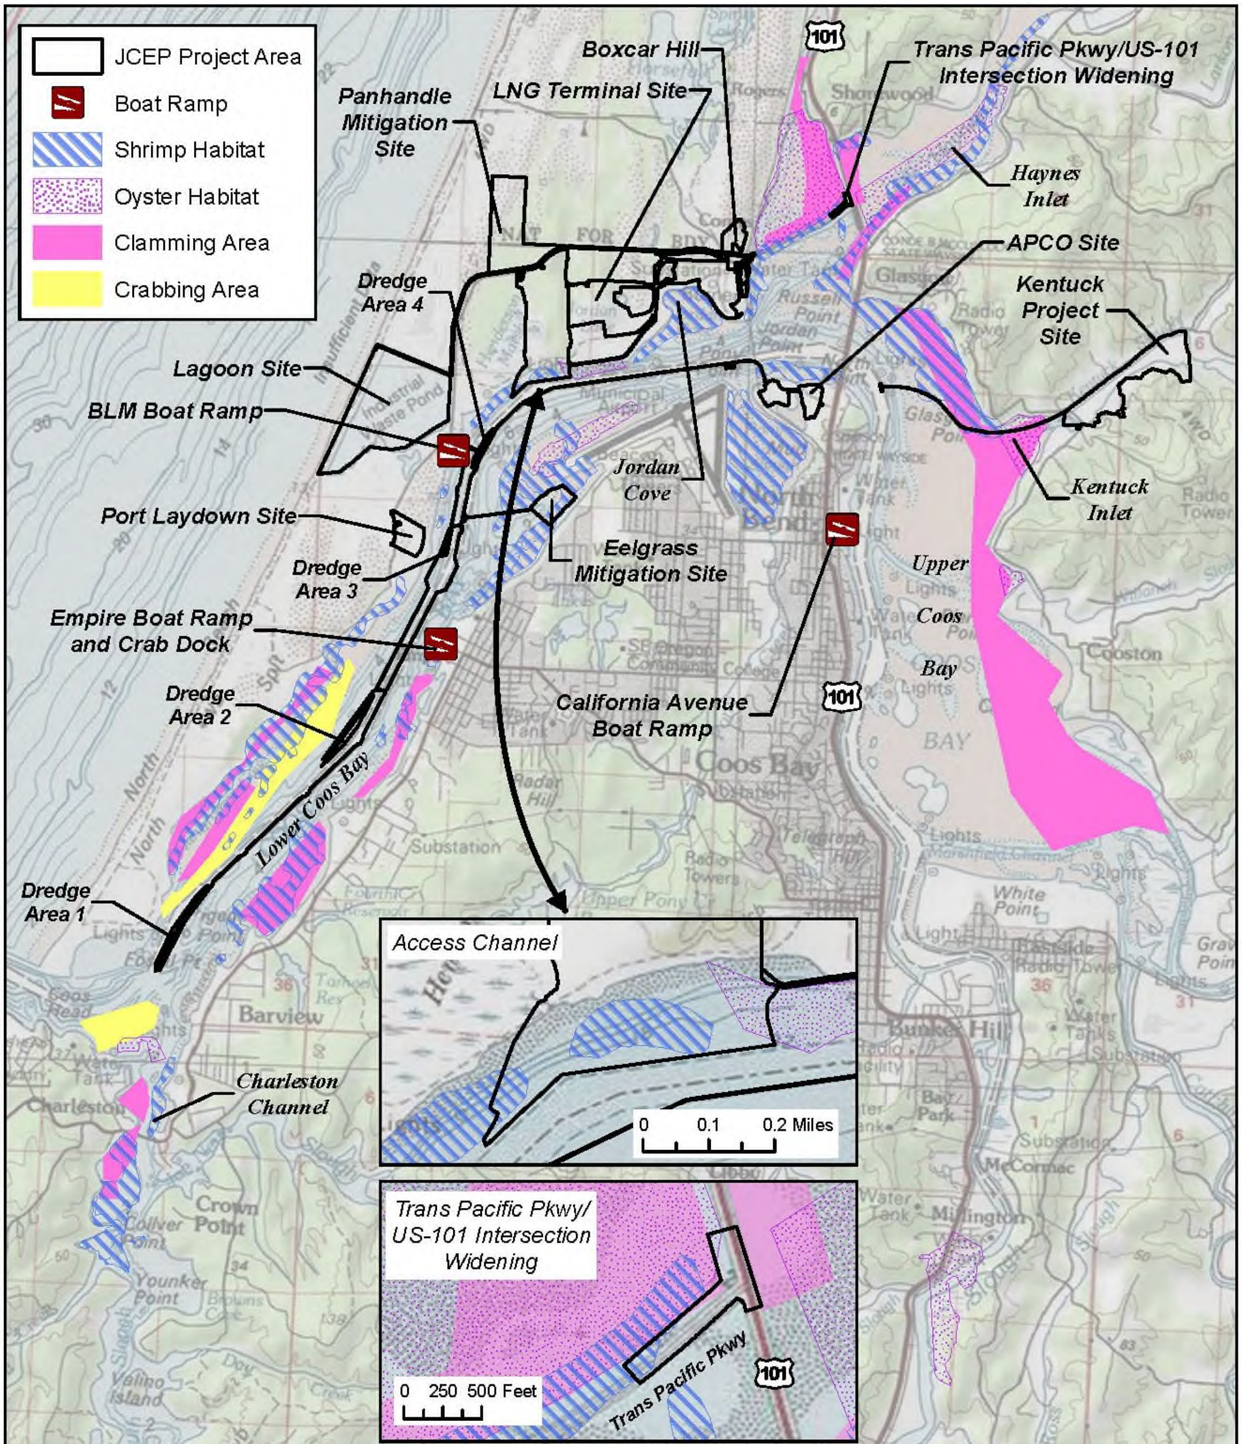

Figure 4.5-2

Shrimp and Oyster Distributions and Shellfish Areas in Coos Bay

The slip, access channel, MOF, and adjacent rock pile apron for Jordan Cove's terminal would cover about 37 acres below the mean higher high water line. This would include less than 1 acre of salt marsh, about 13 acres of intertidal area of unvegetated sand plus algae/mud/sand habitat, about 4 acres of shallow subtidal, about 18 acres of deep subtidal, and about 2 acres of eelgrass. This would include a pile dike rock apron area that would modify about 2 acres of habitat through intertidal and subtidal addition of small riprap. The habitat areas affected by the access channel are illustrated on figure 4.5-3 and listed in table 4.5.2.2-2. Nearly all this habitat change would be permanently converted to deepwater habitat. Other Project facilities would also temporarily disturb intertidal and subtidal habitat during construction (table 4.5.2.2-2). The largest other area disturbing estuarine habitat would be from marine waterway modifications (i.e., the proposed modifications in the navigation channel) totaling about 40 acres of mostly deep subtidal habitat including the 27 acres from dredging and 13 acres from the dredge lines used for this dredging. All other facilities would disturb less than about 5 acres in habitat which includes less than 1 acre of eelgrass habitat.

TABLE 4.5.2.2-2

Estuarine Habitat Affected by Construction of the Jordan Cove LNG Project Facilities and Marine Waterway Modifications in the Federal Navigation Channel

	Acres Affected

TMBB – Temporary Material Barge Berth
a/ Riprap addition

Submerged grasses are one of the important major habitat components in Coos Bay. Recreationally and commercially harvested species such as clams and shrimps, Dungeness crab, English sole, and salmonids use the eelgrass beds extensively. Previous studies (Akins and Jefferson 1973) have reported that Coos Bay has 1,400 acres of lower intertidal and shallow subtidal flats covered by eelgrass meadows. ODFW (1979) conducted habitat mapping in Coos Bay and documented intertidal and subtidal aquatic beds. Submerged grass meadows provide cover and food for many organisms including burrowing, bottom-dwelling invertebrates; diatoms and algae; herring that deposit eggs clusters on leaves; tiny crustaceans and fish that hide and feed among the blades; and, larger fish, crabs and wading birds that forage in the meadows at various tides. Eelgrass provides shelter for a variety of fish and may lower predation, allowing more opportunity for foraging. The protective structure attribute of eelgrass is primarily for smaller organisms and juvenile life history stages of fishes.

Figure 4.5-3

Submerged Aquatic Vegetation within the Slip and Navigation Channel

Project activities associated with the LNG terminal that could potentially affect aquatic resources include in-water construction activities, habitat modification, water appropriations, artificial lighting, and accidental spills of hazardous materials. Measures that would be implemented by Jordan Cove to avoid or reduce effects on aquatic resources are discussed below.

Effects on Aquatic Habitat and Aquatic Species from Construction of the Jordan Cove LNG Facilities

The estuarine portion of the Jordan Cove LNG terminal would include a marine slip, access channel, and MOF. The entire access channel would be located within Coos Bay, while most of the marine slip would be excavated or dredged from existing upland on the North Spit. Many of the construction supplies for the facility would be provided through transport by marine barge and break-bulk ships. This would require the construction of a temporary barge berth. There would also be construction of the Kentuck project site and Eelgrass Mitigation site to mitigate for lost estuarine and wetland habitat (see chapter 2 and section 4.3.3 for further descriptions).

Construction of the LNG facilities and channel improvements would temporarily and permanently affect known oyster and shrimp habitat areas. There are currently about 753 acres of oyster habitat and 1,730 acres of shrimp habitat in Coos Bay. About 3 acres of oyster habitat and 10 acres of shrimp habitat would be permanently reduced primarily from construction and operation of the access channel. The largest temporary effect would be from the construction of the Eelgrass Mitigation site that would reduce shrimp habitat by about 4 acres. Overall, there would be temporary short-term disturbance of about 1 acre of oyster habitat and 6 acres of shrimp habitat primarily from the construction of the Kentuck project and Eelgrass Mitigation sites in addition to temporary effects from construction of the access channel. Less than about 1 acre of shrimp habitat would be disturbed by the construction of the 1,100-foot-long pile dike rock apron, which would include modification from soft bottom to riprap habitat that could affect future habitat suitability for these organisms.

<u>Dredging of the Slip Access Channel, Navigation Channel, and Other Facilities</u>

About 1.4 mcy would be removed by marine dredging during creation of the access channel in the bay. Effects of dredged material placement to terrestrial habitats is addressed in other portions of the EIS including sections 4.3.3 (Wetlands), 4.4 (Upland Vegetation). and 4.5.1 (Terrestrial Wildlife). The creation of the access channel would result in the modification of about 37 acres of present-day subtidal and intertidal habitat to deeper water habitat in the bay. The dredging operation to create the access channel would change physical conditions of the bay bottom in this area, locally altering the bathymetry and potentially altering the morphology and water currents. About 19 acres of intertidal to shallow subtidal habitat, including approximately 2 acres of eelgrass habitat and less than 1 acre of salt marsh, would be modified to primarily deep subtidal habitat during the dredging process of the deepened channel. Increasing depth and removal of vegetation would reduce the quality of habitat for juvenile salmonids and other juvenile marine species.

The construction of the access channel would affect local aquatic resources by removal or conversion of some habitats. This would include construction of the temporary barge landing facility on the southwest portion of the access channel, that would occur prior to the excavation and dredging required to complete the LNG carrier offloading facility. Additionally, the MOF would be constructed in the southeast portion of the entrance as a permanent facility to allow offloading of large equipment. There would also be short-term turbidity from dredging in the bay, and additional erosion of the shoreline during construction activities could result in sedimentation. To control upland soil erosion and potential sedimentation, Jordan Cove would follow the measures outlined in its ESCP; for marine waters, measures in their *Dredged Material Management Plan*[116] would be followed.

There is also the potential for an accidental oil or fuel leak from dredging equipment to affect aquatic resources in the bay. To avoid or reduce effects from oil or fuel leaks, Jordan Cove developed a preliminary SPCC Plan.[117]

About 37 acres of current upland habitat excavated and dredged to create the marine slip would be converted to open water, primarily deep subtidal habitat. While this area would have little intertidal habitat due to steep banks, it would supply some subtidal habitat that would not have been present without the Project. This habitat, however, would be highly disturbed due to large vessel arrivals and departures, and would generally be of low quality habitat for most species because of its armored banks, steel retaining walls, and lack of current in the slip.

To improve navigation reliability for LNG carriers, Jordan Cove proposes to excavate four submerged areas in Coos Bay along the vessel access route. This would include the dredging of some 27 acres of deep subtidal habitat at bend areas along the route and the dredge lines for this activity would include another 13 acres of mostly deep subtidal habitat modification. These dredging activities and follow-up maintenance dredging would disturb this habitat and, in the short term, reduce function of these areas primarily from disturbance to benthic and epibenthic organisms living in these areas and organism that feed in these areas.

The installation of the pile dike rock apron would change habitat from soft bottom to rock habitat over an area of about 2 acres. The construction would include short-term increase of local turbidity from bottom disturbance and initial loss of benthic organisms by burial. While the preferred placement of the riprap would be from a barge, some may occur in the intertidal area by land-based equipment, which may cause short-term effects on benthic organisms from transit of vehicles across the intertidal areas as part of rock placement. Construction would be limited to one in-water work window period when many important fish species, such as salmon, are of low abundances, reducing potential effect from local turbidity increases and loss of benthic and epibenthic resources from rock placement and shoreline vehicle transit used to place the rock. Increased rock areas may supply more habitat for rock-oriented species and cover for potential juvenile salmonid predators. Jordan Cove has identified two specific sites in Coos Bay that would be set aside and/or developed as compensatory wetland mitigation[118] for loss of intertidal and subtidal habitat from dredging. Their construction would also contribute to local turbidity.

The loss of 2 acres of eelgrass would be mitigated by off-site development and planting of a minimum of 6 acres of eelgrass habitat in the bay. The area proposed has been used successfully for eelgrass mitigation in the past. Donor stock eelgrass would be obtained from a combination of sites, including managed commercial oyster beds and existing high-density eelgrass areas, for use

---

[116] The plan was attached as Appendix N.7 to Resource Report 2, as part of Jordan Cove's application to the FERC filed in September 2017.

[117] This plan was attached as Appendix F.2 to Resource Report 2 of Jordan Cove's application to the FERC filed in September 2017.

[118] Jordan Cove included a *Compensatory Wetland Mitigation Plan*, attached as Appendix O of their *Draft Applicant-Prepared Biological Assessment.*

in establishing new eelgrass beds at the mitigation site. There would be some short-term loss of eelgrass habitat from those areas dredged during construction and from the removal of donor stock areas when the Eelgrass Mitigation site is planted. The use of salvaged eelgrass from commercial oyster beds and taking donor stock only from high-density areas would reduce short-term effects caused by developing the Eelgrass Mitigation site. As noted above, the total area of eelgrass affected is small relative compared to that habitat in Coos Bay, but some local short-term reduction in productive estuarine habitat would result.

Disturbance to 17 acres of other estuarine habitats (non-eelgrass) would be mitigated with re-establishment of estuarine habitat on about 91 acres of unvegetated mudflats at the Kentuck project site. This mitigation site would reestablish 67 acres of tideland habitat and additional wetland acreage. It would be a combination of native estuarine habitats (saltmarsh, tidal sand/mudflats) and freshwater wetland habitat (forested, scrub/shrub and emergent) (see section 4.3.3). Kentuck Slough is located on the east shore adjacent to the main inner bay between the area affected by the Project and Coos River mouth. This area would be modified with the addition of some of the dredged tailings from the LNG slip excavation. Additionally, 2.7 acres of floodplain habitat would be re-established adjacent to Kentuck Creek and would include stream enhancements including realignment of Kentuck Creek through the site. This area is close to the main Coos Bay river channel, which would benefit early marine-rearing juvenile salmonids.

The details of the plan, measures of success, and contingencies are provided in the *Compensatory Wetland Mitigation Plan*; however, final acceptance of the adequacy of the plan by ODSL or other resource agencies is pending. Therefore, Jordan Cove must continue to consult with the COE, NMFS, ODSL, and ODFW and other appropriate resource agencies to develop a final wetland mitigation plan for permanent effects on eelgrass and other estuarine habitats (see section 4.3).

Considering the mitigation measures proposed, and the implementation of mitigation plans, dredging activities would have only short-term effects on subtidal and intertidal habitat in Coos Bay.

Increased turbidity and sediment from dredging for the slip construction and navigation channel expansion would also affect marine and estuarine organisms. There are other project actions that would also increase local turbidity such as eelgrass mitigation site dredging, pile dike rock apron construction, and others. These are discussed in section 4.3.2.2 of this EIS.

Jordan Cove has stated that their construction plans, including their ESCP, would prevent turbid water from on-land construction, dredge material placement, and slip formation to be discharged or allowed to flow into Coos Bay. All in-water work would be restricted to the in-water work window from October 1 to February 15, contributing to reducing effects on fish habitat and species.

A large quantity of suspended sediment can reduce light penetration, which in turn reduces primary production of both pelagic and benthic algae and grasses. Increased suspended sediment can affect feeding of benthic and pelagic filter feeding organisms (Brehmer 1965; Parr et al. 1998), and the settling of the suspended particles can cause local burial, affect egg attachment, and modify benthic substrate. High enough levels can have direct adverse effects on fish ranging from avoidance to direct mortality. Use of pumps to convey the material in a hydraulic dredging operation would serve to contain most of the siltation caused by the dredging. The siltation would be conveyed with the material removed to the disposal area where it would settle out before being discharged back to the waterbody. The suspended sediment and turbidity levels would decline to ambient levels following completion of dredging activities.

Because of the short duration and small areas of in-water work for project activities other than dredging, effects on aquatic organisms from elevated turbidity would be localized and short term, likely diminishing in a few hours. However, dredging of the access channel would require in-water work that would occur over a longer timeframe and larger area. Dredging of the access channel would result in temporary siltation and sedimentation effects similar to those that currently occur during COE maintenance dredging of the Coos Bay navigation channel. On average, the COE removes approximately 550,000 cy from the bar, 200,000 cy from NCM 2 to 12, and 150,000 cy from NCM 12 to 15 each year. In-water dredging of the slip and access channel would occur over four in-water work periods totaling about 4 to 6 months.

The ambient turbidity levels in the water (generated by flows, waves and ship traffic) create a background level of turbidity. Within Coos Bay, turbidity measurements observed as total suspended solids (TSS) at the Charleston Bridge over a two-year period show an average summer TSS level of 10 mg/l and an average winter level of 27.3 mg/l. Some individual events (e.g., winter storms) measured at the Charleston Bridge were recorded between 100 and 500 mg/l. Therefore, aquatic organisms in Coos Bay are adapted to and exposed to periods of high to moderate turbidity during the winter months. Dredge operations are expected to result in similar effects, with higher concentrations of TSS in the immediate area of dredging.

Jordan Cove conducted modeling to estimate turbidity and suspended sediment that would result from access channel construction (Moffatt & Nichol 2006a) and the construction and maintenance dredging for all proposed bay activities (Moffatt & Nichol 2017c). The details of the model results on quantity and distribution of these parameters are discussed in section 4.3.2.1. The maximum TSS at a specific dredge site using a clamshell dredge was estimated to be about 6,000 mg/l decreasing substantially away from the dredge location. Moffatt & Nichol (2006a) also estimated that average turbidity levels during dredging operations (covering changing tidal directions) would not exceed background levels (about 10 to 30 mg/l) for the mechanical dredge at the slip. These levels would be even less for the hydraulic dredge beyond the actual dredge location, while elevated levels would occur outside of the actual dredge area for periods not exceeding 2 hours in duration depending on tidal direction. At lower tidal velocities, values would not exceed 30 mg/l outside of 200 meters, and at high tidal velocity less than 50 mg/l in 200 meters.

The concentrations and distribution are partly dependent on the type of dredging method that would be used. Proposed methods for dredging include use of mechanical or hydraulic (suction) dredging equipment. While the hydraulic cutter suction dredge is preferred due to its lower turbidity generation, a type of mechanical dredge may be used, especially in portions of the nearshore area due to buried wood. Model results for the access channel and slip construction indicate that elevated TSS above background would extend about 0.2 to 0.3 mile beyond the dredge sites during a full tidal cycle with any method considered and would exceed about 500 mg/l for about 0.1 mile. Maximum concentrations outside of the specific dredge location would only occur for about 2 hours or less over the tidal cycle with the plume moving upstream or downstream of the dredge site on flood or ebb tide, respectively. TSS concentrations at the four navigation channel expansion sites (i.e., part of the marine waterway modifications) would reach background level (about 20 mg/l) over a distance of about 1.2 miles[119] with any of the dredging methods. However, hopper style suction dredging would have much higher concentrations during construction with TSS over 500 mg/l extending about 1.0 mile across the dredging site, while the hydraulic cutter suction dredge or mechanical clamshell dredge would produce TSS of 500 mg/l extending about 0.1 mile from the dredge site. The distribution of and concentrations of suspended sediment would be the same for construction or maintenance dredging. If a mechanical excavator would be used for the eelgrass site construction, a confined area of elevated TSS would extend less than 0.1 mile from point of dredging (Moffat & Nichol 2017c). The more limited effect of tidal flow over the area would help confine the distribution of the elevated sediment plume. These elevated levels would be short term and highly localized to the nearshore area of the eelgrass site.

During the dredging process, some small fish (such as sandlance), larvae, and fish eggs could be entrained. Larger fish would be able to avoid this process and would likely actively avoid the area during the dredging disturbance process. In a review of many maintenance dredge studies through 1998, Reine and Clarke (1998) concluded that "much of the available evidence suggests that entrainment is not a significant problem for many species of fish and shellfish in many bodies of water that require periodic dredging." However, Dungeness crab in some studies are highly susceptible to entrainment (Reine and Clarke 1998; Pearson et al. 2002, 2005). Based on this review, it appears that entrainment of marine fish and shellfish species would not be a substantial effect on the local marine resources, although some important fish and shellfish may be reduced in abundance locally. Effects would be minimized by the current in-water work windows (October 1 to February 15) and by maintaining the cutterhead near the bottom if a hydraulic dredge is used.

If salmonids are exposed to moderate to high levels of TSS for prolonged periods, many adverse effects could occur including behavioral changes, sub-lethal effects, and increased mortality from predators. Dredging is expected to create spikes of high to moderate turbidity in a localized area. Effects on estuarine organisms and their habitat are expected to be slight and not measurable due to the limited area affected and the short duration of dredging operations, and limitations on construction periods. Rearing and migrating salmonids including ESA listed salmon, which should be uncommon in Coos Bay during the in-water work window, would likely avoid active work areas.

In Coos Bay, suspended sediment from dredging activity could affect shellfish, including clams and oysters and other filter feeders in the immediate vicinity and downstream of the access channel dredging site. Depending on dredging-induced elevated suspended concentration and exposure duration, effects on individual species and life stage from elevated suspended sediment could include no, minor, or major behavioral effects, physiological stress, reduced growth, or reduced survival and reduced egg hatching success (Wenger et al. 2018). Entrainment of organisms, especially eggs and larvae, may also occur. Dredging of the access channel and marine waterway modifications would be in deep water areas away from major commercial oyster areas as well (figure 4.5-2) and would likely not results in substantial effects from elevated turbidity or entrainment of commercial shellfish.

Jordan Cove's dredging would also directly remove benthic organisms (e.g., worms, clams, benthic shrimp, starfish, and vegetation) from the bay bottom within the access channel and navigation channel modifications. Mobile organisms such as crabs, many shrimp, and fish could

[119] Plume distance noted includes total spread both upstream and downstream of dredge site.

move away from the region during the process, although some will be entrained during dredging so that direct mortally or injury could occur. Based on 1978 maps of shellfish (Gaumer et al. 1978), shrimp, soft shell calms, bentnose clams, and cockles are located within the intertidal areas near the slip and within dredge areas (west of the Roseburg Forest Products Company site). The four navigation channel modifications are not located in known clamming or crabbing areas, or shrimp or oyster habitat (figure 4.5-2). ODFW captured Dungeness crab and red rock crab in this area during 2005 seining efforts near the access channel location. Varied species could be injured or killed during dredging operations. Dredged areas typically have edge areas sloped to maintain their stability, reducing the potential for bank sloughing and restricting direct impacts on areas dredged. Dungeness crabs and sand shrimp (Crangon spp.) can be especially susceptible to entrainment, although many survive dredging (Reine et al. 1998). Dungeness crab entrainment has been reported as substantial in some areas depending on season, salinity, location, and type of dredge used (Pearson et al. 2005, 2002). Reine and Clark (1998) reviewed dredging studies and concluded that "much of the available evidence suggests that entrainment is not a significant problem for many species of fish and shellfish in many bodies of water that require periodic dredging." Dredge entrainment studies over a four-year period in the Columbia River found no juvenile or adult salmonids entrained during dredging, although some other pelagic fish including eulachon were entrained (Larson and Moehl 1990).

When benthic communities on mud substrates have been disturbed by dredging in Coos Bay, they typically recovered to pre-dredging conditions within 4 weeks (McCauley et al. 1977, as cited in Wilber and Clarke 2007). However, recovery in estuarine channel muds has been reported in a review paper of dredging to be typically six to eight months (Newell et al. 1998). In the lower Columbia River, McCabe et al. (1997, 1998) noted benthic organism recovery in three months. Studies of a dredged sandy substrate area in Yaquina Bay Oregon found recovery of benthos took one year (Swartz et al. 1980, as cited in Wilber and Clarke 2007). Because of the large quantity being dredged and type of substrate, it may take longer than a four-week period relative to typical dredging and thus the benthic communities in the areas to be dredged may take a more varied time period to recover. The similarity of sandy substrate, like that of Yaquina Bay, suggest it is likely that recovery would be closer to a year for benthic resources particularly in the navigation channel modifications.

We would also expect increased organic matter production to the Coos Bay system from Jordan Cove's proposed eelgrass and wetland mitigation sites. The Kentuck project would provide about 67 acres of shallow water habitat as mitigation for the loss of about 16 acres of shallow estuarine water habitat at the access channel and the Eelgrass Mitigation site would provide 6 additional acres of eelgrass habitat as mitigation for the loss of 2 acres of eelgrass habitat. The affected shallow water habitat is suitable habitat for oysters (about 3 acres) and shrimp (about 10 acres). The development of the Kentuck project would likely contribute to replacing this type of habitat loss since existing oyster and shrimp habitat is present near Kentuck Slough.

Additionally, although sediment samples to date have not indicated high organic content sediment, some high oxygen demand sediment could be encountered during dredging. This could remove oxygen from the local water areas, putting local organisms at risk from insufficient oxygen. This effect would be temporary, and tidal exchange would be expected to replenish oxygen. In most cases, where dredging and disposal occurs in open coastal waters, estuaries, and bays, localized removal of oxygen has little, if any, effect on aquatic organisms (Bray et al. 1997). Also, Nightingale and Simenstad (2001b) reviewed literature in a summary document on effects of dredging and could find no empirical data indicating reduction in oxygen was an issue of concern for estuarine and marine organisms for dredging actions.

Dredging may also resuspend nutrients to the water column and could affect primary production. At low levels, this could be of benefit, increasing phytoplankton production, which could benefit prey species eaten by fish. However, in estuaries, this production is limited by turbidity and flushing, so any effects would be slight and local.

The initial marine waterway modifications (i.e., widening) in four areas would have minor habitat changes in Coos Bay. Deepwater habitat area would be further deepened in the four areas totaling about 27 acres of benthic deepwater habitat disturbance, plus an additional 10 acres deepwater habitat for the slurry transport lines. Less than an additional acre of shallow water habitat would be disturbed from the dredge lines used. The deeper water habitat is generally less productive than the shallow water environments. As with all dredging, there would be an initial loss of benthic resources from the dredging of the navigation channel that would recover over time. Overall habitat structure of the bay would remain essentially unchanged from the widening of the channel in these areas. Some of this net loss would be offset by added annual benthic production from the newly formed 37-acre slip habitat, even though it would likely be of poor quality.

In conjunction with all dredging activities would be the placement of temporary pipelines (18 to 20 inches in diameter) possibly on the bottom of Coos Bay to the deposition areas of the dredged sediment. This would include a pipeline route up to about 7 miles from the navigation widening area 1 to 4 miles to APCO Sites 1 and 2, one from the Eelgrass Mitigation site to APCO Sites 1 and 2 (about 0.5 mile), and another line extending from the shipping channel near the APCO Site to the Kentuck project (about 1.5 miles). These would have some initial bottom disturbance from placement and would likely kill benthic organisms (e.g., clams, worms) that are under the pipe placements. Most of the line would be in deep water paralleling the navigation channel from the four navigation modifications, which is an area often currently disturbed by shipping and maintenance dredging. Overall, there would be some reduction in benthic organism abundance from this direct placement of the pipes. The effective periods of this activity would be brief each year, occurring only during the construction in-water work window taking about 5 months total over four in-water work windows.

Maintenance dredging would occur every three to five years, with dredging taking about a month for the slip and access channel and a week for the navigation channel modifications. This would keep the navigation channel depth as it is currently, and the LNG slip depth as originally developed. Thus, after the project-developed initial widening, the current habitat structure of the navigation channel would remain unchanged and slip area would be as originally developed following each maintenance dredging cycle.

Construction windows for in-water dredging, developed by the state, are intended to minimize effects on the overall aquatic environment. The in-water work window (October 1 through February 15) would minimize the exposure of juvenile salmonids to increased turbidity during outmigration but would occur during much of the adult salmonids' upstream migration. Resident estuarine species, however, would be present during the in-water work window.

New Deepwater Habitat

The construction of the slip and berth would add a new region of deeper water habitat in Coos Bay. The area would have steep riprap sides that would have little biological diversity in shoreline habitat. The deeper areas may have slightly different fish composition than the main bay but overall the change in depth would be slight relative to the main adjacent navigation channel. Based on COE surveys, the navigation channel adjacent to the proposed site is 44 feet deep, with proposed slip depth 45 feet similar to the local deep bay areas, although to the side of the channel. While future composition of the channel species cannot be predicted, it appears conditions would not be substantially different than the adjacent navigation channel area. This may, however, result in some species composition differences locally. It would remain a relatively disturbed area for organisms, with the frequency of LNG carrier traffic likely reducing its overall benefit to fish and invertebrate resources. However, the final use of this new environment and changes in use from the existing conditions cannot be completely estimated now and conditions may take time to fully develop. This also holds for the four navigation channel modifications; however, these areas are already deep (all greater than 26 feet and would be deepened to 37 to 41 feet) and would include gradually sloped banks to prevent slumping in these areas. Aquatic resources, such as fish, shellfish, and marine mammals that may use Coos Bay, are under the management of ODFW and NMFS. In its response to the FERC staff's pending BA and EFH Assessment (see section 4.6 of this EIS), the NMFS can impose conditions through its BO to protect aquatic resources in the new deepwater habitat created by the Jordan Cove terminal slip.

Pile Driving Acoustic Effects

There are three basic types of pilings proposed: steel sheet pile, steel post piles, and wood post piles. The methods of installation that can be used for installation is a vibratory hammer or impact hammer, with some piling installed using both methods. Generally, noise levels are less with the vibratory hammer. Most of the construction-related pilings would be installed well away from the water. However, some pilings would be installed directly in the water or near the water where sound waves may transmit substantially into the water. Jordan Cove would install pipe piles and sheet piles for the Project including the marine and upland piles (see chapter 2). About 600 of these pilings are associated with the marine facility. These steel piles would be for the LNG carrier berth and MOF on the southeast side of the marine slip. Most of these piles would be driven land-side adjacent to the berth and while the upland portions of the marine berth are still isolated from the bay by the berm. Additionally, about five metal piles would be installed in the shallow water in support of dredge tailings pipeline over eelgrass beds to the APCO Site. Some additional temporary pilings would be installed in the wet[120] for the MOF, temporary material barge berth (TMBB), temporary dredge off-loading areas, road widening area, and access bridge to the APCO site. A total of 119 in-water steel pipe piles would be driven for the Project considering all these facilities with a lesser number of sheet piles (most driven primarily by vibratory hammer and some limited impact hammer use). An additional 1,150 wood piles would be installed for the road widening at U.S. Highway 101.

Underwater noise that may result in harassment and/or take of marine mammals is regulated by the NMFS under the MMPA. Under the MMPA, Level A harassment is statutorily defined as any act of pursuit, torment, or annoyance that has the potential to injure a marine mammal or marine

[120] Installing a piling "in the wet" or "in water" means the piling is in direct contact with the water body when it is driven into the substrate with an impact or vibratory hammer

mammal stock in the wild; however, the actionable sound pressure level is not identified in the statute. Level B harassment is defined as any act of pursuit, torment, or annoyance that has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns, including, but not limited to, migration, breathing, nursing, breeding, feeding, or sheltering.

In July 2016, the NMFS finalized their *Technical Guidance for Assessing the Effect of Anthropogenic Sound on Marine Mammals* (NMFS 2016c). Under this new NMFS guidance, Level A harassment is said to occur as a result of exposure to high noise levels and the onset of permanent hearing sensitivity loss, known as a permanent threshold shift (PTS). This revision to earlier NMFS guidelines is based on findings published by the Noise Criteria Group (Southall et al. 2007), which concluded that for transient and continuous sounds, the potential for injury is not just related to the level of the underwater sound and the hearing bandwidth of the animal, but is also influenced by the duration of exposure. The evaluation of the onset of PTS provides additional species-specific insight on the potential for affect that is not captured by evaluations completed using the previous NMFS thresholds for Level A and Level B harassment alone.

Frequency weighting provides a sound level referenced to an animal's hearing ability either for individual species or classes of species, and therefore a measure of the potential of the sound to cause an effect. The measure that is obtained represents the perceived level of the sound for that animal. This is an important consideration because even apparently loud underwater sound may not affect an animal if it is at frequencies outside the animal's hearing range. In the NMFS (2016c) final Guidance document, there are five hearing groups: low-frequency (LF) cetaceans (baleen whales), mid-frequency (MF) cetaceans (dolphins, toothed whales, beaked whales, bottlenose whales), high-frequency (HF) cetaceans (true porpoises, Kogia, river dolphins, cephalorhynchid, *Lagenorhynchus cruciger* and *L. australis*), Phocid pinnipeds (true seals), and Otariid pinnipeds (sea lions and fur seals). All of the above-listed species except Otariid pinnipeds potentially occur in the aquatic analysis area.

There are specific hearing criteria thresholds provided by the NMFS for each functional hearing group. These criteria apply hearing adjustment curves for each animal group known as M-weighting (see table 4.5.2.2-3).

TABLE 4.5.2.2-3

M-Weighted PTS Criteria and Functional Hearing Range for Marine Mammals

Functional Hearing Group	PTS Onset Impulsive	PTS Onset Non-Impulsive	Functional Hearing Range
LF cetaceans (baleen whales)	219 dB_{peak} & 183 dB SEL_{cum}	199 dB SEL_{cum}	7 Hz to 35 kHz
MF cetaceans (dolphins, toothed whales, beaked whales, bottlenose whales)	230 dB_{peak} & 185 dB SEL_{cum}	198 dB SEL_{cum}	150 Hz to 160 kHz
HF cetaceans (true porpoises, Kogia, river dolphins, cephalorhynchid, *Lagenorhynchus cruciger* and *L. australis*)	202 dB_{peak} & 155 dB SEL_{cum}	173 dB SEL_{cum}	275 Hz to 160 kHz
Phocid pinnipeds (underwater) (true seals)	218 dB_{peak} & 185 dB SEL_{cum}	201 dB SEL_{cum}	50 Hz to 86 kHz
Otariid pinnipeds (underwater) (sea lions and fur seals)	232 dB_{peak} & 203 dB SEL_{cum}	219 dB SEL_{cum}	60 Hz to 39 kHz

NMFS has defined the threshold level for Level B harassment at 120 decibels root mean squared (dB_{RMS}) for continuous noise and 160 rms_{90} sound pressure level (SPL) for impulse noise. Within this zone, the sound produced by the Project may approach or exceed ambient sound levels (i.e., threshold of perception or zone of audibility); however, actual perceptibility will be dependent on the hearing thresholds of the species under consideration and the inherent masking effects of ambient sound levels. The Level B harassment threshold was not updated with the July 2016 technical guidance.

Underwater noise from project construction activities could affect fish resources in Coos Bay. State agencies in Washington, Oregon, and California along with federal agencies including the FWS and NMFS have developed interim noise exposure threshold criteria for pile-driving effects on fish (WSDOT 2011; Fisheries Hydroacoustic Working Group 2008; Popper et al. 2006). These threshold criteria are considered levels below which injury effects would not occur to fish from in-water noise. These thresholds should be suitable for all forms of in-water noise. Interim noise exposure threshold criteria for pile driving effects on fish include: 1) a cumulative sound exposure level (SEL_{cum}) of 187 dB re 1 μPa^2 s for fishes more than two grams, 2) a SEL_{cum} of 183 dB relative to 1 square microPascal (re 1 μPa^2) for fishes less than two grams, and 3) a single-strike peak level (SPL_{peak}) of 206 dB re 1 μPa for all sizes of fishes (Fisheries Hydroacoustic Working Group 2008; WSDOT 2011). Generally, the high peak value is associated with potential mortal injury and forms of recoverable injury while the cumulative values are associated with forms of impairment that are likely recoverable forms of injury (Popper et al. 2014). While more recent studies based on additional information have recommended slightly different guidelines (Popper et al. 2014) these have not yet been implemented by the above agencies as new criteria. Piling location relative to water area, substrate piling is driven into, type of piling, and method of pile driving all influence the magnitude of in-water noise level and therefore the likelihood of noise levels injuring marine mammals and fish.

The potential noise levels relative to fish and mammal criteria of sheet pile and post pilings that would be installed at the LNG site out of the water were modeled (Deveau and MacGillvray 2017; O'Neill and MacGillivray 2017b; Wladichuk et al. 2017; Wladichuk et al. 2018). The sheet pile installation modeled were those that would be closest to the water. These sheet piles would be installed behind a 30-foot-wide berm separating the installation from the water. Wladichuk et al. (2018) modeled the installation of 36-inch steel post pilings by impact hammer located 100 feet back from sheet piles and adjacent to the water at the MOF.

The available information on decibel levels from these models were entered in the NMFS impact model for fish (NMFS 2009) for vibratory sheetpile installation to approximate the extent of potential noise effects from a general location in Coos Bay. Model results based on data from Deveau and MacGillvray (2017) indicate essentially no likely affect to fish from sheet piles installed away from the water. If any sheet piles were installed in or near the water edge, some adverse effects on fish that remain near the installation site (table 4.5.2.2-4).

Impact hammer use on steel post piles also was modeled for those near the MOF. Using the criteria noted above, estimated extent of potential injury to fish from these of pile installation are shown in table 4.5.2.2-4. While not directly modeled by Wladichuk et al. (2018), there will be unspecified locations in the bay that will have in-water pilings installed to anchor the navigation channel dredging pipes. Since most of these pilings would be installed with a vibratory hammer, effects on fish would limited in most areas. However, if an impact hammer were used, noise effects on fish in these areas would be limited because of the low number of impacts. Therefore, the extent of noise impact distribution is likely to be absent or limited in most other areas; however, where impact hammer is used, effects could be similar to those shown in table 4.5.2.2-4 if noise-dampening mitigation is not applied.

TABLE 4.5.2.2-4

Modeled Onset of Injury Distances of Unmitigated Metal Pile-Driving Sound Effects on Fish in Coos Bay during Construction

	Distance Threshold (ft) to Onset of Physical Injury to fish		
		Cumulative SEL dB by Fish Size	
Criteria and Hammer Type	**Peak dB**	**Fish ≥ 2 grams**	**Fish < 2 grams**
dB Criteria Threshold	206	187	183
Vibratory Hammer a/	0 ft	380 ft	380 ft
Vibratory Hammer b/	0 ft	<10 ft	< 10 ft
Impact Hammer MOF100-ft set back c/	120 ft	0.5 miles	0.5 miles
Impact Hammer MOF at shore c/	120 ft	1.1 miles	1.1 miles

a/ In water sheet pile noise level values averaged from data in Illinworth and Rodkin (2007). Model estimate from NMFS (2009); assumed 10,000 hammer impacts in 24 hours

b/ Sheet pile 30 feet back from water, peak value from Deveau and MacGillvray (2017). Model estimate from NMFS (2009); assumed 10,000 hammer impacts in 24 hours

c/ Assume 10,000 and 20,000 hammer impacts within 24 hours (Source: Wladichuk et al. 2018)

In addition, there would be 1,150 wood piles and sheet piles constructed at the Trans-Pacific Parkway/U.S. 101 intersection widening. These piles may be installed above or below water level depending on tide level. The methods for wood pile installation are unknown, but sheet piles would be installed by vibratory hammer with an impact hammer being used if necessary. One report measured peak values of 180 dB 10 meters from wood piling when using an impact hammer (Illinworth and Rodking 2007). Data are not available on noise levels from a vibratory hammer on wood, but vibratory hammer noise levels are generally much lower at peak noise production than those from an impact hammer. With the number of pilings to be installed, the frequency of piling contacts would be high. There is some risk of cumulative noise levels associated with wood pile-driving being an issue if peak noise values were near 180 dB. Jordan Cove has indicated that an impact hammer would not be used on sheet piles if they were inundated by high tides; implementation of this commitment would reduce the effects of cumulative and peak noise levels on fish.

Mitigative actions would be taken to reduce the potential effects of noise on fish. The estimates of noise levels that may cause injury to fish (table 4.5.2.2-4) assume that no mitigation (such as a bubble curtain) is in use, and that fish would remain in the area of adverse noise effects during the whole period of installation. Jordan Cove would implement sound attenuation measures in accordance with NMFS guidelines as needed, and fish are mobile and unlikely to remain in areas where cumulative noise levels would result in injury. All in-water pile driving would also occur only during the ODFW in-water approved construction window of October 1 to February 15, which would avoid noise injury to most salmonids.

General equipment used (e.g., trucks, compressors) and construction activity other than pile driving would all have noise levels below any that would affect marine mammals or fish (all less than 90 dB maximum). Noise in air produced by pile driving was modeled by Jordan Cove, and it was found that peak noise within 23 feet for all piles (18- to 72-inch diameter) being driven would be less than 117 dB and maximum of 101 dB at 50 feet, well below levels that would affect fish even if in the water. During pile driving, noise levels in air would decrease to below 90 dB_{RMS} (current in-air behavioral disruption threshold for harbor seals) at approximately 920 feet from the nearest piling rig. The current in-air behavioral disruption threshold for pinnipeds other than harbor seals (e.g., the California sea lion and Steller sea lion) is a less stringent 100 dB_{RMS} (NMFS 2018a). As a result, marine mammals within this distance could experience some behavioral disruption during pile driving.

Marine mammals inside Coos Bay may be affected by underwater noise from pile-driving during construction. The greatest distance at which PTS due to impulsive peak noise may possibly occur is around 250 feet for the harbor porpoise. Outside Coos Bay, the potential for effects on marine mammals from piling is limited to behavioral disturbance due to noise. Vibratory sheet pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 120 dB re 1 µPa at distances of up to 1.2 miles (Deveau and MacGillvray, 2017). Impact pipe pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 160 dB re 1 µPa at similar distances (O'Neill and MacGillvray 2017).

Jordan Cove would consult with the NMFS to design a monitoring and adaptive management plan including the development of a pinniped safety zone. If sound levels are determined to exceed NMFS Level A regulatory thresholds for marine mammals or guidelines for listed salmonids, sound attenuation measures would be used in accordance with NMFS guidelines. The NMFS has indicated that they may require additional monitoring as well as noise mitigation for the Project, including potentially the use of bubble curtains, sediment curtains, as well as various ongoing monitoring programs. These measures would be included, if required, in the NMFS BO.

Erosion and Runoff from Upland Facilities

Effects on marine resources could occur from the clearing of vegetation at the terminal, erosion and sediment runoff, and potential hazardous substance spills during construction. While no streams are present in the upland portion of the terminal, the removal of current vegetation could modify the character and amount of water runoff into the bay.

Nearshore vegetation clearing could indirectly affect aquatic resources in the bay; however, the amount of nearshore vegetation that would be removed for this Project is small. No planned nearshore disturbance would occur outside of the upland and shoreline that would be excavated and dredged to create the marine slip for the terminal. Jordan Cove would prevent uncontrolled releases of sediment runoff during construction by implementing erosion control and revegetation measures from its ESCP.

During construction of the LNG terminal facilities, stormwater runoff could erode disturbed soils, creating sediment in nearby surface waters, and affect local aquatic resources. Stormwater runoff from the disturbed portions of the site would be managed in accordance with Jordan Cove's ESCP and ODEQ-approved *Storm Water Management Plan* (see section 4.3.2.2). Following appropriate treatment, such as electro-coagulation, chemical flocculation, or filtration, if needed, all construction stormwater from the LNG terminal site would be directed toward Coos Bay.

Additionally, accidental spills of hazardous materials (e.g., equipment fuel, oils, and paints) during construction could have effects on aquatic resources in the bay. Jordan Cove prepared a preliminary SPCC Plan for construction to minimize the potential for accidental releases of hazardous materials.

Hydrostatic Testing

Water would be used for hydrostatic testing of the LNG storage tanks and piping prior to placing them in service (see chapter 2). The source of water would be local untreated potable supply from the CBNBWB. After completion of the test, the water would be discharged by filtration through the ODEQ-approved stormwater system or through the existing industrial wastewater pipeline. Permits would be obtained for all wastewater discharges as required by ODEQ. Water discharges would be treated, if necessary, to comply with discharge permits. If treatment were required, treatment procedures would be developed prior to discharge. The discharge through the existing industrial wastewater discharge pipeline, which connects to the previously existing ocean discharge diffuser location, would be at a rate of about 2.9 mg/d. Given that the water would be used inside the LNG storage tanks, chemicals would not be added, the water would be tested for quality and treated if necessary prior to discharge and would enter the ocean through a diffuser allowing rapid dissipation and mixing, the release of hydrostatic test water would not likely affect the ocean aquatic environment.

Construction Supply Vessel Transit

Much of the supplies needed for construction of the terminal and related facilities may be transported by break bulk ships and barges. These vessels would be similar to those used for typical transport of materials into Coos Bay. Approximately 60 deep-draft commercial cargo ships and 50 barges arrive in Coos Bay per year currently; while the frequency of vessel traffic would increase during the construction period, effects on marine resources would be similar to those that normally occur during commercial vessel traffic. The types of effects would be similar to those described for LNG carrier traffic but likely less due to a reduced number of trips and smaller vessel size. This would include effects of vessel strikes, ship grounding, shoreline erosion and fish stranding from vessel transit in the bay, fuel and oils spills and introduction of nuisance species. See section 4.5.2.1 for details of analysis of LNG transport effects addressing these parameters.

Effects on Aquatic Habitat and Aquatic Species from Operating the Jordan Cove LNG Project

Water Use by LNG Carriers at Berth

Jordan Cove estimates that about 110 to 120 LNG carriers would visit its terminal each year. While at the terminal dock for a period of about 17.5 to 24.5 hours, these LNG carriers would release ballast water while taking on LNG cargo. They also would take in water from the marine slip to cool their engines and would slightly affect the temperature of the water in the slip due to either the release of warm water after engine cooling or contact with the cool hull after taking on LNG cargo. These activities could have effects on aquatic resources in the slip.

Ballast Water

LNG carriers would discharge ballast water into the slip after arriving at the terminal berth and taking on cargo. As explained in section 4.3.2.2, Jordan Cove estimated that an LNG carrier taking on cargo at its berth would discharge about 9.2 million gallons of ballast water into the marine slip during the 17.5 hours it would be hoteled at the terminal. Ships may actually spend 24 hours at the berth so water use may be higher, as noted below. The potential of introduction of nuisance species from vessel transit including ballast water discharge was discussed earlier in section 4.5.2.1. Because the ballast water would have been taken on at sea, it might have slightly higher salinity than the water in Coos Bay that is fed from upstream fresh water sources. The tidal cycling of water in Coos Bay would reduce the effect of more saline seawater from ballast release in the slip on local aquatic resources. We estimate the total slip area to cover about 4.8 mcy (3.7 million m^3) of water. Therefore, the ballast water release would only amount to 1 percent of the entire size of the marine slip. By following Coast Guard and EPA procedures for ballast water, Jordan Cove and the LNG carriers visiting its terminal would probably not introduce exotic non-native organisms from a foreign port into Coos Bay.

Entrainment and Impingement from Vessel Cooling Water Intake

During operation of the terminal, LNG carriers at berth may entrain marine organisms through water taken from the slip to cool engines. Jordan Cove estimates that a 148,000 m^3 steam-powered LNG carrier would take in about 69.7 million gallons (264,000 m^3) of water from the slip for engine cooling while during their 24-hour loading period at the terminal dock. Dual-fuel diesel electric propulsion vessels (160,000 to 170,000 m^3) would take in 20.3 million gallons (76,800 m^3) less than steam-powered vessels over 24 hours.

Currently, no additional screening system other than that already employed on the LNG carriers, is proposed for water intakes. The current screen bar spacing on most LNG carriers is about 24 millimeters (mm; about 1 inch), bar width is 4.5 mm, and the total open area (considering screen open area is about 70 percent of total intake size) of the cooling water intake is about 3.5 to 4.2 m^2 or 36 to 45 square foot intake area. Additional finer mesh screens are located internally on the vessels to prevent larger items from entering the system. These screens would not meet NMFS (1997a) screening criteria for juvenile salmonids. The estimated velocity at the opening of the cooling water intake would range from 1.0 to 4.3 fps (0.30 to 1.32 meters/second), depending on the intake rate of cooling water used and intake area. The NMFS recommends an approach velocity of 0.33 fps for screening systems for salmonids of less than 60 mm, and 0.8 fps for larger juvenile salmonids. These guidelines also include other requirements such as sweeping velocity and type and size of openings that are not present on these screens. The result is likely to be that fish at fry and larger juvenile size salmonids near the intakes may be entrained or impinged during cooling water intake.

In addition, smaller marine and estuarine fish, juvenile stages of crab and shrimp, as well as other zooplankton and eggs and larvae fish could also be entrained. Some estuarine organisms potentially including juvenile salmonids would be removed from Coos Bay with this process during every loading cycle. It is expected that a high portion of juvenile larval stages of fish and invertebrates entrained or impinged would result in mortality. Nevertheless, natural mortality of these early life stages is extremely high. The result would be less than 1 percent of earliest life stages reaching adult size, with natural mortality over 20 to 30 percent per day during earliest growth periods (Comyns pers. comm. 2003). For example, data from an estuarine cooling water intake site determined that intake water larval stage entrainment, had very low natural survival (Marine Research Inc. 2004, as cited in FERC 2005). On a typical LNG carrier, the location of the water intake would be near the inner portion of the slip at depth of about 30 feet, which would likely reduce overall abundance of juvenile salmonids but not necessarily other organisms in the intake area. Salmonids migrating in Coos Bay would more likely be swimming in the main channel, away from the shoreline and the inset slip, reducing their chance of encountering the LNG carrier intakes. Other fish may have more varied distribution relative to the intake location. Therefore, the off-channel artificially created marine slip at the Jordan Cove LNG terminal would probably have a lower presence of juvenile salmonids but more varied overall fish abundance than the rest of Coos Bay.

To make a reasonable estimate of potential loss from cooling water intake, we compared the relative amount of water used by an LNG carrier while at dock at the terminal to the amount of water carried by the tide in Coos Bay past the Project vicinity. There are several assumptions with this method; the three major ones are: (1) organism distribution would be similar in water used to that in the bay as a whole, (2) all organisms entrained would be lost to the system, and (3) no avoidance to entrainment would occur. In addition, the estimate of entrainment loss was compared to what typical natural mortality loss would be for invertebrate and vertebrate life stages that are common in zooplankton as potential fish food sources. This information provides a perspective of how entrainment loss may influence food supply relative to natural conditions. This approach was developed in the Shanks et al. (2010, 2011) documents.

The period at the dock would span approximately two tidal cycles (each tidal cycle takes approximately 12 hours). We used data from Shanks et al. (2010, 2011) to make an average estimate that 106.1 million m3 of water would be passing through Coos Bay in the vicinity of the Jordan Cove terminal during one tidal cycle. This means that conservatively[121] from 0.07 to 0.25 percent of the water passing the marine slip would be taken in for engine cooling while an LNG carrier is at dock at the terminal, based on average tidal exchanges. Theoretically, organisms in this entrained water would be lost to the Coos Bay system and therefore not available as a food source. Based on the assumption that the concentration of various planktonic organisms is homogeneous in the resident water in Coos Bay, only about 0.07 to 0.25 percent of the planktonic population would be affected by each LNG carrier.

The loss of these organisms from entrainment can also be compared to loss from natural mortality in the bay environment by comparing estimated loss from entrainment to that occurring from natural mortality of typical pelagic organisms. This comparison was based on comparing instantaneous natural mortality rate (per day) loss, to loss from potential entrainment assuming all entrained organisms suffer 100 percent mortality. The natural mortality rate for various marine pelagic organisms was obtained from Rumrill (1990) and McGurk (1986). Using these rates, comparisons can be made to potential loss from entrainment to that that would naturally occur on a daily basis for a variety of typical marine organisms (table 4.5.2.2-5).

[121] Values is conservative (likely high) because total cooling water intake/discharge period is about 24 hours while we used the one tidal exchange period, about 12 hours for the estimate. Actual volume of water passing area would be about double, but some portion would be the “same” water.

TABLE 4.5.2.2-5

Comparison of Relative Loss of Larval Invertebrates and Larval Fish from Entrainment to Natural Mortality During Cooling Water Intake for One LNG Vessel Docked at the Jordan Cove Terminal

Mortality Category in Literature Source	Taxa Groups b/	Sample size	Natural Mortality Rate M (daily)(M=ln(S)/-t) c/	Estimated Percent Loss from Entrainment Relative to Daily Loss from Natural Mortality a/	
				Low Intake	High Intake
Lowest	Larval Invertebrate 1	14	0.0305	2.4%	8.2%
Lowest	Larval Invertebrate 2	28	0.0161	4.5%	15.5%
Lowest	Larval Fish	29	0.0200	3.6%	12.5%
Average	Larval Invertebrate 1	14	0.1450	0.5%	1.7%
Average	Larval Invertebrate 2	28	0.2470	0.3%	1.0%
Average	Larval Fish	29	0.1969	0.4%	1.3%

a/ Values based on average daily Coos Bay tidal water exchange rate of 106,000,000 m^3, and one LNG carrier water intake of 76,800 m^3 (low) and 264,000 m^3 (high) over 24 hours. Assumes 100% mortality of entrained organisms.
b/ Sources: Invertebrates from Rumrill (1990), and fish from McGurk (1986).
c/ S= Daily Survival, t=days, ln=natural log base e

Average and lowest mortality rates data for larval invertebrates and larval fish from these two sources were similar. Average loss of organisms from entrainment during one LNG carrier loading event would be low, ranging from 0.3 to 1.7 percent of what would occur from natural morality in one day. For the lowest literature mortality rate of larval taxa among those reported, daily entrainment loss would be much higher ranging from 2.4 to 15.5 percent depending on what water volume was used during one vessel loading cycle and which taxa group data are used. These values are conservative estimates when compared to natural mortality that would occur in the Coos Bay system overall because entrainment would not occur daily whereas natural mortality would, not all entrained organisms would suffer mortality, and, as noted, we assumed half the daily water volume passing the loading area.

Because about 110 to 120 LNG carrier trips a year would occur, LNG loading and water intake use would occur on average every 3 days. Therefore, relative fish food organism loss from entrainment annually would be considerably less than that estimated. Overall reduction in food sources for marine predators from entrainment of planktonic organisms appears to be slight, considering numerous factors. On average, water intake would be less than 0.3 percent of the water in Coos Bay passing by the terminal location on a daily tidal cycle, so relatively few organisms would be subject to entrainment assuming similar planktonic organism distribution at the intake. Typical “loss” on average would be about 1.7 percent or less of loss from natural mortality of invertebrate and fish larvae during the day of LNG cargo loading (table 4.5.2.2-5). Even though the number of fish individuals lost is not expected to be large, some mortality would occur. It is expected that the greatest portion of organism and fish that would be entrained would likely be early life stages, as these are unable to avoid entrainment. As noted above, natural mortality is high for these early stages.

We also considered what effect the direct loss of young stages may have on production of older individuals. EPA (2004) examined the effects of entrainment by California power plants on marine fish and shellfish. The document developed natural mortality information by life stage of common marine and estuarine species or groups of species present in the California coastal region. Many of the species groups are common to Coos Bay. This information supplies an additional indication that loss of early life stages because of high natural mortality would not markedly reduce later life stages. Table 4.5.2.2-6 shows the relative survival percent from one life stage to the next up to age 2, and overall percent survival from larval to age 1 and 2, based on the EPA (2004) document. For most taxa, less than 1 percent of larvae would be expected to survive to age 1, as the highest rate of mortality occurs in early life stages. Adult or harvestable populations of a fish species are also affected by many factors (e.g., currents, food, temperature, usable habitat) that are generally independent of numbers or survival of early life stages. Overall, the loss of marine fish and their prey resources from entrainment, relative to numbers in Coos Bay, would be small based on the information discussed.

TABLE 4.5.2.2-6

Selected Survival Values by Life Stage of Marine Species That May Be Entrained or Impinged

	Percent Survival by Life Stages a/				
Taxa Group/Species b/	**Larvae to Juvenile**	**Juvenile to Age 1**	**Age 1 to Age 2**	**Larvae to Age 1**	**Larvae to Age 2**
Anchovies	0.03%	12.00%	49.66%	<0.01%	<0.01%
Longfin Smelt	0.17%	40.01%	51.17%	0.07%	0.03%
Pacific Herring	0.90%	50.01%	62.31%	0.45%	0.28%
Other Forage Fish	0.05%	27.53%	19.79%	0.01%	0.00%
Flounder	0.19%	31.98%	69.56%	0.06%	0.04%
Rockfish	36.79%	36.79%	80.65%	13.53%	10.92%
Cabezon	1.87%	40.01%	26.18%	0.75%	0.20%
Sculpins	2.26%	40.01%	65.70%	0.90%	0.59%
Dungeness Crab	30.12%	30.12%	60.65%	9.07%	5.50%
Commercial Shrimp	4.98%	11.53%	11.53%	0.57%	0.07%
Forage Shrimp	0.31%	41.85%	33.29%	0.13%	0.04%
Average	**7.06%**	**32.90%**	**48.23%**	**2.32%**	**1.607%**
Median	**0.90%**	**36.79%**	**51.17%**	**0.45%**	**0.07%**

a/ Values based on natural mortality rates by life stage.
b/ Groups include multiple species defined in Appendix B1 of EPA (2004).

Loss of juvenile salmonids from entrainment or impingements could also reduce adult returns. Survival from smolt stage is highly variable among salmonid size, species, and year and easily can range from less than one to more than 10 percent. NMFS (2008b) in their assessment of effects of the Coos Bay airport expansions used a value of 4 percent survival for coho salmon smolts to returning adults. Even so, due to the extremely small portion of total water intake relative to the volume of Coos Bay, likely intake locations (30 feet deep, in the back of the isolated slip) likely away from concentrations of juvenile salmonids, the relative portion of juvenile salmonids that would be entrained and suffer direct mortality would be small.

Overall, the extremely small portion of total water intake relative to the volume of Coos Bay per LNG carrier (0.07 to 0.25 percent) suggests that the loss of zooplankton and ichthyoplankton, other marine invertebrates, eggs, larvae, shellfish, and fish including juvenile salmonids due to operation of the Jordan Cove Project would be low in comparison to total available entrainable size organisms in the bay and occurring from natural mortality. Therefore, we conclude that entrainment and impingement from LNG carrier water intakes at the terminal would not have substantial adverse effects on any marine phase of aquatic resources (e.g., the juvenile stage of salmonids) or their food sources.

Water Temperature in the Slip and Bay

LNG carriers at berth at Jordan Cove's terminal have the potential to both warm the temperature of the marine slip while discharging engine cooling water, and to cool the temperature of the marine slip while loading LNG cargo. Moderate to large temperature increases have the potential to reduce fish and invertebrate growth, reproductive success, and if high enough cause direct mortality. Fish of the north Pacific, including those found in Coos Bay, are adapted to cool water conditions and could be adversely affected by sharp increases in water temperature. Coos Bay temperatures historically remain less than 20°C (McAlister and Blanton 1963).

Moffat & Nichol (2018a) developed a temperature plume model for cooling water discharge from the LNG carriers during LNG gas loading. The model assumed that steam turbine vessel and dual-fuel diesel electric vessel would have a cooling water temperature of 2.0°C (3.6°F) and 2.8°C (5.0°F) above ambient at the point of discharge, respectively. Discharge rate would be 11,000 m^3/hour and 3,200 m^3/hour for about 24 hours of loading, for the former and latter vessels, respectively. Moffat & Nichol modeled the extent of the plume to where plume temperature would decrease to 0.3°C (0.6°F) over ambient water temperature. This model was run for varied bay water temperatures. The result was that the maximum distance from the port discharge point where the plume would reach this temperature was 80 feet for the steam turbine vessel and 37 feet for the dual fuel diesel electric vessel. The average water temperature increases for the total slip volume for one day when an LNG carrier is at dock for the vessel using the larger volume (steam turbine vessel) would range from 0.03 to 0.06°F (see section 4.3.2.2). We expect the actual average increase in water temperature in the slip would be less than the higher value estimated due to tidal exchange and the vessel uptake of heat from its surroundings due to the transfer of liquid gas into the vessel at -260°F (-162°C). While marine species would likely have a range of temperature tolerance, salmonids are known to be sensitive to elevated temperatures. The modified water temperature would be well below levels that would be considered lethal in the short term (a few days) for salmonids, which would be over about 24 to 26°C (WDOE 2002). Mortality of juveniles starts to occur at constant exposure to temperatures above 71.6°F (Hicks 2000), with an acute lethal temperature of 78.4°F (Beschta et al. 1987), while optimum temperatures are much lower for salmonids, with preferred ranges generally between 50ºF and 59ºF for rearing juvenile coho salmon (Brett 1952; Reiser and Bjornn 1979; Jobling 1981; Konecki et al. 1995; McCullough 1999; Sullivan et al. 2000; Carter 2008). Juvenile coho salmon are taxed in the temperature range of 60.1ºF to 68.5ºF but are still capable of growing at a reduced rate (Stenhouse et al. 2012). Short-term local temperature increases would remain well below short-term adverse levels for salmonids, and any small changes in temperature including to the area within 80 feet of the discharge port would be easily avoided by fish. Therefore, the cooling water discharge should result in no adverse effect on salmonid resources from temperature changes. Since salmonids are not tolerant of elevated temperatures, they are likely a reasonable indicator that other estuarine species (which may be less sensitive) would also not be adversely affected by small temperature changes. Considering the total volume of water in Coos Bay, in comparison to the small volume of heated water discharged, virtually no change in bay temperature would occur from operation of the LNG Project.

Water Runoff and Spills of Hazardous Materials

After construction of the terminal, about 100 acres would be covered by impervious surfaces (e.g., compacted gravel). There is the potential for stormwater to run off these hard surfaces into the marine slip or bay, carrying sediment or hazardous materials, which may harm aquatic resources. However, before stormwater is discharged, it would be directed to areas for treatment (see section 4.3.2.2). Low oil potential runoff would be treated primarily by filtration, although cartridge filtration may be implemented, as designated in Jordan Cove's *Stormwater Management Plan*. Examples where cartridge filter would be used are paved roads, parking lots, and dense-grated gravel process areas. As mentioned in section 2.1.1.5, Jordan Cove would design and construct a stormwater drainage and collection system for its terminal. Runoff, including potential hazardous materials from the site, would be designed to meet regulatory requirements from both NMFS and ODEQ, and would be managed by following the ODEQ-approved *Storm Water Management Plan*. Stormwater from areas that have no potential for contamination would be allowed to flow into the slip or bay through designed discharge ports. Stormwater collected in areas that are potentially contaminated with oil or grease would be directed to sumps and then processed through an oily water separator before discharge to the industrial wastewater pipeline. Industrial wastewater would be conveyed to the Port's existing ocean outfall, pursuant to the NPDES permit issued by the ODEQ. Stormwater collection and treatment facilities would be designed in consultation with NMFS and the ODEQ.

All areas where LNG may be present would be curbed and graded so that any spill would flow to containment trenches leading to impoundment basins. The two LNG storage tanks would be surrounded by a 65-foot-high barrier. Any spills of hazardous materials would be handled in accordance with Jordan Cove's SPCC Plan (see section 4.3.2.2).

Terminal Lighting

Localized changes in light regime have been shown to affect fish species behavior in a variety of ways (Simenstad et al. 1999; Valdimarsson et al. 1997; Tabor et al. 2004; Nightingale and Simenstad 2001a). Disorientation may cause delays in migration, while avoidance responses may cause diversion of migratory routes into deeper, less protected waters. In some cases, increased light may attract both predators and potential prey species (Simenstad et al. 1999; Valdimarsson et al. 1997; Tabor et al. 2004). Juvenile coho salmon show no response to moderately high light intensity but become inactive in very low light (Hoar et al. 1957). Other fish may respond differently; for example, schools of juvenile chum salmon show marked preference for light, while juvenile sockeye prefer the dark. Depending on their reaction, fish may have migration delayed, be moved into less protected deepwater habitat, or they may become more susceptible to predation, as light can attract predators and increase their ability to see fish. Some adverse modification in fish behavior could occur from the lighting present at the terminal, possibly delaying migration, moving fish to less desirable habitat conditions, or subjecting juvenile fish to greater nighttime predation.

Lighting at the LNG terminal would likely include a mixture of low-power fluorescent lighting and higher intensity security lighting that would primarily be located on shore, in and adjacent to the slip. Lighting used at the LNG terminal would be similar to that already in place at other Coos Bay facilities. The facility would have its highest intensity lighting on shore away from the water, although some lower level lighting would be present near the water. Lighting on the tug dock would be low intensity lighting adequate for safety. No high intensity lighting would be present near the water except possibly during vessel docking. When an LNG carrier is not in the berth, the lighting would be reduced to that required for security and would be focused upon the structures and not be in proximity to the water; therefore, the lighting would not serve as an attractant or deterrent to fish species. When an LNG carrier is at the berth, it would physically block the lighting on the berth from the slip waters and, due to its proximity to the slip wall, would block the fish from getting too close to the lighting on the berth. Lighting used would be similar to that already in place at other Coos Bay facilities.

The location of the facility, set back from the main channel of Coos Bay, would reduce fish encountering any shoreline lighting effects. The reduced lighting levels near the water should reduce any behavioral effects on fish near the terminal. As mentioned above, we have recommended that Jordan Cove develop the details of its final lighting plan in consultations with the FWS, NMFS, and ODFW to minimize potential effects on aquatic resources. The limited height intensity lighting and overall large habitat area available for fish avoidance of these regions, and plans to obtain an approved plan with managing agencies, are anticipated to reduce the potential for adverse effects on local and migratory fish resources.

Maintenance Dredging

Jordan Cove has estimated that maintenance dredging would occur every three to five years with varied amounts removed ranging from 115,000 cy to 160,000 cy each dredging cycle for slip and access channel (see section 4.3.2.2 for details). An additional 27,000 cy would be removed from the navigation channel about every three years. Jordan Cove proposes to place maintenance dredged material at land storage sites APCO Sites 1 and 2 (figure 4.5-2).

Modeling conducted by Jordan Cove and the Port (Moffat & Nichol 2006a) suggests a very narrow range of elevated suspended sediment (greater than 100 mg/l) during low tidal velocity extending out a few hundred feet from where the maintenance dredging area of the slip would occur in Coos Bay using a mechanical (clamshell) dredge. The highest concentration levels would occur at lowest tidal velocity when dispersion of suspended sediment would be the least. Peak value at the lowest modeled tidal velocity—the point of clamshell dredging—is estimated to be 830 mg/l, with decreasing values away from the actual dredging site to about 125 mg/l at 200 m (660 feet) from the site. During typical tidal cycles, turbidity would be up to 75 mg/l out about 0.2 to 0.4 mile from the dredging site. Moderately low values of 25 to 50 mg/l may extend out to about 3.5 miles depending on flow, sediment composition, and equipment used, for brief peak periods (about 2 hours daily). During high current velocity, peak values at the point of dredging would be about 90 mg/l, decreasing to 25 mg/l in 100 m (330 feet). Average daily (24-hour) values outside of the direct area being dredged would remain in the range of seasonal background levels of 25 to 50 mg/l during the ODFW-allowed dredging window. Maintenance dredging of the marine waterway modifications (i.e., the navigation reliably improvement areas) is expected to have similar turbidity effects but could be less if a hydraulic suction dredge is used. The number of days dredging would occur would depend on details of equipment used but would likely range from a few days to about a month of dredging to remove about 142,000 cy every three years (COE 2011). If dredging were to occur at the estimated removal rate of about 7,000 cy per day estimated for hydraulic dredging in Jordan Cove's *Dredged Material Management Plan*, active maintenance dredge would occur over 20 days.

Fish are likely to move from this narrow band of elevated suspended sediments during peak occurrences for short durations during dredging (likely several hours over the largest area affected). Additionally, some benthic organisms (e.g., clams, shrimp, and tubeworms) would be removed during this dredging. Maintenance dredging would occur from October 1 to February 15 during the Coos Bay in-water work window which would avoid major juvenile salmonid presence in the region.

Because all dredged material would be placed on land where runoff is controlled, there would be no effect on the estuary or marine environment from dredged material disposal. However, the final transport method of the dredged material to these sites has not been finalized and may include some bottom disturbance or effects from piping used to transport the discharge material. These are expected to be small areas of potential direct effects from pipeline impacting bottom areas and would not have substantial effects on benthic organisms.

Operational Acoustic Effects

LNG carrier and tugboat operations along the waterway, operational noise at the terminal, and maintenance dredging would generate underwater sounds pressure levels that could elicit responses in aquatic organisms. State agencies in Washington, Oregon, and California along with federal agencies (FWS and NMFS) have developed interim noise exposure threshold criteria for pile-driving effects on fish (WSDOT 2011; Fisheries Hydroacoustic Working Group 2008; Popper et al. 2006). These threshold criteria are described above for pile-driving acoustic effects during construction.

Underwater noise levels are expected to vary by ship type and by vessel length, gross tonnage, vessel speed, and, to some extent, vessel age as older vessels tend to be louder than newer vessels. Based on the general trend for higher underwater noise generated by larger vessels (McKenna et al. 2012), it is possible that some of the LNG carriers could generate more noise if they are larger than the LNG carrier built in 2003 with a 138,028 m^3 capacity reported by Hatch et al. (2008). The vessel in that study produced sound levels (with one standard error) of 182 ± 2 dB re: 1 µPa at 1 meter that attenuated to 160 dB at 35 ± 11 meters and to 120 dB at 16,185 ± 5,359 meters. These vessel noise levels are therefore generally less than threshold levels considered to cause direct harm to fish. Upland operational noise may also travel over water, but is not likely to affect fish, although there may be effects on marine mammals close to the terminal.

Generally, response to changes in noise levels would be behavioral and perceptual, and not physiological in nature, as fish and marine mammals would tend to avoid the area during periods of high noise output. We conclude that operational noise would not have significant adverse effects on aquatic resources.

4.5.2.3 Pacific Connector Pipeline Project

The Pacific Connector pipeline would cross or affect 352 waterbodies: 69 perennial streams, 270 intermittent streams (99 of these are considered ditches), 9 ponds (i.e., all ponds are adjacent to the line and would not be directly crossed), and 4 estuarine channels. Available data indicate that about 71 of these waterbodies are known or assumed to be inhabited by fish. Appendix I, table I-2, lists information on waterbodies crossed or potentially affected and known fish distribution and classification relative to the crossing.

Aquatic Habitat in the Coos Bay Estuary

The pipeline would cross under about 2.3 miles of Coos Bay in two separate crossings. Coos Bay consists of about 14,000 acres of varied intertidal and subtidal substrate habitat conditions including algae beds, eelgrass sites, marsh lands, and mostly unconsolidated substrate. The upper Coos Bay estuarine habitat contains important rearing habitat supplied by estuarine wetlands, algae, and eelgrass beds, which are important conditions for estuarine fish and migratory salmon, as well as commercial oyster beds. The estuarine habitat of the Coos Bay estuary along the pipeline route is in a mix of shallow regions of the Coos Bay near Kentuck Slough and deeper areas under the two navigation channels crossed (see figure 4.5-1). Most of the route and associated work areas are in nearly equal amounts of shallow intertidal and subtidal fine bottom and unconsolidated bottom habitat, with a few regions of mixed seabed of eelgrass, attached algae, tidal marsh and deep navigation channel. The fisheries in these habitats include a mix of anadromous and marine species, as well as shellfish, and are described above in section 4.5.2.1.

Aquatic Habitat in Inland Waterways

The freshwater streams crossed by pipeline route include six major subbasins of rivers in southern Oregon. The aquatic habitat crossed by the pipeline outside of Coos Bay is primarily coldwater streams, but with a few warmwater ponds adjacent to the pipeline. Most stream riparian areas crossed are heavily forested, and are therefore shaded by a mix of conifer and hardwood trees, providing typical salmon and/or trout habitat. Several waterbodies crossed are large (over 100 feet wide), but the majority are small waterbodies with generally no or low flow ,as about 75 percent are intermittent streams. Most of the major streams and many of the minor streams crossed contain salmon and steelhead, some of which are federally listed as threatened fish species.

Fishery Types and Fish Status

Fish species present in the pipeline area can be classified as warmwater, coolwater, coldwater resident, anadromous, and estuarine fish. Freshwater streams with habitat suitable for coldwater resident fish and anadromous fish are the most common along the pipeline route and associated facilities other than in the Coos Bay estuary, while warmwater fish species are typically associated with ponds in southeast Oregon. The status of federally listed fish species and other commercial fish species that are managed under the MSA will be presented in our pending BA and EFH Assessment that will be submitted to the FWS and NMFS. Endangered and threatened species and their respective critical habitat, and other special status species are addressed in section 4.6. The status of other state-listed fish species and fisheries of concern are also discussed in section 4.6. The EFH assessment summary relative to pipeline-related actions is included in appendix I.

<u>Warmwater, Coolwater, and Coldwater Fish</u>

Typical warmwater species in the pipeline area include black (*Pomoxis nigromaculatus*) and white crappie (*Pomoxis annularis*), and brown bullhead (*Ameiurus nebulosus*), which are not native to the region. Warmwater species are present in several lakes near the route and are present at pipeline crossing areas, and are likely in some Klamath Basin streams crossed by the pipeline.

Coolwater fish present in the area affected by the Project include both non-native and native species. Some important non-native species include smallmouth bass (*Micropterus dolomieu*) and yellow perch (*Perca flavescens*), as they are a common sport fish. These fish are often present in lakes, and smallmouth bass may be found in some larger rivers. Other native coolwater species of note include the ESA listed Lost River sucker (*Deltistes luxatus*), ESA listed shortnose (*Chasmistes brevirostris*) and Klamath largescale (*Catostomus snyderi*) suckers, and blue chub (*Gila coerulea*). These latter species occur primarily in the Klamath Basin, in Upper Klamath Lake and its tributaries. Umpqua chub (*Oregonichtyhys kalawatseti*) are a FWS species of concern, as this fish species has declined precipitously in the last decade. The pipeline would cross habitat occupied by Umpqua chub.

Resident coldwater fish species spend their entire lives in fresh water. Various waterbodies crossed by the Pacific Connector pipeline provide year-long habitat for several resident coldwater fish species. Resident cutthroat trout (*O. clarki*), rainbow trout (*O. mykiss*), and redband trout (*O.*

m. gibbsi) are the most common resident coldwater game species along the route. Non-game fish species, some of which migrate between freshwater and marine habitats (e.g., threespine stickleback [*Gasterosteus aculeatus*]), and others that are freshwater residents (e.g., speckled [*Rhinichthys osculus*] and longnose [*R. cataractae*] dace, sculpins, chiselmouth [*Acrocheilus alutaceus*], sucker) also may occur in waterbodies in the pipeline area.

Anadromous Fish

Anadromous fisheries in the pipeline area comprise eight species: Chinook salmon, coho salmon (including two ESA listed coho salmon ESUs), chum salmon, steelhead, coastal cutthroat trout, Pacific lamprey, river lamprey, Pacific eulachon, and green sturgeon (also ESA listed) (see section 4.5.2.1). Section 4.5.2.1 summarizes most of the major runs of anadromous salmon, steelhead, and trout species in the area affected by the Pacific Connector Project and their general timing of life phases.

Marine (Estuarine) Fish

The marine species that may be present along about 2.3 miles of the pipeline route where it would cross under Coos Bay at two locations between about MPs 0.3 and 1.0 and MPS 1.5 and 3.0 are the same as those discussed above for the Coos Bay portion of the waterway for LNG carrier marine traffic to and from the terminal (section 4.5.2.1).

Marine (Estuarine) Shellfish

Major invertebrate taxa present in Coos Bay are described in section 4.5.2.1. Invertebrate groups include pelagic (in the water column), epibenthic (residing on sediment surface), and benthic (residing in the sediment) organisms. Pelagic invertebrates include juvenile and larval stages of many species, such as crab, shrimp, clams, worms (polychaetes) as well as adult and juvenile crustacean zooplankton (e.g., copepods). Epibenthic organisms including harpacticoid copepods, snails, amphipods, mussels, oysters are all present to varying degrees. Benthic organisms include clams and the most abundant polychaetes and amphipods, the latter an important food for juvenile salmonids.

Estuarine Oysters

There are two different types of oysters identified along the pipeline route at the two Coos Bay crossings: 1) commercially grown non-native Pacific oysters; and 2) native Olympia oysters. Neither species can be legally harvested for recreational purposes. Native oyster populations are state-protected to encourage their recovery. Pacific oysters are the private property of their commercial growers.

Four companies lease state lands in Coos Bay to raise Pacific oysters commercially, two of which are near the pipeline crossing. They seed their beds with juvenile oysters (spat) and later harvest adults. These commercial beds are located on the north and east side of Coos Bay from Glasgow Point (north) to Crawford Point (south) in intertidal areas. Another commercial oyster operation is in South Slough. The pipeline route would go directly under one commercial oyster area owned by Clausen Oysters west of Kentuck Slough.

Olympia oysters can be found in the subtidal and intertidal zones of Coos Bay from Haynes Inlet south to Isthmus Slough. Pacific Connector surveyed nearly 7,000 feet of relatively shallow intertidal habitat for Olympia oysters along the previously proposed pipeline route in Haynes Inlet during late June 2011. Olympia oysters were found growing on riprap at the mouth of Haynes Inlet and on substrates within the pipeline right-of-way. Generally, Olympia oysters were found almost exclusively where hard surfaces (e.g., riprap, old oyster or clam shells) are present (Ellis Ecological Services 2011).

Marine Mammals

The marine mammals that may be present along the pipeline route in Haynes Inlet are the same as those discussed for the Coos Bay portion of the waterway for LNG carrier transit to and from the terminal (see section 4.5.2.1), except for large whale species that only inhabit the deep, open ocean. It is possible that killer whales, gray whales, and pinnipeds could be found in Coos Bay. The potentially present marine mammals are protected under the MMPA.

Freshwater Mussels

Limited native freshwater mussels may be present in some streams along the route. Only eight native mussels are present west of the Continental Divide, most of which belong to the genus *Anadonta* (Nedeau et al. 2009). This genus tends to occur more often in lakes and pond and quiet pools but may found in swifter waters in protected areas without current sheer. Another species, the Western pearlshell (*Margaritifer falcate*), while most common in large streams can be found in cold small streams only a few feet wide (Nedeau et al. 2009). The distribution relative to the project crossing for mussel species in not known; however, it is possible that some may be present near crossings, especially in larger, low-gradient streams. Two sensitive species (see appendix I) may be present in streams along the route: California floater mussel (*Anadonta californiensis*) and Western ridged mussel (*Gonidea angulata*). Both species are also addressed in the Forest Service's Biological Evaluation (BE; appendix F of this EIS).

Effects on Aquatic Habitat and Aquatic Species from Construction of the Pacific Connector Gas Pipeline Facilities

The pipeline route would cross under 2.3 miles of estuarine habitat in Coos Bay and cross or pass near an additional 349 waterbodies, of which about 71 are known or presumed to be inhabited by fish. In addition, 4 new stream crossings would occur along the 10 temporary or 15 permanent roads, 2 of which are known to have fish. Existing roads used by the pipeline project for construction would use existing stream crossings although final design may include new or modified structures at some locations (see below), with a total of 47 streams crossed, 5 of which are perennial streams with 1 known to have fish. One new permanent construction road would also cross a known fish-bearing stream (PAR 15.07 crossing an intermittent tributary to Stock Slough).

Pacific Connector proposes to cross under the two Coos Bay estuary crossing locations and three large river crossings (Coos, Rogue, and Klamath Rivers), using HDD methods. At two crossings of the South Umpqua River, Pacific Connector would use a diverted open-cut method at one and a DP method at the other. Pacific Connector proposes to cross Medford Aqueduct using a conventional bore. An additional 24 bore crossings would be used primarily at ditches and canals. All other stream crossings would employ a dry, open-cut method. General stream crossing methods for each of these are described in section 2.4.2.2, and specific crossing methods are listed in appendix I, table I-2. General Project activities potentially affecting aquatic resources include frac-out at estuarine and large river crossings, freshwater in-water construction activities, terrestrial/riparian habitat modification, accidental spills or leaks of hazardous materials, and periodic maintenance of the pipeline.

Right-of-way clearing would occur during the early spring through late fall unless site-specific deviations are proposed. The baring of soil upslope of streams has the potential to contribute sediment and elevated turbidity when near streams, especially if on steep slopes; however, the pipeline route has been selected to minimize steep slopes and unstable areas. Additionally, there is an ECRP which includes implementation of BMPs such as silt fences, water bars, slash filter windrows, and other general procedures. Additionally, an upland erosion control and revegetation plan is in place that identifies where specific actions would be needed to curtail substantial erosion and sediment runoff to streams. Therefore, upland erosion from right-of-way clearing would not contribute substantial new sediment to streams, thus avoiding adverse effects on aquatic systems.

Construction of the Pacific Connector pipeline in-water stream crossings would only occur during ODFW recommended in-water construction windows. This timing would minimize the coincidence of pipeline construction with upstream adult salmonid migration and spawning as well as juvenile outmigration. Resident salmonids, which would be primarily cutthroat and/or rainbow trout, and juvenile coho salmon would be present at pipeline crossings during construction. During construction in the Coos Bay estuary (October 1 through February 15), adult anadromous salmonids, green sturgeon, and possibly eulachon would be present (ODFW 2007b).

The extent of effects on aquatic resources from pipeline construction would depend on the waterbody crossing method, adjacent clearing methods, erosion control, the existing conditions at each crossing location, and the timing of construction. Potential short-term effects that degrade habitat could occur with trenching and laying of the pipe at waterbody crossing sites and sometimes adjacent slope runoff. The installation of the pipeline across a waterbody may result in temporary deposit of a limited amount of sediment in that stream, with associated short-term turbidity affecting aquatic species. Pacific Connector would install erosion control devices during construction to reduce sedimentation and in-stream turbidity at waterbody crossings. Right-of-way clearing would be 75 to 95 feet wide at stream crossings and a permanent 30-foot-wide access route maintained in herbaceous non-forest vegetation. We expect the pipeline right-of-way to be restored and revegetated immediately after pipeline installation. Except for forested areas, vegetation would be expected to re-establish in the area within three years (see section 4.4).

Long-term degradation of habitats can occur if flow or sediment regimes are modified in a manner that results in morphological changes to the bed and banks of the channel. Also, in forested areas, shade would be reduced at waterbody crossings for the time it would take trees to grow after restoration and revegetation. In streams that have very small flows, lack of shade may raise stream water temperatures and reduce LWD supply, which could in turn affect aquatic species. However, streams with low or intermittent flow generally support smaller fish populations and less diverse species composition.

Pacific Connector developed its project-specific ECRP which includes specifications for waterbody crossing techniques and associated sediment and erosion controls to be implemented during waterbody crossings. A detailed description of construction and mitigation measures that Pacific Connector would implement at waterbody crossings is included in section 4.3.

In addition to actual waterbody crossings by the pipeline, several of the project-related construction activities, such as improving existing access roads (EARs), PARs, TARs, and TEWAs within riparian areas, could indirectly affect aquatic resources by increasing erosion and runoff to nearby streams, losing future large wood input to streams, and increasing stream temperatures. The potential effects on fish or their habitat would be minimized by BMPs including the ECRP and procedures in place to eliminate or reduce potential effects on streams.

Fish passage is a potential issue relating to streams crossing by roads that would be used by the project. The final locations of all road-stream crossing and road use levels would not be determined until a construction contractor can assess what final road use would be needed and final designs are developed. However, Pacific Connector, in consultation with ODFW, has developed general plans and designs for methods to be use for road-stream crossings to ensure fish passage is maintained and other effects are minimized (Pacific Connector Gas Pipeline LP 2015). For temporary and permanent roads, designs may include use of existing instream structures, which could include the protection, repair or replacement of these stream-crossing structures. New culverts may be needed in some areas. Fish passage would be ensured for all life stages for any new structure. However, Pacific Connector would not modify the fish passability of existing structures if they use them without needing to replace them. Pacific Connector would submit a fish passage plan to ODFW, and the NMFS or FWS as applicable, and would not construct the crossing until approval is received.

Temporary bridges may be used before culverts are installed. These bridges would span above the ordinary water level and be maintained to stay above water levels during use. All new or temporary crossing structures would meet state fish passage requirements and NMFS fish passage criteria. Any culvert installation would occur during state designated in-water work windows unless otherwise approved by the ODFW, and the NMFS or FWS as applicable on streams with ESA listed fish, and fish passage would be maintained during construction if passage occurred at the crossing prior to construction. If temporary bridges are used, they may be installed outside of the in-water work window if the ODFW and NMFS approve. To provide equipment and material access up and down the construction right-of-way, temporary bridges would be installed outside of the ODFW in-water work window. For flowing waters, efforts would be made to span the water with a temporary bridge from the bank without entering the water. Where bridges cannot safely be installed this way, only equipment needed to install the bridge would be allowed in the stream, minimizing water disturbance. These bridges would have suitable clearance to allow higher flows to pass without inhibition, and any temporary bridges remaining in the fall would be removed before high flows. All installation structures would be approved by the COE, ODSL, ODEQ, ODFW, and, as appropriate, the Forest Service and BLM. Currently, there are no plans to have equipment cross flowing water streams for other purposes. In-water activities would meet state turbidity standards reducing turbidity effects. With procedures in place, disturbance to aquatic systems would be kept to a minimum during periods of greater sensitivity outside of the in-water work window. Riparian disturbance would be kept to that needed for construction. These actions would maintain adequate fish passage and minimize stream disturbance from the use and installation of road-stream crossing structures.

Construction in Estuarine Habitats

During in-water pipeline installation within Coos Bay, fish and other aquatic resources are unlikely to be affected unless a frac-out were to occur. Construction of the pipeline across the Coos Bay estuary would not directly disturb the substrate as crossings utilize HDD crossing methods. The current pipeline route in the bay would be two HDD spans of 0.7 and 1.6 miles with no planned subtidal or intertidal habitat disturbance. Generally, an HDD would avoid direct effects on the bay and associated estuarine resources. However, an HDD requires the use of drilling mud as a lubricant during the process. This fluid is under pressure and there is a possibility of an inadvertent release of drilling mud through a substrata fracture, allowing it to rise to the surface (also referred to as a frac-out).

Drilling mud primarily consists of water mixed with bentonite, which is a naturally occurring clay material. Bentonite by itself is essentially non-toxic (Breteler et al. 1985; Hartman and Martin 1984; Sprague and Logan 1979). However, bentonite can act like a fine particulate sediment in water, which could affect aquatic resources. The dispersal of drilling mud from a frac-out in the bay could interfere with oxygen exchange by clogging the gills of aquatic organisms (EPA 1986). The degree of interference generally increases with water temperature (Horkel and Pearson 1976). Sediments in high concentrations can clog gills, impair vision, make it difficult to feed, and increase the chance of predation. Drilling mud that accumulates on the bay bottom could cover over benthic organisms and estuarine food sources. Most highly mobile aquatic organisms, such as fish, crabs and shrimp, would be able to avoid or move away from the affected area. Local elevation of turbidity could affect fish, including salmonids if present, but with construction occurring during the in-water work window abundance in this area would be low further reducing the likely hood of adverse effects from elevated local turbidity. Other less mobile or immobile organisms, such as echinoderms, clams (i.e., *Macoma* sp.), Pacific oyster, Olympia oyster, and coral/anemone polyps (*Anthoszoa*) (Miller et al. 1990) and other macroinvertebrates, would incur short-term effects from direct mortality if smothered by the drilling mud. However, benthic communities on mud substrates in Coos Bay that were disturbed by more intensive effects from past dredging activities recovered to pre-dredging levels in four weeks (Newell et al. 1998). Some effects may be long term if important habitat elements are affected, such as the effects of turbidity on eelgrass growth (Martin and Tyrrel 2002).

The pipeline route does pass via HDD under commercial Pacific oyster designated areas and native oyster could also be present so there is some risk for oysters should frac-out occur directly in this area. While oyster surveys have not been conducted along the current proposed route, some oysters are likely to be present in the intertidal and shallow subtidal areas where hard surfaces (like Pacific oyster shells) are available. However, typical oyster habitat is not common in the bay because most bottom areas consist of sand and fines.

Attached algae and eelgrass could also be affected by direct burial. Effects would be localized and short term, limited to species in the immediate vicinity of the frac-out, and ameliorated by tidal exchange volume. While tidal exchange would keep much of the bentonite in suspension, because much of the area is shallow and intertidal, depending on timing, some would settle to the bottom, but may be resuspended during tidal change. In these mostly shallow bay areas, accumulation could be contained and removed. Because of the above, effects on benthic organisms from burial under a release of drilling mud are likely to be low.

To prevent a frac-out or address impacts should one occur, Pacific Connector developed its *Drilling Fluid Contingency Plan for Horizontal Directional Drilling Operations*.[122] As discussed in chapter 2, the contingency plan would be implemented in the case of a frac-out into an estuarine or aquatic environment. These measures include, but are not limited to:

- temporarily halting the HDD, and sealing the source of the leak in the fractured zone;
- contacting agencies and developing a site-specific treatment plan;
- adding higher viscosity drilling fluid or lost circulation material to help seal leaks if required:
- deploying containment structures, if feasible;
- monitoring locations downstream of the HDD to identify areas of drilling mud accumulation;
- in estuary possibly remove muds during low tide if they are exposed; and
- in streams removing the drilling mud from substrate and streambanks, if possible.

The precise amount of drilling lubricant that would escape to water from a frac-out cannot be determined because of the many variables that affect quantity (proximity to water where frac-out occurs, length of time active drilling occurs after a frac-out begins, where in the process and flow rate where it occurs). However, with current designs and contingencies that would be in place at the site of any frac-out, the time period of drilling mud released into a waterbody would likely be short term if it were to occur. The *Drilling Fluid Contingency Plan* includes active monitoring of drilling activity that has procedures in place to detect potential drilling fluid spill such as monitoring sudden drops in drilling fluid pressure that would cause cessation of drilling. If monitoring detected a frac-out, the HDD activity would be immediately stopped. Detailed surveys and plans[123] have been made for each of the HDD crossing sites. Furthermore, the HDD locations are all under a large estuary or major rivers, with large volumes of water and swift flows, where the drilling mud would be diluted. Finally, frac-out most often occurs near the entry and exit locations, which are often landward of the stream channel. Displaced soil and a return flow of the bentonite slurry is another potential source of sediment from HDD crossings. As discussed in chapter 2, the drilling mud returns would be hauled offsite after completion of the HDD crossing and disposed of at an approved disposal facility in accordance with all applicable federal and state regulations. Therefore, we conclude that an inadvertent release of drilling mud from an HDD would have minor, short-term adverse effects on estuarine or aquatic resources.

There could also be oil or fuel leaks from construction equipment. Pacific Connector would implement the measures outlined in its SPCC Plan to avoid or reduce effects from an equipment oil or fuel leak.

Aquatic Nuisance Species in Coos Bay

Invasive species have the potential to modify the food base and induce other ecological modifications in the estuarine area of Coos Bay. Non-indigenous aquatic species (NAS) are aquatic species that degrade aquatic ecosystem function and benefits, in some cases completely altering aquatic systems by displacing native species, degrading water quality, altering trophic

[122] This plan was attached as Appendix 2.H of Resource Report 2, in Pacific Connector's September 2017 application to the FERC.
[123] See Appendix G.2 of Resource Report 2, in Pacific Connector's September 2017 application to the FERC.

dynamics, and restricting beneficial uses (Hanson and Sytsma 2001). Within the Coos Bay estuary, over 67 NAS have been identified (Aquatic Nuisance Species Taskforce 2006). All the invertebrate NAS in the Coos Bay estuary have been introduced by ship fouling or discharge from ballast water of ocean-going vessels.

Pacific Connector identified two NAS that may occur in the Coos Bay estuary: New Zealand mud snails (*Potamopyrgus antipodarum)* and brackish water snail *(Assiminea parasitologica).* Pacific Connector would filter hydrostatic test water and discharge to upland areas through straw to reduce chance of transporting organisms between waterbodies and Pacific Connector proposes to use a treatment of 2 ppm or 2 mg/l of free chlorine residual with a detention time of 30 minutes to treat all non-municipal surface waters that would be used as a water source for hydrostatic testing purposes, and follow ODEQ criteria for this action. Additionally, the applicant did state it would not obtain hydrostatic test water from either Coos Bay or the Coos River, to prevent the spread of NAS from the estuary to inland watersheds.

Construction Across Stream Habitats

Construction of the pipeline would affect 69 perennial stream sites, 270 intermittent stream sites, 9 ponds, and 4 estuary channels (table 4.5.2.3-1; including Coos Bay crossings discussed above). A total of 285 locations would be direct channel crossings, while 67 would be locations where the waterbody is in the right-of-way clearing area. Direct effects on four perennial streams (and Coos River estuarine channel) would be avoided by placing the pipeline beneath them by HDD, DP, or conventional boring. Another 26 intermittent streams would be bored or employ DP technology under the channel.

At one crossing of the South Umpqua River, Pacific Connector would use a diverted open cut. All other waterbody crossings that have flow at the time of construction would be crossed using dry open cut, which is designed to minimize activities directly in flowing water. Of streams that would be crossed using the dry open-cut method, about 29 are known to support anadromous salmon and/or steelhead and another 13 streams are assumed to also have anadromous species. Thirty-four streams crossed are known to support primarily coldwater resident fish, estuarine fish, or important endemic species in the Klamath River Basin. Eighteen additional streams that would be crossed with dry open cut are assumed to support important resident fish. Resident trout are mostly cutthroat trout. In all, about 71 of the waterbodies that would be crossed by, or adjacent to, the pipeline are known or assumed to have fish. Pipeline construction could adversely affect EFH species in up to 55 streams, as well as streams with numerous special status fish species crossings (see section 4.6 for ESA listed species). Our pending EFH assessment and BA will describe effects on those species occupying inland streams, and measures Pacific Connector would implement to avoid, minimize, or mitigate the effects.

In-stream construction could interfere with essential life processes of aquatic species. Most of the waterbodies identified as known, presumed, or classified as being fish bearing would be crossed using isolated or "dry" crossing construction techniques including the flume or dam-and-pump method if water is flowing in the waterbody at the time of construction. At one site on South Umpqua, the diverted open cut method used would require diversion of the flow to one side of the channel at a time. Potential effects of trapping fish from these methods are discussed under Entrainment and Entrapment subsection below.

a/ None directly crossed but in ROW adjacent to direct pipeline locations.
b/ Known and assumed, possible or likely (value in parentheses) crossings or pipeline proximity with indicated fish category designation.
c/ Includes primarily coldwater trout, but also estuarine species in Coos Bay and lower Coos system, and endemic species in the Klamath Basin.

Timing of Construction

The degree of effects on aquatic resources associated with construction activities would depend on the timing of in-water construction. Construction during periods of sensitive fish activity (i.e., spawning, juvenile and adult rearing, and migration) can have a greater effect on fish than construction during other periods. Pacific Connector would cross fish-bearing waterways during the in-water work windows specified by the ODFW in consultation with the NMFS within the range of anadromous fish, and with the FWS as appropriate.

The timing restrictions would prevent construction during periods of sensitive fish use and would typically allow construction only in periods of lower flow rates in streams. In general, construction of the pipeline would be timed to miss periods of major juvenile or adult anadromous salmonid migrations in freshwater based on allowed fishery construction windows, typically July 1 to mid-September for most streams, and some other dates for specific waterbodies. These are tentative dates and timing restrictions would be subject to change by the ODFW. Any modifications to the allowable construction windows would be dictated by stream and fish migration conditions in the year of construction, and would be stated as conditions of state water crossing permits.

Sedimentation and Turbidity Resulting from Pipeline Installation Across Freshwater Streams and Effects on Aquatic Resources

Pipeline crossings of surface waterbodies would cause some downstream turbidity and sedimentation. The type of crossing and stream sediment characteristics can affect turbidity and suspended sediment in streams. Nearly all streams (88 percent) would be crossed using the dry open-cut method (flume and dam-and-pump) (table 4.5.2.3-2). Both "dry" techniques produce much less sediment in the water than alternative "wet" open cut methods (Reid and Anderson 1999; Reid et al. 2002; Reid et al. 2004). While several factors affect the effectiveness of dry construction methods, dry open-cut construction across waterbodies, if properly installed and maintained during construction and restoration, would produce minor levels of sediment and turbidity. Pacific Connector would minimize effects on surface waters and aquatic resources by implementing the waterbody crossing and erosion and sediment control measures as described in its project-specific ECRP, which would reduce the risk of sediment releases during construction.

a/ Waterbodies within the construction right-of-way that would not be crossed.
b/ Dry open-cut streams with bedrock streambeds which may require special construction techniques to ensure pipeline design depth including rock hammering, drilling and hammering, or blasting. The need for blasting would be determined by the contractor and would only be initiated after ODFW blasting permits are obtained. These streams are in addition to regular dry open-cut streams.

Duration of crossing can ultimately influence periods of downstream turbidity and suspended sediment elevation to aquatic resources. If channels are dry during construction, small streams (channel width less than 10 feet) are projected to be crossed in less than 24 hours, and intermediate streams (channel width 10 to 100 feet) usually in less than 48 hours. Reid et al. (2004) examined stream crossing data from 46 crossings (23 dam and pump, 12 flumed, and 11 open cut) over a range of stream types across Canada and the U.S. from streams that were mostly less than 10 meters wide. Reid et al. (2004) noted that, in flowing streams they monitored, instream work averaged 38 and 64 hours for dam-and-pump and flumed crossings, respectively. However, the times noted for crossings include all activities that occur, which influence when active suspended sediment may occur, but do not indicate the actual periods when increased suspended sediment development would occur, which is mostly influenced by periods of active instream installation or removal of flow diversions for dry open-cut methods. Additionally, failure of flow sealing and other instream structures at upstream diversions structures can occur from a variety of malfunctions such as pump failure, dam and flume failure, poor dam seal and others. Reid et al. (2004) noted seal failures of monitored diverted open cut crossing in 1 of 23 dam-and-pump projects and 5 of 12 flumed projects. Should these occur, suspended sediment would be relatively elevated over those without failure, but immediate repair work could reduce magnitude and duration of elevated suspended sediment.

Increased sediment loads associated with high turbidity can have effects on fish behavior and physiological processes (e.g., blood chemistry, gill trauma, immune system resistance), and can result in mortality. Salmonids (e.g., trout and salmon) are the most common, abundant, and important species in Project streams and often the most sensitive of common freshwater fish species to elevated suspended sediment. Approximately 27 percent all streams crossed contain salmonids that could be affected if TSS levels are elevated. Salmonids exposed to moderate to high levels of suspended sediment for extended periods could be adversely affected. At high levels, turbidity and suspended sediment directly affects survival and growth of salmonids and other species and interferes with gill function (reviewed and compiled by Bash et al. 2001). Turbidity can also reduce aquatic plant cover (over the long term) by limiting photosynthesis (Goldsborough and Kemp 1988), as well as adversely affecting fish vision, which is a requisite for social interactions (Berg and Northcote 1985), feeding (Vogel and Beauchamp 1999; Gregory and Northcote 1993), and predator avoidance (Meager et al. 2006; Miner and Stein 1996).

Sediment stirred into the water column can be redeposited on downstream substrates, which could bury aquatic macroinvertebrates (an important food source for salmonids, and other fish in estuarine areas). Additionally, downstream fine particle sedimentation could affect spawning substrate habitat, spawning activities, eggs, larvae, and juvenile fish survival, as well as benthic community diversity and health (reviewed and compiled by Bash et al. 2001).

Some studies related specifically to pipeline stream crossing have found varied effects from sediment. For example, rapid recolonization of benthic organisms has been documented on 30 pipeline projects post-construction (Gartman 1984). One long-term study (construction through three years post-construction) of multiple pipeline crossings of a coldwater streams found no measurable effect on fish or benthic resources or their habitat within two months to three years after construction (Blais and Simpson 1997). Reid et al. (2008) found similar conditions for benthic resources ranging from no effect on reductions in abundance or diversity for periods of less than a year, all for wet open-cut crossings, which is not likely representative of most dry crossings.

Dry open-cut construction methods may have the potential to alter fish abundance over the short term. Reid et al. (2002) found that fish abundance downstream of dam-and-pump or flumed crossings reduced immediately after construction in two of four sampled sites, but concluded these reductions were likely not the result of sediment. Additionally, one year after construction, Reid et al. (2002) found no difference in fish abundance below these two sites from preconstruction levels.

Newcombe and Jensen (1996) compiled research from many sources that demonstrates effects on anadromous and resident salmonids by various levels of suspended sediment concentration and exposure duration. They used this information to develop models that estimated the severity of these effects based on sediment concentration and exposure duration.

Output from the model provides severity-of-ill-effects (SEV) scores that are summarized below. Values range from 0 to 14, where an SEV of 0 indicates no effects, an SEV between 1 and 3 indicates behavioral effects, an SEV from 4 to 8 indicates sublethal effects, and an SEV from 9 through 14 indicates lethal and paralethal effects (see Table 1 in Newcombe and Jensen 1996).

1) Behavioral Effects SEV scores
    - 1 = Alarm reaction
    - 2 = Abandonment of cover
    - 3 = Avoidance response

2) Sublethal Effects SEV scores
    - 4 = Short-term reduction in feeding rates and/or feeding success
    - 5 = Minor physiological stress (increase coughing rate and/or increased respiration rate)
    - 6 = Moderate physiological stress
    - 7 = Moderate habitat degradation; impaired homing
    - 8 = Major physiological stress; long term reduction in feeding rate- feeding success; poor condition

3) Lethal and Paralethal Effects SEV scores
    - 9 = Reduced growth rate and/or delayed hatching and/or reduced fish density
    - 10 = 0 to 20 percent mortality and/or increased predation and/or moderate to severe habitat degradation
    - 11= >20 to 40 percent mortality (SEV scores exceeding 11 predict increased mortality rates)

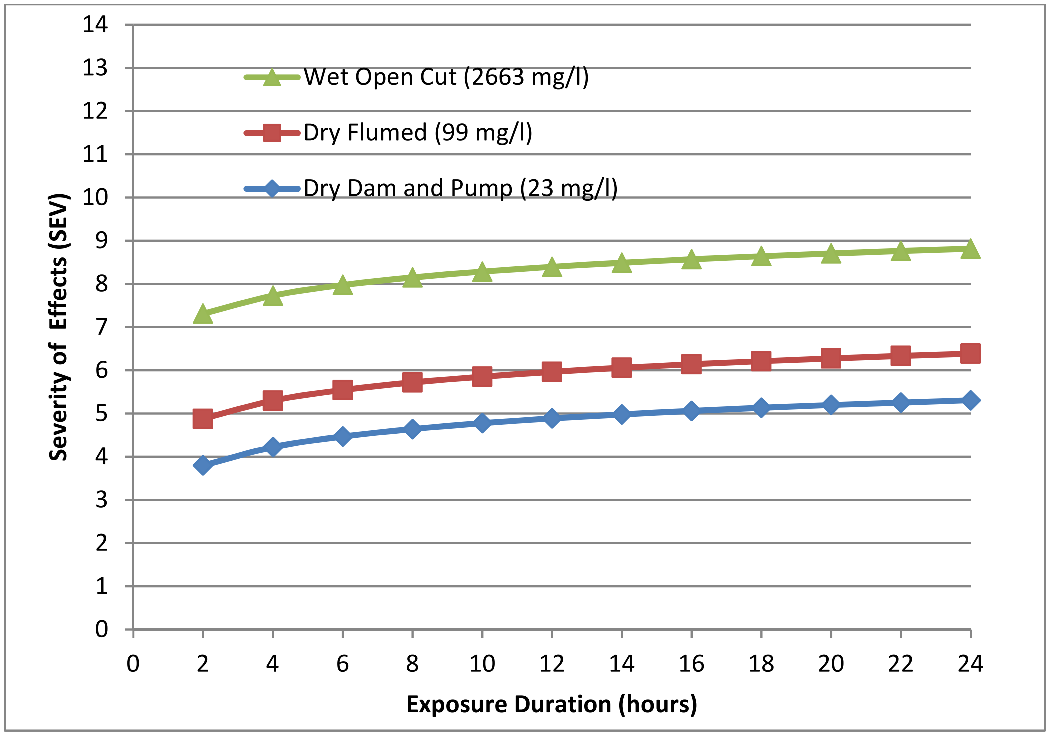
Newcombe and Jensen (1996) developed varied models for this assessment method. The one most relevant for this study is Model 1, which is used to estimate effects on both juvenile and adult salmonids and is based on 171 different study results.

Because of the uncertainty of both available site-specific information and the accuracy of models when applied to varied locations, two approaches were taken to estimate the concentration of suspended sediment and its effect on aquatic resources. One method used literature values from other stream pipeline studies concerning concentrations and durations of the activity to estimate reasonable approximations of likely sediment concentrations and effects on fish. The other was a detailed approach using models to predict sediment concentrations at Project stream pipeline-crossing sites based on known and assumed values, as presented in Pacific Connector's Resource Report 3.

Literature-Based Assessment of Sediment Effects

Application of the Newcombe and Jensen (1996) model to a collection of stream pipeline crossing locations supplies an approximation of what the likely range of effects may be to fish resources (primarily salmonid). The Reid et al. (2004) data are the most complete set of literature information available on likely ranges of suspended sediment that may occur from various crossing methods and likely in-stream construction duration. Reid et al. (2004) measured suspended sediment downstream from 12 flumed pipeline crossings and 23 dam-and-pump crossings (dry open-cut or isolated pipeline construction crossings) and 11 wet open-cut construction crossings. He noted that average suspended sediment concentrations near these 11 "wet cut" crossing sites were 2,663 mg/l, whereas values were much lower at "dry crossing" sites, which averaged 99 mg/l (12 sites) and 23 mg/l (23 sites) for flumed and dam-and-pump sites, respectively. Using the mean sediment concentration values from Reid et al. (2004) and the Newcombe and Jensen (1996) sensitivity Model 1, the effects on salmonid resources can be approximated (see figure 4.5-4).

While crossing times for construction may be in the range of less than one day to four days for dry crossings, actual periods of elevated sediment would occur primarily during periods of installation and removal of isolation structures. Therefore, time of elevated sediment for any one crossing would only be a few hours, which is why the range of duration in the figure 4.5-4 is limited to 24 hours which would more than cover the period of likely elevated sediment resulting from crossing under normal crossing conditions.



Note: Based on the Newcombe and Jensen (1996) effects model based on typical suspended sediment concentrations levels (data from Reid et al. 2004) by crossing type.

Figure 4.5-4. Effects of Pipeline Stream Crossing Suspended Sediment Concentrations on Salmonids

Based on the estimate of likely average conditions of construction at a crossing assuming the average of the Reid et al. (2004) suspended sediment values, SEVs for dam-and-pump crossings would be most likely in the range of 4 to 5, which could include short-term reduced feeding rate or minor physiological stress. Flumed crossing sites would on average have slightly greater effects, with SEVs mostly in the range of 5 to 6, which could result in minor to moderate physiological stress. If some failure occurred in crossing methods, short-term concentrations and duration would be greater with SEV values similar to those of wet open-cuts, likely in the range of SEV 8, implying adverse factors such as long-term reduction in feeding success and major physiological stress, with wet open cut crossing time closer to 14 hours (Reid et al. 2004). All levels of effects would remain sublethal even with some short-term failure in crossing methods, based on the literature concentration and duration values.

Active monitoring of pipeline crossing construction of mostly coldwater fish streams in New Hampshire found similar SEV level results to those shown above. Trettel et al. (2002) monitored suspended sediment levels within 50 to 150 meters (160 to 500 feet) downstream of the active pipeline crossing constructions sites and used information from 75 perennial streams consisting 71 dry dam-and-pump or flumed crossings and 4 open-cut wet sites to estimate SEV levels. They found that the average SEV of the dry crossings was 6.5 with no measurable difference between types of dry crossing, while the four wet crossings averaged an SEV of 7.4. The SEV level of 6 corresponds to moderate stress while SEV 7 suggests the lowest level where some habitat effects would occur. They found that about one-third of the dry crossings equaled or exceeded this SEV level (7) of potential adverse habitat effects. Additionally, 99 percent of all crossings were less than the designated paralethal or lethal range (SEV of 9 or above). The biggest factor affecting elevated SEV levels was the portion of fines in the sediment at the crossing. These results suggest a very low probability of any direct fish mortality from construction, with local crossing area effects consisting of mostly sublethal effects (e.g., physiological stress, short-term reduction of feeding), and limited habitat degradation.

The distance downstream effects could occur is dependent on many factors (e.g., substrate composition, velocity, flow, channel width). Ritter (1984) estimated that for a minor perennial stream (likely average only half a foot deep, and less than 20 feet wide), suspended sediment concentrations may be near background levels in the range of 60 meters (200 feet) to 150 meters (500 feet) downstream during open-cut crossings. These stream sizes would be most typical of crossings along the pipeline route. Reid et al. (2002) found that below four separate dam-and-pump crossings, mean suspended sediment was less than 20 mg/l within 30 meters (100 feet) downstream. However, at another crossing where some high suspended sediment concentrations occurred from leakage, values 340 meters (1,100 feet) downstream were reduced to 20 percent of those at 45 meters (150 feet) downstream. Low concentrations during construction of crossings appear to be more common when BMPs are closely followed. For example, according to Pacific Connector, a Williams Northwest pipeline completed in Washington State had only one state turbidity standard exceeded out of 67 waterbodies crossings. Pacific Connector estimated the changes of suspended sediment concentrations based on the Ritter (1984) model downstream of 13 Project subwatersheds using estimates of substrate sediment composition and other physical conditions at the crossing sites (e.g., width, depth, and flow).

Based on the Reid et al. (2004) average values, effects on salmonids would be low, other than when sealing failure events occur at the planned dry crossings; the effects would likely range from short-term behavioral to short-term sublethal effects, likely lasting a few hours or days depending on severity. Trettel et al. (2002) monitoring suggests adverse effects may be somewhat greater but still sublethal, with occasional local habitat degradation.

Model Estimates of Effects of Suspended Sediment

Pacific Connector incorporated site data, regional data, and available literature-based models to provide an estimate of both suspended sediment level and extent of effects on aquatic resources from pipeline stream crossing construction based on their estimates of sediment concentration and exposure duration. The parameters used in this model assessment are variable and are based on a combination of data. Thus, the results may be considered an approximation, rather than the exact suspended sediment levels that would be observed.

The method for approximating the concentration of suspended sediment at the specific crossing sites and the distance downstream that various concentrations travel relies on the use of two separate models and empirical suspended sediment value comparisons from typical crossing sites for each crossing method. The first is a regression model that estimates the concentration at or near the representative installation area (Reid et al. 2004) (see above) based on selected physical stream conditions. The second model estimates the distance various concentrations of suspended sediment travel downstream (Ritter 1984) based on selected physical site data.

The Reid et al. (2004) model uses site-specific physical parameters at representative crossing to predict sediment concentrations from a wet open-cut crossing at each stream reach in each watershed crossed by the Project. The basic stream reach data were obtained from the ODFW Aquatic Inventories Project. These data were not specifically from a proposed crossing site in a watershed but were considered to be representative of physical conditions of streams crossed in each watershed. Since all crossings would be dry cut, these model estimates were adjusted downward to equal predicted dry cut crossing values based on the average relationship between wet cut and dry cut methods in the Reid et al. (2004) article. Mean suspended sediment concentrations generated during dry open-cut construction for dry fluming construction were 3.7 percent of the wet open-cut concentrations and 0.85 percent of the wet open-cut concentrations for dam-and-pump construction. Pacific Connector assumed in their model that if sealing of the site from stream flow failed during construction, the average suspended sediments levels at the crossing would be equal to wet cut crossing values.

All parameters used in this model (flow, stream width, velocity, percent silt and clay), except for median sediment size (this had a regressed value based on percent fines for each stream reach), were taken from subbasin stream measurements report in ODFW's Aquatic Inventory database from fifth-field watersheds. This information was used to estimate what sediment concentrations would be for a wet open cut at the stream specific set of data.

The model by Ritter (1984) for small stream crossings was used to predict change in concentrations downstream of crossings based on stream characteristics (e.g., flow, depth, roughness). The details of how this model operates are provided in a revision to Pacific Connector's Resource Report 3.[124]

Estimates were made for 9 to 99 stream crossings per fifth-field watershed (average 51 per fifth-field watershed) for which sufficient data were available to conduct the analysis. These crossings were representative of the Project regions and ranges of stream width/gradient that would have normal dry open-cut crossings. Streams not modeled included the Upper Klamath River (except Spence Creek) and Lost River subbasins crossings, other HDD or boring sites, and bedrock stream crossings that would have low sediment during crossings. Due to the dynamic nature of sediment movement in streams, however, some bedrock crossings may have other substrate at the time of crossing.

The resulting estimates of potential suspended sediment concentrations (without major crossing area sealing failures) indicate that suspended sediment concentrations would remain low in most project regions (table 4.5.2.3-3) (See appendix I, tables I-10, I-11, and I-12 for details by watershed). These estimates are based on the average range of suspended sediment concentrations by watershed during low flows, the period when in-stream construction would occur. Estimates of suspended sediment concentrations produced during pipeline construction under summer low-flow conditions may be highest for the waterbodies crossed in the Coos Bay-Frontal Pacific Ocean fifth-field watershed, followed by crossings in the North Fork Coquille River and Myrtle Creek fifth-field watershed,

[124] Attachment FERC-PCGP-RR3-10 submitted to the FERC in a supplemental filing on May 4, 2018.

which is the result of assumed high fines concentrations at the crossings. For flumed crossings, suspended average watershed values ranged from 27 to 153 mg/l, with values even lower for dam and pump crossings, ranging from 7 to 35 mg/l among the 14 watersheds. Exposures to suspended sediment concentrations from any crossing method would decrease to background levels from about 0.6 to 19 kilometers downstream, among the 14 watersheds (table 4.5.2.3-3).

a/ Stream-specific values are provided in Appendix X of the APDBA. Nearly all watersheds with at least 12 streams each, usually with multiple reaches per stream.

m – meter; mg/l – milligram per liter; TSS – total suspended solids (sediment)

If there is a failure of isolation structures during either type of dry open-cut construction, it is assumed that the suspended sediment generated during the failure would be similar to suspended sediment generated during wet open-cut construction. Suspended sediment concentrations assumed to occur during failure of isolation structures could be substantial. For the watersheds with highest concentrations, waterbodies in the Coos Bay-Frontal Pacific Ocean, Myrtle Creek, and North Fork Coquille River fifth-field watersheds, modeled suspended sediment assuming average wet open-cut values might be as high as 4,102 mg/l (Coos Bay -Frontal). Other watersheds could be as low as 712 mg/l (Shady Cove-Rogue River) 50 meters (164 feet) downstream from construction (table 4.5.2.3-3). However, each of these watershed values is based on the average of single point estimates from multiple streams but without consideration of how precise the model value is or how the variability of input parameters may affect the model output.

As noted above, Newcombe and Jensen (1996) developed models that estimate severity of effects on fish (primarily salmonids) based on the suspended sediment concentration and the amount of exposure time (i.e., assumed in-water peak disturbance period length) for various fish life stages. Model 1 (effects on juvenile and adult salmonids) was used for the analysis because those are the primary life stages and species of concern that may be present at locations and time of construction. The model requires estimates of both suspended sediment and the duration that values would occur in the stream.

While the actual full process of flumed or dam and pump crossing construction may last more than a day, elevated concentrations would likely peak over a two- to six-hour period, depending on stream width and construction methods with smaller streams taking less time. The number of dry open-cut crossings by stream size category for all watersheds assessed (two Lost River subbasins watersheds not included) is shown in table 4.5.2.3-4 (the number by watershed is given in appendix I, table I-10). Most crossings were of very small (less than 10-foot-wide) streams. Duration time ranged from two hours to six hours. To assess the potential sediment effects if major problems occurred with sealing during installation, a period of six hours duration was applied to sediment concentration estimates developed for wet open-cut crossing values. These times were used to estimate the duration of elevated sediment levels and used in the Model 1 of effects discussed above.

a/ Worst-case estimate as many of the smaller streams would be dry during construction.
b/ Total Dam and Pump and Flumed crossing for all watersheds except those in the Lost River subbasin.

Where flumed crossings are used, the magnitude of maximum average watershed severity of sediment effects for juvenile and adult salmonids for most stream crossing (i.e., smallest stream, less than 10 feet wide crossed) would be at most SEV 5 (minor physiological effect) in some of the 14 watersheds. This effect level would occur within 30 meters of stream crossings in six of the watersheds and not in the others. The lowest level of sublethal effect (SEV=4) (short-term reduction of feeding success) would occur in all watersheds to a distance average of about 800 meters below crossing (see appendix I, table I-11). With the longer duration of elevated sediment, severity of effects would be slightly greater for small stream crossings (i.e., 10-25 feet wide), with SEV 5 (minor physiological stress) occurring in about half of the watersheds at an average distance of about 100 meters below the crossings, while lowest sublethal effects (SEV 4) would occur in all watersheds and extend an averaged about 1,800 meters downstream. Except for two watersheds, effect levels on larger streams would be SEV 5 or less. This level would extend on average 180 meters for streams 25 to 50 feet wide (medium), and 280 meters for greater than 50-foot-wide (large) streams. SEV 4 would extend on average about 2,120 and 2,380 meters in the watersheds for the medium and large stream crossings, respectively. While the model results suggest some potential behavioral effect (SEV 1-3) may occur farther downstream in any stream crossing, the sediment concentration that could generate these effects is near background suspended sediment levels (e.g., 2 mg/l), so these effects would be similar to existing stream conditions.

Dam and pump crossings typically have lower suspended sediment generation so almost none of the crossings on the smallest streams (a majority of streams less than 10 feet wide in table 4.5.2.3-4)[125] would have suspended sediment levels reaching any sublethal SEV levels for any watershed, and the few that do would extend less than 50 meters. For the small stream crossing (10-25 feet wide), about half (8 of 14) the watersheds would have some areas reaching the lowest sublethal level (SEV 4), with most of these having sediment effects reduced to potentially only behavioral effects in less than 100 meters from the crossing. For the limited number (up to 21 crossings) of remaining medium and large stream crossings (table 4.5.2.3-4), if dam-and-pump crossings were used, a few watersheds would have no modeled sublethal effects, while the remaining 8 watersheds and up to 13 crossing would be at the lowest sublethal level (SEV 4) (appendix I, table I-11). In these crossings, severity levels would decrease to less than sublethal levels typically in less than about 200 meters of the pipeline crossings.

If the selected dry open-cut method has a failure in sealing, the in-stream construction area sediment levels would be higher than estimated for the crossing type. As noted earlier, if that occurred, then potential wet open-cut suspended sediment concentrations would be assumed. The severity effects model estimate of this assumed elevated sediment level would occur for about six hours (see above). Based on model results, the highest sublethal model effect of SEV 8 (major physiological stress, long-term reduction in feeding rate) would occur within at most 50 meters downstream of the crossing in any watershed, with about half (8 of 14) the watersheds having lesser sublethal effects (i.e., SEV 7 or lower). For most watersheds, if this crossing type occurs, severity levels of SEV 7 (moderate habitat degradation, homing effects) would extend downstream below the crossing between 500 and 2,000 meters (average about 1,000 meters; see appendix I, table I-11). Levels of SEV 6 or less would diminish in distance downstream of these areas as sediment settles. The minimal sublethal effects SEV 4 would still occur mostly from about 5 to 9 kilometers (average about 6.5 kilometers) downstream among the watersheds, over a 6-hour period. No watershed is modeled to have levels reaching the lethal or paralethal range (SEV $\geq$9) at any distance below crossings. In the unlikely event that dry crossing methods fail completely and wet open-cut methods must be implemented to complete the crossing, if suspended sediment conditions are high, the longer duration of elevated levels could result in the potential for severity levels to be higher (e.g., SEV 9, reduced fish density) over a limited stream area.

Overall, these effects would be short term, all less than a day as modeled. Some lower levels of effect would occur due to lower suspended sediment concentrations sporadically occurring during the actual crossing activity, and some resuspension of settled sediment with most lasting less than two or three days (Reid et al. 2004). As noted above for value estimates of suspended sediment, the SEV estimates should be considered approximate because the range of accuracy and variability of the input parameters is not directly included in the model estimates. However, the results are reasonable considering that typical dry crossing methods have relatively low concentrations of

[125] Number of streams that would definitely be crossed by dam-and-pump or flumed crossings will be determined during construction, but dam and pump is more often used on smaller streams.

suspended sediment (Reid et al. 2004) of short duration, likely less than 24 hours (Harper and Trettel 2002).

Sediment may also be contributed to fish streams from pipeline crossings of upstream feeder tributary streams. There were some 22 stream crossings of intermittent stream channels that could result in unlikely (due to lack of flow during crossing) sublethal effects (all SEV 4) to the downstream fish stream, and another seven tributary crossing of perennial streams that could result in sublethal effects (SEV 4 or 5) extending into downstream fish streams from these crossings (appendix I, table I-12).

The South Umpqua River diverted open-cut crossing would also result in some increase in suspended sediment. While not directly modeled, the coarse sediment at this crossing area would limit fine sediment distribution downstream of this crossing, likely less than 150 feet, based on model estimates of sediment transport distance, and would likely be less than levels that cause minor physiological stress (SEV 5). Elevated sediment and effects would be mostly reduced within a day of crossing activity termination.

No open-cut or dry-cut crossings would occur when any known adult salmonid resource, including spring Chinook salmon, would be spawning near a crossing during the designated approved construction window. Therefore, direct effects on spawning would be unlikely. Overall, the potential effect of suspended sediment on spawning activities of spring Chinook salmon would be restricted to the South Umpqua River diverted open-cut crossing, which would be limited in its downstream distribution as noted above.

Summary of Suspended Sediment Effects

While the modeled results supply a reasonable estimate of likely level of effects on primarily salmonid fish resources, the models rely on multiple input parameters (e.g., substrate composition and size distribution of fines, median substrate size (d_{50}), and water velocity at each stream) that are specific to fish streams in the watershed but not to specific crossing locations. Therefore, overall summary assessment of effects considered both literature results from other pipeline crossings and the modeled results of Project streams. For both modeled and literature-based assessments, effects would be mostly short term (less than 1 to 4 days) and remain at a near to moderate distance from the crossing location (downstream distance a few hundred feet based on literature, and a few hundred to a few thousand feet based on models).

Overall model results are based on regional watershed averages, but site-specific conditions may vary from these averages. However, the literature-based values of typical project-wide effects provide comparable results, suggesting more specific model estimated effects are reasonable. The results for either method is that crossings would cause at least some short-term adverse effects, primarily avoidance, short-term feeding reduction, and likely minor to moderate stress, but unlikely any direct effects on growth, fish density, or survival. No long-term adverse effects are expected unless some major failure occurred during construction. However, if failure occurred under certain conditions, some marked effects could be expected such as reduced fish density of salmonids in a limited stream area.

Sediment releases would affect primarily short-term stream habitat conditions. Sediment from stream crossings could affect spawning habitat below crossings as Project-generated sediment could increase gravel embeddedness downstream, although elevated fall and winter flows following crossing would likely flush fines from any local spawning sites. Habitat quality, including fish food sources, would be temporarily decreased downstream (e.g., visibility, flushed and covered benthic organisms, reduced fish movement) with overall habitat suitability (Anderson et al. 1996) temporarily decreasing, though not necessarily to levels that would cause moderate habitat degradation (SEV 7).

The Project could result in short-term adverse effects on estuarine and freshwater critical habitat for the Oregon Coast ESU of coho salmon. Short-term effects on critical habitat within the estuarine analysis area would include effects on food and rearing habitat as a result of dredging the access channel, marine waterway modifications, and the slip. Dredging in proximity to the Coos Bay shipping channel would decrease water quality and affect cover (e.g., aquatic vegetation and eelgrass).

Because of the linear nature of the Pacific Connector Project, the number of stream crossings and ultimately total area of stream habitat and individual streams that would be affected in any watershed would be extremely small. There would be 249 actual dry open cut stream channel crossings (table 4.5.2.3-2) in 231 miles of pipeline route over 17 fifth-field watersheds (watersheds with no crossing not included). Since almost no individual stream would have more than one crossing, effects on each stream would be limited to the crossing location. As an example of the relative portion of streams that may be affected in the short term by stream crossings, we examined the potential stream area affected in the four fifth-field watersheds of the Coquille subbasin, a route area with a high number of stream crossings. Those four watersheds have 3,093 miles of stream (Ecotrust 2015). The Project would cross 37 stream channels by dry open cut crossings in that length. Assuming the area affected from sediment to be 1,000 feet per stream crossing, about 0.2 percent of all stream length in this subbasin would have some short-term effect from sediment during construction. Overall cumulative effects would be unsubstantial based on the dispersed distribution of crossings and magnitude of effects at each and lengths of stream channel potentially affected.

<u>Inadvertent Release of Drilling Mud from HDDs and DPs</u>

Pacific Connector proposes to use the HDD method to cross under the Coos, Rogue, and Klamath Rivers. Generally, an HDD would avoid direct effects on a river and its associated aquatic resources. However, as discussed above for the Coos Bay crossing, an HDD requires the use of drilling mud (bentonite) as a lubricant which may leak (also referred to as a frac-out). This fluid is under pressure and there is a possibility of an inadvertent release of drilling mud through a substrata fracture, allowing it to rise to the surface.

As noted above, this release of drilling muds could interfere with various life activities for fish and benthic organisms. Drilling mud that accumulates on the stream bottom could cover over food sources and fish eggs. The majority of highly mobile aquatic organisms, such as fish, would be able to avoid or move away from the affected area while less mobile organisms could incur direct mortality if smothered by the drilling mud. These effects would be localized and short term, limited to species in the immediate vicinity of the frac-out, and ameliorated by river volume.

The effects of an in-stream frac-out on spawning habitat, eggs, and juvenile survival depend on the timing of the release. If spawning habitat is nearby, redds could be affected near a frac-out (Reid and Anderson 1999). During establishment of the spawning bed, the female as part of the normal preparation behavior would likely clean out a minor addition of sediment. However, a heavy sediment load dispersing downstream could settle into spawning beds and clog interstitial spaces, reducing the amount of available spawning habitat, which could be a limiting factor in areas of already reduced habitat. When redds are active, eggs could be buried, disrupting the normal exchange of gases and metabolic wastes between the egg and water (Anderson 1996). The effects of sediment intrusion into the redd on larval survival are more severe during the earlier embryonic stages than following development of the circulatory system of larvae, possible because of a higher efficiency in oxygen uptake by the older fish (Shaw and Maga 1943; Wicket 1954). Clogging of interstitial spaces also reduces cover and food availability for juvenile salmonids (Cordone and Kelley 1961). Benthic organisms could also be affected by burial. However, bentonite is more likely to stay in suspension and less likely to immediately settle than common bottom sediment so, in flowing water effects on benthic organisms from burial under a release of drilling mud are likely to be low and unsubstantial. As discussed earlier, Pacific Connector developed a Contingency Plan that includes measures to reduce effects should frac-outs occur.

DP technology would be used to cross the South Umpqua River at MP 71.3. Like HDD, DP crossings use a bentonite lubricant that theoretically could have an inadvertent return to the surface where it could enter the water contributing to suspended sediment levels. Because the excavated hole is continuously supported and the risk of hydraulic fracture is low, the DP alignment can be designed much shallower than is typical for HDD. Because of the limited amount of lubricant used and relatively low pressure of this construction, the chance of any inadvertent return occurring is remote. Therefore, the chance of accidental contribution of increased suspended sediment to this crossing is unlikely and adverse effects on fish and aquatic organisms at this crossing are likely to be unsubstantial.

Overall drilling mud releases to any waterbody would be short term and diluted from large river water volumes and swift flows. Additionally, frac-out most often occurs near entry and exit points, which may be out of the stream channel. Also, as noted for the HDD crossing in Coos Bay, Pacific Connector has conducted detailed crossing plans for each site and has contingency plans in place should it occur.

Streambank Erosion and Stream Bed Stability

The clearing and grading of vegetation during construction could increase erosion along streambanks, resulting in sedimentation and higher turbidity levels in the waterbodies crossed. Alteration of the natural drainage ways or compaction of soils by heavy equipment near streambanks during construction may accelerate erosion of the banks, runoff, and the transportation of sediments into waterbodies. Erosion, sedimentation, and higher turbidity levels related to the Project could affect aquatic resources, as discussed above. Effects on aquatic organisms due to erosion would depend on sediment loads, stream velocity, turbulence, streambank composition, and sediment particle size.

The rootwad network of trees adjacent to stream supplies bank stability. Those within 25 feet of the stream are considered most important at providing the root source aiding in bank stability (WDNR 1997). To aid in maintaining this bank stability, Pacific Connector would cut most trees near the bank (right-of-way width of 75 to 95 feet at the crossing), except those in the trench line, at ground level leaving the root systems in place helping to maintain short-term bank stability. Roots would be removed over the trench line or from any steam banks that would need to be cut down or graded to accomplish the pipeline crossing. To minimize these effects, Pacific Connector would use temporary equipment bridges, mats, and pads to support equipment that must cross the waterbody (perennial, intermittent, and ephemeral if water is present) or work in saturated soils adjacent to the waterbody. Pacific Connector would also install sediment barriers, such as silt fence and straw/hay bales, across the right-of-way at the edge of waterbodies throughout construction except for short periods when the removal of these sediment barriers is necessary to dig the trench, install the pipe, and restore the right-of way.

Pacific Connector proposes several measures to reduce the risk of erosion, bank failure, bed scour, and channel migration both from initial field evaluations and planned future actions. These are discussed in detail in section 4.3. The ECRP would be followed to help mitigate potential for bank and bed erosion, which would include not using riprap to stabilize streambanks. Immediately after installation of a waterbody crossing, the contours of the streambed, shoreline, and streambanks would be restored to preconstruction configurations (i.e., contour/elevations) to restore the physical integrity/condition of these features and to minimize the loss of stream complexity. Additional erosion control measures would include the installation of erosion control fabric (such as jute or excelsior) on streambanks at the time of recontouring. Stream banks would be restored to original contours, and selected site-appropriate riparian vegetation plantings would occur.

Pacific Connector has conducted a scour and channel migration analysis that identified channels with high risk of potential scour or migration, and pipe exposure. The channel migration and scour analysis rated crossings as to their risk of pipe exposure. Based on this analysis, Pacific Connector proposes to implement site-specific crossing methods at 11 waterbody crossings to reduce the risk of pipe exposure and reduce changes in stream channel habitat at potential areas of risk. Additionally, Pacific Connector has conducted an initial assessment of crossing conditions of all streams suitable for analysis based on the FWS risk matrix (GeoEngineers 2017d, 2018a, and 2018b). This assessment was intended to determine where stream crossings may pose significant risk to increase streambank erosion and streambed instability. GeoEngineers, using a combination of field and GIS data, rated the 173 pipeline stream crossings based on the matrix. Streams were lumped into categories based on their relative risk of project actions at that site affecting the stream and the sensitivity of the stream crossing to be affected crossing actions. The ratings help determine what kinds of BMPs would be most appropriate for each stream category depending on how the stream crossing were ultimately rated for project actions and stream conditions at that site based on the risk category the crossing fell into. Stream crossings that are unstable can ultimately adversely affect aquatic resources from such factors as loss of local habitat and addition of sediment to downstream habitat; these effects would last as long as it takes the crossings to stabilize.

Relatively few of the streams were considered to have marked potential for bank instability. Most streams were determined to be adequately protected with standard BMPs. Some streams would require additional specific BMPs to protect the stream channel and bank conditions (GeoEngineers 2017d, 2018b, and 2018c). Seven stream crossings were considered to need site-specific crossing measures to reduce the risk. Additionally, the BLM and Forest Service made recommendations for crossing designs on eight perennial stream crossing on their lands (see section 4.3). Most of these were the same crossing that Pacific Connector had concluded needed site-specific crossing BMPs. These recommended crossing plans were adopted by Pacific Connector for these crossings.

Proper substrate restoration would also be used maintain stream geomorphic and habitat conditions. Substrate characteristics and physical habitat features would be determined through pre-construction surveys, and the upper 1 foot of existing substrate would be replaced with clean cobble or gravel (not derived from crushed gravel), or a combination of both, or in some cases matching existing substrate during reconstruction after pipe installation. Many of these actions would be determined prior to construction based on results of the pre-construction survey (see below) and determined by a qualified EI specifically trained to determine proper restoration actions to implement based on river channel processes or a suitably trained professional. On non-federal lands, this person would have the authority to select appropriate additional BMP construction methods, bank stability actions, and revegetation types and methods to help reduce the risk of instability of the crossing and potential for future erosion (GeoEngineers 2017d and 2018a). Additional oversight would occur on federal land.

A pre-construction survey would be conducted by a technically qualified team of Pacific Connector on all stream crossings to confirm and clarify conditions developed in the aforementioned matrix analysis. This would include surveys of sites currently not accessible due to property ownership issues. Following these surveys, if significant changes were to occur to parameters of the risk matrix for a crossing, changes would be made to risk level and appropriate final methods of crossing and BMPs made at each stream crossing. Following the final surveys, special additional BMPs, as described in GeoEngineers (2017d and 2018a), would be implemented depending on individual site conditions and may include such actions as changes in bank material and bank angle modifications, specific substrate composition used, plants used on the bank, artificial stabilizing bank material, rootwad enhancement, type of bed and bank restoration structure and various other actions. As described in section 4.3, additional specific post-construction monitoring at various intervals over a 10-year period would occur and corrective actions taken if bank or bed issues are encountered. Additionally, as discussed below, Pacific Connector would supplement lost existing LWD and sources of local LWD in nearly all streams to various degrees, which should help stabilize bed, bank and habitat conditions. These actions are expected to reduce the chance of modification of stream habitat from erosion to occur from the result of the crossing actions to be unsubstantial in most areas.

<u>Construction of New TARs, New PARs, EARs, and TEWAs</u>

Construction of all of these facilities has the potential to contribute sediment to streams occupied by fish and influence benthic food organisms as discussed above concerning the effect of added sediment to streams. Section 4.3 addresses the sediment runoff that would occur from numerous TARs, PARs, EARs, and TEWAs that would be constructed or rebuilt along the route.

Within the range of coho salmon along the route, two new road crossings (PARs) would be built, and seven existing road crossing on EARs would also be improved. Road crossings are areas of potentially the highest relative contribution of sediment to streams. An additional five new roads (PARs and TARs) and an additional 15 EAR segments have the potential to contribute sediment to streams because they are within 200 feet of streams in this area. Sediment contribution to streams is affected by many factors (cover, slope, substrate) but typically decreases exponentially in distance from the road to the stream. Most potential sediment runoff to a stream channel from roads would occur within 100 feet of a stream, but some sediment, about 10 percent, can be contributed from roads between 100 and 200 feet, with contribution beyond 200 feet considered to be non-existent (Dube et al. 2004). Most road segments outside of this distance would have minimal potential for sediment delivery to streams. TEWAs near streams are common along the route. While some additional roads would be built or modified in other Project areas, these areas have limited fish streams along the route, and some additional sediment from these roads would have limited potential to affect fish or their habitat.

As discussed in section 4.3, multiple actions would be implemented to reduce potential sediment quantity entering fish streams. These would include such actions as graveling new road surfaces, restoring all TARs to preconstruction conditions, following land-managing agencies' engineering design and road management standards, and installing BMPs according to the ECRP for all related construction actions, which may include silt fence/straw bales, sediment barriers, temporary slope breakers, or prefabricated construction mats to prevent rutting/compaction.

While some additional sediment to streams may occur, implementation of the *Transportation Management Plan*, ECRP, BMPs, and maintenance procedures would minimize the amount of sediment entering streams, especially fish-bearing streams, reducing the potential for adverse effects on fish and their habitat from sediment runoff.

Crossing Unstable Slopes

Slope failure near the waterbody during pipeline operation could result in soil and sedimentation falling into the waterbody. Pacific Connector evaluated all likely unstable areas during selection of the proposed pipeline route and moved the route as necessary to areas considered to have low risk. Field reconnaissance to assess potential risk based on initial assessment of moderate or high risk was done along the proposed pipeline route, and the final assessment determined only two crossings, located near Steinnon Creek between MPs 24BR and 25BR, were considered to have moderate risk along the pipeline crossing area. The risks to the pipeline at these sites were not considered hazardous enough to require additional rerouting or mitigation. The final assessment considered protective measures that would be adequate to reduce this risk. The known landslide risk areas have thus been all but eliminated from the route (see section 4.1).

Resuspension of Potentially Contaminated Sediments

Elevated heavy metals in water and sediment can have adverse effects on aquatic organisms. Fish and other aquatic organisms are sensitive to mercury levels even at very low concentrations. Because of concerns about hazardous waste from historic mining activities near the crossing of the East Fork Cow Creek (approximately MPs 109 to 110), Pacific Connector evaluated the currently proposed route in the area for mercury-contaminated soils and stream sediment. Examination of the underlying rock type (volcanic) of the proposed route indicates it is unlikely to contain elevated mercury in the bedrock (GeoEngineers 2009a). Broeker (2010) examined this route and sampled soil and stream samples near the proposed stream crossings. Of the three crossing measurements, one value (0.29 milligram per kilogram [mg/kg]) exceeded the ODEQ Level II screening value for freshwater (0.2 mg/kg). The other two were less than the freshwater value but two of the three were equal to or exceeded the bioaccumulation value of 0.07 mg/kg. The six soils samples were considered low in mercury, although they were slightly higher than the ambient background levels. Two intermittent stream channels occur up slope in this region that theoretically could carry sediment and related mercury downslope. However, Broeker (2010) concluded that these intermittent streams would stop on upslope benches and not reach the stream. He concluded upslope delivery to streams was not likely unless erosion was not controlled. Special erosion control provisions, in addition to what usually are implemented, were agreed to by Pacific Connector for this region to reduce possibly elevated mercury levels reaching the stream (Pacific Connector 2013).

Additionally, while levels of mercury in the East Fork Cow Creek are sometimes over ODEQ Level II screening levels, little sediment would be disturbed or suspended from the crossing activity since the crossing would be done in the dry. The pipeline route had been moved about 2,500 feet to avoid areas where elevated mercury levels were measured, so soil is unlikely to have concentrations of naturally occurring mercury exceeding those measured. With adjacent upland disturbance following the standard ECRP and supplemental erosion control actions, additional site-specific ground cover actions would be taken at this crossing, and upslope potential sediment entry into the stream would be controlled and minimized. Overall, adverse effects on fish from mercury would not occur from Pacific Connector Pipeline Project actions.

Vegetation and Habitat Removal and Modification

Sections 4.4 and 4.5.1 list the acres of riparian habitat that would be directly affected by all construction-related activities. Much of this habitat is in forested areas, where stream shading and organic input are most prominent. The analyses conducted for considering effects on riparian vegetation present within a one site-potential tree height buffer on either side of a waterbody on both federal and non-federal lands. This area is within one site potential tree height of the stream, the area near streams with the greatest potential effects on stream. Federal lands have additional areas called Riparian Reserves, which are different than the riparian areas shown here. The analyses here do not consider effects on Riparian Reserves because those effects would be limited to certain federal lands; the analyses provided below consider effects on all lands, hence the analysis of effects on Riparian Zones rather than to Riparian Reserves. Table 4.5.2.3-5 lists riparian areas disturbed by construction and the 30-foot-wide maintenance corridor adjacent to perennial and intermittent waterbodies crossed by the pipeline. Tables listing these cleared areas by watershed are presented in appendix I, tables I-8 and I-9. Removal or alterations in other habitats (e.g., clearcut/regenerating forest, shrub and grasslands, and wetlands) would also contribute to effects on aquatic resources, but to a lesser degree because riparian influence (e.g., shade, organic input, sediment and nutrient filtration) on stream conditions would be less.

a/ Project components considered in calculation of habitat "Removed:" Pipeline project construction right-of-way, temporary extra work areas, aboveground facilities, and permanent and temporary access roads (PAR, TAR).

b/ Habitat Types within Riparian Zones generally categorized as: Late Successional (Mature) or Old Growth Forest (coniferous, deciduous, mixed ≥80 years old); Mid-Seral Forests (coniferous, deciduous, mixed ≥40 but ≤80 years old); Regenerating Forest (coniferous, deciduous, mixed ≥5 but ≤40 years old); Clearcut Forests; Forested and Nonforested Wetland, Unaltered Nonforested Habitat (grasslands, sagebrush, shrublands), Agriculture and Altered Habitats (urban, industrial, residential, roads, utility corridors, quarries).

Effects on waterbodies and resident and anadromous fish due to removal of riparian vegetation and maintenance within the construction and operation corridor adjacent to but not crossed by the pipeline Project would be similar to effects on riparian vegetation for streams crossed by the pipeline:

- loss of riparian vegetation along the banks, reducing shade and potentially increasing water temperatures;
- decreased LWD recruitment in streams and on adjacent uplands, although current conditions of LWD in fifth-field watersheds crossed by the pipeline project are generally undesirable;
- removal of an important source of terrestrial food for aquatic organisms; and
- potentially increase in mass slope failures and/or erosion due to surface runoff adjacent to waterbodies that could increase sediment in the waterbody.

Pacific Connector would minimize effects on riparian vegetation by narrowing the width of its standard construction right-of-way at waterbody crossings, and by maintaining a setback between waterbody banks and TEWAs in forested areas. A riparian strip at least 25 feet wide on private lands, including widths ranging from 50 to 100 feet on fish-bearing streams as designated for Oregon State Riparian Management Areas, and 100 feet wide on federally managed lands, as measured from the edge of the waterbody, would be permanently revegetated. Pacific Connector would plant native tree and shrub species along all fish-bearing streams. Within a 30-foot-wide corridor centered on the pipeline, plants would be kept less than 15 feet high. Overall, about 84 acres (23 percent) of former riparian habitat cleared by pipeline construction would be maintained long term in an herbaceous state. The management of vegetation including the riparian areas is presented in detail in section 4.4. Restricting the low-growth vegetation area to a small portion of the total right-of-way clearing would allow much of the ecological function of the riparian conditions relative to fish needs (e.g., shade, future LW, and organic input) to more quickly return. This would limit the overall long-term effects of loss of riparian habitat to a small portion of each stream crossed, reducing future negative effects on fish resources. This would limit the overall long-term impacts of loss of riparian habitat, primarily as a result of LWD reduction, to a small portion of each stream crossed, reducing future negative effects on aquatic resources.

Water Temperature

The effects of water temperature on salmonid life stages have been extensively reviewed by McCullough (1999) and others. Maximum water temperatures ranging from 71.6 to 75.2°F (22 to 24°C) limit distribution of many salmonid species. For spring Chinook salmon, for example, the optimum temperature for growth is 60.1°F (15.6°C) and higher temperatures during summer could reduce growth and lead to increased mortality rates (McCullough 1999). Vegetative cover that provides shade, especially during summer, is one factor that regulates water temperature (WDNR 1997). If sufficient loss of shade occurs, temperatures in streams are known to increase. Increasing stream temperatures can result in reduced fish production and spawning success, and, if high enough, reduced fish survival also, especially for important northwest salmon and trout species found in many Project streams. The current Oregon state water quality temperature standards, which are addressed in section 4.3 of this EIS, include provisions to limit anthropogenic increases in stream temperature especially in salmon- and trout-bearing streams. Construction of the pipeline across waterbodies would necessitate removal of trees and riparian shrubs at the crossing locations that, if extensive enough along any single waterbody, may influence these stream temperatures. Pacific Connector has proposed to mitigate potential temperature increases on waterbodies through riparian plantings. This would include, as mitigation for loss of riparian shade vegetation, replanting the equivalent of 1:1 ratio for construction or 2:1 for permanent riparian vegetation loss with the goal to restore shade along the affected or nearby stream channels in the same watershed (GeoEngineers 2017f). Plantings would incorporate recommendations by the Forest Service and BLM for their lands in Riparian Reserve areas. The lengths of planting areas on streambanks would be determined prior to construction. Plantings are preferred to be continuous and not small parcels. Final plant species and spacing would follow those in the ECRP, which includes specific recommendations by the Forest Service and BLM, unless differently recommended by the landowner.

Temperature modeling was done by the BLM and Forest Service for some of the streams that would be crossed (NSR 2015a, 2015b, 2015c). During the low-flow conditions of 2013, modeled 7-day maximum stream temperatures just below in the three East Fork Cow Creek crossings showed potential increases of 1.0°F to 5.1°F (NSR 2015b). Wetted width on these channels was less than 5 feet, with the smallest channel and lowest flow having the highest temperature increase. The model also tended to overestimate the known temperature, so the results may be elevated, and the 2015 analysis of this creek showed larger temperature increases than those reported in NSR (2009) of similar locations primarily due to much lower flows during 2013. Again, these were very small streams (0.02 to 0.12 cubic foot per second) that also had a natural downstream decrease in temperature below the modeled areas likely from natural groundwater inflow. Steinnon Creek, a small 6-foot-wide stream, was also modeled to have a 7-day maximum stream temperature increase of 0.4°F assuming right-of-way clearing results in zero percent shade, also under the low flow conditions (0.22 cubic foot per second) of summer 2015 (NSR 2015c). Two other modeled creeks (Middle Creek and Big Creek tributary) had estimated increases of 0.1 and 1.1°F in 7-day maximum stream temperature (NSR 2015b). As with other streams, size affected relative change with Middle Creek having a flow of 1.62 cubic feet per second (12 feet wide) and Big Creek tributary 0.08 cubic feet per second (5 feet wide).

The results of the stream temperature model discussed above are likely conservative estimates based on other literature studies and modeling estimates. For example, Pacific Connector modeled 15 streams along the route (GeoEngineers 2017f), where the average temperature increase was modeled at 0.03°F, and the maximum increase among the streams was 0.3°F, with the highest value occurring at one of the smallest streams (table 4.3.2.2-9).

Other studies have noted lower temperature results in similar conditions as well. Two eastern U.S. studies looking at effects of right-of-way clearing in forested areas on stream temperature found no noticeable changes (Brown et al. 2002; Blais and Simpson 1997). More locally (i.e., in the north Oregon Cascades) a study of existing transmission line clearing found no significant downstream temperature changes from the clearings (Tetra Tech 2013). Modeled worst-case temperature conditions changes for this study estimated about 1.1°F (median of about 0.4°F) in the modeled maximum and maximum daily mean temperature across the assumed future clearing of the modeled 22 streams, for an estimated 150-foot-wide clearing (Tetra Tech 2013). The right-of-way width for these studies' crossings was much larger than what is proposed for the Pacific Connector Pipeline Project (i.e., 150 feet wide). Based on the literature studies noted above and project-specific models, estimated stream temperature changes that would result from right-of-way clearing are expected to be minor (see sections of 4.3.2.2 and 4.3.4.2).

These results demonstrate the effects that low-flow conditions, most common in very small channels, have on changes in water temperatures; as noted by Brown and Kygier (1970), given the same solar input, stream temperature is inversely proportional to flow. Observations of these streams also suggest that LWD and low-growing willows, huckleberries, and other brush species can provide effective shade for small, narrow channels. Blann et al. (2002) noted that riparian grasses and forbs supply as much shade as wooded buffers for streams less than 8 feet (2.5 meters) wide. In many cases after completion of pipeline crossing construction, low-growing grasses and brush within and outside of the immediate crossing construction area could minimize shade loss, resulting in lower temperature increases than modeled under zero percent shade.

Models addressing the temperature effect of adding shade from riparian revegetation plantings and other actions is that water temperature would be comparable to the existing condition and remain below ODEQ thresholds on the East Fork Cow Creek. Additionally, any temperature increases in small streams would likely be masked by the assimilative capacity of larger streams at the stream network scale (NSR 2009, 2014) (see section 4.3.2.2).

Over the whole pipeline project region, plantings and regrowth in riparian areas, as suggested by these modeling results, would help moderate potential temperature increases in the short term (a few years). Much of the riparian area would be allowed to regrow from plantings with herbaceous plants (only 10 feet wide would be maintained without some growth) and conifer and other trees (all but 30-foot width). On small streams and, to a lesser extent on larger streams, even 10- to 15-foot-high trees would supply substantial shade, reducing solar heating effects on streams. Additionally, many small streams have intermittent flow (about 80 percent of stream crossings are intermittent) and most would not have flow during periods of greatest temperature, with few of these having fish populations. Thus, the slight effects of solar heating from clearing would gradually be reduced or eliminated over time, based on the model, most between 5 and 10 years, with most areas of potentially higher increases absent flow or fish populations.

As discussed in section 4.3.2.2, potential cumulative watershed temperature increases from Project riparian clearing would be unlikely. GeoEngineers (2017f) provided an estimate the likely relative change in cumulative watershed heat input to streams from Project clearing at stream crossings. While actual total watershed stream temperature changes were not predicted, a relative measure can be approximated through an estimate of increased heat budget from clearing. In the example they provided for the South Umpqua subbasin, the thermal load from the Project due to initial construction clearing in these watersheds was about 16.5 million kcal/day, or about 0.032 percent. The relative unmitigated (i.e., no supplemental riparian plantings) change in heat load to these watershed streams relative to existing uncleared conditions would be an increase of only 0.004 percent once vegetation grows back outside of the 30-foot permanently maintained right-of-way clearing. The regrowth to achieve these levels would be expected to occur within 10 years in the Coos and Coquille subbasins and 20 years in others along the route. Considering the very small portion of total watershed riparian stream cover removed and low estimates of thermal increase, streamside clearing would not result in any measurable cumulative watershed-level changes in water temperature.

Based on available information, we conclude that any changes in water temperature, related to 75- to 95-foot-wide right-of-way vegetation clearing at waterbody crossings, are likely to be very small and undetectable through measurements, except for possibly the very smallest perennial streams and occasional intermittent flowing streams that may have flow during a hot period. Small streams with the greatest potential for measurable temperature increase also often contain limited numbers of fish because small headwater streams are often not fish-bearing or, if fish are present, their small size and often high gradient limit the stream's suitability as fish habitat. Any temperature changes that may occur would gradually be reduced or eliminated over time as most riparian vegetation, from plantings, natural vegetation growth, and size increases would increase stream shading.

Large Woody Debris

One effect on fisheries that would result from forest clearing at pipeline crossings and construction of the pipeline right-of-way within the riparian zone adjacent to but not crossing streams, TEWAS, and PARs, and TARs is the reduction of LWD in streams and on adjacent uplands (Harmon et al. 1986; Sedell et al. 1988). Large logs provide in-stream channel structures (i.e., pools and riffles), which are critical to salmon spawning and rearing. As the size of individual logs or accumulations of logs increases, the size and stability of pools that are created also increase (Beschta 1983). Riparian forests that undergo harvesting of large trees take on secondary-growth characteristics and contribute lower quantities of large wood than unmanaged, old-growth forests (Bisson et al. 1987). However, sufficiently wide, carefully managed riparian buffers that retain a full complement of ages, sizes, and species of native trees and vegetation can ensure adequate recruitment of LWD to streams (Bisson et al. 1987; Murphy and Koski 1989; Morman 1993).

Pacific Connector has proposed to mitigate for effects on waterbodies by installing LWD at agency- and landowner-approved and appropriate areas within the construction right-of-way across certain waterbodies. The use of LWD as a mitigation measure for effects associated with in-stream construction has been documented as an effective means of creating in-stream habitat heterogeneity, reducing streambank erosion, reducing sediment mobilization (Bethel and Neal 2003), and enhancing local fish abundance (Scarborough and Robertson 2002). Placement of LWD on the streambanks and in the streams, can provide slight shade and increase bank stability, while vegetation is maturing following construction. Additionally, placement of LWD in streams or keyed into streambanks can provide habitat for benthic invertebrates and important food source for salmonids, and increase habitat for forage species with the creation of pools and enhancement of the salmonid rearing potential of an area (Cederholm et al. 1997; Slaney et al. 1997).

To mitigate for short-term losses of LWD from riparian clearing and in-stream removal of wood during construction, Pacific Connector has developed a *Large Woody Debris Plan* which includes a proposal to install 733 pieces of LWD over several fifth-field watersheds along the pipeline route where the two ESA-listed coho salmon ESUs are present. Sizes would be based on those recommended by the current ODF and ODFW (1995) protocol for piece size by streambank full width category. The plan includes placing from one to four pieces of LWD per stream crossed in the stream or on the bank, depending on forest conditions, stream flow, and landowner approval. This number of pieces, if no other LWD were present in the stream reach affected by clearing, would be near the range of what is considered "desirable" by ODFW (Foster et al. 2001) for forested streams. Foster et al. (2001) noted that more than 20 LWD pieces/100 meters of stream length (i.e., 4.6 pieces/75 feet of right-of-way clearing) with more than 3 "key" pieces/100 meters (i.e., 0.7 "key" pieces/75 feet right-of-way clearing) is considered "desirable" in forested streams in Oregon. Bilby and Ward (1991) found LWD density in old-growth forest streams in southeast Washington to have a similar range. Based on their LWD regression model estimates using channel width,[126] LWD values in old-growth forest would be expected to range from about 1 to 7 pieces per 75 feet of stream channel length for streams ranging from about 50 to 10 feet wide. The sizes of LWD pieces to be installed are based on ODF and ODFW (1995) guidelines for sizes of LWD pieces to be present in streams to meet habitat needs for specific stream sizes and number of streams crossed. These final numbers would be developed as part of Pacific Connector's Mitigation Plan, which may have some modification prior to construction. Some long-term loss of local stream habitat would remain even with the LWD mitigation due to reduced future sources of LWD from the right-of-way.

Specific streams for LWD installation have been identified by Pacific Connector; however, the specific locations within the streams would be determined through discussion with ODFW, NMFS, and other agencies as appropriate, and in consideration of the BMPs outlined in the *Stream Crossing Risk Analysis Addendum* (GeoEngineers 2018a). The size of LWD installed would follow ODF and ODFW (1995) suggested guidelines for size of LWD based on stream size. Depending on private landholder approval, some pieces may be installed at various times and locations, but in general, LWD would be placed at waterbody crossings during the last phases of pipeline construction and right-of-way restoration. Pacific Connector has proposed that, if for some reason not all pieces proposed are installed, they would be donated to local water conservation groups for installation locally.

Long-term losses of LWD input would largely be mitigated through riparian replanting of conifers in the right-of-way, although some limited long-term reduction would remain from the absence of trees in the 30-foot-wide maintenance corridor and relatively smaller sizes of regrown trees in the remaining 45 to 65 feet of the right-of-way.

The NMFS, upon review of this proposed LWD plan, determined that the applicant's proposed number of LWD pieces, location, and methods of their proposed installation is not adequate to meet the loss of supply of LWD from riparian forest habitat related to right-of-way riparian clearing. However, we conclude that the proposed plan is consistent with ODF and ODFW protocols. Further, we note that the contribution of LWD to a stream from the 75- to 100-foot area cleared on both sides of a stream for construction represents an insignificant source for any stream other than extremely short headwater reaches.

<u>Fish Passage</u>

Waterbody crossings using the dry crossing methods, either flume or dam–and-pump, may result in some fish being trapped in streams. Flumes and dams would be completely installed and functioning before any in-stream trenching disturbance occurs. Up to about 250 stream crossings would be dry open cut, although most of these would be dry during crossing as they are intermittent streams (tables 4.5.2.3-1 and 4.5.2.3-2). Construction across a waterbody would take up to 4 days using dry open-cut methods, but less for small and intermediate streams. At one crossing of the South Umpqua River, a diverted open-cut crossing (only crossing of this type) would be used. This is similar to a dry open cut in that all in channel construction would be done in the "dry" but would require diversion of the flow to one side of the channel at a time. This method could take

[126] Model: Log10 frequency of LWD = -1.12 log10 of Channel Width (m) +0.46

about 14 days to complete. Because one channel would be open during the entire crossing, no passage of fish would be impeded, and no fish removal would be required.

For typical crossings, once streamflow is diverted through the flume pipe, but before pipeline trenching begins, fish trapped in any water remaining in the work area between the dams would be removed and released using the methods in Pacific Connector's *Fish Salvage Plan*.[127] Pacific Connector would use seining[128] as the primary method to salvage fish but would also use electrofishing if all fish cannot be removed by seining. All methods of capture and holding have risks of stress, injury, or mortality of fish and fish inadvertently left in the construction crossing area may die.

Tribal governments have expressed concern that the currently proposed fish salvage methods would not adequately capture and protect lamprey, which is an important resource to tribal communities (see section 4.11). Adult Pacific lamprey are expected to be captured during the proposed salvaging; however, the currently proposed salvage methods (which were developed primarily for salmonids) may not be effective for salvaging lamprey ammocete larvae, which may remain in dewatered sediments. Electrofishing procedures to sample Pacific lamprey larvae have been recommended by the FWS (see Appendix A in FWS 2010a) and the Coquille Tribe has indicated that they can provide Pacific Connector with additional measures that would be effective at salvaging lamprey. Pacific Connector has indicated that it would contract with either the ODFW or a qualified consultant to salvage fish; however, because the salvage methods currently proposed may not be effective at collecting all lamprey life stages, **we recommend that:**

- **<u>Prior to construction</u>, Pacific Connector should file with the Secretary, for review and written approval by the Director of OEP, its final *Fish Salvage Plan*, that addresses methods suitable to collect and salvage all lamprey life stages, to the extent practical, together with documentation that the final *Fish Salvage Plan* was developed in consultations with interested Tribes, ODFW, FWS and NMFS. The revised *Fish Salvage Plan* should also incorporate the applicable measures of the Handling Guidelines for Klamath Basin Suckers.**

Because the flume would maintain streamflow, some fish may move upstream through the flume. With the dam-and-pump method, the fish would not be able to move upstream or downstream through the work area until the dams have been removed. Flumes and dams would be removed as soon as possible following backfilling of the trench. Based on information from average stream crossing times (Reid et al. 2004) estimated durations when complete or partial blockage may occur for fluming would range from 36 to 92 hours, and for dam-and-pump, the range is from 20 to 56 hours.

<u>Aquatic Nuisance Species</u>

Currently, there are 180 reported NAS in Oregon, of which 134 are documented in the USGS hydrologic basins crossed by the Pacific Connector pipeline (USGS 2005). Some of the major potential aquatic invasive species are mussels, including the zebra and quagga mussels (*Dreissena polymorpha*, and *Dreissena rostriformis bugenisis*), and New Zealand mud snail (*Potamopyrgus antipodarumis*) as well as Cyanobacteria (blue-green algae), and freshwater mold (Saprolegnia). Invasive species can have multiple adverse effects when introduced to their non-native

[127] See Appendix F.3 of RR3 , which was included in Pacific Connector's application to the FERC.
[128] A fine meshed net pulled through the water to capture fish.

environment. The most common effect is competition with native species for habitat and resources, often with the reduction or elimination of the native species. They also may cause effects on human uses of the water. For example, zebra mussels have been found to multiply to such vast numbers that they effectively block water intakes, such as drinking water supplies. Additionally, invasive species may crossbreed with native stocks of organisms indirectly causing the reduction of viable native pure species. Some invasives may directly kill other native species that have no natural defenses against them. Pacific Connector's *Hydrostatic Test Plan*[129] includes measures that would prevent the spread of invasive species from one water basin to another. These plans would also be used for equipment used between waterbodies.

The procedures are outlined in Attachment C to the *Hydrostatic Test Plan*. Additional supplemental invasive species protective actions for cleaning of equipment used among water bodies was developed by ODFW specifically for this project and have been incorporated by Pacific Connector in their *Hydrostatic Test Plan*. Some items in the *Hydrostatic Test Plan* that would aid in ensuring invasive aquatic species are not transported between streams, including preventing the spread of quagga and zebra mussels, New Zealand mudsnail, and aquatic plant invasion, are:

- Clean all aquatic plants, animals, and mud from vehicles, boats, motors or trailers and discarding the debris in the trash. Rinsing, scrubbing, or pressure washing should occur away from storm drains, ditches, or waterways.
- Drain live wells, bilge, and all internal compartments.
- Dry equipment including boats between uses, if possible (leaving compartments open and sponging out standing water).
- Scrub or pressure wash life jackets, waders, boats, landing nets, and other gear that comes in contact with the water.
- Clean and sanitize as needed which may include heated power wash before moving establishing sanitizing areas away from areas where it may enter surface water including use of bleach solution and run through portable pumps for 10 minutes
- Inspect everything for signs of aquatic invasive species before launching and before leaving.

Blasting

Blasting in stream channels can have adverse effects on fish, especially for fish with swim bladders. Explosives detonated near water produces shock waves that can be lethal to fish, eggs, and larvae by rupturing swim bladders and addling egg sacs (British Columbia Ministry of Transportation 2000). Explosives detonated underground produce two modes of seismic wave (Alaska Department of Fish and Game 1991). Shock waves propagated from ground to water are less lethal to fish than those in-water explosions since some energy is reflected or lost at the ground-water interface (Alaska Department of Fish and Game 1991). Peak overpressures as low as 7.2 pounds per square inch (psi) produced by blasting on a gravel/boulder beach caused 40 percent mortality in coho smolts and other studies revealed 50 percent mortality in smolts with peak overpressures ranging from 19.3 to 21.0 psi (Alaska Department of Fish and Game 1991).

The best way to reduce or eliminate effects on fish is to keep fish out of regions where pressure waves are harmful. The Alaska Department of Fish and Game (1991) reported that a pressure change

[129] See Appendix V.2 of Resource Report 3, which was included in Pacific Connector's application to the FERC.

of 2.7 psi is the level for which no fish mortality occurs and is from 1.7 to 4.5 psi below any level where mortality would be expected. Based on normal charges used in trenching (about 1 to 2 pounds at 8-millisecond delay) the zone of the above pressure wave would extend 34 to 49 feet, depending on substrate near the charge (Alaska Department of Fish and Game 1991). Typically, the dry area (where fish could not be) would be at least 25 feet wide during construction. If blasting were to occur with only a 25-foot-wide dry working space buffer between the blast and the stream, the potentially hazardous pressure wave (i.e., greater than 2.7 psi) would extend no more than an additional 25 feet. Likely, the effects would be felt over a much smaller distance as this distance estimate is based on a very conductive energy transfer substrate, which is unlikely to occur at most crossings. Pacific Connector developed a *Blasting Plan* that outlined measures to reduce effects on resources. Prior to any blasting, proper permits would be obtained and agencies notified as required by permits. Blasting may occur in uplands adjacent to streams or in dry streambeds, and Pacific Connector does not anticipate conducting any in-water blasting. Pacific Connector would attempt to minimize shock waves from blasting that may affect aquatic resources by the types of explosives selected, the size of charges, and the sequences of firing. Currently, about 37 crossings have known bedrock, some of which may require blasting (table 4.5.2.3-2). Fish would be removed from the crossing area, in accordance with Pacific Connector's *Fish Salvage Plan*. Where blasting would occur near a crossing, fish would be excluded an additional 25 feet upstream and downstream from the crossing area by use of barrier nets. In addition, bubble/air curtains may be used to disrupt shock waves, depending on input from state agencies during the state permitting process.

Hydrostatic Testing

After the pipeline is installed, Pacific Connector would fill it with water under pressure to test it (see section 2.4.2.1). Total water used for hydrostatic testing would be about 64 million gallons. Pacific Connector would obtain its hydrostatic test water from commercial or municipal sources or surface water rights owners to lakes, impoundments, and streams from possibly 17 different locations. About half of the water would be from impoundments or lakes, and the rest may come from up to nine streams, including Coos River, East and Middle Fork Coquille Rivers, Olalla Creek, South Umpqua River, Rogue River, Lost River, and Klamath River. Pacific Connector estimates it would withdraw just over 39 million gallons from 12 source locations within six construction spreads along the length of the pipeline route. Pacific Connector would obtain all necessary appropriations and withdrawal permits, including from the OWRD, prior to use. All the streams identified as potential test water sources include anadromous salmonids or resident trout. About 3,084 potential discharge locations for the test water have been identified. During the test, it may be necessary to discharge water at each of the sites; however, discharges would be minimized and water would be conserved as much as practical by cascading water between test sections when feasible (pumping from one segment to the next).

Potential effects on aquatic resources associated with hydrostatic testing include entrainment of organisms including fish, reduced downstream flows, erosion and scouring at release points, and the transfer of aquatic nuisance species through the test water from one water basin to another. Estimates of potential water intake amounts from streams indicate flows below intake would be reduced by less than 10 percent of instantaneous flow based on typical monthly flows (cfs) during the month of withdrawal for all but one potential locations, where it would about 35 percent during withdrawal (duration about 6 to 11 days at each potential location) (Ambrose 2018; table 4.5.2.3-6). Final selection of intake rates and sites would be reviewed by ODFW and OWRD prior to testing, so that potential effects on fish habitat from flow reductions would be unlikely. Pacific Connector has developed a *Hydrostatic Test Plan* to minimize effects from hydrostatic testing on resources. This plan is discussed in more detail in section 4.3.2.2 of this EIS.

Source: Table 1 in Attachment F, Hydrostatic Test Water Withdrawal Hydrologic Assessment, to Pacific Connector's updated *Hydrostatic Test Plan* submitted to the FERC November 8, 2018.

To prevent the entrainment of most aquatic species, the pumps and intake hoses for hydrostatic test water removal would be screened, in accordance with NMFS screening criteria. To ensure water withdrawal does not cause downstream water level issues (ramping rate), Pacific Connector would submit their withdrawal plans to ODFW for review prior hydrostatic testing. To prevent the transfer of organisms from one water basin to another, Pacific Connector would try to return hydrostatic test water to its basin of origin. However, given the linear nature of the pipeline and the need to cascade test water from one section to another, such a return may not always be possible. Therefore, Pacific Connector would treat the test water after withdrawal (most likely with chlorine) to prevent the spread of invasive species and pathogens. To prevent erosion or scour at discharge locations, the hydrostatic test water would be discharged at low head into energy dissipating devices and dewatering structures in uplands at least 150 feet from streams. Volume and flow rates would be controlled to prevent overland flows directly to waterbodies. Specific hydrostatic discharge sites have been reviewed and approved by BLM and Forest Service on their lands to minimize runoff and avoid effects on beneficial uses.

The hydrostatic testing would remove water from several different waterbodies along the pipeline route. The NMFS has indicated that to insure fish and aquatic habitats are adequately protected during these withdrawals that no more than 10 percent of existing flow at the time of withdrawal be removed during hydrostatic testing. Therefore, **we recommend that**:

- **<u>Prior to construction</u>, Pacific Connector should file with the Secretary, for review and written approval by the Director of OEP, a revised *Hydrostatic Test Plan* that requires that any water withdrawal from a flowing stream does not exceed an instantaneous flow reduction of more than 10 percent of stream flow.**

<u>Hyporheic Exchange</u>

Mixing of shallow groundwater and surface water in streams is a form of hyporheic exchange and can affect important physical factors such as temperature, dissolved oxygen, and chemical composition of streams that may influence aquatic habitat. As discussed in section 4.3, an assessment was made of likely crossing areas that may affect this exchange rate (GeoEngineers 2017g) and actions taken to reduce potential effects of these crossings. Fifteen stream crossings were categorized as having a "high" sensitivity, which would suggest a high likelihood of a functioning hyporheic zone, mostly associated with larger waterbodies with greater floodplain widths and instream morphologic features. As discussed in section 4.3, however, there are several site-specific crossing construction plans and BMPs in place to help reduce the chance of there being functional effects on this exchange, such as returning natural material to trenched areas and installing trench plugs adjacent to wetlands and waterbodies, all of which would help return natural hyporheic exchange rates after construction is complete. It is anticipated that substantial alterations in these water exchanges would not occur and not affect aquatic habitat in streams crossed.

<u>Fuel and Chemical Spills</u>

For any large construction project, there is the potential for spills of fuel or other hazardous liquids from storage containers, equipment working in or near streams, and fuel transfers. Any spill of fuel or other hazardous liquid that reaches a waterbody would be detrimental to water quality. The chemicals released during spills could have acute, direct effects on fish, or could have indirect effects such as altered behavior, changes in physiological processes, or changes in food sources. Fish could also be killed if a large volume of hazardous liquid is spilled into a waterbody. Ingestion of large numbers of contaminated fish could affect primary and secondary fish predators in the food chain.

To minimize the potential for spills, Pacific Connector has developed an SPCC Plan. Pacific Connector's implementation of this SPCC Plan would minimize the potential for and the effect of any spill near surface waters. The SPCC Plan would be updated with site-specific information prior to construction. Specific measures in this plan include prohibiting liquid transfer, vehicle and equipment washing, and refueling within 100 feet of waterbodies and specific steps to be followed to control, contain, and clean up any spill that occurs. The SPCC Plan is further described in section 4.3.2.2. Pacific Connector's implementation of this SPCC Plan would minimize the potential for and the effect of any spill near surface water on aquatic resources.

Benthic and Sessile Organisms

Benthic and sessile organisms including benthic invertebrates and freshwater mussels would be affected by most of the same factors noted primarily for fish discussed above. This would include effects from elevated turbidity and suspended sediments, release of drilling muds, herbicide application, blasting, fuel and chemical spills, and habitat modification. Mayflies, caddisflies, and stoneflies prefer large substrate particles in riffles and are adversely affected by fine sediment deposited in interparticle spaces (Cordone and Kelley 1961; Waters 1995; Harrison et al. 2007). Fish and benthic macroinvertebrate abundance downstream of pipeline construction sites have been reported short-term reductions following construction-generated suspended sediment (Reid and Anderson 1999). Reid et al. (2008) summarized the results of nine wet open-cut pipeline stream crossing studies and noted all measured effects on downstream stream invertebrate population abundance or diversity (six of nine studies) were less than a year in duration with three studies having no measured effects on invertebrate abundance. Since the proposed action does not include wet open cuts, effects on benthic invertebrates would be limited. Risk of adverse effect on relatively sessile species, such as mollusks, could extend downstream from construction sites if degradation of water quality affects downstream habitats. However, because they are relatively immobile, the trenched crossing would have the greatest effect and would directly kill many at the trenching site because most would be unable to actively move from the area. In the case of many aquatic invertebrates, including insect larvae, these areas would be rapidly (weeks/months) recolonized from upstream drift and new egg deposition from adults. In some cases, for longer-lived organism, such as mussels, recolonization would take longer as they are immobile and most take years to grow to full size. The largest effect on most benthic and sessile organisms would be directly at the crossing location and the effect would be short term. In the case of mussels, local affects may be long term. However, the overall area affected for any given stream would be small so adverse effects on local populations would be slight.

Effects on Aquatic Habitat and Aquatic Species from Operation of the Pacific Connector Gas Pipeline Project

Once installed, maintenance of the pipeline would include activities such as aerial inspections, gas flow monitoring, and visual inspection of surrounding vegetation for signs of leaks, and integrity management, which includes smart pigging[130] to investigate the interior surface of the pipe for any signs of stress cracking, pitting, and other anomalies. All the maintenance activities would be outlined in the *Operations and Maintenance Plan* that would be prepared according to operating

[130] A pig is a remotely operated pipe inspection and cleaning tool.

regulations in USDOT 49 CFR Subpart L, Part 192 and would be completed prior to going in-service. The *Stream Crossing Risk Analysis Addendum* (GeoEngineers 2018a) outlines the measures that will be contained in the final stream crossing monitoring plan. These general maintenance activities would require only surface activities and usage of the existing right-of-way, such as insertion of the pig at one of the pig launching facilities.

Potential estuarine or stream channel disturbance would occur if an integrity issue with the pipeline occurred. If this happened, the pipeline would likely be unearthed (except non-trenched crossings like HDD, which may be rebored) within the right-of-way and repair work done in-water. Within stream sites, repair work could require isolated flow from the section of pipe that is to be exposed. Typically, repairs would be made to the pipe within the right-of-way (within the trench) or, depending on the site-specific conditions and nature of the repair needed, a reroute around the affected section may be considered. Effects would be similar to those discussed above for initial installation except on a much smaller scale, because they would only involve one crossing compared to many streams and, in the case of the estuary, likely just a portion of whole route would be disturbed not the whole 0.7- or 1.6-mile HDD sections, or possibly just rebored without having to disturb the estuary bottom. However, should repairs be needed out of the standard stream crossing window (i.e., during periods of fish spawning or egg incubation) there would be additional adverse effects on key fish resources at the specific site. The actions would include similar BMPs and mitigation. Any future repairs would require additional permit approval from appropriate state and federal agencies, which would determine the acceptable parameters of these actions. Such pipeline integrity-based in-water projects are very infrequent.

Vegetation maintenance would be limited adjacent to waterbodies to allow a riparian strip to permanently revegetate with native plant species across the entire right-of-way. To facilitate periodic pipeline corrosion/leak surveys, a corridor centered on the pipeline and up to 10 feet wide would be maintained in an herbaceous state. In addition, trees that are within 15 feet of the pipeline and have roots that could compromise the integrity of the pipeline coating would be selectively cut and removed from the permanent right-of-way.

Herbicide Application

Pacific Connector would not use herbicides for routine vegetation maintenance; however, Pacific Connector would implement an *Integrated Pest Management Plan*[131] that addresses control of noxious weeds. The plan was developed in consultation with the ODA, BLM, and the Forest Service. The plan would include the selective use of herbicides where necessary to control noxious weeds by limited application from the ground, where allowed by landowners. Pacific Connector would only use agency-approved herbicides authorized in current planning documents to control noxious weeds where infestations occur in the right-of-way after construction and during operation. Herbicides would not be applied by aerial or broadcast spraying. Noxious weeds would be removed only by manual methods in the riparian zones, which is defined as one site potential tree height, and within federal lands Riparian Reserves that are defined as being greater than 150 feet in most areas along the route, and greater than 100 feet in other areas.

Herbicides can have toxic or other adverse effects on fish and other aquatic organisms. In general, most effects on aquatic systems occur from direct spray of herbicides, and possibly drift when herbicides are sprayed, and leaching through soils and groundwater (Tu et al. 2001). Pacific

[131] Appendix N of Pacific Connector's POD.

Connector would not directly spray, or otherwise apply, herbicides in waterbodies or in riparian zones. The risk of drift would be avoided by selectively applying herbicides from the ground. The five types of potential herbicides that could be used have various levels of toxicity to aquatic organisms. However, the restriction to selective applications outside of riparian zones would greatly reduce the potential of adverse effects on fish by keeping herbicides outside of riparian zones and preventing herbicides from reaching streams.

4.5.2.4 Environmental Consequences on Federal Lands

The Pacific Connector Pipeline Project would have some effect on 41 waterbodies and associated riparian areas in the approximately 77 miles of federal lands that would be crossed by the pipeline. The effects on federal lands in designated land use categories (e.g., Riparian Reserve, ACS, Key Watersheds) from the proposed action are addressed fully in section 4.7 and appendix F, and effects on special status species are discussed in section 4.6 and the BE (appendix F). Watersheds crossed on federal lands and characteristics of those watersheds are discussed in section 4.7 and appendix F. Aquatic species present on federal lands would be similar to those discussed in section 4.5.2.3, except no marine and estuarine fish and shellfish are present in the waterbodies crossed on federal lands. Aquatic species found on federal lands would be mostly the same as those on non-federal lands with freshwater habitat. Commercial and recreational fisheries of importance in waterbodies crossed include primarily anadromous salmon and steelhead and resident trout. Specials status species present in some stream segments crossed include federally listed Oregon coastal coho salmon and Southern Oregon/Northern California coastal coho salmon ESU. EFH habitat is also present along the route for coho and Chinook salmon stocks. Other state and federal fish species of special status are discussed in section 4.6. Aquatic habitats that would be affected by the pipeline on federal lands are primarily coldwater and anadromous streams, with a few warmwater ponds adjacent to the construction areas. Much of the stream riparian areas crossed on BLM and NFS lands is heavily forested and shaded by coniferous trees in the Coast Range and mixed conifer-hardwood forest in the Klamath Mountains.

a/ Known and assumed (value in parentheses) crossings by the pipeline with indicated fish category designation
b/ Trout
Note: Based on Pacific Connector's analysis, numbers may differ from federal agency analysis of streams, in some watersheds.

The general effects on aquatic resources, and mitigation for those effects, would be similar on federal lands to those discussed above in section 4.5.2.3 for the entire pipeline. Crossing techniques for most waterbodies would include dry-open cut methods. Thirteen perennial and 28 intermittent streams would be directly crossed by the pipeline construction on federal lands (table 4.5.2.4-1). Of these streams, 4 are known or assumed to contain anadromous fish, and 15 known or assumed to contain resident fish species. ESA species and EFH habitat for salmon may be present in up to 4 stream disturbance areas (table 4.5.2.4-1).

Riparian Reserve Areas

Riparian Reserve is a land use allocation specific to BLM and NFS lands. BLM and Forest Service management objectives include protection of aquatic resources and ESA-listed fish species in streams on both BLM RMP and Forest Service-managed lands. One difference between BLM and Forest Service management of these areas is the width of streamside riparian buffer. The details of these two plans are described in section 4.7 and appendix F. This allocation was developed in conjunction with the ACS (NFS) and Riparian Reserve that are incorporated into each of the BLM and Forest Service LMPs for management of areas associated with streams, lakes, and potentially unstable areas. The ACS was developed as part of the NWFP *Standards and Guidelines* to restore and maintain the ecological health of watersheds and aquatic ecosystems contained within NFS lands (Forest Service and BLM 1994b) for a variety of species. In 2016, the BLM signed a ROD that approved the Northwestern and Coastal Oregon RMP and the Southwestern Oregon RMP and adopted a similar strategy for riparian areas. The Forest Service system for managing primarily stream riparian areas includes components of the ACS are Riparian Reserves and Key Watersheds (see section 4.7 and appendix F). Riparian Reserves are intended to serve as corridors in the matrix and enable the Forest Service to manage these land allocations to maintain and restore riparian structures and functions of these unique and important features. The BLM also has Riparian Reserve under its current management plan. As described in section 4.7 and appendix F, Riparian Reserve has unique sets of guidance that are applicable wherever these occur, although these differ now between the two agency plans. The Forest Service ACS places an emphasis on efforts to maintain and restore aquatic and riparian habitat that is necessary to support anadromous salmonids. The nine objectives listed for the ACS include maintaining and restoring aquatic systems, floodplains, wetlands, upslope habitats, and riparian zones in general to support invertebrate and vertebrate species dependent on those habitats. The description of these nine objectives and how they would be maintained under the proposed actions is presented fully in section 4.7 and appendix F. The BLM's Riparian Reserve land use allocation has associated Management Direction and Management Objectives but does not include Key Watersheds.

The Pacific Connector pipeline would cross Riparian Reserve areas of both NFS and BLM lands along the route. Project effects on Riparian Reserve resulting from all construction activities (e.g., pipeline right-of-way, TEWAs, permanent and temporary access roads) are discussed in section 4.7 and appendix F.

Key Watersheds on NFS Lands

Key watersheds on NFS land, as designated by the NWFP (Forest Service and BLM 1994a), provide high water quality and are crucial to at-risk fish species and stocks. They are the highest priority for watershed restoration. Tier 1 Key Watersheds consist primarily of watersheds directly contributing to anadromous salmonid, bull trout, and resident fish species conservation. Tier 2 watersheds do not necessarily contain at-risk fish stocks but are important sources of high quality water (Forest Service and BLM 1994a). The Key Watersheds include three Tier 1 (Days Creek – South Umpqua River [formerly named South Umpqua River], North and South Forks Little Butte, Spencer Creek) and one Tier 2 (Clover Creek) watershed. Potential effects on these Key Watersheds and actions that would be taken by the Project to ensure Key Watershed functions are maintained are discussed in section 4.7 and appendix F.

Measures That Would Mitigate Effects on Aquatic Resources on Federal Lands

Pacific Connector would develop project design, construction, and operation measures to avoid or minimize effects on aquatic resources to the extent practicable. To compensate for unavoidable effects along streams from loss of upslope and riparian vegetation and LWD input that do not meet the objectives of the ACS, Pacific Connector has developed a *Large Woody Debris Plan* and supplemental riparian plantings efforts to help maintain the functions of the system after construction. Actions that would be taken on NFS lands to help meet ACS objectives on those lands are included in chapter 2. No similar actions have been developed in BLM plans. These additional actions and mitigation measures agreed to for NFS lands are summarized in table 2.1.5-1. The effects of implementation of these measures on meeting the ACS and Riparian Reserve management objectives and management direction are discussed in section 4.7 and appendix F.

To ensure that the Pacific Connector Pipeline Project is consistent with the objectives of the ACS on NFS lands, which would in turn aid fish populations on federal land, Pacific Connector would develop a variety of enhancements (at the direction of the Forest Service): (1) donate LWD to agencies/conservation groups to perform in-stream restoration projects; and/or (2) relocate large boulders greater than 24 inches in diameter for use as fish habitat structures. As part of Project development, the BLM and Forest Service have also developed site-specific stream crossing plans for perennial streams on their lands that include specific riparian plantings and other actions to aid at maintaining stream and riparian functions. To mitigate for Project actions that, even with site-specific actions, may impede maintaining ACS and Riparian Reserve management objectives and direction on each watershed (e.g., pipeline crossing LWD placement and riparian vegetation plantings), Pacific Connector would fund the following types of projects that would be implemented on Forest Service areas not directly affected by Project activity:

- add LWD to several miles of streams outside of the area that would be affected by the Project;
- restore degraded riparian habitats through off-site revegetation projects;
- conduct off-site fish passage projects at road crossings;
- improve stream road crossings and replace or stabilize culverts that may contribute sediment from fill failure to streams;
- conduct pre-commercial thinning projects where feasible to improve riparian habitats;
- install fences in allotments to improve riparian habitats;
- decommission roads and waterbody features (e.g., culverts, crossings, bridges) identified by the Forest Service that are no longer needed for resource management to provide numerous benefits including lower road density, minimization of channel extensions, minimization of sedimentation, improvement of fish passage through culvert removal, and reduction of riparian habitat fragmentation;
- close roads that are not in use, which would reduce sediment runoff to streams; and
- stormproof roads (such as adding water bars, ditch cleaning, culvert bypass) to also reduce fine sediment to streams and reduce the risk of road blow out, which could contribute heavy sediment loads to streams.

The list of mitigation measures noted above is not all that would be in place on NFS lands (see table 2.1.5-1) but identifies some of the major efforts that would be undertaken to reduce and mitigate impacts from the proposed action on aquatic resources. Following Project construction, habitat and ecosystem function would be restored in place as much as possible. However, although mitigation actions would restore habitat and have long-term benefits to wetlands, estuarine ecosystems, and habitat for salmonids in general, there would be effects on some non-target species. The goal of additional mitigation would be to restore habitat with similar ecological function for the remaining effects on aquatic resources to ensure project actions meet the ACS and RMS objectives and direction at multiple scales. These actions would reduce effects on fish resources on Forest Service federal lands by reducing factors known to be harmful or limiting to fish species including elevated suspended sediment and sediment in the stream channel, which affects fish production and survival; loss of LWD in streams, which reduces habitat quality; loss of future riparian LWD and other vegetation supplying input of organic matter; and loss or restriction of fish movement (passage) in streams. Specific sites and actions for the mitigation measures were identified through meetings with the Forest Service. These are provided in the *Mitigation Plan for Federal Lands* included in appendix F of this EIS. The details of these mitigation actions and how they relate to ensuring the ACS and RMS is being met is discussed in section 4.7 and appendix F.

4.5.2.5 Conclusion

Constructing and operating the Project would have both short-term effects on fish and invertebrate individuals as well as short- and long-term effects on aquatic habitat. Individual fish and shellfish as well as their food sources would be directly lost as a result of Project construction, the initial and maintenance dredging, decreased water quality, and entrainment from vessel water intake. Habitat modifications would also reduce local important habitat areas including rearing, spawning, and cover areas (e.g., aquatic vegetation, eelgrass). Short-term effects from the pipeline would also include direct local reduction in food sources primarily from bottom disturbance resulting from stream crossings and short-term elevated turbidity; elevated turbidity would also cause short-term sublethal stress to fish and invertebrate stream organisms and movement blockages over limited specific stream locations and time, while limited reduction of riparian vegetation and trees would have limited short- and long-term reduction in stream habitat components. However, the distribution of adverse effects would be limited to areas near the Project (e.g., at the LNG facilities and near and downstream of pipeline stream crossings), and BMPs and impact avoidance measures implemented during construction as well as mitigative actions implemented following construction would limit long-term adverse effects. As a result, we conclude that the Project would not significantly affect fish and aquatic invertebrates.

4.6 THREATENED, ENDANGERED, AND OTHER SPECIAL STATUS SPECIES

This section analyzes the effects of the Project on special status species. In addition to species listed as threatened or endangered under the federal ESA[133] and Oregon ESA[134], agencies and organizations such as the FWS, BLM, Forest Service, ODA, and ODFW maintain lists of species that are considered special concern, sensitive, rare, or are otherwise offered protections under agency planning documents. These species are broadly defined in this assessment as "special status species."[135] Although the term "special status species" is used differently by various agencies, for the purposes of this assessment, the term "special status species" includes:

- species that are listed or proposed for listing by the federal government as endangered or threatened, or are candidates for listing;
- species that are identified by the BLM or Forest Service as "sensitive species" or "strategic species";
- species listed by the State of Oregon as endangered, threatened, or are candidates for listing; and
- species identified by federal or state agencies as rare or protected by federal or state planning documents (e.g., Standards and Guidelines in resource management plans such as "Survey and Manage" species identified in the NWFP).

Using data from the Oregon Biodiversity Information Center (ORBIC),[136] FWS, NMFS, discussions with Forest Service and BLM specialists, and information reviews of published and unpublished information, the applicants prepared lists of threatened, endangered, proposed,

[133] Federal agencies are required by Section 7 of the ESA (Title 19 U.S.C. Part 1536[c]), as amended (1978, 1979, and 1982), to ensure that any actions authorized, funded, or carried out by the agency do not jeopardize the continued existence of a federally listed endangered or threatened species, or result in the destruction or adverse modification of designated critical habitat of a federally listed species. The action agency (e.g., the FERC) is required to consult with the FWS and/or the NMFS to determine whether federally listed endangered or threatened species or designated critical habitat are found in the vicinity of the Project, and to determine the proposed action's potential effects on those species or critical habitats. For actions involving major construction activities with the potential to affect listed species or designated critical habitat, the federal agency must submit its BA to the FWS and/or NMFS and, if it is determined that the action may adversely affect a listed species, the federal agency must submit a request for formal consultation to comply with Section 7 of the ESA. In response, the FWS and/or NMFS would issue a BO as to whether or not the federal action would likely jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. Jordan Cove and Pacific Connector filed an applicant-prepared draft BA (APDBA) in December 2017, and a revised APDBA in September 2018. We are reviewing the revised APDBA and will prepare a BA and EFH Assessment, which will be submitted to the FWS and NMFS.

[134] Oregon has its own ESA that requires state agencies to protect and promote the recovery of state-listed threatened and endangered species. At the state level, consultation is conducted with the ODA for state listed plant species and the ODFW for fish and wildlife species. However, state regulations pertaining to the protection of botanical resources are limited to ORS 564 and OAR Chapter 603, Division 73. Oregon regulations regarding state endangered and threatened plants only apply on non-federal public lands (e.g., state, county, city, etc. lands).

[135] The term "special status species" is also used by the BLM, but in a narrower agency-specific definition than in this assessment. BLM "special status species" include species listed as threatened or endangered under the ESA, species that are proposed for listing under the ESA, species that are candidates for listing under the ESA, and species designated by the BLM as "sensitive" under criteria in BLM Manual 6840. The Forest Service uses similar designations. For the Forest Service, "Survey and Manage" are managed under specific criteria provided in the Northwest Forest Plan rather than the agency "special status species" programs. Several species are designated as both "special status species" for the Forest Service and "Survey and Manage species." Those species are noted in the assessment and are analyzed here under criteria for both programs.

[136] Formerly known as the Oregon Natural Heritage Information Center (ORNHIC).

candidate, and special status species that potentially occur near the proposed Project, as described in the following sections. Species that were initially considered but were dropped from further consideration due to a lack of habitat or because they were not detected during targeted field surveys are listed in tables I-3, I-4, and I-5 in appendix I.

4.6.1 Federally Listed Threatened and Endangered Species

Table 4.6.1-1 lists the federally endangered, threatened, and proposed species that potentially occur in the Project area and are discussed below. Additional species (beyond those listed in table 4.6.1-1) are federally listed in Oregon (i.e., the Canada lynx, bull trout Klamath River DPS, yellow-billed cuckoo Western DPS, streaked horned lark, and slender Orcutt grass); however, these species are not known or expected to occur within the Project area and are not discussed further in this document (Canada lynx: Verts and Carraway 1998, McKelvey et al. 2000, ORBIC 2006b; bull trout Klamath River DPS: FWS 1998a, 2002a, ORBIC 2006b; yellow-billed cuckoo: FWS 2013b; streaked horned lark: FWS 2017b; SBS 2008a, 2012, 2013, 2014, 2017a; and slender Orcutt grass: ORBIC 2017b, FWS 2006b). In addition, the North American wolverine occurs in Oregon and has been proposed for listing as threatened under ESA; wolverines have been occasionally documented in Oregon, most recently in the Wallowa-Whitman National Forest in Northeast Oregon during 2011-2012 (Magoun et al. 2013), but no evidence for a reproducing, self-sustaining population has been found in the state. There appears to be an extremely remote chance of a wolverine dispersing into southwest Oregon, but that is not foreseeable during the construction of the proposed action, and as a result, the North American wolverine is not discussed further in this document. The Eastern DPS of the Steller sea lion, which occurs on the west coast of the U.S. and within the Project area, was delisted on December 4, 2013 (78 FR 66139), and thus is not discussed in this section.

Table 4.6.1-1 lists all potentially affected federally listed and proposed species, indicates the portion of the Project area where they may occur, and provides our preliminary determination of effect.

a/ Effects Key:
NLAA = Not likely to adversely affect, LAA = Likely to adversely affect, NE = No effect, NJ = not likely to jeopardize the continued existence for proposed species
b/ DPS=Distinct Population Segment
c/ This represents a provisional effect determination for this ESA proposed species. This provisional effect determination would apply if the species becomes listed prior to the completion of consultaion on the Project.

4.6.1.1 Mammals

Gray Wolf (Federal Endangered Species, State Delisted)

The federal ESA in Oregon protects gray wolves west of highways 395-78-95 (ODFW 2017e). Gray wolves were delisted from the Oregon ESA in 2015 (ODFW 2017f). Wolves are habitat generalists that only require the presence of ungulate prey and absence of excessive human-caused mortality (FWS 2013c). Wolf pack territory size is a function of prey density and can range from 25 to 1,500 square miles (FWS 2013c). Both male and female wolves disperse, sometimes greater than 600 miles (FWS 2013c).

A radio-collared male (i.e., OR7) dispersing from a pack in northeastern Oregon has been documented in southwestern Oregon and northern California since 2011, including near the Project in Jackson, Douglas, and Klamath Counties (ODFW 2013b). In 2014, a female joined the male, and they produced their first litter that year consisting of three pups (ODFW 2014e). This was the first evidence of wolves breeding in the Oregon Cascades since the early twentieth century (ODFW 2014d). The den was located within the Rogue River National Forest, between Crater Lake and Mount McLoughlin (Young 2014), approximately 6 miles from the pipeline route. Additional pups were born in 2015, 2016, and 2017 (ODFW 2018b). The Area of Known Wolf Activity (AKWA) initially mapped by ODFW for OR7 in 2014 (ODFW 2014c) is crossed by the pipeline route. The AKWA for OR7 and the Rogue Pack has shifted in size and shape since 2014. As currently mapped, it is less than 5 miles from the pipeline route in Jackson and Klamath Counties.

A second AKWA (Keno) was established in southwest Oregon in 2014 with limited evidence that three wolves inhabited an area approximately 280 square miles. ODFW recently removed the AKWA designation for the Keno wolves and is designating it as no longer active, but possibly used as a corridor for wolves moving between Oregon and California (ODFW 2018b). Approximately 2.48 miles of the pipeline route would pass through this area.

Three other radio-collared wolves dispersed from northeastern Oregon to southwest Oregon. One single male wolf (OR25) dispersed in 2015 and established an AKWA spanning northern Klamath County with portions in adjacent Jackson County and Lake County. A radio-collared female wolf (OR28) dispersed in late 2015 and was joined by a collared male (OR3) to establish the Silver Lake AKWA which coincides with the Silver Lake Wildlife Management Unit in western Lake County. The pair produced one pup in 2016 but the male was killed in 2016 (ODFW 2017g).

Given the occurrence of gray wolves in the areas affected by the Project, potential direct and indirect effects from construction and operation of the pipeline include the following:

- Construction-related noise. Construction would produce noise. Wolves appear most vulnerable to human disturbance in and around denning and rendezvous sites. No active denning sites are known within 1 mile of the pipeline.
- Locally concentrated human activities. Available evidence has shown that wolves subjected to increased vehicular traffic will avoid roads and will move pups if disturbed during denning. Wolves disturbed during winter indicated a physiological stress response to snowmobile stimuli.
- Increased risk of collision with construction vehicles along Project area roadways. Vehicles have killed a small number of wolves; overall, 80 percent of all wolf mortalities in the Northern Rocky Mountain population (which includes wolves in the Project area) are caused by humans but only 3 percent are due to accidental human interactions including vehicle collisions and capture mortality (FWS 2012a).
- Wildland fire as an indirect effect associated with increased human presence. The possibility of ignition in conifer and sagebrush/grass fuel types could range from low to extreme depending on weather conditions and patterns, current fire risk rating, moisture conditions, and fuel loadings. There is some possibility of human-caused fire, whether related to pipeline activities or to Project-induced increase of human presence in the area.
- Habitat alteration. Construction would remove forested habitat that might be used by some species that are preyed upon by wolves. However, corridors created within forested habitats are used for movement and foraging by big game species, which are prey for wolves.

Below is a determination of effects summary for this species and critical habitat. More details will be provided in the pending BA.

The Project **may affect** the gray wolf because:

- dispersing and resident wolves have been documented recently near the Project area;
- the OR7 wolf family den was near the pipeline route in 2014;
- construction noise could disturb wolves if present near the pipeline; and
- increased human presence associated with construction activities could affect wolf behavior and movements, including the chance of collisions with vehicles.

However, the Project is **not likely to adversely affect** the gray wolf because:

- the OR-7 den within the Rogue River National Forest is at least 6 miles from the pipeline;
- Project-related noises are not likely to be substantially different from noises produced by existing recreation and logging activities that wolves have been shown to tolerate;
- during pipeline construction, trash would be removed daily, and roadside carrion is expected to be present as an existing condition, and not substantially increased by the Project; and
- following construction, the restored and revegetated pipeline corridor is likely to increase habitat diversity and forage used by ungulates such as deer (Brusnyk and Westworth 1985; Forman 1995), which are prey for gray wolves.

No critical habitat has been designated or proposed for the gray wolf.

Pacific Marten-Coastal DPS (Federal Proposed Threatened Species, State Sensitive Species)

On October 9, 2018, the FWS proposed to list the coastal DPS of Pacific marten *(Martes caurina)* as a threatened species under the ESA (83 FR 150576). Should the rule for this species be finalized as proposed, it would be protected under ESA. The most current information for this species is provided in an updated species status assessment report, and provides a comprehensive account of the species, its life history needs, and stressors to the overall viability and extinction risk for the coastal marten (FWS 2018a). The coastal marten is a mammal in the weasel family and is native to forests of coastal Oregon and coastal California. They occur primarily in older forests, although there is one remnant population occupying the coastal dune forest of central Oregon. Coastal marten historically ranged throughout coastal Oregon and coastal northern California but have not recently been detected throughout much of the historical range, despite extensive surveys. The species exists in four small populations and is absent from the northern and southern ends of its historical range. In Oregon, there are two identified isolated small extent population areas: Central Coastal and Southern Coastal. The Jordan Cove LNG Project falls within the southern portion of the Central Coastal population area and the Pacific Connector pipeline crosses its historical range.

The Central Coastal Oregon population centers on the coastal forest of the Oregon Dunes National Recreation Area (ODNRA) and is managed by the Siuslaw National Forest. Most of this area comprises coastal forest that is less than 70 years old, and consists of shore pine and transitional shore pine/Douglas–fir–hemlock forests within the ODNRA. These forests grow on nutrient-poor sandy soils, dominated by young stands of shore pine and Sitka spruce. The dense understory is dominated by willow (*Salix hookeri*), Pacific waxmyrtle (*Myrica californica*), and berry-producing ericaceous shrubs such as evergreen huckleberry (*Vaccinium ovatum*) and salal (G*aultheria shallon*). These shore pine forests have a variable tree overstory; however, the common denominator with this habitat and older forest habitats is the presence of dense, spatially extensive ericaceous shrub understories and diverse and abundant prey. Coastal martens have a generalist diet that changes seasonally with prey availability. Overall, their diet is dominated by mammals (primarily voles in Central Coastal population area), but birds, insects, and fruits are seasonally important.

Reports by Zielinski et al. (2001) and Moriarty et al. (2016) noted a relatively high incidence of road kills in the last 30 years (i.e., 17) and it was assumed that animals were abundant. Linnell et al. (2018) used recent surveys to refine the extent of the Central Coastal population size of fewer than 87 adults divided into two subpopulations; however, there is no information at this time on long–term trends in population size. The 2018 species status assessment further divides this population into two subpopulations of approximately 30 adults each, separated by the Umpqua River, a relatively large barrier to movement and dispersal. Martens in this population occur in the highest densities reported for any North American marten subspecies (1.13 per square kilometer; Linnell et al. 2018). The Southern Coastal population area in Oregon is located over 40 miles to the south and would not be affected by the Project.

The 2018 species status assessment identifies various factors (stressors) that are directly and indirectly affecting what the coastal marten needs for long-term viability. These include loss of habitat due to wildfire, timber harvest, and vegetation management. Trapping, collisions with vehicles, and rodenticides are all impacting marten individuals, and the threat of disease carries the risk of further reducing populations. Changes in vegetation composition and distribution have also made coastal martens more susceptible to predation from larger carnivores. These threats are expected to be exacerbated by the species' small and isolated populations. Linnell et al. (2018) suggest that small population size, consistent annual human-caused mortality (primarily trapping and road kills), and isolation indicate this coastal marten population is likely to remain vulnerable to extirpation.

Section 4.4 describes five forested and two woodland vegetation types that may be suitable habitat for marten and would be affected by the construction and operation of the Jordan Cove LNG Project. The vegetation types are shown on figures 4.4-1a and 4.4-1b. Table 4.4.1.5-1 estimates that approximately 76 acres and 62 acres of forested and woodland vegetation would be cleared for the LNG facilities and temporary construction areas, respectively.

Given that the Project falls within the southern portion of the Central Coastal population area and the occurrence of marten habitat within the area of the proposed Project footprint, potential direct and indirect effects from construction and operation of the Project include the following:

- <u>Construction-related noise.</u> Construction would produce noise; and martens appear most vulnerable to human disturbance in and around denning and resting habitat. No active denning sites are currently known in the vicinity of the Project site.
- <u>Locally concentrated human activities.</u> Available evidence has shown that martens are subject to road kills and increased vehicular traffic has the potential to increased vehicle collision mortality.
- <u>Habitat alteration</u>. Construction would remove forested habitat that might be used by martens or species that are preyed upon by martens, or otherwise increase fragmentation within suitable habitat. However, much of the forested portions within the Jordan Cove Project boundaries are already in a disturbed state.
- <u>Wildland fire as an indirect effect associated with increased human presence</u>. The possibility of ignition in conifer and sagebrush/grass fuel types could range from low to extreme depending on weather conditions and patterns, current fire risk rating, moisture conditions, and fuel loadings. There is some possibility of human-caused fire, whether related to construction activities or to Project-induced increase of human presence in the area.

Below is a determination of effects summary for Pacific marten- coastal DPS. At this time, no critical habitat has been proposed or designated for this species. More details will be provided should this species become listed as threatened under ESA, including potential exceptions and/or any designation of critical habitat.

The Project **will not jeopardize the continued existence** of the Pacific marten- coastal DPS; however, in the event that Pacific marten- coastal DPS becomes listed prior to completion of the Project, a provisional effect determination is provided.

The Project **may affect** the Pacific marten- coastal DPS because:

- marten historically used the entire Oregon coastal region;
- the southern portion of the Central Coast population area overlaps with the Jordan Cove LNG Project;
- the Project would remove suitable habitat for the coastal DPS population; and
- increased human presence associated with construction activities could affect marten behavior and movements, including the chance of collisions with vehicles.

However, the Project is **not likely to adversely affect** Pacific marten-coastal DPS because:

- there is a relatively low potential for the coastal DPS individuals to occur based on historical accounts and the current low estimated number of individuals south of the Umpqua River;
- project-related noises are not likely to be substantially different from noises produced by existing recreation and logging activities that martens have been shown to tolerate;
- during Project construction, trash would be removed daily to reduce the potential for predator species; and
- construction-related vehicles and equipment would operate at slower speeds, and therefore not substantially increase the potential for vehicle collisions.

Pacific Fisher-West Coast DPS (Federal Proposed Threatened Species, State Sensitive-Critical Species)

The FWS proposed to list the West Coast DPS of the Pacific fisher as threatened under the ESA on October 7, 2014 (79 FR 60419). In April 2016, the FWS determined that the fisher does not warrant listing under the ESA (81 FR 22710). However, on September 21, 2018, the decision to deny the fisher protected status was rescinded and the comment period for the proposed rule to list the West Coast DPS of the fisher was reopened (84 FR 644). The FWS is scheduled to issue a new finding by March 22, 2019.

Fishers occur in the northern coniferous and mixed forests of Canada and the northern United States (69 FR 18770). The West Coast DPS includes fishers in Washington, Oregon, and California. In Oregon, this species is currently known to occur in Curry, Douglas, Jackson, Josephine, and Klamath Counties (Aubry and Lewis 2003; Aubry pers. comm. 2007 as cited in FWS 2014b). Currently, there are two documented populations of fisher in southern Oregon, one in the northern Siskiyou Mountains and one in the southern Cascade Range, that were believed to be genetically isolated from each other (FWS 2014b). However, recent research shows that the two populations are not genetically isolated (Barry et al. 2018).

Fisher habitat consists of mature, closed canopy coniferous and mixed conifer and hardwood forests at low to middle elevations, including riparian corridors with continuous canopies, and large stands with low levels of fragmentation and a high percentage of dead and downed timber (ODFW 2019; FWS 2016a). Fishers prefer large tracts of contiguous interior forest and typically avoid thinned or open forests, including areas where there is substancial human disturbance. A variety of large conifer tree species are used for denning and resting, including Douglas-fir, white fir, incense cedar, red fir, sugar pine, western white pine, ponderosa pine and lodgepole pine (Aubry and Raley 2006; Cummins et al. 2018). In the southern Oregon Cascades, average home range sizes for females were approximately 9.7 square miles and between 24 square miles for males during the non-breeding season and 57 square miles for males during the breeding season, based on locations of radio telemetered study animals (Aubry and Raley 2006).

Loss and fragmentation of habitat due to timber harvest and thinning, roads, urban development, recreation, and wildfire are the main reasons for the decline of the fisher in the west (FWS 2018b). Habitat loss, modification, and fragmentation continue to occur as a result of forest management practices and stand replacing wildfire, and appear to pose a substantial threat to fishers (FWS 2012b). In addition to removing forage, rest, and den sites, fragmentation can increase predation risk, impede movements, and affect prey species composition, abundance, and availability (FWS 2012b). Fragmentation can also increase energetic costs to fishers, which may result in nutritional stress that can reduce animal condition, ultimately affecting survival, reproduction, and recruitment (Lofroth et al. 2010). Additionally, linear infrastructure such as roads, power lines, and pipelines can also affect fisher populations and their habitat (FWS 2016a). As well as being sources of mortality from vehicle collision, these linear infrastructure features can result in permanent removal or alteration of potential fisher habitat and can disrupt movement patterns (FWS 2016a). However, linear infrastructure is considered to be a low-level impact to fishers currently and in the future (FWS 2016a).

Recent telemetry studies in the southern Oregon Cascades identified fisher home ranges that overlap with the Project on the Winema National Forest (Cummins 2018). Location databases show one observation within 1 mile and one observation within 1 to 3 miles of the Project on the Winema National Forest. These observations, together with the availability of suitable habitat within the pipeline ROW, indicate that there is potential for fishers to be present within the analysis area.

Section 4.5 discusses the various wildlife habitat types (from Johnson and O'Neil 2001) crossed by the Project. Late successional and old-growth forest within five forest and woodland habitat types crossed by the pipeline may provide habitat for the fisher. These habitat types include Westside Lowland Conifer-Hardwood Forest, Montane Mixed Conifer Forest, Southwest Oregon Mixed Conifer-Hardwood Forest, Westside Riparian-Wetlands, and Eastside Riparian-Wetlands. Table 4.5.1.2-5 estimates that approximately 657.9 acres of these habitat types would be cleared for the construction of the pipeline.

Given the potential for occurrence of fishers in the areas affected by the Project, potential direct and indirect effects from construction and operation of the pipeline include the following:

- Construction-related noise. Construction would produce noise. Fishers are vulnerable to human disturbance and fishers have been documented within 1 mile of the pipeline.

- Locally concentrated human activities. Construction activities could affect fishers by disturbing animals. Fishers are sensitive to disturbance and avoid areas used by humans (CBD 2000).
- Increased risk of collision with construction vehicles along Project area roadways. Human-caused mortality from vehicle collisions are listed as one of the threats to fisher populations (FWS 2018b).
- Habitat alteration and fragmentation. Construction would remove forested habitat and would modify habitat, particularly by removing large trees, snags, and large woody debris that are used for fisher den and rest sites. The cleared ROW could also fragment habitat, which is detrimental to fishers because they prefer large areas of contiguous, unfragmented forest (CBD 2000).
- Wildland fire as an indirect effect associated with increased human presence. The possibility of ignition in conifer, hardwood, and sagebrush/grass fuel types could range from low to extreme depending on weather conditions and patterns, current fire risk rating, moisture conditions, and fuel loadings. There is some possibility of human-caused fire, whether related to pipeline activities or to Project-induced increase of human presence in the area.

Below is a determination of effects summary for Pacific fisher-West Coast DPS. At this time, no critical habitat has been proposed or designated for this species. More details will be provided should this species become listed as threatened under the ESA, including potential exceptions and/or any designation of critical habitat.

The Project **will not jeopardize the continued existence** of the Pacific fisher-West Coast DPS; however, in the event that Pacific fisher-West Coast DPS becomes listed prior to completion of the Project, a provisional effect determination is provided.

The Project **may affect** the fisher because:

- fishers have the potential to occur in the fisher analysis area;
- suitable habitat is available within the fisher analysis area and would be impacted by the pipeline;
- construction noise could disturb fishers if present near the pipeline; and
- increased human presence associated with construction activities could affect fisher behavior and movements, including the chance of collisions with vehicles.

The following determination is warranted to receive a conference opinion of **may affect, likely to adversely affect** because:

- Recent telemetry studies in the southern Oregon Cascades identified fisher home ranges that overlap with the Project;
- 657.9 acres of suitable LSOG habitat, including snags, would be removed due to pipeline construction.
- Snags and large trees that could serve as fisher dens would be removed during pipeline construction.

Whales

Eight species of federally listed whales potentially occur off the coast of Oregon, including the blue, fin, southern resident killer, humpback, sei, north Pacific right, gray (Western North Pacific Stock) and sperm whales. All these whale species are federally protected under the MMPA. These species tend to feed during the summer in the northern latitudes and migrate to the tropical southern latitudes in the winter for breeding. However, whales could be encountered off the coast of Oregon throughout the year. Two killer whales were documented near the Project area in May 2017 during marine mammal surveys for the Project, although these were likely transient killer whales not belonging to the southern resident DPS (AECOM 2017). Gray whales have been reported in Coos Bay only on an occasional basis. Project effects on whales would be associated with LNG and construction supply vessel transits in the waterway inbound and outbound from the Jordan Cove terminal, as well as construction activities such as dredging and pile driving. Potential direct effects of the Project could include injury and/or mortality due to ship-strikes, injury or behavioral disturbance due to noise from vessels and construction activities, and potential adverse effects from a ship fuel spill. Spills could indirectly affect whales by harming or contaminating forage species. Additional details on whale densities and potential for ship strikes will be provided in the pending BA.

Below is a determination of effects summary for whales and critical habitat. More details will be provided in the pending BA.

The Project **may affect** federally listed whales because:

- federally listed whales may occur within the aquatic analysis areas (Figure 4.5-1 in section 4.5; includes the Coos Bay estuary and marine environment out approximately 12 nautical miles to the outer continental shelf) during construction and operation of the proposed action;
- vibratory sheet pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 120 decibel (dB) re 1 microPascal (μPa) at distances of up to 1.2 miles (Deveau and MacGillvray 2017) and impact pipe pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 160 dB re 1 μPa at 1.1 miles (O'Neill and MacGillvray 2017); and
- the proposed action would increase shipping traffic (LNG carriers) within the aquatic analysis areas.

However, the Project is **not likely to adversely affect** federally listed whales for the following reasons:

- ship strikes on whales off the Oregon coast are thought to be infrequent based on the Rockwood et al. (2018) assessment of potential whale/vessel collision mortalities for blue, humpback, and fin whales of less than 1 percent, and therefore thought to be discountable;
- 120 LNG carrier trips per year to the LNG terminal are expected to increase the potential in ship strikes to whales over known frequencies of incidents; however, Jordan Cove would provide a ship strike avoidance measures package to LNG carrier operators transporting cargo from the LNG terminal that would consist of multiple measures to avoid striking marine mammals;

- FERC does not have authority over the LNG carrier; however, the independent carrier operators would be required to follow all Coast Guard requirements regarding the operation of LNG carriers, including vessel speeds;
- noise from LNG carriers, dredgers, tugs, and other support vessels could result in behavioral disturbance to listed whales and effects of ship noise on whales could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise (NMFS 2016c, 2017b, 2018c), but LNG carrier noise would not exceed existing background ship noise levels and would not cause injury;
- whales inside Coos Bay in the vicinity of the Jordan Cove LNG Project may be affected by noise from piling during construction, and the use of an impact hammer has impulsive peak source levels that are high enough to cause permantent threshold shift (PTS) (an indicator of hearing damage) in these species; however, listed whales are unlikely to occur within Coos Bay during pile driving (October 1 to February 15), and Jordan Cove has indicated that these activities would be monitored and halted if a whale was detected in the area around the sound source;
- given vessel design, on-board spill kits, safety records, and implementation of Coast Guard recommendations, it is not likely that there would be a major ship spill of hazardous materials that may adversely affect water quality or aquatic species; and
- the relative population density of whales within the marine analysis area[137] would be low enough so that Project-related effects of LNG carrier transit in the waterway would be discountable.

No critical habitat has been designated or proposed for blue, fin, humpback, sei, or sperm whales.

The Project would have **no effect** on designated critical habitat units (CHUs) for the Eastern Northern Pacific Southern Resident stock of killer whales because:

- none of the designated CHUs occur within the marine analysis area off the Oregon coast.

The Project would have **no effect** on designated critical habitat for the North Pacific right whale because:

- none of the designated critical habitat occurs within the marine analysis area off the Oregon coast.

As described above, listed whales inside Coos Bay near the Jordan Cove LNG Project may be affected by noise from pile driving during construction, and the use of an impact hammer has impulsive peak source levels that are high enough to cause PTS (an indicator of hearing damage) in these species. Therefore, **we recommend that:**

- **<u>Prior to construction,</u> Jordan Cove should file with the Secretary, for review and written approval by the Director of OEP, a *Marine Mammal Monitoring Plan* that identifies how the presence of listed whales will be determined during construction,**

[137] Whale density estimates were based on habitat specific densities for blue whales, fin whales, and humpback whales (Becker et al. 2012; Calambokidis et al. 2015). Quantified comparable estimates for other species were not available, but the existing data were examined to qualitatively determine the level of risk to these species. These data sources and analyses are further described in the Applicant Prepared Draft Biological Assessment, filed with the FERC September 14, 2018.

and measures Jordan Cove will take to minimize potential noise effects on whales and other marine mammals, and ensure compliance with NMFS underwater noise criteria for the protection of listed whales.

4.6.1.2 Birds

Short-tailed Albatross (Federal Endangered Species, No State Status)

The short-tailed albatross was listed as endangered throughout its range in the United States on July 31, 2000 (FWS 2000a). In the North Pacific, the coastal habitat for the short-tailed albatross is in high-productivity areas with expansive deep water beyond the continental shelf. Short-tailed albatross rarely occur closer to the coast, but have been documented to occur off the Oregon coast near Coos Bay (in 1961, 2000, and 2001; National Audubon Society 2013). Because the closest breeding population of short-tailed albatross is within the Hawaiian Islands, the Project should not affect recovery criteria for the species. The short-tailed albatross could potentially be encountered within the LNG carrier transit route; however, short-tailed albatross are expected to avoid LNG marine traffic. Below is a determination of effects summary for the short-tailed albatross and critical habitat. More details will be provided in our pending BA.

The Project **may affect** short-tailed albatross because:

- short-tailed albatross may occur within the marine analysis area during operation of the proposed action; and
- the proposed action would increase shipping traffic (LNG carriers) within the marine analysis area.

However, the Project is **not likely to adversely affect** short-tailed albatross for the following reasons:

- other species of albatross have infrequently collided with airplanes in flight but collisions of any albatross species with ships are unknown and are expected to be highly unlikely;
- 120 LNG carrier trips per year to the LNG terminal are expected to cause unmeasurable increase in potential ship strikes on short-tailed albatrosses;
- LNG carriers approaching Coos Bay would be traveling slowly and escorted by tractor tugs from 5 nautical miles offshore; and
- given vessel design, on-board spill kits, safety records, and implementation of Coast Guard recommendations, it is not likely that there would be a major ship spill of hazardous materials that may adversely affect water quality or aquatic species. Any oil released at sea would be in small enough quantities that potential effects on short-tailed albatrosses would be discountable.

No critical habitat has been designated or proposed for the short-tailed albatross.

Western Snowy Plover (coastal) (Federal Threatened Species with Critical Habitat, State Threatened Species)

The Pacific Coast population of western snowy plover has been listed as a threatened species under the ESA since March 5, 1993 (FWS 1993a). The Pacific coast population includes birds that nest adjacent to tidal waters, including all nesting birds on the mainland coast, peninsulas, offshore islands, adjacent bays, estuaries, and coastal rivers (FWS 1993a). The western snowy plover is a year-round, uncommon resident of the North Spit (BLM 2005); the spit supports the most productive snowy plover population segment on the Oregon coast (BLM 2008). Western snowy plovers may be encountered along the LNG carrier transit route from nearshore coastal waters to the LNG terminal. Potential effects include increased noise associated with construction of the Jordan Cove LNG Project, operation activities associated with shipping, increased recreation, increased habitat conversion, habitat degradation by human encroachment, and increased illegal harvest (Comer 1982). Conservation measures proposed to reduce effects include implementation of BMPs, education and outreach, and monitoring. CHUs OR-10 and OR-9 are located 2.6 and 6.9 miles from the LNG terminal, respectively; both units were occupied by western snowy plovers at the time of listing (1993) and in 2012. Below is a determination of effects summary for the western snowy plover and critical habitat. More details will be provided in our pending BA.

The Project **may affect** western snowy plovers because:

- the closest western snowy plover nesting habitat to the Project is on the North Spit approximately 1 mile from LNG terminal site, and contained active nests during 2016 surveys;
- temporary construction activities would occur at the Port Laydown site, which is less than 1 mile from known nesting sites;
- the meteorological station is located east of the foredune, approximately 100 feet from the northern extent of known nesting sites;
- impact hammer noise associated with the Navigation Reliability Improvement temporary facilities is expected to be above ambient levels, and may disturb wintering western snowy plovers if present along the eastern edge of the primary nesting area on the North Spit, which is within 0.25-miles of Dredge Area 1; and
- Jordan Cove terminal construction and operations personnel would likely use the North Spit for recreational purposes and increased recreational use could result in increased plover disturbance including destruction of nests by dogs, off-road vehicle traffic, inadvertent trampling, or increased predation if scavengers and predators (corvids, coyotes, striped skunk, feral cats) are attracted to nesting areas due to the presence of trash and food remains.

However, the Project is **not likely to adversely affect** western snowy plover because:

- Jordan Cove LNG Project construction noise at active nest sites (approximately 1 mile) and critical habitat (approximately 2.6 miles) is not expected be above ambient levels.
- Dredging operations would take place within the ODFW in-water work window, which is outside of the nesting period for western snowy plovers and dredging noise level is unlikely to affect wintering plovers approximately 0.25 miles away. Access to dredging areas would be by marine transport with no land-based access near primary snowy plover habitat.
- The meteorological station would be constructed outside the nesting season (March 15 to September 15) to avoid disturbance to snowy plovers and would include spikes or other deterrent measures on any potential perching surface, bird deterrent measures if guy-lines are required, and shielded security lighting to minimize glare. Operational activities would be maintenance-related and would be scheduled outside of the nesting season.
- Jordan Cove would minimize disturbance by humans, pets, vehicles or human-attracted predators through implementation of (1) BMPs to minimize predator density related to

increased human presence and habitat removal, and (2) education and outreach programs intended to train all construction and operations staff on the need for snowy plover conservation; current snowy plover regulations and recreational use restrictions; and the importance of conservation measures, including: litter control, avoidance of nesting and foraging areas, keeping pets on-leash, and remaining on established roads and trails.

Even though the northern end of CHU OR-10 on the North Spit is located approximately 2.6 miles from the Jordan Cove LNG Project, the Project **may affect** designated critical habitat for the western snowy plover because:

- temporary construction activities would occur at the Port Laydown site, which is approximately 1 mile from critical habitat;
- the Navigation Reliability Improvements Dredge Area 1 is approximately 0.25 mile from critical habitat; and
- the Project would result in a large but temporary increase in people employed on the North Spit during construction, and a much smaller long-term increase of operations staff. The additional human presence is likely to increase use of the North Spit with concomitant potential increase of pets, vehicles, and/or human-attracted predators.

However, the Project is **not likely to adversely affect** designated critical habitat for the western snowy plover because:

- dredging noise level is unlikely to affect physical or biological features (PBF) at CHU OR-10 approximately 0.25 miles away; and
- Jordan Cove would minimize potential secondary effects on the critical habitat PBF that identifies disturbance by humans, pets, vehicles or human-attracted predators through implementation of (1) BMPs to minimize predator density related to increased human presence and habitat removal, and (2) education and outreach programs intended to train all construction and operations staff on the need for snowy plover conservation; current snowy plover regulations and recreational use restrictions; and the importance of conservation measures, including: litter control, avoidance of nesting and foraging areas, keeping pets on leash, and remaining on established roads and trails.

Marbled Murrelet (Federal Threatened Species with Critical Habitat, State Threatened Species)

MAMUs in Washington, Oregon, and California were listed as threatened under the ESA on October 1, 1992 (FWS 1992a). Critical habitat for the MAMU was first designated on May 24, 1996 (FWS 1996) and subsequently revised in 2011 (FWS 2011b, 2016b). Throughout the forested portion of their range, MAMU habitat use is positively associated with the presence and abundance of mature and old-growth forests, large core areas of old-growth, low amounts of edge and fragmentation, proximity to the marine environment, and increasing forest age and height, although the presence of platforms is the most important characteristic of nesting habitat (FWS 2006c).

Through a combination of GIS data provided by the BLM and private timber companies, and field surveys conducted between 2007 and 2018, Pacific Connector identified 175 occupied and presumed occupied MAMU stands within 0.25 mile of the proposed action, or within 0.5 mile of federally-designated critical habitat that would be affected by the proposed action.

Construction of the Project would remove a total of about 806 acres of MAMU habitat (suitable, recruitment, capable), including about 78 acres of suitable habitat removed from 37 stands (18 occupied MAMU stands and 19 presumed occupied stands). There is the potential that effects could extend over a total of about 7,145 acres of suitable nesting habitat in the terrestrial nesting analysis area (i.e., the extent of disturbance/disruption of MAMU during the breeding season; FWS 2014c), where Project-related noise, primarily use of access roads, may affect MAMU behavior, including breeding activities. HDD and DP activities are not anticipated to disturb nesting MAMU as noise associated with this work would attenuate to ambient levels before reaching MAMU stands. Ten occupied and 24 presumed occupied MAMU stands occur within CHU OR-06 (b, c, and d) within the proposed terrestrial nesting analysis area. Overall, construction of the Pacific Connector Pipeline Project would remove about 4 acres of suitable MAMU nesting habitat (PBF-1) and about 12 acres of recruitment habitat and 15 acres of capable habitat (both of which make up PBF-2) within CHU OR-06-d.

Pacific Connector would implement several measures to reduce effects on MAMU habitat, including using UCSAs, and replanting conifer trees outside of the 30-foot-wide maintenance corridor on certain federal lands and non-federal lands. However, replanted trees may be harvested from non-federal lands or federal lands slated for timber harvest (i.e., Matrix lands and Harvest Land Base), and if allowed to grow would provide minimal benefit to MAMUs because it would take decades at a minimum to restore replanted forests to recruitment or suitable habitat conditions. To ensure that trees with active murrelet nests and chicks are not felled, timber would be removed outside of the entire MAMU breeding season (after September 15 but before March 31) within 300 feet of MAMU stands to avoid this direct effect on MAMU. To minimize disturbance and disruption of MAMU during operations and maintenance, vegetation maintenance activities would occur between August 1 and April 15, and Pacific Connector would apply daily timing restrictions during activities to minimize effects on MAMU during the late breeding season (August 6 – September 15).

Below is a determination of effects summary for the MAMU and critical habitat. More details will be provided in the pending BA.

The Project **may affect** MAMUs because:

- suitable habitat is available within the terrestrial nesting analysis area;
- MAMUs have been located within the terrestrial nesting analysis area during survey efforts for the proposed action; and
- MAMUs are expected to forage offshore in the marine analysis area, and within Coos Bay in the estuarine analysis area.

The Project is **likely to adversely affect** MAMUs for the following reasons:

- Disturbance associated with Pacific Connector Pipeline Project activities and construction of the Kentuck project would occur within the critical breeding season and within 0.25 mile of known MAMU stands.
- Proposed actions that generate noise above local ambient levels levels in approximately 7,145 acres of suitable habitat might disturb or disrupt MAMUs and interfere with essential nesting behaviors:

  - 82 MAMU stands (25 occupied and 57 presumed occupied) are within 0.25 mile of the pipeline that could be constructed during the breeding season.
  - 168 MAMU stands (50 occupied and 118 presumed occupied) are within 0.25 mile of access roads that could be used during pipeline construction in the breeding season.
- Blasting for the pipeline trench may occur within 0.25 mile of 11 MAMU stands between April 1 and September 30.
- Helicopter use within 0.25 mile of eight occupied MAMU stands during the breeding period (between April 1 and September 15) could occur and disturb MAMU adults and nestlings, as well as potentially blow nestlings out of the nest tree within six occupied MAMU stands from rotor wash.
- The Pacific Connector Pipeline Project would remove approximately 78 acres of suitable nesting habitat within the range of the MAMU; or approximately 0.5 percent of the 14,310 acres of suitable habitat available in the terrestrial nesting analysis area.
- The Pacific Connector Pipeline Project would remove approximately 307 acres of recruitment habitat and 421 acres of capable habitat within the range of the MAMU. These habitats do not currently support the recovery of the species.
- The Pacific Connector Pipeline Project would modify (cause other indirect effects such as increases in edge habitat and loss of interior forest habitat, including increased predation) approximately 656 acres of suitable, 2,058 acres of recruitment, and 2,449 acres of capable habitat.
- Turbidity generated during HDD if a frac-out occurred could affect local major prey species for chicks such as anchovy, sand lance, and smelt.
- LNG carrier traffic in the estuarine analysis area to the Jordan Cove terminal could cause potential behavioral effects on foraging MAMU, and fuel and lubricant spills from LNG carriers could cause injury or mortality to foraging MAMUs.

The Project **may affect** MAMU critical habitat because:

- the Project occurs within designated MAMU critical habitat; and
- the Project would affect habitat within designated critical habitat areas.

The Project is **likely to adversely affect** MAMU critical habitat because:

- the proposed action could remove or degrade individual trees with potential nesting platforms or the nest platforms themselves, resulting in a decrease in or elimination of the value of the trees for future nesting use (PBF 1, or suitable or potentially suitable habitat); and
- the proposed action could remove or degrade trees adjacent to trees with potential nesting platforms that provide habitat elements essential to the suitability of the potential nest tree or platform, such as providing cover from weather or predators (PBF 2, or recruitment/capable habitat).

As described above, construction of the pipeline (including clearing of timber, access road use, helicopter use, and blasting), as well as pipeline operation and maintenance, would occur within the MAMU breeding season and within 0.25 mile of known MAMU stands. These activities could disturb or disrupt MAMUs and interfere with essential nesting behaviors during the breeding season. Therefore, to reduce these effects during the breeding season, **we recommend that:**

- **<u>Prior to construction</u>, Pacific Connector shall file with the Secretary its commitment to adhere to FWS-recommended timing restrictions within threshold distances of MAMU and NSO stands <u>during construction, operations, and maintenance</u> of the pipeline facilities.**

The FWS timing restrictions for MAMU and NSO, as referenced in the above recommendation, were outlined in FWS (2016c).

Given the anticipated avoidance of disturbance and disruption to MAMU during the breeding season per inclusion of the recommendation above into the proposed action (i.e., implementation of distance and timing restrictions, without exception), noise and visual effects on breeding MAMU as a result of construction would be minimized. However, there would be a loss of future breeding opportunities due to the removal of suitable, recruitment, and capable habitat during construction, as there would be less suitable habitat available for nesting. Additionally, the quality of the remaining habitat would be reduced due to habitat fragmentation and the addition of edge along the pipeline corridor. Removal of suitable nesting habitat by harvest of old-growth timber has been cited as the primary reason for the species' decline (FWS 1992a). Suitable MAMU nesting habitat takes a long time to develop (more than 250 years on average); therefore, any removal of suitable habitat may affect the recovery of the MAMU. Jordan Cove has indicated an interest in working with the FWS to discuss possible mitigation and conservation measures but has not proposed compensatory mitigation. In the absence of mitigation other than avoidance and minimization, the Project would result in long-term negative effects on this this threatened species.

Northern Spotted Owl (Federal Threatened Species with Critical Habitat, State Threatened Species)

In Oregon, the NSO is found in low- and mid-elevation coniferous forest in the Coast, Siskiyou, and Cascade Ranges (Forsman 2003). Suitable habitat for NSOs provides elements necessary for nesting, roosting and foraging. NSOs generally nest in forests with multilayered, multispecies canopies with large (20–30 inches dbh or greater) overstory trees, a high basal area (greater than 240 square feet/acre), and a high diversity of different diameters of trees. NSOs have large home ranges and utilize large tracts of land containing substancial acreage to meet their biological needs and a wide array of forest types and structures are necessary to support the various life histories (FWS 2011a). Typically, a larger area is required for NSOs in more fragmented habitats (Courtney et al. 2004). NSOs remain on their home range throughout the year. As a result, NSOs have large home ranges that provide all the habitat components and prey necessary for the survival and successful reproduction of a territorial pair.

Home ranges contain three distinct use areas: 1) the nest patch, which research has shown to be an important attribute for site selection by NSOs and includes approximately 70 acres of usually contiguous forest (300-meter radius around an activity center; FWS et al. 2008), 2) the core area, which is used most intensively by a nesting pair and varies considerably in size across the geographic range, but on average encompasses approximately 500 acres around the nest site (0.5-mile radius around the activity center), and is generally made up of mostly mature/old-growth forest (FWS 2007c; Courtney et al. 2004), and 3) the remainder of the home range which is used for foraging and roosting and is essential to the year-round survival of the resident pair (FWS 2007c). NSO home range size varies by physiographic province. In the Coast Range

Physiographic Province (MP 0.00 to MP 51.74), the home range is assumed to be circular with a radius of 1.5 miles. Within the Klamath Mountains Physiographic Province (MP 51.74 to MP 122.67), the home range radius is 1.3 miles, and in the West Cascades (MP 122.67 to MP 167.76) and East Cascade Physiographic Provinces (MP 167.76 to MP 190.64) the home range radius is 1.2 miles (FWS 1992b). Surveys conducted by Pacific Connector in 2007 identified 12 NSO pairs and a resident single but no nests. In 2008, surveys found NSO pairs at 20 locations, with two nests identified, and resident singles noted at six sites. Surveys in 2015 along the Blue Ridge route did not document any NSO. In addition to NSO sites identified by these surveys, Pacific Connector also considered home range information from the BLM and Forest Service, historic home ranges, best location home ranges (alternate sites closest to proposed action), and Pacific Connector-assumed home ranges (determined by Pacific Connector's assessment of habitat maps). Taking a conservative approach, all owl sites (known, best location, and Pacific Connector-assumed) were analyzed as if occupied and reproductive.

The Project would affect habitat within 97 NSO home ranges and 9 nest patches. About 37 miles of pipeline route would cross 7 designated critical habitat sub-units. Project construction would remove a total of about 517 acres of nesting, roosting, or foraging (NRF) habitat for NSO, of which 134 acres would be permanently lost within the 30-foot-wide corridor maintained in an herbaceous state. Additionally, 214 acres of NRF habitat for NSO would be modified and used as UCSAs. Approximately 1,158 acres of dispersal habitat (high NRF, NRF, and dispersal only habitat) would be removed by the Project. Approximately 919 acres of NSO capable habitat would be removed by construction of the proposed Project, of which 216 acres would remain in a permanent herbaceous/shrub state within the 30-foot operational ROW. Approximately 13,294 acres of NSO habitat (1,307 acres of high NRF/NRF habitat, 4,147 acres of dispersal only habitat, and 5,690 acres of capable habitat) occur within 100 meters (328 feet) of habitat removal, of which 4,326 acres (or 32.5 percent of NSO habitat within 100 meters of habitat removal) of interior NSO habitat would be indirectly affected (1,586 acres of high NRF/NRF habitat, 1,388 acres of dispersal only habitat, and 1,352 acres of capable habitat). The Pacific Connector Pipeline Project would remove 442 acres from LSRs , of which 379 acres is NSO habitat or capable of becoming NSO habitat (approximately 69 acres of high NRF, 93 acres of NRF [includes about 9 acres of "post-fire" NRF], 71 acres of dispersal only habitat, and 146 acres of capable habitat).

Potential direct effects on NSOs would include the following: (1) removal of a known nest tree during the entire breeding season (March 1 through September 30), and (2) human and noise disturbance due to ROW clearing and construction during the breeding period, including noise due to blasting and helicopter support during construction, and smoke from prescribed burnings. Potential indirect effects include the following: (1) removal or modification of suitable NRF habitat, dispersal habitat, and habitat that would be capable, over the life of the Project, to achieve dispersal or NRF habitat characteristics but for the Project's effects within LSR, Riparian Reserves, or NSO home ranges; (2) habitat fragmentation; and (3) other indirect effects that occur due to Project-related increases in edge habitat and loss of interior forest habitat, including increased predation, increased competition, and effects on prey utilized by NSOs. HDD and DP activities are not anticipated to disturb nesting NSO because noise associated with this work would attenuate to ambient levels before reaching NSO sites.

Pacific Connector would minimize effects on NSO habitat using the BMPs for crossing forested lands described in section 4.4 of this EIS. Pacific Connector would reduce effects on NSO habitat by replanting conifer trees outside of the 30-foot-wide maintenance corridor on certain federal lands and non-federal lands. However, replanted trees may be harvested from non-federal lands or federal lands slated for timber harvest (i.e., Matrix lands and Harvest Land Base), and if allowed to grow would provide minimal benefit to NSOs because it would take 80 years at a minimum to restore replanted forests to suitable habitat conditions. Timber removal would occur outside the entire NSO breeding season (March 1 through September 30) within 0.25 mile of NSO activity centers, and as a result, no nest trees within activity centers would be removed during the NSO nesting period, and disturbance or disruption would also be reduced. Additionally, Pacific Connector would install the pipeline within 0.25 mile of activity centers after the critical breeding period (after July 15). However, activities from pipeline construction during the late breeding period (July 16 through September 30) could disrupt or disturb NSO at 10 NSO activity centers within 0.25 mile of the pipeline ROW, and construction activities off the ROW would occur during the entire breeding season and could disturb NSO at two known activity centers located 0.25 mile of pipeline project components, if NSO are present.

For operations and maintenance activities, Pacific Connector would not conduct vegetation maintenance activities within 0.25 mile of NSO activity centers during the entire breeding season (March 1–September 30) to minimize disturbance and disruption to NSO. Other operations and maintenance activities may occur within the breeding season. Mitigation projects such as snag creation projects proposed by the Forest Service to meet LRMP objectives would benefit NSO.

Below is a determination of effects summary for the NSO and critical habitat. More details will be provided in the pending BA.

The Project **may affect** NSOs because:

- suitable habitat is available within the Provincial Analysis Area;[138] and
- NSO pairs and resident singles have been located within the Provincial Analysis Area during survey efforts.

The Project is **likely to adversely affect** NSOs for the following reasons:

- Noise from blasting during pipeline construction within 0.25 mile of NSO sites during the late breeding season would occur and could increase the risk of predation to fledglings that are generally not as able to escape as adults during the latter part of the breeding season.
- Construction of the Pacific Connector Pipeline Project would remove approximately 517 acres of high NRF and NRF habitat (including 26 acres of "post fire NRF" within the 2015 Stouts Creek fire area) within the provincial analysis area. This would result in effects on nest patches, core areas, and home ranges of known, best location, and Pacific Connector-assumed owls, some of which are currently below thresholds needed to sustain NSOs. Once suitable NRF habitat is reduced or modified in NSOs' home ranges, there is an increased likelihood that NSOs remaining in the Project area would be subject to:
  - displacement from nesting areas;
  - concentration into smaller, fragmented areas of suitable nesting habitat that may already be occupied;

[138] The Provincial Analysis Area includes the extent of the following potential Project effects: 1) habitat removal or modification, and 2) disturbance/disruption of NSO during the breeding season

  - increased interspecific (with barred owls) and intraspecific competition for suitable nest sites and forage;
  - decreased survival due to increased predation and/or limited resource (forage) availability; and
  - diminished reproductive success for nesting pairs.
- Construction of the Pacific Connector Pipeline Project would remove and modify high NRF, NRF, dispersal only, and capable habitat for NSOs throughout the Project area, including removal of habitat within the home range of 97 NSOs, 58 of which are currently below sustainable threshold levels of suitable habitat for continued persistence in their home range and/or core area.
- Construction of the Pacific Connector Pipeline Project would bring one NSO core area (best location activity center affected by 2015 Stouts Creek fire) below the 50 percent NRF threshold, and two NSO home range (known activity centers, one of which was affected by the 2015 Stouts Creek fire) below the 40 percent NRF threshold (best location activity center).

The Project **may affect** NSO critical habitat because:

- the Project would occur within designated NSO critical habitat; and
- the Project would affect habitat within designated critical habitat areas.

The Project is **likely to adversely affect** NSO critical habitat because:

- The proposed action would remove or potentially downgrade PBFs in critical habitat sub-units ORC-6, KLE-1, KLE-2, KLE-3, KLE-4, KLE-5, and ECS-1 as defined in the Final Rule designating critical habitat for the NSO (FWS 2012b).

As described above, construction of the pipeline (including access road use, helicopter use, and blasting), as well as pipeline operations and maintenance, would occur within the NSO breeding season and within 0.25 mile of NSO activity centers. These activities would disturb or disrupt NSOs and interfere with essential nesting behaviors during the entire breeding season. Therefore, to reduce these effects during the breeding season, we have recommended that Pacific Connector adhere to FWS-recommended timing restrictions within threshold distances of NSO activity centers (FWS 2016c; see recommendation above in the MAMU section).

Given the anticipated avoidance of disturbance and disruption to NSO during the breeding season per inclusion of the recommendation above into the proposed action (i.e., implementation of distance and timing restrictions, without exception), noise and visual effects on breeding NSO as a result of construction would be minimized. However, there would be a loss of future breeding opportunities due to the removal of suitable habitat during construction, as there would be less suitable habitat available for nesting. Additionally, the quality of the remaining habitat would be reduced due to habitat fragmentation and the addition of edge along the pipeline corridor. Habitat loss and modification, whether to nesting, roosting or foraging habitats, due to forest clear-cutting has been the primary factor causing declines of the NSO (FWS 1992c). Habitat losses and habitat fragmentation have indirect effects that can affect survival and reproduction of NSOs. Jordan Cove has indicated an interest in working with the FWS to discuss possible mitigation and conservation measures but has not proposed compensatory mitigation. In the absence of mitigation other than avoidance and minimization, the Project would result in long-term negative effects on this threatened species.

4.6.1.3 Fish

In this section, we summarize the listing status, life history, and presence and determination of Project action effects on the federally listed fish species and their critical habitat that could be affected by the Project. The species addressed include the Coho Salmon-Southern Oregon/Northern California Coast ESU, Coho Salmon-Oregon Coast ESU, North American Green Sturgeon–Southern DPS, Eulachon–Southern DPS, Lost River sucker, and shortnose sucker. Project effects on waterbodies are described in section 4.3 of this EIS. Minimization measures are currently proposed to reduce effects on threatened and endangered fish species. Overall, the types, methods, and magnitude of effects on listed fish species are represented by those presented for fish in general as presented earlier in section 4.5 of this EIS.

Coho Salmon-Southern Oregon/Northern California Coast ESU (Federal Threatened Species, State Sensitive Species)

The Southern Oregon/Northern California Coast (SONCC) ESU coho salmon was listed as a threatened species on June 28, 2005, between Punta Gorda, California, and Cape Blanco, Oregon (70 FR 37160). It includes all naturally spawning populations as well as three artificial propagation programs, of which one, the Cole Rivers Hatchery (ODFW stock #52) located on the Rogue River, is within the Project area.

Critical habitat for the SONCC ESU was designated in May 5, 1999 (74 FR 24249) and includes the accessible reaches of all rivers (including water, substrate, and adjacent riparian zone of estuarine and riverine reaches) between the Mattole River in California and the Elk River in Oregon. The Pacific Connector pipeline route would cross designated critical habitat within waterbodies of the Upper Rogue HUC (17100307) below Lost Creek, Willow Creek, and Fish Lake Dams.

Major rivers, estuaries, and bays known to support coho salmon within the range of the SONCC ESU include the Rogue River, Smith River, Klamath River, Mad River, Humboldt Bay, Eel River, and Mattole River (NMFS 1999), two of which (i.e., the Rogue and Klamath Rivers) are within the Project area although this ESU is currently prevented from accessing the potential Project-affected Klamath River areas due to dam passage barriers downstream.

Direct and indirect effects on SONCC Coho salmon are not expected within the marine analysis area. Coho salmon can avoid acoustic effects from LNG carriers during transit. Potential oil and gas spills from LNG carriers in the marine analysis area are highly unlikely to occur; even if LNG spilled or leaked, it would turn to vapor and would not mix with water, and vessel response plans required to address accidental spills of LNG and other petroleum products onboard would be implemented. Effects within the riverine analysis area are expected from in-water construction activities resulting in short-term increased sediment levels that would be stressful to fish, short-term benthic food source reduction, temporary migration impedance, short-term terrestrial/riparian habitat modifications, and limited long-term reduction in LWD sources. Limited fish mortality would also occur from fish salvage.

Below is the determination of effects summary for SONCC Coho Salmon ESU and critical habitat; see the details in our pending BA.

The Project **may affect** coho salmon in the SONCC ESU because:

- several stages and activities of coho salmon (upstream adult migration, juvenile rearing, and juvenile out-migration) are expected to occur at various locations in the riverine analysis area during construction and operation of the proposed action.

The Project is **likely to adversely affect** Coho salmon in the SONCC ESU for the following reasons:

- Juveniles would be exposed to elevated TSS concentrations during standard dry open-cut construction (fluming or dam-and-pump) for 2 to 5 hours. Such an exposure could cause injury, a short-term reduction in both feeding rate and feeding success, and minor physiological stress.
- A site crossing failure while dry open-cut construction is underway could result in elevated TSS concentrations for six hours while repair of failed isolation structures occurs, which could cause moderate habitat degradation injury, a short-term reduction in both feeding rate and feeding success, impaired fish homing, and possibly major physiological stress.
- Literature-based estimates of suspended sediment effects from pipeline construction on severity of ill effect (SEV) scores suggest typical dry crossing methods could result in SEVs of 4 and 6 for Coho salmon within a few hundred feet (e.g., 150 to 500 feet) below the crossing, which may include factors ranging from short-term reduction in feeding to moderate physiological stress. If failure of sealing occurs, SEV scores for coho salmon could be as high as 8, which may include habitat degradation, major physiological stress, and long-term reduction in feeding rate or success.
- Construction-induced blasting at 13 streams (4 at streams known to contain coho) could cause mortality to fish by rupturing swim bladders, but active fish removal from area prior to blasting would reduce risk of occurrence.
- Fish salvage would occur for some dry stream crossings as discussed in Pacific Connector's *Fish Salvage Plan*.[139] Capture and handling constitutes a taking under ESA and subjects coho salmon to injury and mortality.
- Lack of LWD is a limiting factor in most streams within range of SONCC coho salmon. Removal of mid-seral riparian forest (40 to 80 years old) would have long-term effects on recruitment of LWD, and removal of LSOG forest (80 years old or older) would have permanent effects on recruitment of LWD because planted conifers would not attain those age classes within the 50-year life of the Project, plus the ongoing loss of trees within the 30-foot-wide maintance corridor.

The Project **may affect** designated critical habitat for coho salmon in the SONCC ESU because:

- the Pacific Connector pipeline crosses designated critical habitat within waterbodies of the Upper Rogue HUC (17100307) below the Lost Creek, Willow Creek, and Fish Lake Dams.

[139] Appendix L of Pacific Connector's POD filed with the FERC in January 2018.

The Project is **likely to adversely affect** designated critical habitat for coho salmon in the SONCC ESU for the following reasons:

- a failure of dry open-cut crossing could cause moderate or more severe habitat degradations in some crossing areas;
- increases in turbidity are expected to temporarily affect the water quality downstream from stream crossing sites during construction;
- food resources would potentially be affected over the short term by dry open-cut and diverted open-cut construction methods that would remove substrate and benthos at crossing sites;
- freshwater migration corridors would potentially be affected over the short term by dry open-cut and diverted open-cut construction methods that would create temporary barriers to in-stream movements; and
- approximately 17 acres of native riparian vegetation (forest, wetlands, unaltered, and nonforested habitats) and altered habitat would be removed during construction within riparian zones associated with designated critical habitat. Adverse effects on riparian zones associated with critical habitat would be long term or permanent depending on whether mid-seral riparian forests (7 acres) or LSOG riparian forests (2 acres) are removed.

Coho Salmon-Oregon Coast ESU (Federal Threatened Species, State Sensitive Species)

This Coho salmon ESU was first proposed for listing on July 25, 1995 (60 FR 38011) and subsequently listed as threatened on June 20, 2011 (76 FR 35755). The Oregon Coast ESU includes all naturally spawned populations of coho in Oregon coastal streams south of the Columbia River and north of Cape Blanco, including the Cow Creek (ODFW stock #37) coho salmon hatchery program (NMFS 1995). Critical habitat for Oregon Coast coho salmon was designated on February 11, 2008 (73 FR 7816) and includes water, substrate, and adjacent riparian zones of estuaries and rivers within the range of the Oregon Coast ESU. There are three subbasins that coincide with the Project: South Umpqua Subbasin (HUC 17100302) and Coquille Subbasin (HUC 17100305), which are crossed by the Pacific Connector pipeline; and Coos Subbasin (HUC 17100304), which includes the Coos Bay estuary where the LNG terminal, slip, navigation channel improvements, and HDD portion of the Pacific Connector pipeline route would be located contain critical habitat watersheds. Within these subbasins are eight fifth-field watersheds crossed that contain designated critical habitat. Life stage requirements of coho salmon, within freshwater habitats in the Oregon Coast ESU, are expected to be similar to those described above for Coho salmon in the SONCC ESU.

Coho salmon would be expected to avoid acoustic effects from LNG carriers during transit of marine areas, and no substantial adverse oil and gas marine spills from LNG carriers are expected. Short-term adverse effects on coho salmon in the estuarine analysis area would result from locally increased turbidity from dredging activities and LNG carrier propeller wash and ship wake, causing avoidance and short-term reduction in food supply. Entrainment and impingement of coho salmon could occur in LNG carriers' cooling water intake port during LNG carrier loading and possibly dredging. Acoustic effects would likely cause at least avoidance during LNG terminal construction. Habitat modification would occur from all dredging activity and restoration activities at the Kentuck project site. Suspended sediment released accidentally during HDD construction across Coos Bay and the Coos River would also result in elevated sediment levels.

Effects within the riverine analysis area primarily from in-water construction activities would include short-term increased sediment levels causing fish stress, reduced short-term benthic food supplies, temporary migration impedance, terrestrial/riparian habitat modifications, and limited long-term reduction in LWD sources. Limited mortality from fish salvage would also occur.

Below is the determination of effects summary for Oregon Coast Coho Salmon ESU and critical habitat; see our pending BA for details.

The Project **may affect** coho salmon in the Oregon Coast ESU because:

- several stages and activities of coho salmon (upstream adult migration, juvenile rearing, and juvenile out-migration) are expected to occur at various locations in the riverine analysis area during construction and operation of the proposed action;
- several stages and activities of coho salmon (juveniles, adults) are expected to occur within the estuarine analysis area during construction and operation of the proposed action; and
- juvenile and adult coho salmon area expected to occur within the marine analysis area during operation of the proposed action.

The Project is **likely to adversely affect** coho salmon in the Oregon Coast ESU for the following reasons:

- Short-term increase in noise associated with in-water or nearwater pile driving at various temporary construction activities throughout the bay may cause disturbance and physical injury to Oregon Coast coho if they are in proximity to the noise during construction.
- Some juvenile coho may be subject to localized entrainment by dredging associated with the access channel and Navigation Reliability Improvements, as well as ongoing maintenance dredging.
- Local short-term increases in suspended sediment in Coos Bay from in-water construction, particularly during dredging of Jordan Cove terminal access channel and navigation channel widening, may result in behavioral effects on rearing coho salmon juveniles with physiological consequences that may affect growth and survival.
- Short-term effects on the benthic community and potential food resources for Oregon Coast coho would result from dredging the proposed marine waterway modifications in Coos Bay.
- Installation of the proposed pipeline beneath Coos Bay and the Coos River using HDD construction would avoid effects on coho unless an inadvertent return of drilling fluid occurred. An inadvertent return would temporarily increase sedimentation and turbidity and likely result in behavioral avoidance of the affected area.
- Individual Coho salmon may be directly affected by local restoration activities at the Kentuck project due to short-term construction-related increases in turbidity, in-water work, and isolation measures.
- Water intakes by LNG carriers at the Jordan Cove terminal berth during engine cooling operations could entrain or impinge juvenile salmon.
- Dredging of the Jordan Cove terminal access channel in Coos Bay in the short term could remove eelgrass and benthic community that provide potential food resources and rearing habitat for Oregon Coast Coho salmon;

- Removing eelgrass from donor stocks in the bay to develop the Eelgrass Mitigation site may reduce cover and food sources for rearing juvenile coho salmon in the short term:
- Exposure to TSS concentrations during dry open-cut construction (fluming or dam-and-pump) for 2 to 6 hours could potentially cause minor physiological stress (increased coughing rate and/or increased respiration rate) in juvenile coho salmon.
- A site crossing failure while dry open-cut construction is underway could result in elevated TSS concentrations for six hours while repair of failed isolation structures could cause moderate habitat degradation, impaired homing by fish, moderate to major physiological stress, and, in very limited areas, reduced growth and reduced fish density.
- Literature-based estimates of suspended sediment effects from pipeline construction on SEV scores suggest typical dry crossing methods could result in SEVs between 4 and 6 for coho salmon within a few hundred feet (e.g., 150 to 500 feet) below the crossing, which may include factors ranging from short-term reduction in feeding to moderate physiological stress. If failure of sealing occurs, SEV scores for coho salmon could be as high as 8, which may include habitat degradation, major physiological stress, and long-term reduction in feeding rate or success.
- Blasting at 22 streams (12 known or assumed to have Coho salmon at the crossing) could cause mortality to fish by rupturing swim bladders but active fish removal from the area prior to blasting would reduce risk of occurrence.
- Fish salvage would occur within isolated construction sites, possibly when adult and juvenile coho salmon are present. Coho salmon are considered vulnerable to electrofishing, subject to injury and mortality. Seining, electrofishing, and handling during salvage may adversely affect Oregon Coast coho salmon.
- Lack of LWD is a limiting factor in most streams within range of Oregon Coast coho salmon. Removal of mid-seral riparian forest (40 to 80 years old) would have long-term effects on recruitment of LWD, and removal of LSOG forest (80 years old or older) would have permanent effects on recruitment of LWD because planted conifers would not attain those age classes within the 50-year life of the Project, plus the ongoing loss of trees within the 30-foot-wide maintance corridor.

The Project **may affect** designated critical habitat for coho salmon in the marine analysis area, the estuarine analysis area, and the riverine analysis area for the Oregon Coast ESU because:

- construction and operation of the Project would occur in or cross designated critical habitat within waterbodies of the Coos, Coquille, and South Umpqua subbasins.

The Project is **likely to adversely affect** proposed critical habitat for coho salmon in the Oregon Coast ESU for the following reasons:

- dredging of the Jordan Cove terminal access channel in Coos Bay and marine waterway modifications could remove eelgrass and benthic community that are potential food resources and rearing habitat for Oregon Coast coho salmon;
- increases in turbidity are expected to temporarily affect the water quality downstream from stream crossing sites during construction;
- TSS concentrations generated during dry open-cut construction and potential failure of isolation structures would adversely affect freshwater habitats by changing coho habitat preferences (SEV = 3) or causing moderate habitat degradations (SEV = 7 or 8);

- a failure of dry open-cut crossing lasting up to 6 hours could cause moderate or more habitat degradations in some streams;
- food resources would potentially be affected over the short term by dry open-cut and diverted open-cut construction methods that would remove substrate and benthos at crossing sites;
- freshwater migration corridors would potentially be affected over the short-term by dry open-cut and diverted open-cut construction methods that would create temporary barriers to in-stream movements; and
- approximately 88 acres of native riparian vegetation (forest, wetlands, and nonforested habitats) and altered habitat would be removed during construction within riparian zones associated with designated critical habitat associated with waterbodies within range of Oregon Coast coho ESU. Adverse effects on riparian zones associated with critical habitat would be long term or permanent depending on whether mid-seral riparian forests (14 acres) or LSOG riparian forests (4 acres) are removed.

North American Green Sturgeon – Southern Distinct Population Segment (Federal Threatened Species, State Sensitive-Critical Species)

On January 23, 2003 (NMFS 2003), NMFS determined that the North American green sturgeon comprises two DPSs that qualify as species under the ESA: (1) a northern DPS consisting of populations in coastal watersheds northward of and including the Eel River in California; and (2) a southern DPS consisting of coastal and Central Valley populations south of the Eel River, with the only known spawning population in the Sacramento River. On April 7, 2006, NMFS listed the southern DPS as federally threatened under the ESA, including spawning populations of green sturgeon south of the Eel River, principally the Sacramento River spawning population (71 FR 17757). Designated critical habitat extends from U.S. marine waters to 110 meters depth (360 feet) or 60 fathoms from Monterey Bay, California, north to Cape Flattery, Washington, including the Strait of Juan de Fuca (74[195] FR 52300 [October 9, 2009]). Critical habitat includes three components that are occupied by and are essential to different life stages of green sturgeon: (1) freshwater riverine systems, (2) estuarine areas, and (3) nearshore marine waters. No rivers in Oregon were included in the listing. However, many estuaries were part of the critical habitat proposal in Washington, Oregon, and California. Estuaries in Oregon proposed for inclusion were the Columbia River estuary, Winchester Bay, Yaquina Bay, Nehalem Bay, and Coos Bay. Large numbers of this green sturgeon DPS are within Coos Bay. Subadults and adults may occupy Coos Bay for feeding, optimization of growth, and thermal refuge, and the Bay supplies oversummer habitat. Similarly, coastal marine waters 110 meters deep or less. The North American green sturgeon (both northern and southern DPSs) occurs within Coos Bay and its adjacent waterbodies (Israel and May 2007) and is considered abundant in the bay (73 [174] FR 52084 [September 8, 2008]). This fish may also occur in the lower portions of the Coos River.

Green sturgeons spawn every three to five years in deep pools in large, turbulent river mainstems, generally from March through July (Tracy 1990; Moyle et al. 1992). Little is known about sturgeon feeding, but some studies have found that adults and juveniles feed on benthic invertebrates including shrimp, mollusks, amphipods, and even small fish (Moyle et al. 1992; Radtke 1966). Natural reproduction in this estuary is considered low (Wagoner et al. 1990). The Coos River system is not considered to provide suitable spawning habitat for green sturgeon (Whisler et al. 1999). Green sturgeon, likely less than three years of age, may utilize both shallow and deep-water habitats within the estuarine area, though there is no information relating individual occurrence to DPS membership. Green sturgeon may also occur in bottom areas along the LNG carrier transit route, in waters mostly less than 110 meters deep, which would be primarily only during entry and exit of the vessels as they would travel in deeper water during transit between ports.

Direct and indirect effects on green sturgeon in the southern DPS are not expected within the marine analysis area. Green sturgeon might detect noise from LNG carriers but would be able to avoid adverse effects from noise. Potential oil and gas spills from LNG carriers in the marine analysis area are unlikely to affect aquatic resources because they are highly unlikely to occur; if LNG spilled or leaked, it would turn to vapor, would not mix with water, and would not contaminate surface water; and vessel response plans required to address accidental spills of LNG and other petroleum products onboard would be implemented. Effects on green sturgeon in the estuarine analysis area include acoustic effects such as avoidance during terminal construction, increased turbidity sedimention affecting benthic food sources from dredging activities, bed and bank erosion from LNG carrier propeller wash and ship wake, loss of forage from removal of eelgrass and shallow water habitat, and elevated suspended sediment released from an accidental drilling mud release during HDD construction across Coos Bay and the Coos River. Effects within the riverine analysis area include increased turbidity and sedimentation causing short-term avoidance and food source reduction from in-water construction activities on Stock Slough.

Below is the determination of effects summary for the Southern DPS of green sturgeon and critical habitat. Details will be provided in our pending BA.

The Project **may affect** green sturgeon (Southern DPS) because:

- adult and/or subadult green sturgeon may occur within the estuarine analysis area during construction and operation of the proposed action;
- adult and/or subadult green sturgeons may occur within the marine analysis area during operation of the proposed action; and
- the proposed action may affect potential food resources and water quality during the short-term construction period and maintenance dredging within the estuarine analysis area.

The Project is **likely to adversely affect** green sturgeon (Southern DPS) because:

- short-term increase in noise generated from in-water and nearshore pile driving at various temporary construction sites throughout the bay may cause disturbance and physical injury to green sturgeon if individuals are in proximity to the noise during construction;
- exposure to TSS concentrations during dry open-cut construction (fluming or dam-and-pump) could potentially cause minor physiological stress, a short-term reduction in feeding rate, and short-term reduction in feeding success in the Stock Slough estuarine stream/river channel crossed by the pipeline if present there at the time of construction;
- on a localized basis, the proposed action may affect migratory and feeding behavior, potential food resources, and water quality (TSS) during the short-term construction period and periodic maintenance dredging within the estuarine analysis area;
- bottom disturbance from Project construction, navigation channel widening, and maintenance dredging may reduce the abundance and diversity of benthic food supply within Coos Bay; and

- short-term increased turbidity could cause avoidance in Coos Bay or lower Coos River HDD if frac-out were to occur.

The Project **may affect** critical habitat for green sturgeon (Southern DPS) because:

- Project activities would occur within portions of the Coos Bay estuary, Stock Slough, and coastal marine waters, which have been designated as critical habitat;

The Project is **likely to adversely affect** critical habitat for the southern DPS of green sturgeon because:

- bottom disturbance from Project construction, navigation channel widening, and maintenance dredging may disrupt local food supply and habitat usability within Coos Bay; and
- suspended sediment produced during dry open-cut crossing Stock Slough could affect water quality in freshwater riverine critical habitat.

Eulachon – Southern Distinct Population Segment (Federal Threatened, No State Status)

On March 18, 2010, the NMFS published in the Federal Register the final rule to list the southern DPS of the Pacific eulachon as threatened under the ESA (75 FR 13012 [March 18, 2010]). The NMFS has identified the eulachon southern DPS as those populations which spawn in rivers south of the Nass River in British Columbia, Canada, to and including the Mad River in California (NMFS 2008c). The southern DPS has been further segregated into four subareas: Klamath River, Columbia River, Fraser River, and British Columbia coastal rivers south of the Nass River (NMFS 2008c). A total of 16 distinct regions in Washington, Oregon, and California have been designated as critical habitat for Pacific eulachon (76 FR 65323 [October 20, 2011]). No part of the Project or its effects would occur within waterbodies included in the eulachon critical habitat designation.

Adult Pacific eulachon usually spend three to five years in saltwater before returning to freshwater to spawn from late winter though early summer in rivers (74 FR 10857 [March 13, 2009]). Fertilized eggs adhere to river bottoms and shortly after hatching, the larvae are carried downstream and dispersed by estuarine and ocean currents (74 FR 10857 [2009]). No recent spawning runs have been documented for the Coos River, although some may have occurred historically and have recently been found in Winchester Creek, a major tributary to South Slough that enters Coos Bay near the ocean (Willson et al. 2006; Wagoner et al. 1990, NMFS 2018b).

Little is known about the use of marine waters by eulachon and, due to paucity of sampling, little specific information exists on eulachon distribution off the U.S West Coast, including Oregon (Gustafson et al. 2010). Larvae and young juveniles become widely distributed in coastal waters, with fish found mostly at depths up to 15 meters (171 feet) but sometimes as deep as 182 meters (597 feet; Hay and McCarter 2000). Larger rearing fish have been reported to be in the near benthic habitats in open marine waters of the continental shelf between 20 and 150 meters (66 to 492 feet) deep (Barraclough 1964 as cited in Gustafson et al. 2010).

Adults and juveniles commonly forage at moderate depths (15 to 182 meters [50 to 600 feet]) in inshore waters, feeding on zooplankton, primarily eating crustaceans (Hay and McCarter 2000). Adults are found rarely in Coos Bay (64 FR 66601 [1999]), but have been reported to utilize both shallow and deep habitats in the estuary (64 FR 66601 [1999]). A 1971 report (Cummings and Schwartz 1971) noted their distribution only in the outer 7 miles of Coos Bay. Detailed larvae and juvenile fish sampling in Coos Bay over a 3.5-year period (1998-2001) found no eulachon (Miller and Shanks 2005). More recently, pelagic Tucker trawl samples over a 17-month period found larvae and small juveniles of a close relative, surf smelt, but no eulachon near the proposed terminal in Coos Bay (Shanks et al. 2011). However, given the limited survey effort and highly variable presence of eggs and larvae, eulachon occurrence in Coos Bay could not be ruled out (Storch and Van Dyke 2014).

Direct and indirect effects on eulachon in the southern DPS are not expected within the marine analysis area. Eulachon might detect noise from LNG carriers, but would be able to avoid adverse effects from noise. Potential oil and gas spills from LNG carriers in the marine analysis area are unlikely to affect aquatic resources because they are highly unlikely to occur; if LNG spilled or leaked, it would turn to vapor, would not mix with water, and would not contaminate surface water; and vessel response plans required to address accidental spills of LNG and other petroleum products onboard would be implemented. Effects on eulachon in the estuarine analysis area include increased turbidity from dredging activities and LNG carrier propeller wash and ship wake causing avoidance and reduced food supply, increased suspended sediment should an HDD construction failure occur in Coos Bay or the Coos River, entrainment and impingement in LNG carriers' water intake ports, acoustic effects including avoidance during terminal construction, habitat modification from dredging, and restoration activities at the Kentuck project site.

Below is the determination of effects summary for Pacific eulachon (Southern DPS) and critical habitat. Details will be provided in our pending BA.

The Project **may affect** Pacific eulachon (Southern DPS) because:

- Pacific eulachon may be present within the estuarine analysis area during construction and operation of the Project;
- Pacific eulachon may occur within the marine analysis area during operation of the proposed action;

The Project is **likely to adversely affect** Pacific eulachon (Southern DPS) because:

- Bottom disturbance and suspended sediment from Project construction, navigation channel widening, and maintenance dredging may affect the abundance and diversity of potential benthic and pelagic food resources, water quality, and suspended sediment during the short-term duration of these actions within the estuarine analysis area.
- Short-term increase in noise generated from the MOF land-based pile driving and in-water pile driving in various Coos Bay estuarine analysis areas may cause physical injury to individual eulachon at a limited distance during construction.
- Although eulachon would be rare in Coos Bay, and their large size would allow most to be able to avoid the LNG carrier cooling water intake, some limited number could be entrained during dredging and vessel loading in the bay.

The Project would have **no effect** on critical habitat for the Pacific eulachon (Southern DPS) because no designated critical habitat is present within the areas affected by the Project.

Lost River Sucker (Federal Endangered Species, State Endangered Species)

The Lost River sucker was listed as a federally endangered species on July 18, 1988, because of a variety of factors including loss of habitat and access to historical range, overfishing, degraded water quality, lack of adaquate recruitment, inadequate regulatory mechanisms, and a variety of other reasons resulting in declining populations (FWS 1988). Lost River sucker critical habitat was originally proposed in 1994 (59 FR 61744) but that proposal was never finalized. In 2011, a revised critical habitat designation was proposed and ultimately finalized in December 11, 2012 (77 FR 73739). Designated critical habitat for the Lost River sucker includes two units: the Upper Klamath Lake Unit and Lost River Basin Unit

The present distribution of the Lost River sucker includes Upper Klamath Lake and its tributaries, Clear Lake Reservoir and its tributaries, Tule Lake and the Lost River, the Klamath River, and Copco, Iron Gate, and John C. Boyle Reservoirs with no substantial change since listing (Reclamation 2007, 2012; FWS 2007d). They have also been found in Tule Lake (Reclamation 2012; FWS 2007d, 2013d). Critical habitat that could potentially be affected by construction of the Pacific Connector pipeline includes the Klamath River.

In the Upper Klamath Lake watershed, the Lost River sucker spawning runs are primarily limited to Sucker Springs in Upper Klamath Lake, and the Sprague and Williamson Rivers. Spawning runs also occur in the Wood River and in Crooked Creek in this watershed. In the Project vicinity, Lost River suckers spawn in the Lost River and are present in John C. Boyle Reservoir, downstream from the pipeline crossing at river mile (RM) 225 (NRC 2004). In addition to collections of Lost River suckers in John C. Boyle Reservoir, ORBIC (2012) cites records of collections in Lake Ewauna and in the Lost River Diversion Channel connecting the Klamath River (at RM 249.8) to the Lost River at the Lost River Diversion Dam, approximately 10 river miles downstream from the Pacific Connector pipeline crossing of the Lost River at RM 9.5.

The Pacific Connector pipeline route would cross Lost River (MP 212.07) 7.6 miles upstream of the known spawning area downstream of Anderson–Rose Dam, using a dry, open-cut method during low flows that coincide with the ODFW instream construction window extending from July 1 through March 31.

Spawning occurs within limited areas of the Lost River (FWS 2013d; Reclamation 2012), and occasional individuals have been found in this stream (NMFS and FWS 2013), which suggests it is possible that Lost River sucker occurs at the Pacific Connector pipeline crossing of Lost River at MP 212.07 during the non-spawning period. An additional 31 dry open-cut small intermittent stream crossings could also contain Lost River suckers as surveys have not been conducted for their presence.

Potential effects on the Lost River sucker are associated with pipeline stream crossings. These effects include the release of drilling mud from Klamath River HDD potential frac-out as well as potential entrainment or entrapment of fish, and increased turbidity and suspended sediment in occupied stream affecting fish avoidance and benthic food supply. Pacific Connector would install a temporary flowing stream crossing by lifting or spanning a structure from a bank so that equipment does not enter flowing waters. However, if it is not possible to do this safely, only equipment necessary to install the bridge would cross the stream. This would cause some limited short-term bottom benthic disruption and possibly elevated suspended sediment. Adults and juveniles subject to fish salvage associated with the Lost River crossing could be injured or killed if electrofishing is used, and stressed if seining is used. Incidental take of a Lost River sucker is possible, but salvage operations would follow Pacific Connector's *Fish Salvage Plan* which describes netting methods (e.g., beach seining, dip netting) that would be used before using electrofishing. There are additional salvage methods that have been specifically developed for these listed suckers to further reduce the potential effects of salvage (see the Klamath Project Operations Biological Opinion [Reclamation 2008] consistent with Reclamation's *Handling Guidelines for Klamath Basin Suckers).*

Below is the determination of effects summary for Lost River sucker and critical habitat. Details will be provided in our pending BA.

The Project **may affect** Lost River suckers because:

- Lost River suckers occur within the Upper Klamath River subbasin and Lost River subbasin, which would be affected during construction of the proposed action.

The Project is **likely to adversely affect** Lost River suckers because:

- Lost River suckers could occur in 19 waterbodies crossed by dry open-cut construction in the Lake Ewauna-Klamath River watershed and in 13 waterbodies west of MP 214.38 (including the Lost River) crossed in the Mills Creek-Lost River watershed and be indirectly affected by elevated suspended sediment levels, streambank erosion and stability, and aquatic nuisance species introductions; and
- fish salvage during the crossing of 31 ditches crossed by dry-open cuts and the Lost River crossing could result in injuring or killing of Lost River suckers if electroshocking is used, and stressing fish if seining is used.

The Project **may affect** designated critical habitat for the Lost River sucker because:

- there is a low risk of HDD failure during crossing of the Klamath River, resulting in a frac-out that releases drilling mud into the river.

However, the Project is **not likely to adversely affect** designated critical habitat for the shortnose sucker because:

- HDD crossing methods would avoid critical habitat in the Klamath River;
- the potential for hydraulic fracture during HDD drilling is so unlikely as to be discountable; and
- in the event of released bentonite, corrective actions would contain and temporally limit drill mud volumes.

Shortnose Sucker (Federal Endangered Species, State Endangered Species)

The shortnose sucker was listed as a federally endangered species on July 18, 1988 (FWS 1988). The final rule to list the shortnose sucker as endangered suggested several reasons for their decline, including the construction of dams, water diversions, overfishing, competition and predation by exotic species, water quality problems associated with timber harvest, removal of riparian vegetation, livestock grazing, lack of adaquate recruitment, inadequate regulatory mechanisms and agricultural practices. Shortnose sucker critical habitat was originally proposed in 1994 (59 FR 61744) but that proposal was never finalized. In 2011, a revised critical habitat designation was proposed and ultimately finalized in December 11, 2012 (77 FR 73739). Designated critical habitat for the shortnose sucker includes two units: the Upper Klamath Lake Unit and Lost River Basin Unit. The Klamath River is the only critical habitat for the shortnose sucker crossed by the pipeline or potentially affected by any Project actions.

Currently, shortnose suckers are present in upper Klamath Lake and tributaries, Lost River, Clear Lake Reservoir, the Klamath River, and three large Klamath reservoirs (Keno, Copco, and possibly Iron Gate Reservoirs) with no substantial change since listing (Reclamation 2007, 2012). They have also recently been found in Tule Lake and Gerber Reservoir (Reclamation 2012; FWS 2007d, 2013e).

Shortnose suckers live in lakes and spawn in rivers, streams or springs associated with the lake habitats, generally from early February through mid-April. After hatching, larval suckers migrate out of spawning substrates, which are usually gravels or cobbles, and drift downstream into lake habitats from early May to mid-June (FWS 1988, 1993b). The shortnose sucker is known to migrate out of Tule Lake to spawn in the Lost River below Anderson–Rose Dam about 7.6 miles downstream from the Lost River crossing. Therefore, the Pacific Connector pipeline would cross the Lost River where shortnose suckers could be present.

Potential effects on the shortnose sucker are associated with pipeline stream crossings. These effects include the release of drilling mud from Klamath River HDD potential frac-out as well as potential entrainment or entrapment of fish, and increased turbidity and suspended sediment affecting fish avoidance and benthic food sources in occupied streams, and fish being injured or killed during fish salvage efforts. Pacific Connector would install temporary flowing stream crossing by lifting or spanning a structure from a bank so that equipment does enter flowing waters. However, if it is not possible to do this safely, only equipment necessary to install the bridge would cross the stream. This would cause some limited, short-term bottom benthic disruption and possibly elevated suspended sediment. Adults and juveniles subject to fish salvage within the isolated construction site at the Lost River could be injured or killed if electroshocking is used and stressed if seining is used. Pacific Connector has included guidelines noted above under the Lost River sucker section in their *Fish Salvage Plan* that would be used near listed suckers. However, despite these measures, it is still possible that shortnose suckers could be killed by salvage operations and modifications to these plans may be needed to reduce this risk (see the Lost River Sucker section above).

Spawning occurs within limited areas of the Lost River (FWS 2013d; Reclamation 2012), and occasional individuals have been found in this stream region (NMFS and FWS 2013), suggesting it is possible that shortnose sucker could occur at the Pacific Connector pipeline crossing of Lost River at MP 212.07 during the non-spawning period. An additional 31 dry open-cut small intermittent stream crossings cannot be ruled out completely from potentially having shortnose sucker present because surveys have not been conducted for their presence.

The Project **may affect** shortnose suckers because:

- shortnose suckers occur within the Upper Klamath River subbasin and Lost River subbasin, which would be affected during construction of the proposed action.

The Project is **likely to adversely affect** shortnose suckers because:

- there is a possibility that shortnose suckers could occur within the Lost River when it would be crossed by the Pacific Connector pipeline and may be affected by elevated suspended sediment;
- shortnose suckers could occur in 19 waterbodies crossed by dry open-cut construction in the Lake Ewauna-Klamath River watershed and in 13 waterbodies west of MP 214.38 (including the Lost River) crossed in the Mills Creek-Lost River watershed and be indirectly affected by elevated suspended sediment levels, streambank erosion and stability, and aquatic nuisance species introductions; and
- adults and juveniles subject to fish salvage within the isolated construction site at 31 ditches crossed by dry-open cuts and the Lost River could be affected if electroshocking is used and stressed if seining is used.

The Project **may affect** designated critical habitat for the shortnose sucker because:

- there is a low risk of HDD failure during crossing of the Klamath River, resulting in a frac-out that releases drilling mud into the river.

However, the Project is **not likely to adversely affect** designated critical habitat for the shortnose sucker because:

HDD crossing methods would avoid critical habitat in the Klamath River;

- the potential for hydraulic fracture is so unlikely as to be discountable; and
- in the event of released bentonite during an HDD crossing, corrective actions would contain and temporally limit drill mud volumes.

4.6.1.4 Amphibians and Reptiles

Oregon Spotted Frog (Federally Threatened Species, Critical Habitat, State Sensitive-Critical)

On August 29, 2014, FWS listed the Oregon spotted frog as threatened (79 FR 51657). Critical habitat for the Oregon spotted frog was finalized in May 2016 and includes critical habitat in Oregon (Units 7 through 14; 81 FR 29335). This species is almost always found in or near a perennial body of water that includes zones of shallow water and abundant emergent or floating aquatic plants, which the frogs use for basking and escape cover (Corkran and Thoms 1996; FWS 2013f). The closest designated critical habitat unit to the Project is CHU 14 – Upper Klamath, which consists of 262 acres of lakes and creeks in Klamath and Jackson Counties and is currently occupied by Oregon spotted frogs (1 FR 2933). The Buck Lake population within CHU 14 is the closest occurrence of Oregon spotted frogs to the Project. This site includes seasonally wetted areas adjacent to the western edge of Buck Lake encompassing Spencer Creek downstream due west of Forest Service Road 46, three unnamed springs, and Tunnel Creek (81 FR 29335).

Oregon spotted frogs at Buck Lake have been consistently monitored from 2012 to 2016, along with other populations in the Oregon Cascades (Adams et al. 2017). Observations of frogs at two sites in Buck Lake and one in Tunnel Creek (both in CHU 14) indicate some variability in counts for each of several life stages but adults and larva or juveniles were found each year. Spencer Creek upstream of Buck Lake is almost equally subdivided into Buck Marsh, closest to Clover

Creek Road, and Buck Meadow, closest to Buck Lake (Lerum 2012). Buck Marsh is fed by several springs with evidence of beaver activity, and Buck Meadow is a pasture that often floods in the spring but does not stay flooded long enough to provide Oregon spotted frog breeding habitat. Further, soils in Buck Marsh are dense, possibly compacted by past heavy livestock use, and provide little water infiltration. Neither Buck Marsh nor Buck Meadow currently provide habitat for Oregon spotted frogs (Lerum 2012). Riparian vegetation is sparse and is unlikely to support beaver occupancy that could help to create suitable habitat (Lerum 2012).

The Project would cross Spencer Creek on the north side of Clover Creek Road, approximately 6,400 feet upstream from the CHU 14 at Buck Lake and pass within 280 feet of critical habitat in Spencer Creek downstream of Buck Lake. Potential effects on Oregon spotted frogs include changes to habitat quality and acoustic. Conservation measures proposed by Pacific Connector to minimize construction and operation effects on waterbodies and riparian zones would apply to Oregon spotted frogs.

Spencer Creek upstream of Buck Lake is not currently suitable habitat for Oregon spotted frogs and is unlikely to become suitable habitat and support Oregon spotted frogs at the time of construction. Clover Creek road separates the ROW from Spencer Creek downstream of Buck Lake so sediment from the construction ROW is not expected to enter Spencer Creek.

The Project **may affect** Oregon spotted frogs because:

- the Pacific Connector pipeline route would cross Spencer Creek, which is hydrologically connected to Buck Lake which is occupied by the frog; and
- the Pacific Connector pipeline route is within 280 feet of Spencer Creek and would cross tributaries to Spencer Creek downstream of Buck Lake, which is occupied by the Oregon spotted frog.

However, the Project **is not likely to adversely affect** Oregon spotted frogs for the following reasons:

- Buck Lake is approximately 6,400 feet downstream from where the pipeline route would cross Spencer Creek. Suspended sediment generated by the proposed action is expected to remain in the water column for 1,450 feet downstream from the construction site.
- Suspended sediment resulting from the crossing of Spencer Creek would pass through Buck Marsh, which Oregon spotted frogs do not currently inhabit. If the Oregon spotted frog does occur in Buck Marsh at the time of pipeline construction, conservation measures would limit potential effects due to acoustic shock, introduction of non-native species and/or disease, fuel and chemical spills, and herbicides.
- Future presence of Oregon spotted frogs in the Spencer Creek upstream of Buck Lake at the time of construction is extremely unlikely and considered to be discountable.
- Although the ROW occurs as close as 280 feet from Spencer Creek downstream of Buck Lake, they are not hydrologically connected because Clover Creek road separates the ROW from Spencer Creek; BMPs and erosion control measures should prevent sediment from the construction ROW from entering Spencer Creek.

The Project **may affect** designated critical habitat for the Oregon spotted frog because:

- the Pacific Connector pipeline route would be within 280 feet of proposed critical habitat within Spencer Creek downstream of Buck Lake.

The Project **is not likely to adversely affect** designated critical habitat for the Oregon spotted frog because:

- the designated critical habitat within 280 feet of the pipeline is not hydrologically connected to the ROW because it is separated by Clover Creek Road; and
- test water from the proposed hydrostatic discharge site at MP 169.52 is not expected to reach the critical habitat in Spencer Creek or Buck Lake, so effects on PBFs from changes in hydrology or introduction of nonnative species from the Project are discountable.

Sea Turtles

Four federally listed sea turtles potentially occur near the Project: green sea turtles, leatherback sea turtle, olive ridley sea turtle, and loggerhead sea turtle. All four species are federally threatened and state endangered.

Green sea turtles have been sighted from Baja California to southern Alaska, but most commonly occur from San Diego south (NMFS 2007a). Green turtles primarily use three types of habitat: oceanic beaches (for nesting), convergence zones in the open ocean, and benthic feeding grounds in coastal areas (NMFS 2007a). Reports of stranding suggest that the green turtle is a frequent visitor to the coast of California. Based on this data, green turtles are likely infrequent, transient visitors to the Oregon Coast, but may occasionally be found in the marine analysis area.

The leatherback sea turtle is the most common sea turtle in United States waters north of Mexico (NMFS and FWS 1998), and numerous sightings have been documented off the Oregon Coast. Adult leatherback turtles are highly migratory and available information indicates that eastern Pacific migratory corridors exist along the west coast of the United States (NMFS and FWS 1998). The west coast of the United States may represent some of the most important foraging habitat in the world for the leatherback turtle (NMFS and FWS 1998). Despite occasional reports of leatherbacks sighted at sea, and a growing database documenting their incidental catch in coastal and pelagic fisheries, there are very few areas where the species is routinely encountered. Exceptions include Monterey Bay, California (NMFS and FWS 1998). These data suggest that leatherback sea turtles would be present in the marine analysis area in higher densities relative to other sea turtle species, but still in low densities overall.

At-sea occurrences of olive ridley sea turtles in waters under United States jurisdiction are limited to the west coast of the continental United States and Hawaii, where the species is rare, but possibly increasing. During feeding migrations, olive ridley turtles may disperse into waters off the Pacific west coast as far north as Oregon (FWS 2013g). Based on sightings off the Oregon coast, olive ridley turtles may occasionally occur in the marine analysis area.

Loggerhead sea turtles occupy three different ecosystems during their lives—the terrestrial zone, the oceanic zone, and the neritic zone (NMFS 2007b). In the United States, occasional sightings are reported from the coasts of Washington and Oregon, but most records are of juveniles off the coast of California (NMFS 2007b). The potential importance of Oregon waters and the marine analysis area to loggerhead turtles is unknown, although two loggerhead turtles have been reported stranded in Oregon and Washington since the beginning of 1997 through 2007 (NMFS 2008d).

Direct effects of the proposed action include injury and/or mortality due to ship-strikes, underwater ship noise, and potential adverse effects from a vessel spill or ship release of LNG and fire at sea. Spills and/or release could indirectly affect federally listed sea turtles by affecting forage species. Below is a determination of effects summary for the federally listed sea turtles and critical habitat. More details will be provided in the pending BA.

The Project **may affect** federally listed sea turtles because:

- these sea turtles may occur within the marine analysis area during operation of the proposed action;
- the proposed action would increase shipping traffic (LNG carriers) within the marine analysis area; and
- the continental U.S. Pacific Coast provides important foraging habitat for leatherback turtles.

However, the Project is **not likely to adversely affect** federally listed sea turtles because:

- ship strike on sea turtles would be highly unlikely;
- Jordan Cove would provide a ship strike avoidance measures package to LNG carrier operators transporting cargo from the terminal that consists of multiple measures to avoid striking marine mammals, which should also benefit sea turtles;
- The FERC does not have authority over the LNG carrier; however, the independent carrier operators would be required to follow all Coast Guard requirements regarding the operation of LNG carriers including carrier speeds;
- noise produced by LNG carriers would contribute to overall noise levels within the marine analysis area en route to the Port of Coos Bay and effects of ship noise on sea turtles could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise (NMFS 2016c, NMFS 2017b, NMFS 2018c), but would not exceed existing background ship noise levels and would not cause injury; and
- given vessel design, on-board spill kits, safety records, and implementation of Coast Guard recommendations, it is not likely that there would be a major ship spill of hazardous materials that may adversely affect water quality or aquatic species. Fuel released at sea, if any, would be in small enough quantities that potential effects on listed sea turtles would be discountable, especially given the low density of sea turtles within the marine analysis area.

No critical habitat has been designated or proposed for the olive ridley or loggerhead sea turtles. Critical habitat was established for the green turtle on Culebra Island, Puerto Rico, on September 2, 1998 (NMFS 1998); however, no critical habitat for green sea turtles occurs on the U.S. Pacific Coast, and the Project would therefore have no effect on designated critical habitat for the green turtle.

The Project **may affect** designated critical habitat for the leatherback turtle because:

- Critical habitat coincides with nearshore waters in the marine analysis area through which LNG carriers would transit to Coos Bay and the LNG terminal.

However, the Project is **not likely to adversely affect** designated critical habitat for the leatherback turtle because:

- LNG carriers and the Jordan Cove LNG Project are not likely to contribute oil, fuel, lubricants, or other contaminants to critical habitat to the extent that would adversely affect the occurrence of prey species, primarily jellyfish, of sufficient condition, distribution, diversity, and abundance to support individual as well as population growth, reproduction and development (PBF 1); and
- disturbance of benthic habitats within Coos Bay due to dredging would be of sufficiently short duration and small scale relative to the area available for settlement of larvae of the scyphozoan prey species within Area 2 that effects on PBF 1 would be unmeasurable and would therefore be discountable.

4.6.1.5 Invertebrates

Vernal Pool Fairy Shrimp (Federally Threatened Species with Critical Habitat, No State Status)

Vernal pool fairy shrimp were listed as threatened under the ESA on September 19, 1994 (FWS 1994a). This crustacean inhabits vernal pools, or seasonal wetlands that fill with water during fall and winter rains, in California and southwestern Oregon. The vernal pool fairy shrimp was identified relatively recently (in 1990) and was not discovered in Jackson County, Oregon until 1998 (FWS 2005s). As a result, it is possible that additional locations for the species will be found in Oregon in the future (FWS 2005a). Suitable vernal pool habitat occurs within and adjacent to Project facilities, some of which has not been surveyed. Additionally, a proposed pipe storage yard is in the Burrill Lumber industrial yard adjacent to the vernal pool fairy shrimp critical habitat unit VERFS 3A. Potential effects on vernal pool fairy shrimp and critical habitat include possible disturbance to pools from driving or storing equipment or pipes near or on pools or wetlands, and alteration of hydrology. Although nine vernal pools within the ROW between MPs 145.3 and 145.4 are outside the known range for vernal pool fairy shrimp, the vernal pools may provide suitable habitat for the species because the pools occur within the appropriate soils type (Agate-Winlo) for vernal pool fairy shrimp, occur near (i.e., within 8.2 miles of) the known and relatively recently (1998) expanded range of the species, and the species' absence has not been confirmed. Based on the relatively recent expansion of the known range of this species and the presence of potentially suitable habitat (including soil type) that has not been surveyed, there is potential for this species to be present within the ROW and be affected by pipeline construction.

These effects would be minimized through avoidance and minimization measures. Specifically, Pacific Connector has indicated they would avoid using areas within yards that may contain vernal pool fairy shrimp and, if this species is noted during survey efforts, they would implement proper sedimentation control barriers to minimize potential effects on the species. Below is a determination of effects summary for the vernal pool fairy shrimp and critical habitat. More details will be provided in the pending BA.

The Project **may affect** vernal pool fairy shrimp for because:

- Potentially suitable habitat for vernal pool fairy shrimp has been identified near four proposed Jackson County pipe storage yards, as well as within and adjacent to the pipeline ROW between MPs 145.30 and 145.40.

The Project is **likely to adversely affect** vernal pool fairy shrimp because:

- Effects on vernal pool fairy shrimp are possible due to the Project's crossing of potentially suitable, unsurveyed habitat within the pipeline ROW between MPs 145.30 and 145.40 (within Agate-Winlo soils).

The Project **may affect** vernal pool fairy shrimp critical habitat because:

- the Project occurs adjacent to designated vernal pool fairy shrimp critical habitat; and
- the Project may affect suitable habitat within designated critical habitat adjacent to the Project.

However, the Project is **not likely to adversely affect** vernal pool fairy shrimp critical habitat because:

- Although the proposed Burrill Lumber pipe yard occurs within 250 feet of designated vernal pool fairy shrimp critical habitat unit (VERFS 3A), it is separated from the critical habitat unit by Agate Road, which is a two-lane paved road that acts as a barrier to hydrologic connectivity that is considered a definitive boundary to the area of effects.
- Burrill Lumber pipe yard has been previously disturbed, and additional surface disturbances and/or soil compaction by heavy machinery from use within Burrill Lumber pipe storage yard should be minimal. Also, Agate Road is located between Burrill Lumber pipe yard and critical habitat unit VERFS 3A, which is raised and paved, and would serve as an existing barrier between the pipe yard and critical habitat unit. Therefore, use of the Burrill Lumber pipe storage yard is not expected to adversely modify geographic, topographic, and edaphic features potentially within 250 feet of the yard that support systems of hydrologically interconnected pools, swales, and other ephemeral wetlands and depressions within the matrix of surrounding uplands (PBF 2).
- Proposed conservation measures would reduce the potential for increased sediment mobilization, increased fugitive dust, and the potential spread of invasive species to suitable vernal pool habitats.

4.6.1.6 Plants

A botanical analysis area applies to the extent of Project-related effects on listed plant species. The botanical analysis area for this Project extends to 98 feet (30 meters) each side of the pipeline project (i.e., construction ROW, TEWAs, UCSAs, rock source and disposal sites, proposed storage yards, and aboveground facilities) as well as the footprint for the Jordan Cove LNG Project. The botanical analysis area, in general, includes the area surveyed for sensitive and listed plant species (at least 100 feet from habitat removal on federal lands and at least 50 feet from habitat removal on non-federal, private lands) and distance that indirect effects on plants would be expected. Surveys are incomplete in areas of potential habitat along the pipeline route where landowner permission was denied. Pacific Connector would survey these areas after the Project is certificated, but before construction begins (i.e., if the Project is approved and Pacific Connector gains access using eminent domain proceedings under Section 7h of the NGA). Pacific Connector identified unsurveyed areas that may contain suitable habitat for listed species, as will be discussed in our pending BA.

Pacific Connector has developed a *Federally-listed Plant Conservation Plan* to address how avoidance, minimization, propagation, restoration, and other conservation measures would be applied to protect listed plant species, as well as how potential effects on unsurveyed lands would be addressed. For example, if populations of listed plant species are identified where surveys were previously denied, Pacific Connector would apply mitigation measures that have been developed for surveyed lands to minimize and avoid effects on these species including (1) minor alignment or route adjustments; (2) narrowing or necking-down the construction ROW; or (3) eliminating or removing a portion of a TEWA or UCSA (depending on where new populations of these species were identified). Additional construction measures that would be implemented in areas that contain listed plants to minimize and avoid effects on these species, if they occur, include the following measures listed below.

- The construction ROW and TEWAs would be surveyed and flagged to clearly mark the limits of construction disturbance (i.e., clearing/grading).
- Where feasible, the EI would monitor the survey and flagging efforts and would provide additional protective buffers or neckdowns to ensure protection of adjacent plant populations or provide additional avoidance. The EI would consult with Pacific Connector's Chief Inspector and the construction contractor during construction to determine where additional buffer protections or neckdowns could be accommodated without affecting construction safety.
- Known plant populations adjacent to the construction ROW or other plants populations identified during preconstruction surveys would be protected by a safety fence and silt fence to ensure these plants are not inadvertently affected by Project activities.
- BMPs outlined in Pacific Connector's *Air, Noise and Fugitive Dust Control Plan*[140] to minimize wind erosion and fugitive dust emissions during construction and restoration activities would be implemented. Water would be used to control fugitive dust along the construction ROW (no Dustlok® would be used within 150 feet of any listed plants). Only enough water would be sprayed to control the dust or to reach the optimum soil moisture content to create a surface crust; no runoff would be generated.
- Equipment would be inspected and cleaned of potential noxious weed seed or plant parts consistent with the requirements of Pacific Connector's *Integrated Pest Management Plan*.
- Topsoil salvaging would occur within affected populations after species-specific seed, bulb, or whole plant salvage has occurred. The salvaged topsoil would be returned to its original location during restoration.
- During restoration, all areas would be regraded as closely as possible to the original contours to ensure preconstruction drainage patterns are not affected.

[140] Appendix B in Pacific Connector's POD filed with the FERC in January 2018,

- The construction ROW would be restored to its original contours and reseeded with an appropriate seed mixture recommended by FWS prior to the following growing season.
- When feasible, Pacific Connector would collect and bag seeds and/or bulbs of affected listed plants and provide these seeds and/or bulbs to a suggested repository. Upon FWS approval, the collected seeds would be replanted within or adjacent to the construction ROW on suitable federal lands where future protection can be managed or on private lands where a conservation easement has been acquired.
- Construction activities would occur in the fall and winter outside the critical growing, flowering, and seeding periods.
- Wetland mats would be used in travel areas in saturated soil areas to minimize soil rutting and soil compaction and protect existing plants that may be present.

The *Federally-listed Plant Conservation Plan* includes specific mitigation plans for Applegate's milk-vetch, Gentner's fritillary, Kincaid's lupine, and Cox's mariposa-lily. In addition, the Forest Service has developed mitigation measures/requirements related to their ROW Grant that may also indirectly benefit listed plant species (see chapter 2 of this EIS and appendix F).

Below is a discussion of each federally-listed plant species that could be affected by the Project. The mitigation measures discussed above would apply to all federally-listed plants discussed in this section.

Applegate's Milk-vetch (Federally Endangered Species, State Endangered Species)

FWS listed Applegate's milk-vetch (*Astragalus applegatei*) as endangered on July 28, 1993 (FWS 1993c). This species has a narrow range, known only in the Lower Klamath Basin (the plain containing Lower Klamath Lake), near the city of Klamath Falls in southern Oregon. It was believed to be extinct until its rediscovery in 1983 and at the time of listing was only known from two extant sites. Applegate's milk-vetch grows in flat-lying, seasonally moist, alkaline soils with underlying clay hardpans. The species' habitat was historically characterized by sparse, native bunchgrasses and patches of bare soil, allowing for some seed dispersal by wind. Today, dense coverage of the habitat by introduced grasses and weeds means seed dispersal is highly localized, with most seedling establishment found adjacent to mature plants (FWS 1998b). Continued destruction, modification, and/or curtailment of its habitat or range due to urban and commercial development, and loss of habitat through competition with non-native weeds, are the principal threats to the survival of the species (FWS 2009a).

The Pacific Connector Project is located within known and historic Applegate's milk-vetch range between MPs 191.20 to 214.30. The "Collins Tract site," which is located within and adjacent to the botanical analysis area between approximately MP 195.3 and MP 196.7, contains 19 sub-populations of Applegate's milk-vetch, several of which were discovered by FWS and SBS during surveys conducted for Pacific Connector. This area was revisited in 2018 and no new sites were documented. Pacific Connector has revised its proposed route slightly in this area to avoid direct effects on the plants identified in 2008 within the Collins Tract site. Survey efforts of the pipeline route subsequent to these initial survey efforts in 2007 and 2008 have not identified any additional plants; however, Pacific Connector has not surveyed all potential habitat. Additionally, in 2009, the FWS and The Nature Conservancy documented 1,260 plants within and adjacent to the proposed Klamath Falls Memorial Drive 2 pipe storage yard, in an area that has not been surveyed for the Project (ORBIC 2017a).

The route has been relocated to avoid known populations of Applegate's milk-vetch as well as suitable habitat found during surveys conducted during summer 2008; therefore, no direct effects on known plants in those sites are expected. Additionally, Pacific Connector would resurvey the Klamath Falls Memorial Drive 2 pipe storage yard prior to construction and avoid the use of the proposed yard within 30 meters of known and documented Applegate's milk-vetch plants. Project surveys of all suitable habitat have not been completed for this species; therefore, additional plants could potentially be encountered and affected by the Project. Measures to reduce impacts on unidentified plants are included in the *Applegate's Milk-vetch Mitigation Plan*; however, the FWS has indicated it may require additional mitigation for these potential impacts as part of their BO (including additional survey, seed collection, and salvage requirements). Below is a determination of effects summary for Applegate's milk-vetch and critical habitat. More details will be provided in the pending BA.

The Project **may affect** Applegate's milk-vetch because:

- suitable habitat is available within the botanical analysis area; and
- individual plants have been located within the analysis area during survey efforts.

The Project is **likely to adversely affect** Applegate's milk-vetch because:

- approximately 175.3 acres of potential suitable habitat that has not been surveyed occurs within the botanical analysis area along the pipeline route, which includes 77 acres within the pipeline ROW; therefore, it is possible that unidentified plants occur within the construction ROW and workspace;
- surface disturbance and excavation would occur within potentially suitable habitats and could impact unidentified plants (including in areas where surveys have not been completed); and
- indirect effects, including potential changes in hydrology and soil characteristics, introduction and spread of invasive plants and noxious weeds, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust, could impact documented or suspected plants and habitat outside the construction ROW, but within 30 meters of the Project pipeline.

Critical habitat has not been designated for Applegate's milk-vetch.

Gentner's Fritillary (Federally Endangered Species, State Endangered Species)

FWS listed Gentner's fritillary (*Fritillaria gentneri*) as endangered on December 10, 1999 (FWS 1999). Gentner's fritillary is found in small, scattered locations in the Rogue and Klamath River watersheds in Jackson and Josephine Counties in Oregon (FWS 2003c; 2016d). This species is highly localized, with populations occurring within a 30-mile radius of Jacksonville Cemetery in Jacksonville, Oregon (FWS 2003c). Since the 2003 publication of the recovery plan, nine new Gentner's fritillary populations (approximately 131 flowering plants within 1.6 acres) have been detected outside of the four recovery unit boundaries (FWS 2016d). It is difficult to census populations of Gentner's fritillary because this species does not flower every year and individuals can remain dormant for one or more years underground.

Gentner's fritillary is often found on the edge of dry woodland and forests where the overstory can be dominated by Oregon white oak, madrone, Douglas-fir, and ponderosa pine; it also occurs in open chaparral and grassland environments. It occurs at a wide range of elevations, from 1,000 to 5,100 feet, and is usually associated with shrubs that provide protection from the wind and sun (FWS 2003c).

The Pacific Connector Project crosses the plant's range between approximately MP 113 through MP 155. Surveys for Gentner's fritillary have occurred within suitable habitat near the pipeline from 2007 through 2018. Surveys are expected to continue to complete recommended second year survey efforts, where necessary. Additionally, surveys will be initated in other areas that receive survey permission. Since 2007, survey efforts have identified Gentner's fritillary individuals in five locales: (1) approximately 0.38 mile north of MP 128.0 near Indian Creek and 50 feet below a four-wheel drive road; (2) 21 feet from TEWA 128.01-W; (3) 100 feet from proposed access road EAR-128.05; (4) near MP 129.1 approximately 54 feet from TEWA 128.96-N; and (5) within 21 feet of TEWA 142.07-N near MP 142.1. Of these five sites, three are located within the analysis area. Direct impacts on known individuals of Gentner's fritillary would be avoided; however, unidentified *Fritillaria* plants near MP 142.1 that could be Gentner's fritillary occur within the pipeline ROW and would be impacted if a reroute of the pipeline alignment is not implemented (additional details to be provided in our pending BA). Additionally, unidentified *Fritillaria* plants near MP 129 that could be Gentner's fritillary occur within the analysis area and could be indirectly affected.

Additionally, Project surveys of all suitable habitat have not been completed for Gentner's fritillary; therefore, additional plants could potentially be encountered and affected by the Project. The FWS will require two-year protocol surveys in unsurveyed, potentially suitable habitat and in suitable habitat where surveys are older than 10 years. However, indirect impacts on known individuals could be eliminated with minor modifications to the construction ROW. Therefore, **we recommend that:**

- **Prior to end of the draft EIS comment period, Pacific Connector should file with the Secretary revised alignment sheets that eliminate or relocate TEWA 128.01-W, TEWA 128.96-N, TEWA 142.07-N. and EAR-128.05.**

Below is the determination of effects summary for Gentner's fritillary; more details will be provided in our pending BA.

The Project **may affect** Gentner's fritillary because:

- suitable habitat is available within the analysis area; and
- individual plants have been located within the analysis area during survey efforts.

The Project is **likely to adversely affect** Gentner's fritillary because:

- approximately 240.9 acres of potential suitable habitat that has not been surveyed occurs within the botanical analysis area along the pipeline route, which includes 50.4 acres within the pipeline ROW; therefore, it is possible that unidentified plants occur within the construction ROW and workspace;

- *Fritillaria* spp. have been identified within and adjacent to areas that would be affected by the Project;
- Gentner's fritillary can remain dormant underground for one year or longer, does not flower every year, and has been documented to not flower for several years; therefore, it is possible that protocol surveys conducted for the Project did not locate this species; and
- indirect effects, including potential changes in hydrology and soil characteristics, introduction and spread of invasive plants and noxious weeds, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust, could impact documented or suspected plants and habitat outside the construction ROW, but within 30 meters of the Project pipeline.

Critical habitat has not been designated for Gentner's fritillary.

Western Lily (Federally Endangered Species, State Endangered Species)

FWS listed the western lily (*Lilium occidentale*) as endangered on August 17, 1994 (FWS 1994b). This lily is currently known from 23 small populations in freshwater marshes and swamps, early successional fens (bogs), coastal scrub and prairie, openings in coastal, Sitka spruce–dominated coniferous forests, as well as other poorly drained soils along the coast of southern Oregon and northern California (FWS 2009b). Western lilies have an extremely restricted distribution, and only occur along the coast within 4 miles of the Pacific Ocean. Occurrences within the Coos Bay area are reported to occur in Blacklock soils; however, it also grows in soils that are well drained that have a substancial layer of organic soil (SHN 2013c).

The closest known western lily occurrence in relation to the Project is approximately 1 mile south of the Myrtlewood Off-site Park & Ride at the Hauser Bog (ORBIC 2017b). However, the Myrtlewood Off-site Park & Ride is located completely in the paved parking lot and does not contain suitable habitat for the western lily. There are no other known occurrences within two miles of the Project (ORBIC 2017b). There are no records of western lily north of Hauser, and the FWS typically considers Hauser the northern extent for the species along the Oregon coast.

Surveys for western lily within potential habitat in the analysis area (i.e., poorly drained bogs with acidic organic soils and within six miles of the coast below 300 feet elevation) were conducted between 2006 and 2017 (SHN 2013c; SBS 2008a, 2012, 2013, 2014, 2017a). Jordan Cove conducted surveys at the LNG terminal site in 2006, 2012, and 2013 and surveys were conducted by SBS for Pacific Connector between 2007 and 2017. No occurrences of western lily were detected during these surveys, and only limited areas of potential suitable habitat were identified. More details will be provided in our pending BA.

Although no plants were identified in the area that would be affected by the Project and potential occurrence of this species in this area is low, surveys of all potential habitat in the area have not been completed for this species; therefore, western lily could potentially be encountered and affected by the Project. Additionally, this species is difficult to detect when not flowering, and surveys may overlook western lily juveniles or vegetative adults, especially non-flowering individuals growing within dense vegetation (FWS 2008b). Below is the determination of effects summary for western lily and critical habitat.

The Project **may affect** the western lily because:

- known populations occur within 1 mile of the botanical analysis area; and
- potential suitable habitat is available within the analysis area.

The Project is **not likely to adversely affect** the western lily because:

- surveys of potential western lily habitat at the Jordan Cove site and associated facilities and along the pipeline route did not document western lily and potential suitable habitat within the botanical analysis area is limited;
- surveys in potentially suitable habitat would occur prior to ground-disturbing activities; if plants are identified, conservation measures developed to avoid or minimize effects on any documented plants would be implemented; and
- consultations with the FWS would be reinitiated if this species is found to be present in the area and effects cannot be avoided.

Critical habitat has not been designated for the western lily.

Large-Flowered Meadowfoam (Federally Endangered Species, State Endangered Species)

The large-flowered meadowfoam (*Limnanthes pumila* ssp. *grandiflora*) was federally listed as endangered on November 7, 2002 (FWS 2002b). It is an endemic species restricted mostly to the Agate Desert area in the Rogue River Valley of southern Oregon. It grows on the wetter, inner edges of vernal pools at elevations between 1,220 and 1,540 feet. The plant is capable of self-fertilization and self-pollination. In the Rogue River Valley, large-flowered meadowfoam is often found in the same vernal pool habitats as Cook's lomatium (*Lomatium cookii*) and the vernal pool fairy shrimp.

In 2010, FWS designated eight CHUs (5,840 acres) for the large-flowered meadowfoam in the Agate Desert complex in Jackson County, Oregon. Two of the units designated are shared by the designated habitat for Cook's lomatium. All designated CHUs are currently occupied (or expected to be occupied; FWS 2010b). Within the vicinity of White City, Oregon, where multiple pipe storage yards would be located, CHUs RV6 (6A through 6H) and RV8 have been designated. Industrial parks surround all units. Unit RV6C is across an existing paved road from the Burrill Lumber pipe storage yard, and Unit RV6D is 590 feet northeast of this pipe storage yard. RV8 is over 1.8 miles west of the proposed Rogue Aggregates and the other three pipe storage yards.

Botanical surveys were conducted within identified suitable habitat for this species where access was permitted, during the flowering season in April 2007. In 2007, survey efforts documented approximately 36 large-flowered woolly meadowfoam plants approximately 850 to 1,165 feet east of the proposed Burrill Lumber pipe storage yard. Additionally, ORBIC (2017a) has reported several other subpopulations of large-flowered woolly meadowfoam (approximately 16,200 plants) near proposed pipe storage yards, including within the Ken Denman State Game Management Preserve across an existing paved road east of the Burrill Lumber pipe storage yard.

No surveys have been permitted within Avenue F & 11th Street and WC Short pipe storage yards; however, off-site observations identified approximately 0.48 acre of highly modified, low-quality vernal pool habitat within 250 feet of the Avenue F & 11th Street and WC Short pipe yards. This area is associated with active industrial sites or previously disturbed industrial areas and is not expected to provide high-quality vernal pool habitat or support individuals of large-flowered woolly meadowfoam. Additionally, no direct or indirect effects on potential vernal pool habitat are expected from use of the Avenue F & 11th Street and WC Short pipe storage yards.

The Project **may affect** large-flowered woolly meadowfoam because:

- the pipeline occurs near occupied, large-flowered woolly meadowfoam habitat.

The Project is **not likely to adversely affect** large-flowered woolly meadowfoam because:

- surveys of potentially suitable habitat at proposed pipe storage yards in Jackson County and along the Project did not document large-flowered woolly meadowfoam plants;
- the 0.48-acre of unsurveyed potential habitat within the Avenue F and 11th and WC Short pipe storage yards consists of low-quality vernal pool habitat within active industrial sites or previously disturbed industrial areas and is unlikely to contain large-flowered woolly meadowfoam;
- Pacific Connector would avoid using portions of the pipe storage yards within 250 feet (indirect effect) of this species or potentially suitable vernal pool habitat;
- effects on suitable habitat are likely to be discountable to the point where no meaningful measurement, detection, or evaluation of effects would be possible (i.e., effects would not reach a level where individual plants would be lost);
- sedimentation barriers would be used, as appropriate, to prevent run-off and changes in hydrology;
- conservation measures have been developed to avoid or minimize effects on any plants identified during surveys prior to construction; and
- construction of the pipeline is not expected to adversely modify hydrology in nearby suitable habitat areas within 250 feet of proposed pipe storage yards.

The Project **may affect** designated critical habitat for large-flowered woolly meadowfoam because:

- the Project occurs adjacent to large-flowered woolly meadowfoam critical habitat.

The Project is **not likely to adversely affect** large-flowered woolly meadowfoam critical habitat because:

- Construction of the pipeline is not expected to adversely modify designated critical habitat areas within 250 feet of pipeline components (i.e., subunit RV6C); existing features (i.e., paved Agate Road) and proposed conservation measures would provide sufficient protection from adjacent development and invasive plant and noxious weed sources; and

- The Burrill Lumber pipe yard is hydrologically disconnected from subunit RV6D due to topography (flow is away from RV6D) and distance (greater than 590 feet) and is hydrologically isolated from subunit RV6C by the raised Agate Road.

Cook's Lomatium (Federally Endangered Species, State Endangered Species)

Cook's lomatium was listed as federally endangered on November 7, 2002 (FWS 2002b). Its range is on seasonally wet soils limited to two areas: (1) along vernal pools in the Agate Desert area of the Rogue River Valley, Jackson County, and (2) in seasonally wet serpentine-derived grassland meadows, sloped mixed-conifer forest openings, and and along roadsides edges in shrub dominated plant communities or adjacent to meadows within the Illinois River Valley area near Cave Junction, Josephine County. The Jackson County populations occur along the margins and bottoms of vernal pool habitats within a 20,510-acre landform known as the Agate Desert. The plant flowers from late March to May and is pollinated entirely by insects. In the Rogue River Valley, Cook's lomatium is often found in the same vernal pool habitats as the large-flowered meadowfoam and the vernal pool fairy shrimp.

In 2010, the FWS designated 16 units (6,289 acres) of critical habitat for the Cook's lomatium, including three CHUs in Jackson County, totaling 2,282 acres. Two of the designated units in Jackson County are shared by the designated habitat for large-flowered woolly meadowfoam. All designated CHUs are currently occupied (FWS 2010b). CHUs RV6 (A, F, G, and H) and RV8 have been designated within the vicinity of White City, Oregon, where multiple pipe storage yards would be located. Industrial parks surround these units. CHUs RV6A and RV6H are located approximately 0.5 mile south and 0.8 mile southeast, respectively, of the Avenue F & 11th Street and WC Short pipe storage yards.

Four pipe storage yards, Burrill Lumber, WC Short, Avenue F & 11th Street, and Rogue Aggregates, occur within the Agate Desert near White City in proximity to known occupied vernal pools. No vernal pool habitat or individuals of Cook's lomatium were observed during surveys of the Burrill Lumber and Rogue Aggregates pipe storage yards, and no potential vernal pools were located within 250 feet of the Burrill Lumber pipe storage yard. Although the layout for the Rogue Aggregates pipe storage yard has been reconfigured since surveys in 2007, unsurveyed portions do not contain suitable soil types for Cook's lomatium. Several patches of Cook's lomatium have been documented in the Denman Wildlife Management Area and Agate Desert Preserve, 0.5 mile south of the Avenue F & 11th Street and WC Short pipe storage yards (Friedman 2006, ORBIC 2017a). Surveys have not been conducted within the Avenue F & 11th Street and WC Short pipe storage yards because access has not been granted; however, based on aerial photography and off-site observation in April 2018, Avenue F and 11th and WC Short pipe storage yards do not appear to contain suitable habitat for Cook's lomatium. A long drainage ditch running along the northern edge of the Avenue F and 11th pipe storage yard, which could provide low-quality habitat for Cook's lomatium, was observed during these off-site surveys.

Below is the determination of effects summary for Cook's lomatium and critical habitat; more details will be provided in our pending BA.

The Project **may affect** Cook's lomatium because:

- suitable, occupied habitat is available within the vicinity of the Project.

The Project is **not likely to adversely affect** Cook's lomatium because:

- surveys of suitable habitat at pipe storage yards in Jackson County and along the pipeline did not document Cook's lomatium;

- Pacific Connector would avoid using portions of pipe storage yards within 250 feet of high-quality vernal pool habitat, as well as areas with potential vernal pool habitat;
- effects on suitable habitat are likely to be discountable to the point where no meaningful measurement, detection, or evaluation of effect would be possible (i.e., effect would not reach a level where individual plants would be affected);
- sedimentation barriers would be used, as appropriate, to prevent run-off and changes in hydrology;
- conservation measures have been developed to avoid or minimize effects on any plants identified during surveys prior to pipeline construction;
- known sites within the vicinity of the Project are farther than 0.5 mile from pipe storage yards; and
- unsurveyed habitat is low-quality vernal pool habitat located over 0.25 mile from known sites with no apparent hydrologic connectivity.

The Project would have **no effect** on designated Cook's lomatium critical habitat because:

- the pipeline is over 0.5 mile from the nearest critical habitat subunit RV6A; and
- the proposed action is not expected to adversely modify habitat areas that provide buffer protection from adjacent development and weed sources, continuous nonfragmented habitat, and intact hydrology (PBFs 1 and 4).

Kincaid's Lupine (Federally Threatened Species, State Threatened Species)

Kincaid's lupine was listed as federally threatened on January 25, 2000 (FWS 2000b). It is a long-lived perennial herb inhabiting native prairies and foothills (FWS 2000b). In Douglas County, Oregon, it occupies sites that are more shaded, occurring in areas with tree (i.e., Douglas-fir, California black oak, Pacific madrone, ponderosa pine, incense cedar, hairy manzanita, and poison oak) and shrub canopy cover of 50 to 80 percent (FWS 2006f). About 600 acres have been designated as critical habitat for this species; however, all of these designated habitats are located outside of areas that would be disturbed by the Project.

The pipeline is located within known or historical Kincaid's lupine range between MPs 46.8 and 99.3. Multiple populations of lupine have been identified in the Project's botanical analysis area within Douglas County, including 11 sites within 2.5 miles of the pipeline (ORBIC 2017a). Surveys in 2007 identified three populations of Kincaid's lupine in the vicinity of the pipeline: 1) within and adjacent to the construction ROW on private land between approximately MPs 57.84 and 57.92; 2) on private land near MP 59.60 (approximately 300 feet north of MP 59.60; 67 and 222 feet to the north and west of TEWA 59.30-N; and approximately 40 and 85 feet to the south and west of EAR 59.62); and 3) and on private land within the construction ROW and along proposed access roads between MPs 96.48 to 96.90.

Pacific Connector has modified the pipeline route to avoid the population located within the construction ROW between MP 57.84 and MP 57.92. No direct impacts are anticipated to the population near MP 59.60, as plants are located at least 67 feet from pipeline facilities. The two sites, near MP 57.84-57.92 and 59.60, were revisited in 2017, and both populations appeared to be stable or slightly increasing (SBS 2017b).

Pacific Connector also modified the construction ROW between MP 96.48 and 96.90 to avoid direct impacts on the Kincaid's lupine individuals identified during surveys in 2007. Additionally, the population between MP 96.48 and 96.90 was burned during the 2015 Stouts Creek fire. This population was revisited in 2016 to determine the affect of the fire, associated fire-suppression activity, and subsequent logging activities. Kincaid's lupine was observed in only 2 of the original 28 subpopulations documented in the area during surveys in 2007, and no viable plants were observed in the pipeline ROW or within proposed access roads (SBS 2016). Although no plants were relocated along the construction ROW between MP 96.48 and 96.90 in 2016, it is possible that construction of the pipeline and use of access roads could affect this population if plants resprout in this area. Pacific Connector would conduct additional surveys within the Stouts Creek fire area (MP 96.48 to 96.9) prior to ground disturbance.

No additional plants have been documented in other areas of the pipeline route, where access was granted, during subsequent surveys. However, not all suitable habitats within the Project area have been surveyed to date, indicating that additional unknown populations may be present within areas that could be affected by the Project. If other Kincaid's lupine populations are identified during additional surveys, Pacific Connector would implement applicable mitigation measures, such as necking down the construction right-of way, excluding a portion of an identified TEWA or pipe storage yard, and erecting a protective fence or barrier, to avoid or minimize impacts on newly observed populations. Persisting subpopulations at MPs 96.48 to 96.9 would be flagged/fenced to minimize potential disturbance.

The Project could affect unknown populations of Kincaid's lupine within and adjacent to the pipeline ROW. The *Federally-listed Plant Conservation Plan* contains a Kincaid's Lupine Mitigation Plan that specifically addresses mitigation that would be implemented for Kincaid's lupine; however, the FWS may require additional mitigation for these potential impacts as part of their BO (including additional survey, seed collection, and salvage requirements). Below is the determination of effects summary for Kincaid's lupine and critical habitat.

The Project **may affect** Kincaid's lupine because:

- suitable habitat is present within the analysis area; and
- individual plants have been located within the analysis area during survey efforts.

The Project is **likely to adversely affect** Kincaid's lupine because:

- approximately 991.6 acres of potential suitable habitat that has not been surveyed occurs within the botanical analysis area along the pipeline route, which includes 448.7 acres within the pipeline ROW; therefore, it is possible that unidentified plants occur within the construction ROW and workspace;
- surface disturbance and excavation would occur within potentially suitable habitats, and could impact unidentified plants (including in areas where surveys have not been completed);
- indirect effects, including potential changes in hydrology and soil characteristics, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust, could impact documented or suspected plants and habitat outside of the construction ROW, but within 30 meters of the Project pipeline and along access roads; and

- trenching activities associated with the pipeline could affect below-ground stems, and the expected effect to extant plants is unknown.

The Project would have **no effect** on Kincaid's lupine critical habitat because:

- the pipeline does not occur within designated Kincaid's lupine critical habitat.

Rough Popcornflower (Federally Endangered Species, State Endangered Species)

The rough popcornflower was federally listed as endangered on January 25, 2000 (FWS 2000c). It is found in seasonal wet meadows or wet prairies in poorly drained clay or silty clay loam soils at elevations ranging from 100 to 900 feet. This plant occurs mostly on private lands in the Umpqua River drainage near Sutherlin and Yoncalla in northern Douglas County (FWS 2003d). As of 2010, there were 14 extant populations of rough popcornflower distributed from Yoncalla Creek near Rice Hill, south to Sutherlin Creek near Wilbur, of which five populations have been introduced (FWS 2010c). Six populations are considered protected and have a documented occupancy of at least 5,000 plants (FWS 2010c).

The closest known occurrences of rough popcornflower to the Project include multiple subpopulations approximately 1.7 miles north of the Winchester pipe storage yard and 17.5 miles north of the pipeline ROW at MP 68 (ORBIC 2017a, 2017c). Surveys for rough popcornflower have been conducted in potential habitat between MPs 51.7 and 67.0. To date, no individuals of rough popcornflower have been documented during surveys. However, Pacific Connector has not been granted access to approximately 99.83 acres of potentially suitable rough popcornflower habitat within the analysis area, the majority of which is associated with the Winchester pipe storage yard.

Due to the potential for the plant to occur within areas of potential habitat that have not been surveyed by Pacific Connector and may be disturbed by construction activities, the Project may affect rough popcornflower. Below is the determination of effects summary for rough popcornflower and critical habitat.

The Project **may affect** rough popcornflower because:

- populations occur near a pipe storage yard; and
- potential suitable habitat might be present within the 98-foot (30-meter) botanical analysis area.

The Project is **not likely to adversely affect** rough popcornflower because:

- where access has been granted, surveys for the Project have not documented individuals of rough popcornflower; surveys in potentially suitable habitat identified within the Winchester pipe storage yard would occur prior to ground-disturbing activities; if plants are identified, Pacific Connector would not use either the pipe storage yard or portions of the yard where plants are documented;
- surveys within potential habitat along the pipeline ROW would occur prior to ground disturbing activities; if any plants are identified, conservation measures developed to avoid or minimize effects on documented plants would be implemented; and
- consultation with the FWS would be reinitiated if this species is found to be present in the area and effects cannot be avoided.

Critical habitat has not been designated for rough popcornflower.

4.6.1.7 Conclusions and Recommendations for Threatened and Endangered Species

Based on informal consultations with the FWS and NMFS, 34 federally listed and proposed species were identified as potentially occurring near the Project. The FERC would only authorize the Project to proceed if the FWS' and NMFS' BOs find the Project, as described, would not jeopardize the continued existence of listed species or result in the destruction or adverse modification of designated critical habitat. Further, to ensure compliance with the ESA, **we recommend that:**

- **Jordan Cove and Pacific Connector <u>should not begin construction until</u>:**
  - **a. the Commission staff completes formal consultations with the NMFS and FWS; and**
  - **b. Jordan Cove and Pacific Connector have received written notification from the Director of OEP that construction and/or implementation of conservation measures may begin.**

4.6.2 State-Listed Threatened or Endangered Species

In addition to species that are federally threatened or endangered, there are 13 species designated as threatened or endangered by the State of Oregon that could potentially occur in the area affected by the Project (table 4.6.2-1).

TABLE 4.6.2-1

State-Listed Species Potentially Occurring in the Area Affected by the Proposed Project

Species	FWS Status	ODFW Status	Portion of the Project Area Where Species Potentially Occur
Mammals			
Kit fox *Vulpes macrotis*	None	Threatened	Pacific Connector Pipeline
Gray Whale *Eschrichtius robustus* (Eastern North Pacific stock)	Delisted	Endangered	LNG carrier transit in the waterway, Navigation Reliability Improvements Dredge Areas
Birds			
California brown pelican *Pelecanus occidentalis*	None	Endangered	Navigation Reliability Improvements Dredge Areas, Jordan Cove terminal
Plants			
Pink sand verbena *Abronia umbellata* ssp. *Breviflora*	Species of Concern	Endangered	Jordan Cove terminal
Point Reyes bird's-beak *Cordylanthus maritimum* ssp. palustre (*C. maritimus* ssp. *palustris*)	Species of Concern	Endangered	Jordan Cove terminal; Pacific Connector pipeline
Wayside aster *Eucephalis vialis* (*Aster vialis*)	Species of Concern	Threatened	Pacific Connector pipeline
Peck's milk-vetch *Astragalus peckii*	None	Threatened	Pacific Connector pipeline
Pumice grape-fern *Botrychium pumicola*	None	Threatened	Pacific Connector pipeline
Cox's mariposa-lily *Calochortus coxii*	Species of Concern	Endangered	Pacific Connector pipeline
Umpqua mariposa-lily *Calochortus umpquaensis*	Species of Concern	Endangered	Pacific Connector pipeline

TABLE 4.6.2-1

State-Listed Species Potentially Occurring in the Area Affected by the Proposed Project

Species	FWS Status	ODFW Status	Portion of the Project Area Where Species Potentially Occur
Dwarf woolly meadowfoam *Limnanthes pumila ssp. pumila*	Species of Concern	Threatened	Pacific Connector pipeline
Silvery phacelia *Phacelia argentea*	Species of Concern	Threatened	Jordan Cove terminal Pacific Connector pipeline
Wolf's evening primrose *Oenothera wolfii*	None	Threatened	Jordan Cove terminal

4.6.2.1 Mammals

Kit Fox (No ESA Status, State Threatened Species)

The kit fox reaches its northern limit in southern Oregon. In Oregon, it is found in arid desert valleys dominated by halophytic plants like greasewood and shadscale, intermingled with sagebrush. Although the Project may affect suitable kit fox habitat, the expected distribution of this species does not include the Project area. Because kit foxes have not been recently observed within the area affected by the Project (ORBIC 2017a), the Project is not expected to affect this species.

Gray Whale (Eastern North Pacific stock; Federal Delisted Species, State Endangered Species)

The gray whale is a large baleen whale that is distributed in the northern Pacific Ocean in western and eastern stocks. The eastern stock, found along the west coast of North America, was federally delisted on June 16, 1994 (59 FR 115), but remains state endangered in Oregon. The eastern Pacific stock feeds in the summer in the Chukchi Sea, the western Beaufort Sea, and the northern Bering Sea. They migrate south from November through early February to lagoons on the Pacific coast of central and southern Baja California. Northward migration occurs after the calving and breeding season, from early February to May. These whales have the longest known migration of any mammal. Gray whales feed on infaunal benthic species that are buried in sediments (Maser et al. 1981). Gray whales are federally protected under the MMPA.

Potential effects on gray whales include injury and/or mortality due to ship strikes, underwater ship noise, construction noise (including pile driving and dredging) and potential adverse effects from a ship fuel spill at sea. Spills could indirectly affect gray whales by impacting forage species. These potential effects would be similar to the effects on federally listed whales that are discussed above, except that gray whales migrate in coastal waters north and south parallel to the Pacific Coast, making them more susceptible to ship strikes in nearshore waters during migration.

According to the Oregon Parks and Recreation Department (OPRD 2007), gray whales are the most predominant whales seen along the Oregon coast. They migrate twice a year, in winter and spring, and about 200 of them feed along the coast during the summer months. Gray whales have on occasion entered Coos Bay beyond the Jordan Cove LNG Project site and have been seen in Coos Bay at about the same frequency as killer whales. Gray whales may be encountered along the LNG carrier transit route during their southern migration from November through early February or from early February to May during the northern migration. Based on data in Pacific waters between 1999 and 2003, gray whales are struck by ships at a rate of 1.2 whales annually (Angliss and Outlaw 2007). The increase in shipping traffic resulting from LNG carriers could cause an increase in the probability of whales being struck by ships, or of being disturbed during migration. Measures that Jordan Cove would implement to avoid or minimize effects on federally listed whales (see section 4.6.1.1) would serve to avoid or minimize effects on the gray whale.

4.6.2.2 Birds

California Brown Pelican (Federal Delisted Species, State Endangered Species)

The brown pelican was listed as a federally endangered species on June 2, 1970, within California, Oregon, Texas, and Washington states, as well as Central and South America (FWS 1970). It was delisted in December 2009 (FWS 2009c); however, Oregon still considers the brown pelican an endangered species under state law (ODFW 2017h).

The California brown pelican is a primarily coastal species, rarely seen inland or far out at sea (FWS 2005b). They feed mostly in shallow estuarine waters, normally staying within 20 miles of shore (FWS 2005b). Pelicans make extensive use of sand spits, offshore sand bars, and islets for nocturnal roosting and daily loafing, especially by non-breeders and during the non-nesting season (FWS 2005b).

Brown pelicans nest in colonies, mostly on small coastal islands in California (FWS 1985, 2007e). Brown pelicans generally breed between February and October and are most abundant in Oregon during post-breeding migration (FWS 2005b). In Oregon, numbers peak in late August through October and gradually decline from October through early November as birds move south (Gilligan et al. 1994). Since brown pelicans have wettable feathers, they return to land daily to roost and dry their feathers (FWS 2005b). Sand islands within three large estuaries in Oregon and Washington serve as primary night roosts (Jaques and O'Casey 2006 as cited in FWS 2007e). The total number of brown pelicans in Oregon in 2001 was estimated to be 6,095 (Marshall et al. 2003).

Brown pelicans are regularly seen in moderate numbers during the summer months in Coos Bay, and they also occur in small numbers in the winter (Contreras 1998). Coos Bay provides excellent habitat for this species. Brown pelicans were recorded foraging near the Project site more than 500 feet from the shore and loafing across the bay in moderate numbers daily during surveys in October 2012 (SHN 2012). The species was also observed during surveys conducted in 2005-2006 until early September (LBJ 2006). The Project site provides no nesting habitat for the brown pelican. Roosting and feeding sites have been documented within the Project area, although the last observation was in 1985. Roosting was reported on the north side of Coos Bay on a sunken jetty close to the Bay mouth and on a sand spit on the North Spit of Coos Bay, as well as on dredge spoil islands around MPs 3R through 4R (ORBIC 2017a).

In the past, California brown pelicans have been affected by human disturbances at nesting colonies and roosting habitats. Existing nesting and roosting habitats within the Coos Bay Estuary and Jordan Cove LNG Project area have not been documented. If they occur within the estuary during construction and operation of the proposed action, pelicans may be associated with on-shore fish-cleaning stations where they possibly feed on offal (Marshall et al. 2003). Existing fish-cleaning stations are present at the Empire Boat Ramp, Oceanside RV Park and Bastendorff Beach County Park, both in Charleston. Fish-cleaning could also occur at the Charleston Marina, California Street Boat Ramp, and BLM Boat Ramp, though they are not designated as such.

Noise and human activities associated with construction and operation of the Project are likely to be the only direct effect to brown pelicans if they occur within one or more of the Project's analysis areas. Jordan Cove is proposing construction of its access channel in Coos Bay during the ODFW recommended in-water work window between October 1 and February 15. This schedule would minimize effects on brown pelicans because there is a gradual decline in populations in Oregon as birds move south from October through early November (Gilligan et al. 1994). However, noise created by pile driving and construction in general is likely to affect brown pelicans if present and could disrupt brown pelican feeding behavior.

Brown pelicans that forage within the vicinity of the Jordan Cove LNG Project (i.e., the estuarine analysis area) could ingest low levels of contaminants through the food web that are re-suspended from dredging activities. However, sediments at the Jordan Cove LNG Project site and pipeline route within Coos Bay are not expected to contain levels of sediment contaminants that could adversely affect brown pelicans. Access channel dredging and maintenance dredging would not occur during the period of peak pelican abundance in the lower bay. Therefore, dredging activities would not substancially disrupt normal behavior patterns for brown pelicans.

Pacific Connector is proposing construction across Coos Bay using HDD construction in two segments (MP 0.12 to MP 1.11 and MP 1.40 to MP 3.09). It is possible that the brown pelican could be present within Coos Bay and its vicinity during the time of construction (see Contreras 1998). Therefore, noise and human activities associated with construction and operation of the pipeline are likely to affect brown pelicans as sources of disturbance and disruption if they are present and could disrupt brown pelican feeding behavior.

There is some evidence in the literature that high intensity continuous anti-collision lights on structures may result in an increased number of bird strikes, especially at night or during fog and overcast conditions. The number of strikes can apparently be reduced by strobe or blinking the anti-collision lights. The LNG storage tanks would not be illuminated with high intensity lighting. The intensity and number of lights would be limited to what is required for security and operations. With the low-intensity lighting to be used, the likelihood of adverse effects on brown pelicans from collisions with the LNG storage tanks is minimal.

Brown pelicans may be encountered during any portion of the LNG carrier transit route in the waterway. There is no evidence that pelicans are struck by current cargo ships using the Port.

During operation of the Pacific Connector pipeline, aerial inspection of the pipeline route would occur within the permanent ROW. Aerial inspections would generally occur during all times of year, although inspections would not affect nesting or breeding brown pelicans since they do not nest or breed within Coos Bay. Additionally, aerial inspection should not disturb migrating, roosting, or foraging brown pelicans since air traffic is a constant disturbance within Coos Bay from the existing North Bend airport.

The proposed action would create auditory and visual disturbances that are likely to cause foraging brown pelicans to temporarily avoid areas of high activity. The proposed action area does not contain existing nesting or roosting habitat and would not affect nesting or roosting individuals. As a result, the proposed action would temporarily affect foraging individuals but is not expected to affect nesting or roosting by brown pelicans

4.6.2.3 Plants

Pink Sand Verbena (Federal Species of Concern, State Endangered Species)

The historical range of pink sand verbena (*Abronia umbellata* ssp. *breviflora*) was from northern California to Vancouver British Columbia, Canada (ODA 2017c). Its present range is along coastal beach and foredune, predominantly from Cape Blanco (Curry County), southern Oregon to Point Reyes National Seashore in Marin County, California and sporadically along Oregon's northern and central coast. Pink sand verbena only inhabits the littoral sandy beach areas and unstabilized sand dunes of the coastal strip and usually occurs on beaches in fine sand between the high-tide line and the driftwood zone, and in areas of active sand movement below the foredune (ORBIC 2010). In the northern portion of its range, most populations of pink sand verbena occur on broad beaches and/or near the mouths of creeks and rivers.

Of the 12 reported occurrences in Oregon, only 2 have more than 50 plants; many of the populations consist of only one plant and will probably not persist. Two populations of pink sand verbena documented near the mouth of Coos Bay, contained approximately 300,000 plants when surveyd in 2012 (ORBIC 2017a). Approximately 15 miles north of the entrance to Coos Bay, 19 plants were documented in 1995 within a protected (public entry prohibited) snowy plover nesting area (ORBIC 2012). There are no known occurrences of pink sand verbena within two miles of the Jordan Cove Project area (ORBIC 2017a). No pink sand verbena plants have been reported within the Pacific Connector pipeline area (ORBIC 2006a) and the pipeline route would not affect coastal sand dune habitat; therefore, Pacific Connector has not conducted botanical surveys for this species and no incidental documentations of this species has occurred.

Jordan Cove identified suitable habitat for the plant along the eastern portion of the LNG terminal in areas of actively moving dunes and European beachgrass. However, surveys conducted at the Jordan Cove Project area in 2006, 2012, and 2013 did not locate any pink sand verbena plants (SHN 2006b, 2013c). As surveys conducted within the Jordan Cove Project area, as well as historic data, indicate that pink sand verbena is not present within the Project area, the Project is not expected to affect this species.

Point Reyes Bird's-beak (Federal Species of Concern, State Endangered Species)

Point Reyes bird's-beak (*Cordylanthus maritimum* ssp. *palustre* [*C. maritimus* ssp. *palustris*]) inhabits salt marshes along the coast, sometimes growing just above tidewater in wet areas. Its habitat requirements are specific: approximately 7.5 to 8.5 feet (2.28 to 2.59 meters) above mean lower low water, soil salinity of 34 to 55 parts per thousand, sandy substrate covered by 1 to 10 cm (0.39 to 3.93 inches) organic silt, and less than 30 percent bare soil in summer. Point Reyes bird's-beak occurs along the Pacific Coast from Tillamook County, Oregon, south to Santa Clara County, California. In Oregon, the species is restricted to Netarts Bay, Yaquina Bay, and Coos Bay, with most known occurrences located in Coos Bay. Within the counties crossed by the Project, Point Reyes bird's-beak is found in Coos County.

Several occurrences of Point Reyes bird's-beak are near both the Jordan Cove LNG Project and the Pacific Connector Pipeline Project. Populations with 1,000 to 10,000 plants are located along the margins of Coos Bay and on sand salt marshes near the edge of high water marks (ORBIC 2017a). Several occurrences of Point Reyes bird's-beak are near the Jordan Cove LNG Project, and this species is known to occur within the intertidal wetland between APCO Sites 1 and 2;

however, there is no suitable habitat on APCO Site 2 as this area is dominated by upland vegetation. This species also occurs outside the LNG terminal area along the west and southeast shoreline of the South Dunes site (ORBIC 2017a) and potential habitat for this species has also been observed along the shoreline south of the South Dunes site. Jordan Cove would conduct an additional survey in this area of potential habitat prior to construction.

The area affected by the Pacific Connector Pipeline Project is within the vicinity of documented populations of Point Reyes bird's-beak and the pipeline route would cross suitable habitat. Populations with 1,000 to 10,000 plants were located in 1982 and 1999 along the margins of Coos Bay approximately 260 feet south of TEWA 0.10 (HDD pull-back) and on sand salt marshes near the edge of high water marks on the west side of Haynes Inlet approximately 815 feet north of the Jordan Cove Meter Station near the proposed HDD across Coos Bay (ORBIC 2017a). These plants are farther than 100 feet from the pipeline route and should not be affected by construction. Surveys conducted for Pacific Connector in 2007 located one population of about 1,000 Point Reye's bird's-beak plants approximately 1.7 miles south of MP 1.7 (FERC 2009). Additional surveys occurred in 2017 along the pipeline route near MPs 0.3, 1.0, and 1.47 near the edge of high water marks where the pipeline HDD exits and enters land. Approximately 30 Point Reyes bird's beak plants were located at the margin of Coos Bay near MP 0.9, approximately 475 feet northwest of the construction right-of way and 700 feet west/northwest of TEWAs 1.09-N and 1.09-W. This portion of the pipeline would be constructed by HDD and should not affect plants observed at this location.

Point Reyes bird's-beak is found within and near the Jordan Cove and Pacific Connector Project areas; however, construction of the Project should not directly affect individual plants. Additionally, Pacific Connector has committed to protecting plants adjacent to the pipeline construction ROW through the appropriate installation of safety and silt fence as determined by Pacific Connector's EIs.

Wayside Aster (Federal Species of Concern, State Threatened Species)

The wayside aster's (*Eucephalis* [*Aster*] *vialis*) range is limited to central, southern, and western Oregon and the northern California state line (ORBIC 2010). About 100 populations are known, totaling fewer than 9,000 individuals. Most populations are centered in the southern Willamette Valley of Lane County or in southern Jackson and Josephine Counties, although a few populations exist in the adjacent counties of California (ORBIC 2010). None of the known populations are protected, and many populations are along roadsides and in areas of residential development. Wayside aster occurs in areas of natural and man-made disturbance, edges and openings in woodlands and forests, in second and old-growth, and in shaded roadsides.

Several populations of wayside aster plants have recently been documented within Douglas and Jackson Counties; however, except for one site discussed below, these records are more than 0.5 mile from the Pacific Connector Project area. Botanical surveys for this species in potential habitat have been conducted by Pacific Connector in Coos Bay, Roseburg, and Medford BLM Districts; Umpqua National Forest; and Jackson County. This species was documented in 2007 adjacent to a previously proposed existing access road that would require improvements; however, this road is no longer proposed for use as an access road. This site was revisited in 2009 and additional surveys were conducted within 0.25 mile of this site; however, no plants were located.

Although the species is documented near the Project, surveys conducted by Pacific Connector for the wayside aster did not detect this plant's presence. Construction of the pipeline, including the use of access roads, is not anticipated to affect this species.

Peck's Milk-vetch (Federal Species of Concern, State Threatened Species)

Peck's milk-vetch (*Astragalus peckii*) occurs east of the Cascades Mountain range. Most populations of Peck's milk-vetch are centered in three separate areas: one in north-central Deschutes County, another in north-central Klamath County, and the third in south-central Klamath County. These populations total about 300,000 individuals. The plant occurs in very dry sites, on loose, sandy soil or pumice, often in or along dry water courses, in sagebrush or rabbitbrush openings in ponderosa pine forests (in the south) or in western Juniper woodlands (in the north), and occasionally on barren flats.

Peck's milk-vetch has not been documented within the vicinity of the Project (ORBIC 2006a). No suitable habitat for Peck's milk-vetch occurs within the areas crossed by the pipeline route; therefore, Pacific Connector did not conduct botanical surveys for this species. As this species is not expected to occur along the pipeline route, it would probably not be affected by construction and operation of the Project.

Pumice Grape-Fern (No ESA Status, State Threatened Species)

This species is one of the rarest grape-ferns, and in Oregon is found only within the Crater Lake area and Paulina Mountains in Deschutes and Klamath Counties. Most known populations are found in fine pumice gravel at elevations above 7,800 feet (2,400 meters). It has also been located within frost pockets in lodgepole pine forests with bitterbrush, in areas with deep, sterile pumice. In Oregon, pumice grape-fern *(Botrychium pumicola*) is typically associated with Brewer's sedge and buckwheat (*Eriogonum* spp.) species (Eastman 1990; ORBIC 2010).

The Project is not located near known sites of this plant, and no suitable habitat for this plant occurs within the areas crossed by the pipeline route; therefore, Pacific Connector did not conduct botanical surveys for this species. As the pumice grape-fern is not expected to occur along the pipeline route, the Project would probably have no effect on this species.

Cox's Mariposa Lily (Federal Species of Concern, State Endangered Species)

The Cox's mariposa lily (*Calochortus coxii*) is endemic to serpentine and ultramafic soils and is limited to a small area (30 square meters) along a 10-mile serpentine ridge system in Douglas County, Oregon. All known populations are on serpentine soils, mostly on shady, north-facing, mesic sites near ridgelines, typically, growing in serpentine grasslands and forest margins. Population monitoring studies on BLM land from 2011 through 2015 demonstrated relatively high interannual variation in population estimates for Cox's mariposa lily. For example, 6,966 plants were observed in 2011, whereas 13,865 individuals were observed in 2012 (Gray and Bahm 2015). Populations are also known to occur on private lands; however, surveys haven't been conducted on private lands since the early 1990s (ORBIC 2017a; Aaron Roe, Botanist Roseburg BLM District, personal communication, February 1, 2019). Threats to this species include fire exclusion, encroachment by conifers, noxious weed invasion, logging, grazing, road construction, and off-highway vehicle recreational use (Gray and Bahm 2015; BLM and FWS 2004).

Based on existing data, the Pacific Connector pipeline route would cross one population between MP 74.1 and 75.0 on lands administered by the BLM Roseburg District (ORBIC 2017a). In 2012, surveys conducted by the BLM documented approximately 1,300 plants within and adjacent (within 100 meters) to the Project, with approximately 300 plants occurring in the construction ROW (BLM 2017c). However, modifications have been made to the pipeline route subsequent to these surveys. In 2018, surveys for Cox's mariposa lily were conducted during the flowering season on approximately 65 acres between MPs 74 and 75 of the revised pipeline route. The 2018 survey data are currently under review by the BLM. Additionally, there are approximately 45.3 acres of potential suitable Cox's mariposa lily habitat on private lands within the pipeline route that have not been surveyed.

Individuals of Cox's mariposa lily occur along the pipeline route; therefore, construction and operation of the Project would directly and indirectly affect this species and this species' habitat. In addition to the direct removal of individuals, construction of the pipeline would fragment approximately 0.9 mile of of suitable Cox's mariposa lily habitat. Potential indirect effects to documented or suspected plants and habitat include potential changes in hydrology and soil characteristics, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust.

Pacific Connector has developed a Cox's mariposa lily specific mitigation plan (included as an attachment to the *Federally-Listed Plant Conservation Plan*[141]) to avoid and minimize potential effects on this species. As described in the mitigation plan, Pacific Connector would determine if site-specific neck-downs can be incorporated into the construction ROW to minimize direct effects on the population of Cox's mariposa lily between MPs 74 and 75. The construction ROW in this area utilizes the typical 95-foot width with TEWAs because of the steep and narrow ridgeline alignment; thus, neck-downs would be dependent on site-specific conditions and would be based on species presence and the work area requirements to ensure safe pipeline installation. Appropriate barriers would be installed along areas that contain this species to ensure that the mariposa lily populations in the vicinity are not affected by sediments and debris from the ROW. In locations where individual plants cannot be avoided by construction activities, plants would be salvaged during the late summer or fall after the growing season of the year preceding actual pipeline construction. Additional mitigation techniques that would be employed to protect these populations of Cox's mariposa lily include seed collection and bulb salvage, and site restoration and monitoring. However, there has not been any research on the effectiveness of seed collection and bulb salvage as mitigation techniques for this species. Based on comments provided by the BLM, the BLM may require additional mitigation measures for the Cox's mariposa lily as part of their review of the ROW application.

Umpqua Mariposa Lily (Federal Species of Concern, State Endangered Species)

The Umpqua mariposa lily (*Calochortus umpquaensis*) is known to occur within 17 localities; none of which are protected. This plant grows in both forests and meadows on serpentine soils at elevations below 2,500 feet, but it is the most vigorous in margins between forests and meadows. In southwestern Oregon, it is associated with a diverse array of plants, and it is found in diverse soils, aspects, and slopes.

[141] Appendix J to Pacific Connector's POD filed with the FERC in January 2018.

Several large populations of this plant (5,000 to 60,000-plus) have previously been documented approximately 1.3 and 2.5 miles east of the pipeline alignment near MP 99.55, adjacent to the Green Butte (EAR 102.30) and Callahan Creek (EAR 104.24) access roads. Pacific Connector conducted botanical surveys for this species between 2007 and 2017 in potential habitat within the vicinity[142] of the pipeline in lands administered by the Roseburg BLM District and Umpqua National Forest. In 2016, seven plants were observed adjacent to EAR 102.3 and 25 feet east of the Hatchet Quarry MP 102.3 Rock Source/Disposal Site near a previously (1992) documented population. Additionally, potential suitable habitat would also be crossed by the pipeline near the site where Cox's mariposa-lily was documented (MPs 74.08 to 75.02), although no individuals of Umpqua mariposa lily were observed during surveys conducted for the pipeline in this location.

Although, Umpqua mariposa lily individuals have been documented adjacent to EARs 102.30 and 104.24, no road improvements are necessary. Additionally, plants are separated from the access roads by topography and/or Callahan Creek; therefore, it is not expected that use of the existing access roads would directly or indirectly affect these populations. The population along EAR 102.30 and 25 feet east of the Hatchet Quarry MP 102.3 Rock Source/Disposal Site may be indirectly affected by the Pacific Connector Project; however, construction of the Project should not directly affect individual plants. Additionally, Pacific Connector has committed to protecting plants adjacent to the pipeline construction ROW through the appropriate installation of safety and silt fence as determined by Pacific Connector's EIs.

Dwarf Woolly Meadowfoam (Federal Species of Concern, State Threatened Species)

Dwarf woolly meadowfoam's (*Limnanthes pumila* ssp. *pumila*) range is restricted to two small protected areas, totaling about 2 square miles with at least 10,000 individuals (ORBIC 2010). Dwarf woolly meadowfoam inhabits small depressions in thin clay soil overlying old basalt at the edges of deep vernal pools, which are dry by mid-summer and generally exposed to full sunlight. The only known occurrences are on Table Rock in Jackson County (on Lower and Upper Table Rocks); which is over 12 miles southwest of the Pacific Connector pipeline and 1.4 to 2.4 miles north of four proposed Jackson County pipe storage yards (ORBIC 2006a).

Because the dwarf woolly meadowfoam is endemic to vernal pools at Table Rocks, Pacific Connector did not conduct botanical surveys for this species. Additionally, this species was not documented incidentally during survey efforts for other vernal pool–associated species conducted for the Project. As this species is not expected to occur along the pipeline route, it would probably not be directly affected by construction and operation of the Project.

Silvery Phacelia (Federal Species of Concern, State Threatened Species)

The silvery phacelia (*Phacelia argentea*) is known from 24 occurrences, totaling 15,000 individuals, along the coastline of Coos and Curry Counties and in adjacent northern California, Del Norte County (ORBIC 2010). In March 2015, a petition was submitted to the FWS to list the silvery phacelia as a threatened or endangered species (FWS 2015a); however, the petition was denied in 2015 due to lack of substantial information that this species was a listable entity (FWS 2015b). Silvery phacelia is the only phacelia growing along the coastline in open sand or on dunes

[142] Provided in Pacific Connector's Initial Response to the FERC staff's Environmental Information Request dated January 3, 2018, filed with the FERC on January 23, 2018.

along the south coast of Oregon. It inhabits sandy beach dunes and bluffs near the coast, and some partially-stabilized or unstabilized dunes.

Silvery phacelia has not been documented in the vicinity of the Project and the closest known plants are located more than 10 miles south of the entrance to the Coos Bay Estuary (ORBIC 2017a); however, suitable habitat for this species does exist at the LNG terminal area, in regions of active and semi-active dunes where the European beachgrass and the red fescue-salt rush herbaceous vegetation associations occur (see section 4.4 of this EIS). There is marginal habitat at the APCO Site and the meteorological station, although the European beachgrass in these areas is generally too dense to support this species. Surveys conducted by Jordan Cove have not detected this species (SHN 2006b, 2012) and, due to the lack of suitable habitat, botanical surveys for this species were not conducted along the pipeline route. Based on the lack of occurrences (from both historical data as well as surveys), it is not expected that the Project would affect this species.

Wolf's Evening Primrose (No ESA Status, State Threatened Species)

Wolf's evening primrose (*Oenothera wolfii*) occurs in well-drained sandy soils with adequate moisture in coastal bluff scrub, coastal prairie, roadsides, and coastal dune habitats from Curry County in southern Oregon to the northern California coast (Tibor 2001). This species is associated with a high disturbance regime and several occurrences in California are located along roadsides with sandy soil (CNDDB 2005 as cited in FERC 2015). Wolf's evening primrose is typically associated with low elevation coastal habitats, but there have been reported occurrences in lower montane coniferous forest in California, at elevations greater than 2,500 feet (Tibor 2001).

The closest known occurrence of Wolf's evening primrose to the Project is in Port Orford, Oregon, approximately 60 miles to the south of the Jordan Cove LNG terminal site; however, suitable habitat for this species is present at the LNG terminal site. There is marginal habitat at the APCO Site and the meteorological station, although the European beachgrass in these areas is generally too dense to support this species. Surveys conducted at the LNG terminal site did not detect the Wolf's evening primrose (SHN 2006b, 2012). Considering the lack of occurrences (based on historic and recent survey data), it is not expected that the Project would affect this species.

4.6.3 Other Special Status Species

In addition to the federal and state threatened, endangered, and proposed species described above, there are species that have been given special status designations by federal or state agencies and Indian tribes that could potentially occur in the Project area (see tables I-3, I-4, and I-5 in appendix I). The FWS and NMFS maintain a list of federal species of concern, which are species whose conservation standing is of concern but for which status information is still needed. The ODFW also assigns special status to fish and wildlife species that are not listed. State special status designations include sensitive and sensitive-critical (ORBIC 2016). Sensitive refers to fish and wildlife that are facing one or more threats to their populations and/or habitats. Species or taxa with a sensitive-critical subdesignation are sensitive species of particular conservation concern. Sensitive-critical species have current or legacy threats that are impacting their abundance, distribution, diversity, and/or habitat. They may decline to the point of qualifying for threatened or endangered status if conservation actions are not taken.

In addition to the threatened and endangered plant species described above, ODA designates candidate species for listing. ODA candidate species include any plant species designated for study by the director of ODA whose numbers are believed low or declining, or whose habitat is sufficiently threatened and declining in quantity and quality, so as to potentially qualify for listing as a threatened or endangered species in the foreseeable future (ODA 2017d).

4.6.3.1 U.S. Fish and Wildlife Service and National Marine Fisheries Service

The FWS (2006d, 2006e, 2013h, 2017c) and NMFS (2006) list 69 fish and wildlife species of concern that potentially occur in counties coinciding with the Project. The list of federal species of concern includes 14 mammals, 20 birds, 3 reptiles, 10 amphibians, 10 fish, and 12 invertebrates. These species, and expected habitat for each species, are listed in tables I-3 and I-4 in appendix I of this EIS. The FWS has noted that the Umpqua chub may be present in the Umpqua River, and this species is of concern because it has rapidly decreased in abundance. This species is discussed in detail in the BE (see appendix F.7 of this EIS).

The FWS lists one plant species as a federal candidate for listing, and 52 federal plant species of concern that potentially occur in counties coinciding with the Project. These species are listed in table I-5 in appendix I of this EIS, along with expected habitat for each species.

4.6.3.2 Oregon Department of Fish and Wildlife

The ODFW (2016) identified 71 state sensitive species that potentially occur in counties coinciding with the Project area, some of which (i.e., 37) are also considered federal species of concern. This list includes 15 mammals, 28 birds, 13 fish, 2 reptiles, and 13 amphibians. The ODFW does not assign special status for invertebrates. Tables I-3 and I-4 in appendix I provide the following information for each state special status species: expected habitat and documentation within each county, BLM district, and National Forest crossed by the Pacific Connector pipeline and vicinity.

Although the state sensitive species listed in tables I-3 and I-4 may occur in counties noted by FWS (2006d, 2006e) and ODFW (ORBIC 2006a, 2012), distributions and/or habitat associations of some preclude their potential occurrence in the area that would be affected by the Project.

4.6.3.3 Oregon Department of Agriculture

The ODA identified 41 candidates for listing that potentially occur in counties coinciding with the Project area, 26 of which are also federal species of concern. Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species as a result of the Project are presented in table I-5 in appendix I.

4.6.3.4 Tribal Species of Concern

The CIT identified the following plant and animal species as species of concern. According to the CIT, this list is not comprehensive, but does represent the most significant and important traditional cultural plant and animal species that are found on the Coquille Forest and other Tribal lands. A more complete list and description of plant usage can be found in "Ethnobotany of the Coquille Indians". Significant and important plants include, but are not limited to:

- Trees (bark and wood): Port Orford cedar, western red cedar, Sitka spruce, big leaf maple, myrtle, red alder, madrone, Pacific yew.

- Shrubs (wood, nuts and berries): elderberry (*Sambucus* spp.), willows, hazel, vine maple, rhododendron, azalea (*Rhododendron* spp.), manzanita, ocean spray, Labrador tea (*Ledum* spp.), huckleberry, salal, thimbleberry, salmonberry, Oregon grape.
- Flowers and vines (roots and fiber): yarrow (*Achillea millefolium*), camas (*Camassia*), tiger lily (*Lilium columbianum*), columbine (*Aquilegia* spp.), various *Lomatium* and *Brodiaeas*, iris (*Iris* spp.), trailing blackberry (*Rubus ursinus*), yerba buena (*Clinopodium douglasii*), beargrass (*Xerophyllum tenax*).
- Wet Meadow/Riparian Plants: cattail, tule (*Schoenoplectus* spp.), various sedges and ferns, skunk cabbage, various mosses.
- Marine/Estuary: eelgrass, giant kelp (*Macrocystis* spp.), bull kelp (*Nereocystis luetkeana*), sea lettuce (*Ulva* spp.), surfgrass (*Phyllospadix* spp.).

Impacts on these species would be similar to the impacts on vegetation described in section 4.4. Project effects on the wetland and estuary species of traditional-cultural importance would be as described for wetlands and waters in section 4.3. Species that are protected by federal and/or state jurisdictions (e.g., various sedges) are also addressed elsewhere in this section and in appendix I.5.

The following list of mammals, bird, and fish is also not comprehensive, but does represent many of the CIT's species of concern:

- Terrestrial: deer, elk, coyote, cougar, bear, bobcat, raccoon, beaver, squirrel.
- Marine/ Estuary: lamprey, salmon (all available species), shellfish, crab, sea mammals, rockfish, lingcod, sculpin, halibut, flounder, perch, herring, greenling, candlefish (i.e., eulachon), snails, mussels, barnacles, chiton, sea urchin, abalone (*Haliotis spp*.), dentalium (*Dentalium spp*.) (other seasonally available estuary species).
- Streams: salmon (all available species), lamprey, sturgeon, trout, mussels.
- Birds: Eagles, hawks, owls, cormorant, kingfisher, herons, osprey, flicker (*Colaptes auratus*), woodpeckers (particularly pileated), grebe, crows and ravens, and colorful neo-tropicals.

Impacts on these species would be similar to the impacts on wildlife and aquatic resources described in section 4.5. Species that are protected by federal and/or state jurisdictions (e.g., owls) are also addressed elsewhere in this section and in appendix I.3.

4.6.3.5 Assessment of Other Special Status Species

Of the other special status species identified above as potentially occuring in counties coinciding with the Project, only a subset have the potential to be affected by the Project. Table 4.6.3.5-1 identifies the number of these other special status mammals, birds, fish, amphibians, reptiles, invertebrates, and vascular plants potentially affected by the Project. For species that are also BLM and Forest Service sensitive species or the Forest Service's Survey and Manage species, occurrence and potential effects on federal lands are also described below in section 4.6.4, Environmental Consequences on Federal Lands.

TABLE 4.6.3.5-1

Numbers of Other Special Status Species Potentially Affected by the Project a/

Taxonomic Group	Federal Status: FWS or NMFS Species of Concern	State Status: ODFW Sensitive or ODA Candidate	Total b/
Mammals	12	12	16
Birds	19	24	31
Non-anadromous Fish	4	4	5
Anadromous Fish	3	5	7
Amphibians and Reptiles	7	9	9
Aquatic Invertebrates	3	N/A	3
Terrestrial Invertebrates	1	N/A	1
Vascular Plants	2	2	2

Sources: FWS (2006d, 2006e, 2017c), NMFS (2006d), ORBIC (2006a, 2006b, 2017a), ODFW 2016b.

a/ Other Special Status Species include FWS and NMFS fish, wildlife, and plant species of concern and candidate species, ODFW Sensitive fish and wildlife species, and ODA candidate species for listing. Forest Service sensitive and Survey and Manage species and BLM sensitive species are only tallied here if they meet this criteria for Other Special Status Species. Species are not tallied here if they are also federal or state listed or proposed.

b/ Rows do not sum because a species is tallied in multiple columns where it is considered special status by multiple agencies.

Descriptions of expected habitat, documented or suspected occurrences, and potential Project effects on these other special status species within the Project area are presented in tables I-3, I-4, and I-5, respectively, in appendix I. Additionally, effects on these species and proposed measures to minimize effects would be similar to the those described for general fish and wildlife in section 4.5 of this EIS.

4.6.4 Environmental Consequences on Federal Lands

The BLM and Forest Service maintain lists of sensitive species to ensure that their actions do not contribute to or cause a trend toward listing under the ESA. Additionally, until 2016, the BLM and Forest Service maintained a list of Survey and Manage species, or species that are rare and uncommon or poorly understood that are closely associated with late successional or old-growth forests within the range of the NSO (Forest Service and BLM 2001a). In August 2016, the BLM issued two RODs for two new RMPs (BLM 2016a and 2016b). These two plans supersede the NWFP on BLM lands, and eliminated requirements to survey and manage for species included on the 2001 ROD Survey and Manage species list on BLM lands. Potential effects on Survey and Manage species on NFS lands are discussed here.

Species that are on both the sensitive list and the Survey and Manage list are discussed on NFS land under section 4.6.4.3, Survey and Manage Species. Additionally, although the Forest Service and BLM include federal and state threatened, endangered, proposed, and candidate species on their species lists, these species are not discussed in this section as they are presented above.

4.6.4.1 Description of BLM and Forest Service Sensitive Species

The BLM maintains a list of Special Status Species (including BLM sensitive species) as required by BLM 6840, Special Status Species Manual, to ensure that BLM actions do not contribute to a loss of viability or cause a trend toward listing under the ESA. Like the BLM, the Forest Service is required by Forest Service Manual (FSM) 2760 to maintain a list of sensitive species for each region, including species listed as federally threatened, endangered, or proposed under the ESA, as well as species that are threatened by human activities. Activities on NFS lands must be managed to ensure that current federally listed species do not become extirpated or that activities do not result in ESA listing for other sensitive species. As required in FSM 2760, the Forest Service is obligated to evaluate Project effects on sensitive species in a BE (see appendix F.7).

The Pacific Northwest Regional Office of the Forest Service and Oregon/Washington State Office of the BLM established an interagency program for the conservation and management of special status species. New criteria for BLM Special Status Species and Forest Service Sensitive Species were jointly approved in 2015 by the Region 6 Regional Forester and BLM Oregon/Washington State Director for determination of species included within the BLM and Forest Service Sensitive Species Program. The new criteria were designed to make the BLM and Forest Service more consistent in their approaches to the development of lists of species with conservation concerns. The BLM (2015) and Forest Service (Forest Service 2015) identify federally listed, federally proposed, and sensitive species required under their respective policies. Additionally, they have identified “strategic species” that are not considered sensitive under those policies. Strategic species include species with information gaps (e.g., distribution, habitat, threats, taxonomy) that are suspected to occur on NFS or BLM lands.

According to Instruction Memorandum No. OR-2015-028, sensitive species are those that are documented or suspected endangered or threatened at the federal or state level, federal de-listed species, are Oregon Heritage List 1 or List 2, and have been documented on at least one Oregon BLM district. These species should be managed to ensure that activities on BLM lands do not contribute to their listing.

Strategic species are not classified as Special Status for management purposes. The only requirement for this group of species is to record sites found during any survey efforts. Therefore, strategic species are not discussed in this section unless observed during surveys.

Table 4.6.4.1-1 lists the BLM and Forest Service sensitive species documented or suspected to occur within the districts and forests crossed by the Pacific Connector pipeline (BLM 2015; Forest Service 2015).

Not all species documented or suspected in BLM districts and national forests crossed by the Project occur within the area affected by the Project. Many were excluded from consideration after review of range and habitat information. Other species were excluded if they were not known to occur in the Project vicinity based on special status species locations within 3 miles of the Project obtained from the BLM Geographic Biotic Observations (GeoBOB) database and Forest Service Natural Resource Information System (NRIS) database (BLM 2006a, 2012, 2017a; Forest Service 2006, 2012, 2017c; NSR 2012), and through ORBIC data requests (ORBIC 2006a, 2012, 2017a).

TABLE 4.6.4.1-1

Numbers of BLM and Forest Service Sensitive Species within the Four BLM Districts and Three National Forests Crossed by the Proposed Pacific Connector Pipeline a/

	Number in BLM Districts				Number in National Forests		
Taxonomic Group	**Coos Bay**	**Roseburg**	**Medford**	**Lakeview**	**Umpqua**	**Rogue River-Siskiyou**	**Fremont-Winema**

Vascular Plants	35	36	91	44	31	99	49

Note: A species is tallied in multiple columns where it occurs and is sensitive on multiple BLM Districts or National Forests.
a/ Source: BLM 2015; Forest Service 2015

Pacific Connector conducted surveys from 2007 through 2018 for special status species, including BLM and Forest Service sensitive species. Special status mollusks, fungi, and vascular and non-vascular plants not detected during these complete, targeted surveys were determined to not be present, and thus not affected by the Project. Forest Service and BLM sensitive species that are documented or suspected to occur on BLM districts and/or national forests crossed by the Project, but were dropped from further consideration due to a lack of habitat or because they were not detected during targeted field surveys are listed in tables I-3, I-4, and I-5 in appendix I. Information provided for each of these species in appendix I includes expected habitat, county, national forest, and BLM district distribution, known occurrences in relation to the Project, and effects determination and rationale for this determination.

BLM and Forest Service sensitive species that may be affected by the Project are listed below in table 4.6.4.1-2, excluding the state and federally listed, proposed, and candidate species discussed above, and the Survey and Manage species on NFS land discussed below. Where suitable habitat was documented for a species, but species-specific surveys were not conducted, presence was assumed, and potential effects on these species are discussed here.

a/ Excluding state and federally listed, and select proposed and candidate species and Survey and Manage species, which are discussed in other sections of this EIS.

Excluding federal and state threatened, endangered, and select proposedand candidate species (discussed above), and Survey and Manage species on NFS lands (discussed below), a total of 60 BLM and Forest Service sensitive species have the potential to be affected by the Project: 5 mammal, 19 bird, 1 reptile, 1 amphibians, 20 invertebrate, 6 fish, 7 vascular plant, and 1 lichen species(table 4.6.4.1-2). Tables I-3, I-4, and I-5 in appendix I provide habitat descriptions for these species. Forest Service sensitive species that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7), and Survey and Manage species that would potentially be affected by the proposed action on NFS lands are addressed in more detail in the Survey and Manage Report (appendix F.5 of this EIS).

4.6.4.2 Assessment of BLM and Forest Service Sensitive Species

BLM and Forest Service sensitive species that may be present and potentially affected by construction of the pipeline on federal lands are described here. If species were documented during targeted surveys, those locations and potential effects are also described.

Mammals

There are five BLM and Forest Service sensitive mammals that may be present and potentially affected by construction of the pipeline on federal land: the pallid bat (*Antrozous pallidus pacificus*), Townsend's big-eared bat (*Corynorhinus townsendii*), fringed myotis (*Myotis thysanodes*), marten (*Martes caurina*), and fisher (*Pekania pennanti*). Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species within the Project area are presented in table I-3 in appendix I. As all five of these species are Forest Service sensitive, they are additionally addressed in the BE if effects are anticipated on NFS lands (appendix F.7). Marten and fisher are also discussed above as federal proposed threatened species.

Birds

There are 19 BLM and/or Forest Service sensitive birds that may be present and potentially affected by construction, maintenance, and operation of the pipeline on federal land. Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species as a result of the Project are presented in table I-3 in appendix

I. Forest Service sensitive birds that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7).

Fish

There are six BLM and/or Forest Service sensitive fish species that may be present along the LNG carrier transit route, in the waters of Coos Bay potentially affected by construction of the pipeline, or in waters crossed by the pipeline. Of these species, four are anadromous and two are non-anadromous. Descriptions of life histories, expected habitat, and potential occurrences of these special status fish species within the Project area are presented in table I-4 in appendix I. Forest Service sensitive fish that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7).

Amphibians and Reptiles

There are two BLM and Forest Service sensitive amphibians and reptiles that may be present and potentially affected by construction of the pipeline on federal land: western pond turtle (*Actinemys marmorata*) and foothill yellow-legged frog (*Rana boylii*). Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species within the Project area are presented in table I-3 in appendix I. As both species are Forest Service sensitive, they are additionally addressed in the BE (appendix F.7).

Invertebrates

<u>Aquatic</u>

There are nine BLM and Forest Service sensitive aquatic invertebrates that may be present and potentially affected by construction of the pipeline on federal land. All these species are associated with freshwater environments. Table I-4 in appendix I summarizes the life history, habitat associations, and occurrence of these invertebrates. Eight of these species are Forest Service sensitive aquatic invertebrates, and thus are additionally addressed in the BE if effects are anticipated on NFS lands (appendix F.7).

<u>Terrestrial</u>

There are 11 BLM and Forest Service sensitive terrestrial invertebrates that may be present and potentially affected by the construction of the pipeline on federal land. Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species within the Project area are presented in table I-3 in appendix I. As all 11 species are Forest Service sensitive terrestrial invertebrates they are additionally addressed in the BE (appendix F.7).

Approximately 20 acres of the ROW near known populations of two Forest Service sensitive terrestrial invertebrates (Mardon skipper and short-horned grasshopper) on the Dead Indian Plateau would be restored with grasses (including *Festuca* sp.) preferred by these species in addition to the rehabilitation required under BMP guidelines. This mitigation on the Rogue River National Forest has the potential to increase the habitat and local range for these two species.

Three BLM and Forest Service sensitive mollusk species were located during surveys for the Project: Siskiyou hesperian, traveling sideband, and Oregon shoulderband. These three species are discussed in the following paragraphs; Siskiyou hesperian and traveling sideband are additionally addressed in the BE as they were observed on NFS lands during surveys (appendix F.7).

Field Survey Locations and Potential Effects

Traveling sideband is a BLM and Forest Service sensitive species (BLM 2015; Forest Service 2015) and an Oregon endemic terrestrial snail. During surveys in 2007 and 2010, this species was observed at nine locations on the Rogue River and Winema National Forests (between MP 154.9 and 175.4), and at six locations on BLM land in the Lakeview and Medford BLM Districts (MPs 116.3 to 176.9). Shells and live individuals were located within and outside the ROW, as well as within proposed TEWAs and UCSAs (SBS 2008a, 2011b). During surveys in 2012 and 2015, this species was observed at five locations on the Rogue River and Umpqua National Forests (between MP 104.9 and 162.5) and four locations on BLM land in the Roseburg and Medford BLM Districts (MPs 91.7 to 116.9), adjacent to the ROW and TEWAs.[143]. Direct mortality could occur to this species if they are within the ROW during Project clearing or construction due to their low mobility. Clearing of the ROW could affect habitat by removing forest overstory, potentially making the area unsuitable for this species. Indirect effects could result from the alteration of composition and structure of vegetation resulting in changes in microclimate. Realignments following the 2007 and 2010 surveys resulted in avoidance of some but not all the sites observed during Project surveys. As currently proposed, Pacific Connector would directly affect 5 of the 14 sites observed during Project surveys on NFS lands, and 4 of the 10 sites observed during Project surveys on BLM-managed lands. Indirect effects are expected to the traveling sideband sites observed even if direct effects on these sites are avoided because 5 and 4 of the sites are within approximately 100 feet of Project disturbance on NFS lands and BLM-managed lands, respectively, and thus would be affected by changes in microclimate conditions.

Siskiyou hesperian is a BLM and Forest Service Sensitive species (BLM 2015; Forest Service 2015) and a riparian associated terrestrial snail. During Project surveys in 2007, 2008, and 2010, this species was observed at 14 locations on the Rogue River and Umpqua National Forests (between MPs 110.2 and 164.7), and 10 locations in the Medford and Roseburg BLM Districts (MPs 79.8 to 151.5). In 2011, 2012, and 2014, this species was observed at nine locations within the Rogue River and Winema National Forests (between MPs 154.5 and 168.9), and two locations in the Medford BLM District (MP 148.7 and 153.5). Shells and live individuals were observed within and outside the ROW, as well as proposed TEWAs and UCSAs (SBS 2008, 2011b; April 27, 2015 response to FERC data request). During surveys in 2015, this species was observed at eight locations on the Rogue River National Forest (between MP 155.7 and 160.6) and one location on BLM land in the Medford BLM District (MP 128.8), within and adjacent to the ROW and TEWAs.[144] During surveys in 2017, active individuals were observed at one location on the Rogue River National Forest (MP 154.6; Tona 2018). Direct mortality to individuals could occur if they are located within the ROW during Project clearing or construction. Another potential direct effect is destruction or alteration of hydrology of riparian, wetland, or aquatic habitats used by this species. Indirect effects could result from the alteration of composition and structure of vegetation resulting in changes in microclimate. The increase in sun exposure could reduce moisture levels

[143] See Table D.3-10 in Pacific Connector's Resource Report 3, included as part of their September 2017 filing with the FERC.
[144] See Table D.3-10 in Pacific Connector's Resource Report 3, included as part of their September 2017 filing with the FERC.

and potential decrease dispersal between populations or suitable habitat. As currently proposed, Pacific Connector would directly affect 11 of the 31 sites observed during Project surveys on NFS lands, and 6 of the 13 sites observed during Project surveys on BLM-managed lands. Indirect effects are expected to the Siskiyou hesperian sites observed even if direct effects on these sites are avoided as 16 and 5 of the sites on NFS lands and BLM-managed lands, respectively, are within approximately 100 feet of Project disturbance, and thus would be affected by changes in microclimate conditions.

Oregon shoulderband is a BLM and Forest Service sensitive species (BLM 2015; Forest Service 2015) and a terrestrial snail endemic to northern California and southwest Oregon. This species is also managed as a Survey and Manage species on NFS lands; however, it was not observed on NFS lands during surveys for the Project. During Project surveys in 2007, this species was observed at five locations in the Roseburg BLM District (MPs 64.6 to 76.0). Shells and live individuals were observed within and outside the ROW (SBS 2008a). Direct mortality to individuals could occur if they are located within the ROW during Project clearing or construction. Clearing of the ROW could affect habitat by removing forest overstory, potentially making the area unsuitable for this species. Indirect effects could result from the alteration of composition and structure of vegetation resulting in changes in microclimate. The increase in sun exposure could reduce moisture levels and potential decrease dispersal between populations or suitable habitat. As currently proposed, Pacific Connector would directly affect two of the five sites observed during Project surveys on BLM-managed lands. Indirect effects are expected to the Oregon shoulderband sites observed even if direct effects on these sites are avoided as two of the sites on BLM-managed lands are within approximately 100 feet of Project disturbance, and thus would be affected by changes in microclimate conditions.

Plants and Fungi

A total of 270 BLM and/or Forest Service sensitive bryophyte, lichen, fungus, and vascular plant species were identified as potentially occurring within the Project area (see table I-5 in appendix I). Between 2007 and 2018, SBS surveyed for special status fungi and vascular and non-vascular plant species in suitable habitat, where access was granted, within 50 feet (non-federal lands) or 100 feet (federal lands) of the ROW, TEWAs, UCSAs, and access roads (note that surveys continued through 2018). Plant and fungus species documented on federal lands during surveys are described below. Descriptions of expected habitat, documented or suspected occurrences, and potential Project effects on all species within the area affected by the Project are presented in table I-5 in appendix I. Forest Service sensitive plants and fungi that would potentially be affected by the proposed action are additionally addressed in the BE (appendix F.7).

Of the 41 BLM and/or Forest Service sensitive bryophytes identified as potentially occurring within the area affected by the Project, none were documented during surveys of the currently proposed route. Two strategic bryophyte species (*Andreaea nivalis* and *Orthotrichum euryphyllum*) were documented during surveys. See table I-5 in appendix I for a list of sensitive and strategic bryophyte species identified as potentially occurring within the area affected by the Project, descriptions of their expected habitat, and documented or suspected occurrences, including documented occurrences of the two strategic species observed during Project surveys.

Lichens

There are 16 BLM and/or Forest Service sensitive lichens identified as potentially occurring within the area affected by the Project. Potential Project effects on lichens include trampling or killing of individual plants. One BLM and Forest Service sensitive species, *Bryoria subcana*, was documented during surveys of the currently proposed route. This species is also an Survey and Manage species under the 2001 ROD list (Forest Service and BLM 2001a).

Bryoria subcana is a BLM and Forest Service Sensitive coastal lichen species and was observed during Project surveys in the BLM Coos Bay District, approximately 100 feet of the ROW near MP 21.88BR. The species was observed just east of the area affected by the Project and may be avoided by activities within the corridor; however, construction would disturb vegetation and soils within 200 feet of the site and could modify microclimate conditions around the observation. The removal of trees and woody debris could negatively affect *Bryoria subcana* in adjacent areas by removing its habitat and affecting its association with the trees, affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions within 200 feet of the observation as a result of the Project construction and operation would likely make habitat within the site no longer suitable for the species. Restored portions of the corridor and TEWAs would be dominated by early seral vegetation for approximately 30 years, which would result in long-term changes to habitat conditions. A portion of the corridor would be maintained in low-growing vegetation for pipeline maintenance and would not provide habitat for the species during the life of the Project. *Bryoria subcana* is not likely to persist at the site following Project implementation; however, remaining sites of this species would continue to provide a reasonable assurance of species persistence.

Five BLM and/or Forest Service strategic lichen species (*Collema curtisporum, Collema quadrifidum, Leptogium platynum, Peltula euploca,* and *Sclerophora amabilis*) were also observed during Project surveys. See table I-5 in appendix I for a list of sensitive and strategic lichen species identified as potentially occurring within the Project area, descriptions of their expected habitat, and documented or suspected occurrences, including documented occurrences of the one sensitive and five strategic lichen species observed during Project surveys.

Fungi

Of the 25 BLM and/or Forest Service sensitive fungi identified as potentially occurring within the Project area, none were documented during surveys. Thirteen Forest Service and BLM strategic fungi were observed during surveys. See table I-5 in appendix I for the locations of these observations in relation to the Project.

Vascular Plants

There are 188 BLM and/or Forest Service sensitive vascular plants identified as potentially occurring within the Project area, 10 of which were documented during Project surveys: Rogue Canyon rockcress (*Arabis modesta*), Bensonia (*Bensoniella oregana*), Cox's mariposa lily, Umpqua mariposa lily, bristly sedge (*Carex comosa*), coastal lip fern (*Cheilanthes intertexta*), pine woods cryptantha (*Cryptantha simulans*), clustered lady's slipper (*Cypripedium fasciculatum*), California globe-mallow (*Iliamna latibracteata*), and Bellinger's meadowfoam. Two of these species—Cox's mariposa lily and Umpqua mariposa lily—are also state-listed species and are discussed above in section 4.6.2.3. One of these species, clustered lady's slipper, is a Forest Service Survey and Manage species and is discussed below under section 4.6.4.3. Potential effects on Umpqua mariposa lily, pine woods cryptantha, California globe-mallow, and Bellinger's meadowfoam on NFS lands are additionally discussed in the BE (appendix F.7 of this EIS).

Field Survey Locations and Potential Effects

Rogue Canyon rockcress is a regional endemic found within chaparral and lower montane coniferous forests in northern California and southern Oregon (CNPS 2018). In Oregon, it is only known from Jackson and Josephine Counties (NRCS 2018). This species has been found on dry, serpentine soils on exposed slopes and rocky cliffs in the Rogue River canyon at elevations between 490 and 1,480 feet (NatureServe 2018). Two sites of Rogue Canyon rockcress were observed during Project surveys in 2017 on state forest lands 24 feet and 90 feet north/northwest of TEWA 124.30-N. This species was not observed on BLM or Forest Service land during Project surveys.

Bensonia is found mainly within the Siskiyou Mountains of southwestern Oregon in Curry and Josephine Counties, with a few small disjunct populations in adjacent Humboldt County, California (NatureServe 2018). The rhizomatous species grows in wet meadows and edges near bogs and springs. Populations seem to be associated with cloud or fog banks that blanket the mountain tops at certain times of year. Most plants are in meadows on gentle slopes, and they thrive on partial shade. The species has been found at elevations between 2,000 to 4,750 feet (Hoover and Holmes 1998). One bensonia site was noted near the Project in 2011 in the Roseburg BLM District, approximately 100 feet east of the existing Signal Tree Road Quarry at MP 47. Pacific Connector surveyed this area in 2013 and no special status species were observed, including bensonia. Due to the distance between this site and the Project, no effects are anticipated.

Bristly sedge is found from Quebec to Minnesota and south, as well as in the Pacific Northwest and Montana (NatureServe 2018). This species habitat includes marshes, lakeshores, and wet meadows. In Oregon, this species is known from Columbia, Klamath, and Multnomah Counties; although it is believed to be extirpated or possibly extirpated in Columbia and Multnomah Counties (NatureServe 2018). One population of bristly sedge was documented in 2012 on private land 66 feet south of TEWA 184.30. This species was not observed on BLM or Forest Service land during Project surveys.

Coastal lip fern grows in crevices and bases of rocks and is found mainly in California, although it also occurs in Oregon and Nevada (The Jepson Herbarium 2018). In Oregon, this species is known from Douglas and Jackson counties (NRCS 2018). Two observations of coastal lip fern site were noted near the Project in the Medford BLM District. One observation is located approximately 65 feet west of the pipeline ROW near MP 148.9 and the other observation is greater than 100 feet from the pipeline ROW near MP 149.9. Due to the distance between these sites and the Project, direct effects are not anticipated; however, the Project could potentially indirectly affect individuals and/or habitat of this species.

Pine woods cryptantha is found in dry gravelly sites, disturbed areas, and open conifer forests from elevations between 820 and 8,530 feet (The Jepson Herbarium 2018). This species' range includes California north to Washington and east to Idaho (NRCS 2018). Five observations of pine woods cryptantha were documented during Project surveys in 2017. One site was located in the Rogue River-Siskiyou National Forest approximately 96 feet northwest of MP 155.8. One site was located on the Fremont-Winema National Forest pm the edge of Clover Creek Road and 10 feet from the pipeline ROW near MP 175.3, and two sites were located in the Lakeview BLM District:

1) within the ROW near MP 176.96 and 2) on the edge of Clover Creek Road near MP 176.98. Because this species was observed within the pipeline ROW, the Project may directly and indirectly affect individuals and habitat of this species.

California globe mallow is found in southwestern Oregon, extending into Humboldt County in northern California (Malaby 2005). This species inhabits moist forests, streamsides, lower montane coniferous forests, and montane chaparral; often in recently burned areas (Malaby 2005; CNPS 2018). In Oregon, California globe mallow is found in coastal ranges in Coos and Douglas counties and is also known from Curry, Jackson, Josephine, and Linn Counties. Three observations of California globe mallow were observed during Project surveys in 2017: one in the Roseburg BLM District and two in the Umpqua National Forest. The observation in the Roseburg BLM District was located within the pipeline ROW near MP 99.9, within the are burned during the Stouts Creek fire in 2015. The sites in the Umpqua National Forest are in the pipeline ROW near MP 106.2 and MP 106.7; both sites were in recently burned areas. Because this species was observed within the pipeline ROW, the Project may directly and indirectly affect individuals and habitat of this species.

Bellinger's meadowfoam (*Limnanthes floccosa* ssp. *bellingeriana*) is associated with vernally wet meadows or vernal pools and is generally found on basalt scablands at elevations between 1,000 and 4,000 feet in Jackson and Klamath Counties, Oregon, and Shasta County, California. Six Bellinger's meadowfoam populations were located in the Project area. Two populations were in the Rogue River-Siskiyou National Forest: within the pipeline ROW near MP 154.1 and within the pipeline ROW between MP 154.71 to 154.82. The other four populations were in the Medford BLM District: near MPs 120.3, MP 128.8, and MP 129.0, and TEWA 128.79-N. All these observations are located greater than 100 feet from the pipeline route, except for the observation in TEWA 128-79. Six hundred plants were observed in and near TEWA 128.79-N during Project surveys in 2017.

In 2010, 30,000 plants within less than one acre were documented between MPs 154.8 and 154.7, near Heppsie Mountain (SBS 2011a), also within the Rogue River National Forest. Potential effects on this site include removal of individuals, temporary disturbance, and permanent loss or alteration of habitat including changes in hydrology. The site is in a vernally moist scabland meadow within the ROW and a TEWA and therefore would be disturbed by the Project (SBS 2011a; Rolle 2014). Measures to avoid this site considered but excluded to avoid a rare fungus, *Gymnomyces abietis*, which was also found at the same location on the north end of the meadow at MP 154.8. *Gymnomyces abietis* is a Forest Service Survey and Manage species, discussed below in section 4.6.4.3. Although Project activities would affect the local population at MP 154.7, the species would not likely be eliminated from the site as it is able to grow on disturbed soil (Rolle 2014). Conservation measures at this site include recontouring, reseeding, and controlling for noxious weeds. Additionally, although the site that would be affected is one of only a few Bellinger's meadowfoam sites on NFS land, a large number of sites are known from BLM and private land in eastern Jackson County. More undocumented sites are likely to occur on unsurveyed private lands (Rolle 2014). Consequently, the expected loss of individuals and habitat at this site is not expected to affect the viability of Bellinger's meadowfoam over the broader geographic area of the low mountains and foothills of eastern Jackson County (Rolle 2014).

4.6.4.3 Survey and Manage Species

The BLM and Forest Service first identified Survey and Manage species in 1994 as rare amphibians, mammals, bryophytes, mollusks, vascular plants, fungi, lichens, and arthropods that occupy LSOG forests in the range of the NSO (see Forest Service and BLM 1994a, the NWFP ROD). The agencies established standards and guidelines for management of these rare species in the *Standards and Guidelines for Management for Late-Successional and Old-Growth Related Species in the Range of the Northern Spotted Owl* (Forest Service and BLM 1994b). The NWFP ROD established overall objectives for managing Survey and Manage species populations that were referred to as “persistence objectives.” These objectives were based on the Forest Service viability provision in the 1982 National Forest System Land and Resource Management Planning Regulation for the National Forest Management Act of 1976.

In 2001, the Record of Decision and Standards and Guidelines for Amendments to the Survey and Manage, Protection Buffer, and other Mitigation Measures Standards and Guidelines (2001 ROD; Forest Service and BLM 2001a) modified the management direction provided in the NWFP ROD for Survey and Manage species and amended BLM and Forest Service land management plans in the range of the NSO accordingly. The management direction for Survey and Manage species varies based on its assigned category, which establishes varying levels of surveys and management of known sites (refer to the 2001 ROD and appendix F.5 to this EIS for additional details on the categories). For the Survey and Manage Standards and Guidelines, the major elements were retained with some restructuring for clarity, and the 1994 list of Survey and Manage species was modified to remove 72 species in all or part of their range because new information indicated they were secure or otherwise did not meet the basic criteria for Survey and Manage. Based on the history of the Survey and Manage rule, it should be noted that by definition, there is a general concern for persistence for any of the species listed in the 2001 ROD. That concern is the basic reason species are listed in the Survey and Manage Standards and Guidelines.

In 2004 and again in 2007, the BLM and Forest Service issued a ROD to eliminate the Survey and Manage requirements of the 2001 ROD and to provide protection for species on the Survey and Manage lists by managing them under the agencies’ special-status species programs. In 2014, the Court issued a remedy order in the case of *Conservation Northwest et al. v. Bonnie et al.*, No 08-1067-JCC (W.D. Wash.)/No. 11-35729 (9th Circ.). As the latest step in the ongoing litigation challenging the 2007 ROD, this remedy order vacated the 2007 ROD to remove or modify the Survey and Manage mitigation measure standards and guidelines, which returned the agencies to the status quo in existence prior to the 2007 ROD. Thus, the 2001 ROD was reinstated, including any amendments or modifications to the 2001 ROD that were in effect as of March 21, 2004, returning the species to the category assigned in the 2001 ROD.

In accordance with the 2014 Court decision, this assessment was completed using the 2001 ROD Survey and Manage Standards and Guidelines, with the 2003 Annual Species Review (ASR) modifications for the species list and category assignments (excepting the 2003 ASR red tree vole removal).

In 2016, the BLM approved two new RMPs, including the Northwestern and Coastal Oregon RMP and the Southwestern Oregon RMP (BLM 2016a, 2016b). All lands managed by the BLM that occur in the Pacific Connector Project are within the revised RMPs’ management areas. The past RMPs were developed consistent with the 1994 NWFP and thereby included Survey and Manage species measures. The 2016 RMPs revises the past RMPs in their entirety and removes all measures for Survey and Manage species, although Forest Service Survey and Manage species identified as BLM sensitive species would continue to receive protections consistent with BLM's sensitive species management program.

Although some species covered by the Survey and Manage Standards and Guidelines also occur on private land, land managed by the BLM, and areas outside the NSO range, the requirements of the 1994 NWFP and 2001 ROD apply only to lands managed by the Forest Service within the range of the NSO.

The NWFP ROD and the 2001 ROD do not prescribe a well-defined process for evaluating effects on species persistence or viability from a proposed activity. The 2001 ROD states "instead, common sense and agency expertise must be used in making determinations of compliance with the viability provision" (Standards and Guidelines). The Forest Service has embraced this approach for evaluating effects of the Project on the persistence of affected Survey and Manage species in the NSO range. The Standards and Guidelines and 2001 ROD are intended to "provide a reasonable assurance of species persistence" for all the Survey and Manage species. If the Project is constructed, it would affect numerous known sites of Survey and Manage species. This assessment seeks to determine, should the Project be constructed, whether there would be a reasonable assurance of species persistence for those Survey and Manage species affected by the Project in the NSO range. The evaluation of species persistence is presented in appendix F.5 to this EIS, and this section summarizes the results of the evaluation. Attachment A to appendix F.5 lists the Survey and Manage species considered in the persistence evaluation.

This section is organized by taxonomic group and includes a brief overview of the species considered in the persistence evaluation; a summary of the distribution of sites of the species in the NSO range; an analysis of the effects of the Project on the sites; and breakdowns of the number of sites of each species in the NSO range, the number of affected sites of each species across the analysis area, and the number of affected sites on the Umpqua, Rogue River-Siskiyou, and Fremont-Winema National Forests. Details on the methodology used for the persistence evaluation (e.g., establishment of sites for each species, mapping of general habitat and site distribution, analysis of effects on sites) and a glossary of key terms used in the evaluation available in appendix F.5. The factors used to evaluate the Project effects are outlined in appendix F.5 and were derived from the 2001 ROD criteria for species persistence and relative rarity. This persistence evaluation is not intended to serve as an annual species review or an evaluation of the relative rarity of the species. This analysis is focused only on the effects on the species that could result from implementation of the Project and is intended to provide sufficient information to support subsequent findings by the Forest Service.

This assessment provides a conservative site-specific analysis of effects on sites, which consist of the recorded observations of Survey and Manage species from agency geodatabases and a surrounding protection buffer, and generally assumes that site persistence would not be maintained following Project implementation if a site falls within the analysis area. This conservative approach was considered sufficient if Project-related effects on the sites would not substantially alter the distribution of the species across the NSO range (e.g., the species would still be well distributed or locally abundant near the Project area). However, if the initial analysis revealed that remaining sites (i.e., those not affected by the Project) may not provide a reasonable assurance of species persistence, a closer evaluation of the effects on each site was conducted to further assess effects of the Project and determine if site persistence would be maintained at any of the sites following Project implementation, or if measures would be needed to protect or avoid the site(s). Additional details on the methodology used to evaluate effects are presented in appendix F.5.

Incomplete or Unavailable Information

CEQ regulations 40 CFR 1502.22 require a discussion of incomplete or unavailable information. Information is incomplete or unavailable for:

- **Total populations of Survey and Manage species beyond those represented in the geodatabases of the agencies used in this report.** Although a statistically reliable region-wide survey has been completed for most of the Survey and Manage species (Forest Service and BLM 2007: 142), the results of those surveys have not been biologically interpreted, and the final results have not yet been published. In absence of a published interpretation of the results of those regional surveys, this assessment relies on the known sites of affected species that have been inventoried and recorded in the known site geodatabases of the BLM and Forest Service. These data constitute "best available information" for populations of Survey and Manage species and provide sufficient information to make a reasoned choice between the alternatives and to make an informed decision related to the persistence standards of the 2001 Survey and Manage ROD. A total population estimate is not necessary to make a reasoned choice between the alternatives.
- **Total acres of the specialized microsites and habitats used by certain Survey and Manage species.** This analysis was completed using geodatabase records of observations (i.e., "known sites"), regionally available vegetation inventory data, and evaluation criteria developed from the 2001 ROD. In many cases, Survey and Manage species rely on specialized habitats that may not be catalogued in agency geodatabase records or vegetation inventories. This is one of the reasons why pre-Project surveys are required for Survey and Manage species. Habitat requirements for each of the species considered are discussed in detail in appendix F.5. In this assessment, estimates are provided of the general areas where specialized habitats may be found, but these should not be interpreted as the actual acres of available specialized habitats; the actual acres of available specialized habitats are typically a fraction of the general habitat description. For example, some mollusks rely on moist microsites found in late-successional coniferous forests. A regional inventory of late-successional coniferous forests is available, but a regional inventory of moist microsites is not; there are many, many more acres of late-successional forests than there are acres of moist microsites within those forests. This assessment identifies known sites and broad habitat classifications such as "late-successional coniferous forests below 6,000 feet" where specialized habitats and the species in question may be found, but makes no estimates of, nor does the analysis rely on, estimates of specialized habitats that may exist within those broad vegetation categories. The cost of acquiring such an inventory of microsite environments over the entire area of the NWFP would be exorbitant and is not essential to making a reasoned choice between the alternatives. As noted in the Final Supplemental EIS for Survey and Manage Species, "the likelihood that an activity modifying late-successional forest will occur within the range of a truly rare or localized species population must be viewed in light of the relatively conservative degree of modification of late-successional forest projected to occur within the NWFP area. For example, management activities (timber harvest and prescribed fire) are projected to

modify approximately 3 percent of the late-successional forest within the area over the next decade" (Forest Service and BLM 2000: 180). Pre-Project survey data and existing known sites of Survey and Manage species within the area of the NWFP provide sufficient information to determine whether there is a "reasonable assurance of species persistence," which is the standard of the 2001 Survey and Manage ROD.

- **Recovery of occupied sites after disturbance.** Survey and Manage species are associated with LSOG forests on NFS lands. The construction corridor and TEWAs will be reforested and replanted with native vegetation similar to what occupied the Project area prior to disturbance. It will be at least 80 years before those areas provide late-successional habitat. A 30-foot-wide maintenance corridor centered along the pipeline route would be maintained in low growing brush and grass vegetation (no trees) for the life of the Project. When the Project is decommissioned, it would be at least an additional 80 years before this strip provides late-successional stand characteristics. Information is not generally available as to how effectively the affected Survey and Manage species will reoccupy these areas. This analysis presumes that if the "site" is within the construction clearing or TEWAs, the Project would result in a long-term loss of that site. This analysis does not speculate on when or if the affected species may reoccupy the site. Since sites are presumed lost if affected, and that provides the basis for the assessment, data related to recovery or reoccupation of sites are not essential to the decision to be made or the choice between alternatives.

Survey and Manage Species Surveys and Evaluations

Surveys conducted for the Project in and near the Project area through 2016 resulted in numerous observations of Survey and Manage species. These survey results in combination with results from prior surveys conducted near the Project area were used to identify the Survey and Manage species that could be affected by the Project. Observation data stored in agency geodatabases were converted to "sites" or "known sites" using a standardized mapping protocol based on buffer distances described in the 2001 ROD. Species evaluated include those that have sites on NFS lands in or near the Project area. The species considered include 31 fungi, 2 lichens, 1 vascular plant, 2 mollusks, 1 mammal, and 1 bird.

Fungi

The diverse fungi of the Pacific Northwest include several hundred saprobic (decomposers), parasitic, and symbiotic (mutualistic) macro- and micro-fungi species. The 2003 list includes 194 species of fungi under the Survey and Manage Standards and Guidelines. Of these species, 31 are considered in this evaluation of the Project because they have been documented on NFS lands in or near the Project area. Appendix F.5 of this EIS presents additional details on each species, while the key information used to evaluate Project-related effects is summarized in this section.

The fungi considered in this analysis consist primarily of mycorrhizal or symbiotic species, which include truffles, false truffles, chanterelles, boletes, coral fungi, and gilled mushrooms. Some of the species are saprobic gilled mushrooms or parasitic fungi. The mycorrhizal fungi form symbiotic relationships with vascular plants to exchange nutrients and water for photosynthate. The saprobic species are found on dead or decaying wood, including snags. The fungi fruit at different times of year, and many do not fruit annually, although they may still be present in the soil. Although surveys have been conducted across the Project area and in other parts of the NSO range, the difficulty in detecting fungi when fruiting bodies are not present has limited the ability to fully describe the range and distribution of many species within the NSO range. The fungi species considered in this analysis are listed in table 4.6.4.3-1 with the currently known number of sites in the NSO range. Many of these species are likely more abundant than currently documented, and more survey effort would be expected to locate additional sites of the species.

TABLE 4.6.4.3-1

Regional Site Count of Fungi Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/
Albatrellus ellisii	112	72	33 (46%)

Tremiscus helvelloides	318	62	34 (55%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent "Riparian Reserves" across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in NFS reserves to total sites on NFS lands.

Habitat for these species varies and has generally been classified as coniferous, mixed hardwood-coniferous, and/or hardwood forests, including the LSOG component of these forests. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The data are the best available data on forest types across the NSO range but likely overestimate the amount of potential habitat available in the region for many of the species considered in this analysis, particularly those with microsite conditions that have not been mapped at a regional scale. The extent of potential habitat for each species varies based on its distribution across the NSO range and its habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of 31 Survey and Manage fungi at one or more sites in or near the Project area. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soil within sites and could result in the removal of populations or individuals of fungi. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase, although not all species are affected by open corridors or change in forest age (e.g., *P. fallax*, *P. piceae*, *P. sipei*, and *P. spadicea*). The removal of coniferous, mixed hardwood-coniferous, and hardwood forests, including the LSOG component of these forests, and disturbance to soil, understory substrate (e.g., rocks, downed logs), and roots of trees could negatively affect the fungi in adjacent areas by removing their habitat, disturbing soil or duff around trees or roots of trees, and affecting mycorrhizal associations with the trees or other relationships between the fungi and their hosts, potentially affecting site persistence even if the entire site is not disturbed. For some species that are found in more open habitats (e.g., *C. olympianus*, *H. caeruleus*, *S. flavida*), these microclimate changes may not affect site persistence. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor and TEWAs could make habitat within the sites no longer suitable for the species. Material storage within UCSAs would disturb understory habitat in some sites, which could also modify microhabitats near extant populations or individuals, potentially making the habitat no longer suitable for the species. Road improvements and establishment could remove habitat and extant populations or individuals of the fungi. The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-2 presents a summary of the number of sites of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-2

Fungi Sites Potentially Affected by the Project

Tremiscus helvelloides	1	1	61	310

a/ Affected sites are those on NFS land that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5.
b/ Although one or more sites would be affected by the Project, individuals within some of the sites would not be affected, and site persistence would be maintained for those sites following project implementation. The remaining site count includes sites that may be affected, but for which site persistence is expected to be maintained. Only sites for which site persistence would be affected were removed from the remaining site count.

The species listed below appear to be more common than previously documented or are relatively common across the NSO range based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. For these species, the Project would affect individuals or habitat at one or more sites and could affect site persistence, but the remaining sites in the NSO range would continue to provide a reasonable assurance of species persistence:

Clavariadelphus occidentalis
Clavariadelphus sachalinensis
Clavariadelphus truncatus
Collybia bakerensis
Cortinarius olympianus
Cudonia monticola
Galerina atkinsoniana
Gastroboletus subalpinus
Gomphus clavatus
Gomphus kauffmanii
lbatrellus ellisii
Mycena overholtsii
Polyozellus multiplex
Ramaria araiospora
Ramaria coulterae
Ramaria coulterae
Ramaria rubrievanescens
Ramaria rubripermanens
Ramaria rubripermanens
Ramaria stuntzii
Rhizopogon truncatus
Rhizopogon truncatus
Sparassis crispa
Spathularia flavida
Tremiscus helvelloides

The species listed below are not necessarily more common than previously documented despite new information available from pre-disturbance surveys for the Project and/or other sources since these species were listed in the 2001 ROD. For these species, the Project would affect individuals or habitat at one or more sites and could affect site persistence, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence:

Arcangeliella crassa
Boletus pulcherrimus

Choiromyces alveolatus
Collybia racemose
Cortinarius magnivelatus
Cortinarius verrucisporus
Gymnomyces abietis
Hygrophorus caeruleus
Sedecula pulvinata

The species listed below is not necessarily more common than previously documented despite new information available from pre-disturbance surveys for the Project and/or other sources since these species were listed in the 2001 ROD. For this species, the Project would affect site persistence at one or more sites, and the remaining sites in the NSO range may not provide a reasonable assurance of species persistence. These species are known from a low number of sites within a part of the NSO range, has limited habitat requirements, and has a distribution pattern in which every site may be important for dispersal opportunities to ensure the persistence of the species in the NSO range:

Sarcodon fuscoindicus

The Project would affect a portion of one site where two observations of this species have been documented on NFS lands. This site is located in the Trail Creek watershed on the ridge just east of the South Fork Cow Creek watershed between MPs 111.5 and 111.6. Approximately 1.2 acres (30 percent of the site) is associated with the construction corridor (0.8 acres) and associated UCSA (0.4 acres). The location of this site is illustrated in appendix F-5 (Section 2.27, Figure SAFU-5).

The Project would result in ground disturbance and vegetation removal in the eastern half of the site near MP 111.5. The two recorded observations within the site may be avoided by construction activities within the corridor, but fruiting bodies, if present, could be disturbed in one of the observations during material storage within a UCSA (see Figure SAFU-5). The species would also be subject to indirect effects associated with the Project based on the proximity of project activities to the observations.

Establishment of the 95-foot wide construction corridor would disturb vegetation and soils within the site. The area within the site is mostly forested, and the establishment of the corridor could modify microclimate conditions around the recorded observations. The removal of forests and host trees and disturbance to soil could negatively affect *S. fuscoindicus* in adjacent areas by removing its habitat, disturbing soil or duff around trees or roots of trees, and affecting its mycorrhizal association with the trees, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions within 100 feet of an observation as a result of the corridor could make habitat within the site no longer suitable for the species. Restored portions of the corridor would be dominated by early seral vegetation for approximately 30 years, which would result in long-term changes to habitat conditions. A 30-foot wide portion of the corridor would be maintained in low-growing vegetation for pipeline maintenance and would not provide habitat for the species during the life of the Project. Material storage within UCSAs could damage individuals and would disturb understory habitat within the site, which could modify microhabitats near individuals that are not removed or damaged, potential making the habitat no longer suitable for the species.

Based on this analysis of the site on NFS lands, *S. fuscoindicus* is not likely to persist following Project implementation. The site is the only site on NFS lands in the local area and the nearest sites on NFS lands are approximately 45 miles to the northeast and 75 miles to the southwest.

Lichens

Lichens are distinct symbiotic organisms that consist of a fungus and an algae or cyanobacterium, which make them members of two or three biological kingdoms. They play a major ecological role, particularly in old-growth forests, by cycling nutrients and producing biomass. Lichens tend to be dispersal limited and grow slower than vascular plants. The 2001 Survey and Manage ROD including the 2003 ASR modifications to the species list includes 45 lichen species. Of these, two are considered in this evaluation because they have been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on each species, while the key information used to evaluate Project-related effects is summarized in this section.

Both lichens considered in this analysis are epiphytic lichens, which grow directly on trees or shrubs. *Chaenotheca subroscida* commonly occurs on pine trees in upland habitats and *Leptogium teretiusculum* tends to be associated with riparian habitat.

Although surveys have been conducted across the Project area and in other parts of the NSO range, the difficulty in detecting some lichens because of their size has limited the ability to fully describe the range and distribution of some species within the NSO range. The lichen species considered in this analysis are listed in table 4.6.4.3-3 with the currently known number of sites in the NSO range, and the distributions of the species are briefly discussed after the table.

TABLE 4.6.4.3-3

Regional Site Count of Lichen Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/
Chaenotheca subroscida	396	110	73 (66%)
Leptogium teretiusculum	267	16	9 (56%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent “Riparian Reserves” across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands.

Habitat for these species has been classified as coniferous, mixed hardwood-coniferous, and/or hardwood forests, including the LSOG component of these forests. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for each species varies based on its distribution across the NSO range and habitat preferences. Additional details on habitat for these species are presented in appendix F.5.

The Project could affect site persistence of two Survey and Manage lichens at one or more sites on NFS lands in or near the Project area. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soil within sites and could result in the removal of populations or individuals of lichens. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of coniferous, mixed hardwood-coniferous, and hardwood forests, including the LSOG component of these forests, and disturbance to soil, understory substrate (e.g., rocks, downed logs), and roots of trees could negatively affect the lichens in adjacent areas by removing their habitat, disturbing soil or substrate around trees or roots of trees, and affecting associations with the trees or other substrate, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor and TEWAs could make habitat within the sites no longer suitable for the species. Material storage within UCSAs would disturb understory habitat in some sites, which could also modify microhabitats near extant populations or individuals, potentially making the habitat no longer suitable for some of the species. Road improvements and establishment could remove habitat and extant populations or individuals of the lichens. The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-4 presents a summary of the number of sites of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-4

Lichen Sites Potentially Affected by the Project

Species	Total Affected NFS Sites a/	Affected Sites in NFS Reserves	Remaining Sites on NFS Lands in NSO Range	Remaining Sites on all Lands in NSO Range
Chaenotheca subroscida	6	4	104	382
Leptogium teretiusculum	1	1	15	261

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Using the spatial analysis process described in appendix F.5, these sites may be clipped by the Project area or fall outside the Project area, but within the analysis area.

The two lichen species analyzed appear to be more common than previously documented or are relatively common across the NSO range based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. The Project would affect site persistence at one or more sites, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

Measures incorporated into the Project as design features would be implemented to minimize soil and vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on all Survey and Manage lichens in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendment of the land management plans for the National Forests that encompass the Project area. Table 4.6.4.3-5 lists the lichen species and the number of affected sites on each National Forest.

TABLE 4.6.4.3-5

Affected Lichen Sites by National Forest

	Number of Sites Affected a/		
Species	**Umpqua**	**Rogue River-Siskiyou**	**Fremont-Winema**
Chaenotheca subroscida	—	5	1
Leptogium teretiusculum	—	1	—

a/ All sites are directly affected (i.e., are located in the Project area).

Vascular Plants

Vascular plants are the most dominant organism in LSOG forests and serve an essential role by providing a food source and cover or shelter for animals and influencing microclimate conditions for other species, such as fungi and lichens. Vascular plants include seed-bearing plants, such as flowering plants and conifer trees, and spore-bearing forms, such as ferns, horsetails, and clubmosses. The Survey and Manage 2001 ROD including 2003 ASR modifications includes 12 plant species. Of the 12 species, clustered lady's slipper (*Cyripedium fasciculatum*) is evaluated for this Project because it has been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on the species, while the key information used to evaluate Project-related effects is summarized in this section.

Surveys for vascular plants have been conducted in much of the NSO range, and the results of these surveys have contributed information to characterize the known extent of the plants in the NSO range. Additional surveys for Survey and Manage species were conducted for the Project as recently as the fall of 2018.[144] Table 4.6.4.3-6 includes the currently known number of *C. fasciculatum* sites in the NSO range. The range of *C. fasciculatum* in the NSO range is relatively well known, and more survey effort would be expected to locate additional sites of the species within its currently known range.

TABLE 4.6.4.3-6

Regional Site Count of Plant Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/
Cypripedium fasciculatum	1,392	1540	198 (37%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent "Riparian Reserves" across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands.

C. fasciculatum is well distributed across most of its known range in the NSO range. Sites are distributed in two general groups in the Klamath Mountains and Cascade Range in Oregon and California and the eastern Cascade Range in Washington. The species appears to be well distributed in the Klamath Mountains in California and Oregon.

General habitat for this species consists of coniferous and mixed hardwood-coniferous forests, including the LSOG component of these forests, across each species' currently known range. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for each species varies based on its distribution across the NSO range and habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of *C. fasciculatum* at one site on NFS land in the Project area. The site occurs on the Umpqua National Forest. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soil within sites and could

[144] Results from these will be incorporated into the final EIS.

result in the removal of populations or individuals of plants. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of coniferous and mixed hardwood-coniferous forests, including the LSOG component of these forests, and disturbance to soil could negatively affect the plants in adjacent areas by removing their habitat, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor and TEWAs could make habitat within the sites no longer suitable for the species. Material storage within UCSAs would disturb understory habitat in some sites, which could also modify microhabitats near extant populations or individuals, potentially making the habitat no longer suitable for some of the species. Road improvements and establishment could remove habitat and extant populations or individuals of the plants. The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-7 presents a summary of the sties that would remain after the single site is affected by Project activities; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-7

Vascular Plant Sites Potentially Affected by Project

Species	Total Affected NFS Sites a/	Affected Sites in Reserves	Remaining Sites on NFS Lands in NSO Range	Remaining Sites on all Lands in NSO Range
Cypripedium fasciculatum	1	1	1,539	1,390

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Using the spatial analysis process described in appendix F.5, these sites may be clipped by the Project area or fall outside the Project area, but within the analysis area.

Cypripedium fasciculatum appears to be more common than previously documented based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. Many sites have been documented in southwest Oregon since the 2001 ROD was published. Should the Project be constructed, it is unlikely that the loss of one site from Project effects would affect the status of *C. fasciculatum* in the NSO range. The Project would affect site persistence at one site on NFS lands, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

Measures incorporated into the Project as design features would be implemented to minimize soil and vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on Survey and Manage plants in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendments to the land management plans for National Forests that encompass the Project area.

Mollusks

Approximately 350 species of mollusks, including land snails, aquatic snails, slugs, and clams, are found in the Pacific Northwest (Forest Service and BLM 2000). Slugs and snails are found in colonies, which may consist of hundreds to many thousands of individuals. Most mollusks are found in moist forests and riparian areas near streams, springs, and seeps. The 2001 ROD including 2003 ASR modifications includes 38 species of mollusks. Of these species, two are considered in this evaluation of the Project because they have been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on each species, while the key information used to evaluate Project-related effects is summarized in this section.

The mollusk species considered in this analysis include evening fieldslug (*Deroceras hesperium*) and Chace sideband (*Monadenia chaceana*). *Deroceras hesperium* is a land slug that requires high moisture environments and is found along the forest floor. A recent study on the molecular characteristics of *D. hesperium* revealed that the mollusk is likely a variant of the more common *D. laeve* (Roth et al. 2013), and *D. hesperium* may no longer belong on the Survey and Manage list, pending an annual species review. Since the species is on the 2003 list, it is evaluated like other Survey and Manage species on the list in this assessment. *Monadenia chaceana* is a land snail that is found in talus or under rocks in moist forests. Both mollusks may be associated with Riparian Reserves.

Surveys for mollusks have been conducted in parts of the NSO range, and the results of these surveys have contributed information to characterize the known extent of the mollusks in the NSO range. Surveys for the Project resulted in several observations of both species. The mollusk species considered in this analysis are listed in table 4.6.4.3-8 with the currently known number of sites in the NSO range. The ranges of these species in the NSO range are relatively well known, and more survey effort would be expected to locate additional sites of the species within their currently known ranges.

The distribution of the species and their ranges within the NSO range vary. *Deroceras hesperium* has a distribution pattern with limited potential for connectivity between isolated sites or site clusters. Sites are found in four general areas in Oregon, including a relatively large cluster of sites located in the southern Cascade Range, and other clustered sites located in the northern Cascade Range and southern Coast Range. Scattered sites are in the northern Cascade Range, and several isolated sites are in other areas. *Monadenia chaceana* has multiple sites or clusters of sites that are nested within a web of potential interconnections. Sites are primarily found in a large group of several clusters in the eastern Klamath Mountains and southern Cascade Range in Oregon and extreme northern California.

TABLE 4.6.4.3-8

Regional Site Count of Mollusk Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/
Deroceras hesperium	54	27	13 (48%)
Monadenia chaceana	258	246	34 (14%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent "Riparian Reserves" across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands.

General habitat for these species consists of a subcomponent (e.g., moist riparian areas, shaded rocky areas) of coniferous, mixed hardwood-coniferous, and hardwood forests, including the LSOG component of these forests, across each species' currently known range. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for the species varies based on its distribution across the NSO range and habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of two Survey and Manage mollusk species at one or more sites in or near the Project area. Vegetation removal and grading activities in the construction corridor and in TEWAs would disturb vegetation and soils within sites and could result in injury or mortality to individuals of mollusks. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of forests and understory components could negatively affect the mollusks in adjacent areas by removing their habitat, potentially affecting site persistence even if the entire site is not disturbed. In addition, modification of shading, moisture, and habitat conditions as a result of the corridor could make habitat within sites no longer suitable for the species. Material storage within UCSAs could disturb understory habitat in sites, which could remove rocks, logs, or woody debris, potentially making the habitat unsuitable for the species or injuring individuals.

The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-9 presents a summary of the number of sites of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

TABLE 4.6.4.3-9

Mollusk Sites Potentially Affected by the Project

Species	**Total Affected NFS Sites a/**	**Affected Sites in NFS Reserves**	**Remaining Sites on NFS Lands in NSO Range**	**Remaining Sites on all Lands in NSO Range**
Deroceras hesperium	1	1	26	53
Monadenia chaceana	9	9	249	396

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Direct effects are those that would take place within the Project area, such as from ground disturbance, vegetation removal, or removal of individuals. Indirect effects are those that would take place outside of the Project area, such as from edge effects or increased open canopy. Using the spatial analysis process described in appendix F.5, these sites may be clipped by or fall outside the Project area, but within the analysis area.

Deroceras hesperium is not necessarily more common than previously documented despite new information available from pre-disturbance surveys for the Project and/or other sources since this species was listed in the 2001 ROD. The Project would affect site persistence at one site, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence. Although this species has a somewhat limited distribution in the NSO range, the affected site is part of a large cluster of sites in the southern Cascade Range in Oregon. The distribution and connectivity of the species would likely remain the same despite the loss of one site.

Monadenia chaceana appears to be more common than previously documented based on new information available from surveys for the Project and/or other sources since this species was listed in the 2001 ROD. The Project would affect site persistence at nine sites, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

Measures incorporated into the Project as design features would be implemented to minimize soil and vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on Survey and Manage mollusks in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendments to the land management plans for the National Forests that encompass the Project area. Table 4.6.4.3-10 lists the mollusk species and the number of affected sites in each National Forest.

TABLE 4.6.4.3-10

Vertebrates

A diverse array of vertebrate species, including mammals, birds, amphibians, and reptiles, inhabit the forests of the Pacific Northwest and provide essential functions in the ecosystem, such as dispersing fungal spores and lichens and serving as a food source for predators. The 2001 ROD including the 2003 ASR modifications to the species list includes seven vertebrate species. Two vertebrate species are considered in this evaluation of the Project because they have been documented on NFS lands in or near the Project area. Appendix F.5 presents additional details on each species, and the key information used to evaluate Project-related effects is summarized in this section.

The vertebrate species considered in this analysis include red tree vole (*Arborimus longicaudus*) and great gray owl (*Strix nebulosa*). *Arborimus longicaudus* is a small arboreal rodent that lives in tree canopies of coniferous and mixed hardwood-coniferous forests and seldom goes to the forest floor (Forest Service and BLM 2001b). It is a primary prey item of the northern spotted owl, as well as other predators found in coniferous forests. *Strix nebulosa* is a forest owl that uses existing stick nests constructed by other raptors and large corvids, and nests between March 1 and July 31 (Williams 2012). It forages in natural forest openings, typically larger than 10 acres, and nests in coniferous and mixed hardwood-coniferous forests.

Surveys for the vole and owl have been conducted across much of the NSO range, and the results of these surveys have contributed information to characterize the known extent of the species in the NSO range. Surveys for the Project resulted in multiple observations of both species in the surveyed areas. The vertebrate species considered in this analysis are listed in table 4.6.4.3-11 with the currently known number of sites in the NSO range, and the distributions of the species are briefly discussed after the table. The ranges of these species in the NSO range are relatively well known, and more survey effort would be expected to locate additional sites of the species within their currently known ranges.

TABLE 4.6.4.3-11

Regional Site Count of Vertebrate Species Potentially Affected by the Project

Species	Total Sites in NSO Range a/	Sites on NFS Lands in NSO Range b/	Sites in NFS Reserves in NSO Range c/
Arborimus longicaudus	34,946	1,524	624 (34%)
Strix nebulosa	177	55	16 (12%)

a/ Total site count reflects the number of sites generated by the 8/2/17 FME extract.
b/ Site count reflects only those sites on NFS lands using land ownership data for the NSO range (dated October 2011).
c/ Site count reflects only those sites on NFS lands and in reserve land allocations based on 1994 ROD reserve land allocations for the NSO range (data dated December 2002 and September 2009) and National Hydrography Dataset, v. 2.1.0 to represent "Riparian Reserves" across the NSO range. These counts underestimate the number of sites in reserves, but regionally mapped reserve data are not available. The percentage represents the estimated proportion of sites in reserves to total sites on NFS lands

The distribution of the species and their ranges within the NSO range vary. Both species have multiple sites or clusters of sites that are nested within a web of potential interconnections. Most *A. longicaudus* sites are found in the Klamath Mountains in Oregon, where sites are abundant and close together in large clusters or groups. Sites are more scattered in the western Cascade Range in Oregon, although they are still relatively abundant. *Arborimus longicaudus* appears to be well distributed within its range in Oregon. Most *S. nebulosa* sites are found in a large group in the southern Cascade Range and eastern Klamath Mountains, where the species appears to be well distributed.

General habitat for *A. longicaudus* consists of LSOG coniferous and mixed hardwood-coniferous forests across the species' currently known range in Oregon. General habitat for *S. nebulosa* consists of coniferous and mixed hardwood-coniferous forests, including the LSOG component of these forests, with a subcomponent of natural forest openings (e.g., meadows) that are used for foraging. Forests that may provide suitable habitat have been mapped using available data for the NSO range that were also used for the NWFP Effectiveness Monitoring 15-year report to map LSOG forests (Moeur et al. 2011). The extent of potential habitat for the species varies based on its distribution across the NSO range and habitat preferences, and additional details on habitat are presented in appendix F.5.

The Project could affect site persistence of two Survey and Manage vertebrates at more than one site or habitat area in or near the Project area. Vegetation removal in the construction corridor and TEWAs and along roads could result in the removal of trees that support *A. longicaudus* nests or cause injury or mortality to individuals. Construction of the Project would create an open corridor, which would be dominated by early seral vegetation for approximately 30 years. This is a long-term effect that could modify microclimate conditions around populations or individuals adjacent to the corridor during the early seral vegetation phase. The removal of forests and potential nest trees could negatively affect *A. longicaudus* in adjacent areas by removing its habitat and opening the tree canopy, potentially affecting site persistence at the habitat areas even if the entire habitat area is not disturbed. In particular, modification of shading and habitat conditions as a result of the corridor, TEWAs, and roads could make entire habitat areas no longer suitable for the species because of the preference for closed canopy habitats. Activities within the corridor and TEWAs would result in extensive noise disturbance during vegetation clearing, grading, and pipeline installation and could result in *S. nebulosa* nest abandonment and loss of young during the nesting season. No active *S. nebulosa* nest sites were documented in the Project area; therefore, direct effects on the owl (e.g., removal of active nests, injury to owls) are not anticipated. Vegetation removal across the Project area would also result in a long-term loss of habitat that may be suitable for the species. Conversely, if constructed, the construction corridor would also create an early seral plant community suitable for foraging by great grey owls.

The specific effects on sites in and near the Project area vary by species and depend on where the sites are in proximity to the corridor and other activities. Table 4.6.4.3-12 presents a summary of the number of sites (habitat areas for *A. longicaudus*) of each species that would be affected by the Project; additional details for each species are included in appendix F.5.

Both species appear to be more common than previously documented based on new information available from surveys for the Project and/or other sources since these species were listed in the 2001 ROD. The Project would affect site persistence at multiple sites or habitat areas of each species, but the remaining sites in the NSO range would provide a reasonable assurance of species persistence.

TABLE 4.6.4.3-12

Vertebrate Sites Potentially Affected by the Project

Species	Total Affected NFS Sites a/	Affected Sites in NFS Reserves	Remaining Sites on NFS Lands in NSO Range	Remaining Sites on All Lands in NSO Range
Arborimus longicaudus	525 (55) b/	10 (24)	1,469 c/	4,843
Strix nebulosa	1	1	54	171

a/ Affected sites are those that would be directly or indirectly affected by Project activities based on the analyses presented in appendix F.5. Direct effects are those that would take place within the Project area, such as from ground disturbance, vegetation removal, or removal of individuals. Indirect effects are those that would take place outside of the Project area, such as from edge effects or increased open canopy. Using the spatial analysis process described in appendix F.5, these sites may be clipped by or fall outside the Project area, but within the analysis area.
b/ *A. longicaudus* sites are habitat areas (55 sites were converted to 25 habitat areas in the analysis area), as mapped in accordance with the management recommendations for the species (Forest Service and BLM 2001b).
c/ The total of remaining sites is based on site data, not habitat areas. Habitat areas were not produced for the entire regional area, just the analysis area.

Measures incorporated into the Project as design features would be implemented to minimize vegetation disturbance in the Project area and restore areas following construction, which could minimize adverse effects on Survey and Manage vertebrates in and near the Project area. The Forest Service will prepare and implement a monitoring plan that describes specific protocols to monitor affected sites and habitat adjacent to the sites over the long term.

For lands directly affected by the Project, the Forest Service would waive implementation of Management Recommendations for Survey and Manage species through amendments to the land management plans for the National Forests that encompass the Project area. Table 4.6.4.3-13 lists the vertebrate species and the number of affected sites or habitat areas in each National Forest.

TABLE 4.6.4.3-13

Affected Vertebrate Sites by National Forest

	Number of Sites Affected a/		
Species	Umpqua	Rogue River-Siskiyou	Fremont-Winema
Arborimus longicaudus b/	125	—	—
Strix nebulosa	—	0 (1)	—

a/ First number presents sites directly affected (i.e., in Project area), number in parentheses presents sites indirectly affected (i.e., sites wholly in analysis area).
b/ *A. longicaudus* sites are habitat areas, as mapped in accordance with the management recommendations for the species (Forest Service and BLM 2001b).

In conclusion, the Project could affect site persistence of 38 Survey and Manage species at one or more sites or habitat areas in or near the Project area. The remaining sites of 37 of these 38 species, however, would provide a reasonable assurance of these species persistence. The Project as proposed would affect site persistence of the fungi *Sarcodon fuscoindicus* at one or more sites, and the remaining sites may not provide a reasonable assurance of this species persistence. However, above we have recommended that Pacific Connector avoid affecting the *Sarcodon fuscoindicus* site by incorporating a pipeline route variation that avoids this site into the proposed action (see chapter 3). Therefore, the analysis summarized in this section, supported by the information presented in appendix F.5, indicate that construction and operation of the Project would provide a reasonable assurance of persistence of Forest Service Survey and Manage species that would be affected.

4.6 THREATENED, ENDANGERED, AND OTHER SPECIAL STATUS SPECIES

This section analyzes the effects of the Project on special status species. In addition to species listed as threatened or endangered under the federal ESA[133] and Oregon ESA[134], agencies and organizations such as the FWS, BLM, Forest Service, ODA, and ODFW maintain lists of species that are considered special concern, sensitive, rare, or are otherwise offered protections under agency planning documents. These species are broadly defined in this assessment as "special status species."[135] Although the term "special status species" is used differently by various agencies, for the purposes of this assessment, the term "special status species" includes:

- species that are listed or proposed for listing by the federal government as endangered or threatened, or are candidates for listing;
- species that are identified by the BLM or Forest Service as "sensitive species" or "strategic species";
- species listed by the State of Oregon as endangered, threatened, or are candidates for listing; and
- species identified by federal or state agencies as rare or protected by federal or state planning documents (e.g., Standards and Guidelines in resource management plans such as "Survey and Manage" species identified in the NWFP).

Using data from the Oregon Biodiversity Information Center (ORBIC),[136] FWS, NMFS, discussions with Forest Service and BLM specialists, and information reviews of published and unpublished information, the applicants prepared lists of threatened, endangered, proposed,

[133] Federal agencies are required by Section 7 of the ESA (Title 19 U.S.C. Part 1536[c]), as amended (1978, 1979, and 1982), to ensure that any actions authorized, funded, or carried out by the agency do not jeopardize the continued existence of a federally listed endangered or threatened species, or result in the destruction or adverse modification of designated critical habitat of a federally listed species. The action agency (e.g., the FERC) is required to consult with the FWS and/or the NMFS to determine whether federally listed endangered or threatened species or designated critical habitat are found in the vicinity of the Project, and to determine the proposed action's potential effects on those species or critical habitats. For actions involving major construction activities with the potential to affect listed species or designated critical habitat, the federal agency must submit its BA to the FWS and/or NMFS and, if it is determined that the action may adversely affect a listed species, the federal agency must submit a request for formal consultation to comply with Section 7 of the ESA. In response, the FWS and/or NMFS would issue a BO as to whether or not the federal action would likely jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. Jordan Cove and Pacific Connector filed an applicant-prepared draft BA (APDBA) in December 2017, and a revised APDBA in September 2018. We are reviewing the revised APDBA and will prepare a BA and EFH Assessment, which will be submitted to the FWS and NMFS.

[134] Oregon has its own ESA that requires state agencies to protect and promote the recovery of state-listed threatened and endangered species. At the state level, consultation is conducted with the ODA for state listed plant species and the ODFW for fish and wildlife species. However, state regulations pertaining to the protection of botanical resources are limited to ORS 564 and OAR Chapter 603, Division 73. Oregon regulations regarding state endangered and threatened plants only apply on non-federal public lands (e.g., state, county, city, etc. lands).

[135] The term "special status species" is also used by the BLM, but in a narrower agency-specific definition than in this assessment. BLM "special status species" include species listed as threatened or endangered under the ESA, species that are proposed for listing under the ESA, species that are candidates for listing under the ESA, and species designated by the BLM as "sensitive" under criteria in BLM Manual 6840. The Forest Service uses similar designations. For the Forest Service, "Survey and Manage" are managed under specific criteria provided in the Northwest Forest Plan rather than the agency "special status species" programs. Several species are designated as both "special status species" for the Forest Service and "Survey and Manage species." Those species are noted in the assessment and are analyzed here under criteria for both programs.

[136] Formerly known as the Oregon Natural Heritage Information Center (ORNHIC).

candidate, and special status species that potentially occur near the proposed Project, as described in the following sections. Species that were initially considered but were dropped from further consideration due to a lack of habitat or because they were not detected during targeted field surveys are listed in tables I-3, I-4, and I-5 in appendix I.

4.6.1 Federally Listed Threatened and Endangered Species

Table 4.6.1-1 lists the federally endangered, threatened, and proposed species that potentially occur in the Project area and are discussed below. Additional species (beyond those listed in table 4.6.1-1) are federally listed in Oregon (i.e., the Canada lynx, bull trout Klamath River DPS, yellow-billed cuckoo Western DPS, streaked horned lark, and slender Orcutt grass); however, these species are not known or expected to occur within the Project area and are not discussed further in this document (Canada lynx: Verts and Carraway 1998, McKelvey et al. 2000, ORBIC 2006b; bull trout Klamath River DPS: FWS 1998a, 2002a, ORBIC 2006b; yellow-billed cuckoo: FWS 2013b; streaked horned lark: FWS 2017b; SBS 2008a, 2012, 2013, 2014, 2017a; and slender Orcutt grass: ORBIC 2017b, FWS 2006b). In addition, the North American wolverine occurs in Oregon and has been proposed for listing as threatened under ESA; wolverines have been occasionally documented in Oregon, most recently in the Wallowa-Whitman National Forest in Northeast Oregon during 2011-2012 (Magoun et al. 2013), but no evidence for a reproducing, self-sustaining population has been found in the state. There appears to be an extremely remote chance of a wolverine dispersing into southwest Oregon, but that is not foreseeable during the construction of the proposed action, and as a result, the North American wolverine is not discussed further in this document. The Eastern DPS of the Steller sea lion, which occurs on the west coast of the U.S. and within the Project area, was delisted on December 4, 2013 (78 FR 66139), and thus is not discussed in this section.

Table 4.6.1-1 lists all potentially affected federally listed and proposed species, indicates the portion of the Project area where they may occur, and provides our preliminary determination of effect.

a/ Effects Key:
NLAA = Not likely to adversely affect, LAA = Likely to adversely affect, NE = No effect, NJ = not likely to jeopardize the continued existence for proposed species
b/ DPS=Distinct Population Segment
c/ This represents a provisional effect determination for this ESA proposed species. This provisional effect determination would apply if the species becomes listed prior to the completion of consultaion on the Project.

4.6.1.1 Mammals

Gray Wolf (Federal Endangered Species, State Delisted)

The federal ESA in Oregon protects gray wolves west of highways 395-78-95 (ODFW 2017e). Gray wolves were delisted from the Oregon ESA in 2015 (ODFW 2017f). Wolves are habitat generalists that only require the presence of ungulate prey and absence of excessive human-caused mortality (FWS 2013c). Wolf pack territory size is a function of prey density and can range from 25 to 1,500 square miles (FWS 2013c). Both male and female wolves disperse, sometimes greater than 600 miles (FWS 2013c).

A radio-collared male (i.e., OR7) dispersing from a pack in northeastern Oregon has been documented in southwestern Oregon and northern California since 2011, including near the Project in Jackson, Douglas, and Klamath Counties (ODFW 2013b). In 2014, a female joined the male, and they produced their first litter that year consisting of three pups (ODFW 2014e). This was the first evidence of wolves breeding in the Oregon Cascades since the early twentieth century (ODFW 2014d). The den was located within the Rogue River National Forest, between Crater Lake and Mount McLoughlin (Young 2014), approximately 6 miles from the pipeline route. Additional pups were born in 2015, 2016, and 2017 (ODFW 2018b). The Area of Known Wolf Activity (AKWA) initially mapped by ODFW for OR7 in 2014 (ODFW 2014c) is crossed by the pipeline route. The AKWA for OR7 and the Rogue Pack has shifted in size and shape since 2014. As currently mapped, it is less than 5 miles from the pipeline route in Jackson and Klamath Counties.

A second AKWA (Keno) was established in southwest Oregon in 2014 with limited evidence that three wolves inhabited an area approximately 280 square miles. ODFW recently removed the AKWA designation for the Keno wolves and is designating it as no longer active, but possibly used as a corridor for wolves moving between Oregon and California (ODFW 2018b). Approximately 2.48 miles of the pipeline route would pass through this area.

Three other radio-collared wolves dispersed from northeastern Oregon to southwest Oregon. One single male wolf (OR25) dispersed in 2015 and established an AKWA spanning northern Klamath County with portions in adjacent Jackson County and Lake County. A radio-collared female wolf (OR28) dispersed in late 2015 and was joined by a collared male (OR3) to establish the Silver Lake AKWA which coincides with the Silver Lake Wildlife Management Unit in western Lake County. The pair produced one pup in 2016 but the male was killed in 2016 (ODFW 2017g).

Given the occurrence of gray wolves in the areas affected by the Project, potential direct and indirect effects from construction and operation of the pipeline include the following:

- <u>Construction-related noise.</u> Construction would produce noise. Wolves appear most vulnerable to human disturbance in and around denning and rendezvous sites. No active denning sites are known within 1 mile of the pipeline.
- <u>Locally concentrated human activities.</u> Available evidence has shown that wolves subjected to increased vehicular traffic will avoid roads and will move pups if disturbed during denning. Wolves disturbed during winter indicated a physiological stress response to snowmobile stimuli.
- <u>Increased risk of collision with construction vehicles along Project area roadways.</u> Vehicles have killed a small number of wolves; overall, 80 percent of all wolf mortalities in the Northern Rocky Mountain population (which includes wolves in the Project area) are caused by humans but only 3 percent are due to accidental human interactions including vehicle collisions and capture mortality (FWS 2012a).
- <u>Wildland fire as an indirect effect associated with increased human presence</u>. The possibility of ignition in conifer and sagebrush/grass fuel types could range from low to extreme depending on weather conditions and patterns, current fire risk rating, moisture conditions, and fuel loadings. There is some possibility of human-caused fire, whether related to pipeline activities or to Project-induced increase of human presence in the area.
- <u>Habitat alteration</u>. Construction would remove forested habitat that might be used by some species that are preyed upon by wolves. However, corridors created within forested habitats are used for movement and foraging by big game species, which are prey for wolves.

Below is a determination of effects summary for this species and critical habitat. More details will be provided in the pending BA.

The Project **may affect** the gray wolf because:

- dispersing and resident wolves have been documented recently near the Project area;
- the OR7 wolf family den was near the pipeline route in 2014;
- construction noise could disturb wolves if present near the pipeline; and
- increased human presence associated with construction activities could affect wolf behavior and movements, including the chance of collisions with vehicles.

However, the Project is **not likely to adversely affect** the gray wolf because:

- the OR-7 den within the Rogue River National Forest is at least 6 miles from the pipeline;
- Project-related noises are not likely to be substantially different from noises produced by existing recreation and logging activities that wolves have been shown to tolerate;
- during pipeline construction, trash would be removed daily, and roadside carrion is expected to be present as an existing condition, and not substantially increased by the Project; and
- following construction, the restored and revegetated pipeline corridor is likely to increase habitat diversity and forage used by ungulates such as deer (Brusnyk and Westworth 1985; Forman 1995), which are prey for gray wolves.

No critical habitat has been designated or proposed for the gray wolf.

Pacific Marten-Coastal DPS (Federal Proposed Threatened Species, State Sensitive Species)

On October 9, 2018, the FWS proposed to list the coastal DPS of Pacific marten *(Martes caurina)* as a threatened species under the ESA (83 FR 150576). Should the rule for this species be finalized as proposed, it would be protected under ESA. The most current information for this species is provided in an updated species status assessment report, and provides a comprehensive account of the species, its life history needs, and stressors to the overall viability and extinction risk for the coastal marten (FWS 2018a). The coastal marten is a mammal in the weasel family and is native to forests of coastal Oregon and coastal California. They occur primarily in older forests, although there is one remnant population occupying the coastal dune forest of central Oregon. Coastal marten historically ranged throughout coastal Oregon and coastal northern California but have not recently been detected throughout much of the historical range, despite extensive surveys. The species exists in four small populations and is absent from the northern and southern ends of its historical range. In Oregon, there are two identified isolated small extent population areas: Central Coastal and Southern Coastal. The Jordan Cove LNG Project falls within the southern portion of the Central Coastal population area and the Pacific Connector pipeline crosses its historical range.

The Central Coastal Oregon population centers on the coastal forest of the Oregon Dunes National Recreation Area (ODNRA) and is managed by the Siuslaw National Forest. Most of this area comprises coastal forest that is less than 70 years old, and consists of shore pine and transitional shore pine/Douglas–fir–hemlock forests within the ODNRA. These forests grow on nutrient-poor sandy soils, dominated by young stands of shore pine and Sitka spruce. The dense understory is dominated by willow (*Salix hookeri*), Pacific waxmyrtle (*Myrica californica*), and berry-producing ericaceous shrubs such as evergreen huckleberry (*Vaccinium ovatum*) and salal (G*aultheria shallon*). These shore pine forests have a variable tree overstory; however, the common denominator with this habitat and older forest habitats is the presence of dense, spatially extensive ericaceous shrub understories and diverse and abundant prey. Coastal martens have a generalist diet that changes seasonally with prey availability. Overall, their diet is dominated by mammals (primarily voles in Central Coastal population area), but birds, insects, and fruits are seasonally important.

Reports by Zielinski et al. (2001) and Moriarty et al. (2016) noted a relatively high incidence of road kills in the last 30 years (i.e., 17) and it was assumed that animals were abundant. Linnell et al. (2018) used recent surveys to refine the extent of the Central Coastal population size of fewer than 87 adults divided into two subpopulations; however, there is no information at this time on long–term trends in population size. The 2018 species status assessment further divides this population into two subpopulations of approximately 30 adults each, separated by the Umpqua River, a relatively large barrier to movement and dispersal. Martens in this population occur in the highest densities reported for any North American marten subspecies (1.13 per square kilometer; Linnell et al. 2018). The Southern Coastal population area in Oregon is located over 40 miles to the south and would not be affected by the Project.

The 2018 species status assessment identifies various factors (stressors) that are directly and indirectly affecting what the coastal marten needs for long-term viability. These include loss of habitat due to wildfire, timber harvest, and vegetation management. Trapping, collisions with vehicles, and rodenticides are all impacting marten individuals, and the threat of disease carries the risk of further reducing populations. Changes in vegetation composition and distribution have also made coastal martens more susceptible to predation from larger carnivores. These threats are expected to be exacerbated by the species' small and isolated populations. Linnell et al. (2018) suggest that small population size, consistent annual human-caused mortality (primarily trapping and road kills), and isolation indicate this coastal marten population is likely to remain vulnerable to extirpation.

Section 4.4 describes five forested and two woodland vegetation types that may be suitable habitat for marten and would be affected by the construction and operation of the Jordan Cove LNG Project. The vegetation types are shown on figures 4.4-1a and 4.4-1b. Table 4.4.1.5-1 estimates that approximately 76 acres and 62 acres of forested and woodland vegetation would be cleared for the LNG facilities and temporary construction areas, respectively.

Given that the Project falls within the southern portion of the Central Coastal population area and the occurrence of marten habitat within the area of the proposed Project footprint, potential direct and indirect effects from construction and operation of the Project include the following:

- Construction-related noise. Construction would produce noise; and martens appear most vulnerable to human disturbance in and around denning and resting habitat. No active denning sites are currently known in the vicinity of the Project site.
- Locally concentrated human activities. Available evidence has shown that martens are subject to road kills and increased vehicular traffic has the potential to increased vehicle collision mortality.
- Habitat alteration. Construction would remove forested habitat that might be used by martens or species that are preyed upon by martens, or otherwise increase fragmentation within suitable habitat. However, much of the forested portions within the Jordan Cove Project boundaries are already in a disturbed state.
- Wildland fire as an indirect effect associated with increased human presence. The possibility of ignition in conifer and sagebrush/grass fuel types could range from low to extreme depending on weather conditions and patterns, current fire risk rating, moisture conditions, and fuel loadings. There is some possibility of human-caused fire, whether related to construction activities or to Project-induced increase of human presence in the area.

Below is a determination of effects summary for Pacific marten- coastal DPS. At this time, no critical habitat has been proposed or designated for this species. More details will be provided should this species become listed as threatened under ESA, including potential exceptions and/or any designation of critical habitat.

The Project **will not jeopardize the continued existence** of the Pacific marten- coastal DPS; however, in the event that Pacific marten- coastal DPS becomes listed prior to completion of the Project, a provisional effect determination is provided.

The Project **may affect** the Pacific marten- coastal DPS because:

- marten historically used the entire Oregon coastal region;
- the southern portion of the Central Coast population area overlaps with the Jordan Cove LNG Project;
- the Project would remove suitable habitat for the coastal DPS population; and
- increased human presence associated with construction activities could affect marten behavior and movements, including the chance of collisions with vehicles.

However, the Project is **not likely to adversely affect** Pacific marten-coastal DPS because:

- there is a relatively low potential for the coastal DPS individuals to occur based on historical accounts and the current low estimated number of individuals south of the Umpqua River;
- project-related noises are not likely to be substantially different from noises produced by existing recreation and logging activities that martens have been shown to tolerate;
- during Project construction, trash would be removed daily to reduce the potential for predator species; and
- construction-related vehicles and equipment would operate at slower speeds, and therefore not substantially increase the potential for vehicle collisions.

Pacific Fisher-West Coast DPS (Federal Proposed Threatened Species, State Sensitive-Critical Species)

The FWS proposed to list the West Coast DPS of the Pacific fisher as threatened under the ESA on October 7, 2014 (79 FR 60419). In April 2016, the FWS determined that the fisher does not warrant listing under the ESA (81 FR 22710). However, on September 21, 2018, the decision to deny the fisher protected status was rescinded and the comment period for the proposed rule to list the West Coast DPS of the fisher was reopened (84 FR 644). The FWS is scheduled to issue a new finding by March 22, 2019.

Fishers occur in the northern coniferous and mixed forests of Canada and the northern United States (69 FR 18770). The West Coast DPS includes fishers in Washington, Oregon, and California. In Oregon, this species is currently known to occur in Curry, Douglas, Jackson, Josephine, and Klamath Counties (Aubry and Lewis 2003; Aubry pers. comm. 2007 as cited in FWS 2014b). Currently, there are two documented populations of fisher in southern Oregon, one in the northern Siskiyou Mountains and one in the southern Cascade Range, that were believed to be genetically isolated from each other (FWS 2014b). However, recent research shows that the two populations are not genetically isolated (Barry et al. 2018).

Fisher habitat consists of mature, closed canopy coniferous and mixed conifer and hardwood forests at low to middle elevations, including riparian corridors with continuous canopies, and large stands with low levels of fragmentation and a high percentage of dead and downed timber (ODFW 2019; FWS 2016a). Fishers prefer large tracts of contiguous interior forest and typically avoid thinned or open forests, including areas where there is substancial human disturbance. A variety of large conifer tree species are used for denning and resting, including Douglas-fir, white fir, incense cedar, red fir, sugar pine, western white pine, ponderosa pine and lodgepole pine (Aubry and Raley 2006; Cummins et al. 2018). In the southern Oregon Cascades, average home range sizes for females were approximately 9.7 square miles and between 24 square miles for males during the non-breeding season and 57 square miles for males during the breeding season, based on locations of radio telemetered study animals (Aubry and Raley 2006).

Loss and fragmentation of habitat due to timber harvest and thinning, roads, urban development, recreation, and wildfire are the main reasons for the decline of the fisher in the west (FWS 2018b). Habitat loss, modification, and fragmentation continue to occur as a result of forest management practices and stand replacing wildfire, and appear to pose a substantial threat to fishers (FWS 2012b). In addition to removing forage, rest, and den sites, fragmentation can increase predation risk, impede movements, and affect prey species composition, abundance, and availability (FWS 2012b). Fragmentation can also increase energetic costs to fishers, which may result in nutritional stress that can reduce animal condition, ultimately affecting survival, reproduction, and recruitment (Lofroth et al. 2010). Additionally, linear infrastructure such as roads, power lines, and pipelines can also affect fisher populations and their habitat (FWS 2016a). As well as being sources of mortality from vehicle collision, these linear infrastructure features can result in permanent removal or alteration of potential fisher habitat and can disrupt movement patterns (FWS 2016a). However, linear infrastructure is considered to be a low-level impact to fishers currently and in the future (FWS 2016a).

Recent telemetry studies in the southern Oregon Cascades identified fisher home ranges that overlap with the Project on the Winema National Forest (Cummins 2018). Location databases show one observation within 1 mile and one observation within 1 to 3 miles of the Project on the Winema National Forest. These observations, together with the availability of suitable habitat within the pipeline ROW, indicate that there is potential for fishers to be present within the analysis area.

Section 4.5 discusses the various wildlife habitat types (from Johnson and O'Neil 2001) crossed by the Project. Late successional and old-growth forest within five forest and woodland habitat types crossed by the pipeline may provide habitat for the fisher. These habitat types include Westside Lowland Conifer-Hardwood Forest, Montane Mixed Conifer Forest, Southwest Oregon Mixed Conifer-Hardwood Forest, Westside Riparian-Wetlands, and Eastside Riparian-Wetlands. Table 4.5.1.2-5 estimates that approximately 657.9 acres of these habitat types would be cleared for the construction of the pipeline.

Given the potential for occurrence of fishers in the areas affected by the Project, potential direct and indirect effects from construction and operation of the pipeline include the following:

- <u>Construction-related noise.</u> Construction would produce noise. Fishers are vulnerable to human disturbance and fishers have been documented within 1 mile of the pipeline.

- Locally concentrated human activities. Construction activities could affect fishers by disturbing animals. Fishers are sensitive to disturbance and avoid areas used by humans (CBD 2000).
- Increased risk of collision with construction vehicles along Project area roadways. Human-caused mortality from vehicle collisions are listed as one of the threats to fisher populations (FWS 2018b).
- Habitat alteration and fragmentation. Construction would remove forested habitat and would modify habitat, particularly by removing large trees, snags, and large woody debris that are used for fisher den and rest sites. The cleared ROW could also fragment habitat, which is detrimental to fishers because they prefer large areas of contiguous, unfragmented forest (CBD 2000).
- Wildland fire as an indirect effect associated with increased human presence. The possibility of ignition in conifer, hardwood, and sagebrush/grass fuel types could range from low to extreme depending on weather conditions and patterns, current fire risk rating, moisture conditions, and fuel loadings. There is some possibility of human-caused fire, whether related to pipeline activities or to Project-induced increase of human presence in the area.

Below is a determination of effects summary for Pacific fisher-West Coast DPS. At this time, no critical habitat has been proposed or designated for this species. More details will be provided should this species become listed as threatened under the ESA, including potential exceptions and/or any designation of critical habitat.

The Project **will not jeopardize the continued existence** of the Pacific fisher-West Coast DPS; however, in the event that Pacific fisher-West Coast DPS becomes listed prior to completion of the Project, a provisional effect determination is provided.

The Project **may affect** the fisher because:

- fishers have the potential to occur in the fisher analysis area;
- suitable habitat is available within the fisher analysis area and would be impacted by the pipeline;
- construction noise could disturb fishers if present near the pipeline; and
- increased human presence associated with construction activities could affect fisher behavior and movements, including the chance of collisions with vehicles.

The following determination is warranted to receive a conference opinion of **may affect, likely to adversely affect** because:

- Recent telemetry studies in the southern Oregon Cascades identified fisher home ranges that overlap with the Project;
- 657.9 acres of suitable LSOG habitat, including snags, would be removed due to pipeline construction.
- Snags and large trees that could serve as fisher dens would be removed during pipeline construction.

Whales

Eight species of federally listed whales potentially occur off the coast of Oregon, including the blue, fin, southern resident killer, humpback, sei, north Pacific right, gray (Western North Pacific Stock) and sperm whales. All these whale species are federally protected under the MMPA. These species tend to feed during the summer in the northern latitudes and migrate to the tropical southern latitudes in the winter for breeding. However, whales could be encountered off the coast of Oregon throughout the year. Two killer whales were documented near the Project area in May 2017 during marine mammal surveys for the Project, although these were likely transient killer whales not belonging to the southern resident DPS (AECOM 2017). Gray whales have been reported in Coos Bay only on an occasional basis. Project effects on whales would be associated with LNG and construction supply vessel transits in the waterway inbound and outbound from the Jordan Cove terminal, as well as construction activities such as dredging and pile driving. Potential direct effects of the Project could include injury and/or mortality due to ship-strikes, injury or behavioral disturbance due to noise from vessels and construction activities, and potential adverse effects from a ship fuel spill. Spills could indirectly affect whales by harming or contaminating forage species. Additional details on whale densities and potential for ship strikes will be provided in the pending BA.

Below is a determination of effects summary for whales and critical habitat. More details will be provided in the pending BA.

The Project **may affect** federally listed whales because:

- federally listed whales may occur within the aquatic analysis areas (Figure 4.5-1 in section 4.5; includes the Coos Bay estuary and marine environment out approximately 12 nautical miles to the outer continental shelf) during construction and operation of the proposed action;
- vibratory sheet pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 120 decibel (dB) re 1 microPascal (μPa) at distances of up to 1.2 miles (Deveau and MacGillvray 2017) and impact pipe pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 160 dB re 1 μPa at 1.1 miles (O'Neill and MacGillvray 2017); and
- the proposed action would increase shipping traffic (LNG carriers) within the aquatic analysis areas.

However, the Project is **not likely to adversely affect** federally listed whales for the following reasons:

- ship strikes on whales off the Oregon coast are thought to be infrequent based on the Rockwood et al. (2018) assessment of potential whale/vessel collision mortalities for blue, humpback, and fin whales of less than 1 percent, and therefore thought to be discountable;
- 120 LNG carrier trips per year to the LNG terminal are expected to increase the potential in ship strikes to whales over known frequencies of incidents; however, Jordan Cove would provide a ship strike avoidance measures package to LNG carrier operators transporting cargo from the LNG terminal that would consist of multiple measures to avoid striking marine mammals;

- FERC does not have authority over the LNG carrier; however, the independent carrier operators would be required to follow all Coast Guard requirements regarding the operation of LNG carriers, including vessel speeds;
- noise from LNG carriers, dredgers, tugs, and other support vessels could result in behavioral disturbance to listed whales and effects of ship noise on whales could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise (NMFS 2016c, 2017b, 2018c), but LNG carrier noise would not exceed existing background ship noise levels and would not cause injury;
- whales inside Coos Bay in the vicinity of the Jordan Cove LNG Project may be affected by noise from piling during construction, and the use of an impact hammer has impulsive peak source levels that are high enough to cause permantent threshold shift (PTS) (an indicator of hearing damage) in these species; however, listed whales are unlikely to occur within Coos Bay during pile driving (October 1 to February 15), and Jordan Cove has indicated that these activities would be monitored and halted if a whale was detected in the area around the sound source;
- given vessel design, on-board spill kits, safety records, and implementation of Coast Guard recommendations, it is not likely that there would be a major ship spill of hazardous materials that may adversely affect water quality or aquatic species; and
- the relative population density of whales within the marine analysis area[137] would be low enough so that Project-related effects of LNG carrier transit in the waterway would be discountable.

No critical habitat has been designated or proposed for blue, fin, humpback, sei, or sperm whales.

The Project would have **no effect** on designated critical habitat units (CHUs) for the Eastern Northern Pacific Southern Resident stock of killer whales because:

- none of the designated CHUs occur within the marine analysis area off the Oregon coast.

The Project would have **no effect** on designated critical habitat for the North Pacific right whale because:

- none of the designated critical habitat occurs within the marine analysis area off the Oregon coast.

As described above, listed whales inside Coos Bay near the Jordan Cove LNG Project may be affected by noise from pile driving during construction, and the use of an impact hammer has impulsive peak source levels that are high enough to cause PTS (an indicator of hearing damage) in these species. Therefore, **we recommend that:**

- **<u>Prior to construction,</u> Jordan Cove should file with the Secretary, for review and written approval by the Director of OEP, a *Marine Mammal Monitoring Plan* that identifies how the presence of listed whales will be determined during construction,**

[137] Whale density estimates were based on habitat specific densities for blue whales, fin whales, and humpback whales (Becker et al. 2012; Calambokidis et al. 2015). Quantified comparable estimates for other species were not available, but the existing data were examined to qualitatively determine the level of risk to these species. These data sources and analyses are further described in the Applicant Prepared Draft Biological Assessment, filed with the FERC September 14, 2018.

and measures Jordan Cove will take to minimize potential noise effects on whales and other marine mammals, and ensure compliance with NMFS underwater noise criteria for the protection of listed whales.

4.6.1.2 Birds

Short-tailed Albatross (Federal Endangered Species, No State Status)

The short-tailed albatross was listed as endangered throughout its range in the United States on July 31, 2000 (FWS 2000a). In the North Pacific, the coastal habitat for the short-tailed albatross is in high-productivity areas with expansive deep water beyond the continental shelf. Short-tailed albatross rarely occur closer to the coast, but have been documented to occur off the Oregon coast near Coos Bay (in 1961, 2000, and 2001; National Audubon Society 2013). Because the closest breeding population of short-tailed albatross is within the Hawaiian Islands, the Project should not affect recovery criteria for the species. The short-tailed albatross could potentially be encountered within the LNG carrier transit route; however, short-tailed albatross are expected to avoid LNG marine traffic. Below is a determination of effects summary for the short-tailed albatross and critical habitat. More details will be provided in our pending BA.

The Project **may affect** short-tailed albatross because:

- short-tailed albatross may occur within the marine analysis area during operation of the proposed action; and
- the proposed action would increase shipping traffic (LNG carriers) within the marine analysis area.

However, the Project is **not likely to adversely affect** short-tailed albatross for the following reasons:

- other species of albatross have infrequently collided with airplanes in flight but collisions of any albatross species with ships are unknown and are expected to be highly unlikely;
- 120 LNG carrier trips per year to the LNG terminal are expected to cause unmeasurable increase in potential ship strikes on short-tailed albatrosses;
- LNG carriers approaching Coos Bay would be traveling slowly and escorted by tractor tugs from 5 nautical miles offshore; and
- given vessel design, on-board spill kits, safety records, and implementation of Coast Guard recommendations, it is not likely that there would be a major ship spill of hazardous materials that may adversely affect water quality or aquatic species. Any oil released at sea would be in small enough quantities that potential effects on short-tailed albatrosses would be discountable.

No critical habitat has been designated or proposed for the short-tailed albatross.

Western Snowy Plover (coastal) (Federal Threatened Species with Critical Habitat, State Threatened Species)

The Pacific Coast population of western snowy plover has been listed as a threatened species under the ESA since March 5, 1993 (FWS 1993a). The Pacific coast population includes birds that nest adjacent to tidal waters, including all nesting birds on the mainland coast, peninsulas, offshore islands, adjacent bays, estuaries, and coastal rivers (FWS 1993a). The western snowy plover is a year-round, uncommon resident of the North Spit (BLM 2005); the spit supports the most productive snowy plover population segment on the Oregon coast (BLM 2008). Western snowy plovers may be encountered along the LNG carrier transit route from nearshore coastal waters to the LNG terminal. Potential effects include increased noise associated with construction of the Jordan Cove LNG Project, operation activities associated with shipping, increased recreation, increased habitat conversion, habitat degradation by human encroachment, and increased illegal harvest (Comer 1982). Conservation measures proposed to reduce effects include implementation of BMPs, education and outreach, and monitoring. CHUs OR-10 and OR-9 are located 2.6 and 6.9 miles from the LNG terminal, respectively; both units were occupied by western snowy plovers at the time of listing (1993) and in 2012. Below is a determination of effects summary for the western snowy plover and critical habitat. More details will be provided in our pending BA.

The Project **may affect** western snowy plovers because:

- the closest western snowy plover nesting habitat to the Project is on the North Spit approximately 1 mile from LNG terminal site, and contained active nests during 2016 surveys;
- temporary construction activities would occur at the Port Laydown site, which is less than 1 mile from known nesting sites;
- the meteorological station is located east of the foredune, approximately 100 feet from the northern extent of known nesting sites;
- impact hammer noise associated with the Navigation Reliability Improvement temporary facilities is expected to be above ambient levels, and may disturb wintering western snowy plovers if present along the eastern edge of the primary nesting area on the North Spit, which is within 0.25-miles of Dredge Area 1; and
- Jordan Cove terminal construction and operations personnel would likely use the North Spit for recreational purposes and increased recreational use could result in increased plover disturbance including destruction of nests by dogs, off-road vehicle traffic, inadvertent trampling, or increased predation if scavengers and predators (corvids, coyotes, striped skunk, feral cats) are attracted to nesting areas due to the presence of trash and food remains.

However, the Project is **not likely to adversely affect** western snowy plover because:

- Jordan Cove LNG Project construction noise at active nest sites (approximately 1 mile) and critical habitat (approximately 2.6 miles) is not expected be above ambient levels.
- Dredging operations would take place within the ODFW in-water work window, which is outside of the nesting period for western snowy plovers and dredging noise level is unlikely to affect wintering plovers approximately 0.25 miles away. Access to dredging areas would be by marine transport with no land-based access near primary snowy plover habitat.
- The meteorological station would be constructed outside the nesting season (March 15 to September 15) to avoid disturbance to snowy plovers and would include spikes or other deterrent measures on any potential perching surface, bird deterrent measures if guy-lines are required, and shielded security lighting to minimize glare. Operational activities would be maintenance-related and would be scheduled outside of the nesting season.
- Jordan Cove would minimize disturbance by humans, pets, vehicles or human-attracted predators through implementation of (1) BMPs to minimize predator density related to

increased human presence and habitat removal, and (2) education and outreach programs intended to train all construction and operations staff on the need for snowy plover conservation; current snowy plover regulations and recreational use restrictions; and the importance of conservation measures, including: litter control, avoidance of nesting and foraging areas, keeping pets on-leash, and remaining on established roads and trails.

Even though the northern end of CHU OR-10 on the North Spit is located approximately 2.6 miles from the Jordan Cove LNG Project, the Project **may affect** designated critical habitat for the western snowy plover because:

- temporary construction activities would occur at the Port Laydown site, which is approximately 1 mile from critical habitat;
- the Navigation Reliability Improvements Dredge Area 1 is approximately 0.25 mile from critical habitat; and
- the Project would result in a large but temporary increase in people employed on the North Spit during construction, and a much smaller long-term increase of operations staff. The additional human presence is likely to increase use of the North Spit with concomitant potential increase of pets, vehicles, and/or human-attracted predators.

However, the Project is **not likely to adversely affect** designated critical habitat for the western snowy plover because:

- dredging noise level is unlikely to affect physical or biological features (PBF) at CHU OR-10 approximately 0.25 miles away; and
- Jordan Cove would minimize potential secondary effects on the critical habitat PBF that identifies disturbance by humans, pets, vehicles or human-attracted predators through implementation of (1) BMPs to minimize predator density related to increased human presence and habitat removal, and (2) education and outreach programs intended to train all construction and operations staff on the need for snowy plover conservation; current snowy plover regulations and recreational use restrictions; and the importance of conservation measures, including: litter control, avoidance of nesting and foraging areas, keeping pets on leash, and remaining on established roads and trails.

Marbled Murrelet (Federal Threatened Species with Critical Habitat, State Threatened Species)

MAMUs in Washington, Oregon, and California were listed as threatened under the ESA on October 1, 1992 (FWS 1992a). Critical habitat for the MAMU was first designated on May 24, 1996 (FWS 1996) and subsequently revised in 2011 (FWS 2011b, 2016b). Throughout the forested portion of their range, MAMU habitat use is positively associated with the presence and abundance of mature and old-growth forests, large core areas of old-growth, low amounts of edge and fragmentation, proximity to the marine environment, and increasing forest age and height, although the presence of platforms is the most important characteristic of nesting habitat (FWS 2006c).

Through a combination of GIS data provided by the BLM and private timber companies, and field surveys conducted between 2007 and 2018, Pacific Connector identified 175 occupied and presumed occupied MAMU stands within 0.25 mile of the proposed action, or within 0.5 mile of federally-designated critical habitat that would be affected by the proposed action.

Construction of the Project would remove a total of about 806 acres of MAMU habitat (suitable, recruitment, capable), including about 78 acres of suitable habitat removed from 37 stands (18 occupied MAMU stands and 19 presumed occupied stands). There is the potential that effects could extend over a total of about 7,145 acres of suitable nesting habitat in the terrestrial nesting analysis area (i.e., the extent of disturbance/disruption of MAMU during the breeding season; FWS 2014c), where Project-related noise, primarily use of access roads, may affect MAMU behavior, including breeding activities. HDD and DP activities are not anticipated to disturb nesting MAMU as noise associated with this work would attenuate to ambient levels before reaching MAMU stands. Ten occupied and 24 presumed occupied MAMU stands occur within CHU OR-06 (b, c, and d) within the proposed terrestrial nesting analysis area. Overall, construction of the Pacific Connector Pipeline Project would remove about 4 acres of suitable MAMU nesting habitat (PBF-1) and about 12 acres of recruitment habitat and 15 acres of capable habitat (both of which make up PBF-2) within CHU OR-06-d.

Pacific Connector would implement several measures to reduce effects on MAMU habitat, including using UCSAs, and replanting conifer trees outside of the 30-foot-wide maintenance corridor on certain federal lands and non-federal lands. However, replanted trees may be harvested from non-federal lands or federal lands slated for timber harvest (i.e., Matrix lands and Harvest Land Base), and if allowed to grow would provide minimal benefit to MAMUs because it would take decades at a minimum to restore replanted forests to recruitment or suitable habitat conditions. To ensure that trees with active murrelet nests and chicks are not felled, timber would be removed outside of the entire MAMU breeding season (after September 15 but before March 31) within 300 feet of MAMU stands to avoid this direct effect on MAMU. To minimize disturbance and disruption of MAMU during operations and maintenance, vegetation maintenance activities would occur between August 1 and April 15, and Pacific Connector would apply daily timing restrictions during activities to minimize effects on MAMU during the late breeding season (August 6 – September 15).

Below is a determination of effects summary for the MAMU and critical habitat. More details will be provided in the pending BA.

The Project **may affect** MAMUs because:

- suitable habitat is available within the terrestrial nesting analysis area;
- MAMUs have been located within the terrestrial nesting analysis area during survey efforts for the proposed action; and
- MAMUs are expected to forage offshore in the marine analysis area, and within Coos Bay in the estuarine analysis area.

The Project is **likely to adversely affect** MAMUs for the following reasons:

- Disturbance associated with Pacific Connector Pipeline Project activities and construction of the Kentuck project would occur within the critical breeding season and within 0.25 mile of known MAMU stands.
- Proposed actions that generate noise above local ambient levels levels in approximately 7,145 acres of suitable habitat might disturb or disrupt MAMUs and interfere with essential nesting behaviors:

  - 82 MAMU stands (25 occupied and 57 presumed occupied) are within 0.25 mile of the pipeline that could be constructed during the breeding season.
  - 168 MAMU stands (50 occupied and 118 presumed occupied) are within 0.25 mile of access roads that could be used during pipeline construction in the breeding season.
- Blasting for the pipeline trench may occur within 0.25 mile of 11 MAMU stands between April 1 and September 30.
- Helicopter use within 0.25 mile of eight occupied MAMU stands during the breeding period (between April 1 and September 15) could occur and disturb MAMU adults and nestlings, as well as potentially blow nestlings out of the nest tree within six occupied MAMU stands from rotor wash.
- The Pacific Connector Pipeline Project would remove approximately 78 acres of suitable nesting habitat within the range of the MAMU; or approximately 0.5 percent of the 14,310 acres of suitable habitat available in the terrestrial nesting analysis area.
- The Pacific Connector Pipeline Project would remove approximately 307 acres of recruitment habitat and 421 acres of capable habitat within the range of the MAMU. These habitats do not currently support the recovery of the species.
- The Pacific Connector Pipeline Project would modify (cause other indirect effects such as increases in edge habitat and loss of interior forest habitat, including increased predation) approximately 656 acres of suitable, 2,058 acres of recruitment, and 2,449 acres of capable habitat.
- Turbidity generated during HDD if a frac-out occurred could affect local major prey species for chicks such as anchovy, sand lance, and smelt.
- LNG carrier traffic in the estuarine analysis area to the Jordan Cove terminal could cause potential behavioral effects on foraging MAMU, and fuel and lubricant spills from LNG carriers could cause injury or mortality to foraging MAMUs.

The Project **may affect** MAMU critical habitat because:

- the Project occurs within designated MAMU critical habitat; and
- the Project would affect habitat within designated critical habitat areas.

The Project is **likely to adversely affect** MAMU critical habitat because:

- the proposed action could remove or degrade individual trees with potential nesting platforms or the nest platforms themselves, resulting in a decrease in or elimination of the value of the trees for future nesting use (PBF 1, or suitable or potentially suitable habitat); and
- the proposed action could remove or degrade trees adjacent to trees with potential nesting platforms that provide habitat elements essential to the suitability of the potential nest tree or platform, such as providing cover from weather or predators (PBF 2, or recruitment/capable habitat).

As described above, construction of the pipeline (including clearing of timber, access road use, helicopter use, and blasting), as well as pipeline operation and maintenance, would occur within the MAMU breeding season and within 0.25 mile of known MAMU stands. These activities could disturb or disrupt MAMUs and interfere with essential nesting behaviors during the breeding season. Therefore, to reduce these effects during the breeding season, **we recommend that:**

- **<u>Prior to construction</u>, Pacific Connector shall file with the Secretary its commitment to adhere to FWS-recommended timing restrictions within threshold distances of MAMU and NSO stands <u>during construction, operations, and maintenance</u> of the pipeline facilities.**

The FWS timing restrictions for MAMU and NSO, as referenced in the above recommendation, were outlined in FWS (2016c).

Given the anticipated avoidance of disturbance and disruption to MAMU during the breeding season per inclusion of the recommendation above into the proposed action (i.e., implementation of distance and timing restrictions, without exception), noise and visual effects on breeding MAMU as a result of construction would be minimized. However, there would be a loss of future breeding opportunities due to the removal of suitable, recruitment, and capable habitat during construction, as there would be less suitable habitat available for nesting. Additionally, the quality of the remaining habitat would be reduced due to habitat fragmentation and the addition of edge along the pipeline corridor. Removal of suitable nesting habitat by harvest of old-growth timber has been cited as the primary reason for the species' decline (FWS 1992a). Suitable MAMU nesting habitat takes a long time to develop (more than 250 years on average); therefore, any removal of suitable habitat may affect the recovery of the MAMU. Jordan Cove has indicated an interest in working with the FWS to discuss possible mitigation and conservation measures but has not proposed compensatory mitigation. In the absence of mitigation other than avoidance and minimization, the Project would result in long-term negative effects on this this threatened species.

Northern Spotted Owl (Federal Threatened Species with Critical Habitat, State Threatened Species)

In Oregon, the NSO is found in low- and mid-elevation coniferous forest in the Coast, Siskiyou, and Cascade Ranges (Forsman 2003). Suitable habitat for NSOs provides elements necessary for nesting, roosting and foraging. NSOs generally nest in forests with multilayered, multispecies canopies with large (20–30 inches dbh or greater) overstory trees, a high basal area (greater than 240 square feet/acre), and a high diversity of different diameters of trees. NSOs have large home ranges and utilize large tracts of land containing substancial acreage to meet their biological needs and a wide array of forest types and structures are necessary to support the various life histories (FWS 2011a). Typically, a larger area is required for NSOs in more fragmented habitats (Courtney et al. 2004). NSOs remain on their home range throughout the year. As a result, NSOs have large home ranges that provide all the habitat components and prey necessary for the survival and successful reproduction of a territorial pair.

Home ranges contain three distinct use areas: 1) the nest patch, which research has shown to be an important attribute for site selection by NSOs and includes approximately 70 acres of usually contiguous forest (300-meter radius around an activity center; FWS et al. 2008), 2) the core area, which is used most intensively by a nesting pair and varies considerably in size across the geographic range, but on average encompasses approximately 500 acres around the nest site (0.5-mile radius around the activity center), and is generally made up of mostly mature/old-growth forest (FWS 2007c; Courtney et al. 2004), and 3) the remainder of the home range which is used for foraging and roosting and is essential to the year-round survival of the resident pair (FWS 2007c). NSO home range size varies by physiographic province. In the Coast Range

Physiographic Province (MP 0.00 to MP 51.74), the home range is assumed to be circular with a radius of 1.5 miles. Within the Klamath Mountains Physiographic Province (MP 51.74 to MP 122.67), the home range radius is 1.3 miles, and in the West Cascades (MP 122.67 to MP 167.76) and East Cascade Physiographic Provinces (MP 167.76 to MP 190.64) the home range radius is 1.2 miles (FWS 1992b). Surveys conducted by Pacific Connector in 2007 identified 12 NSO pairs and a resident single but no nests. In 2008, surveys found NSO pairs at 20 locations, with two nests identified, and resident singles noted at six sites. Surveys in 2015 along the Blue Ridge route did not document any NSO. In addition to NSO sites identified by these surveys, Pacific Connector also considered home range information from the BLM and Forest Service, historic home ranges, best location home ranges (alternate sites closest to proposed action), and Pacific Connector-assumed home ranges (determined by Pacific Connector's assessment of habitat maps). Taking a conservative approach, all owl sites (known, best location, and Pacific Connector-assumed) were analyzed as if occupied and reproductive.

The Project would affect habitat within 97 NSO home ranges and 9 nest patches. About 37 miles of pipeline route would cross 7 designated critical habitat sub-units. Project construction would remove a total of about 517 acres of nesting, roosting, or foraging (NRF) habitat for NSO, of which 134 acres would be permanently lost within the 30-foot-wide corridor maintained in an herbaceous state. Additionally, 214 acres of NRF habitat for NSO would be modified and used as UCSAs. Approximately 1,158 acres of dispersal habitat (high NRF, NRF, and dispersal only habitat) would be removed by the Project. Approximately 919 acres of NSO capable habitat would be removed by construction of the proposed Project, of which 216 acres would remain in a permanent herbaceous/shrub state within the 30-foot operational ROW. Approximately 13,294 acres of NSO habitat (1,307 acres of high NRF/NRF habitat, 4,147 acres of dispersal only habitat, and 5,690 acres of capable habitat) occur within 100 meters (328 feet) of habitat removal, of which 4,326 acres (or 32.5 percent of NSO habitat within 100 meters of habitat removal) of interior NSO habitat would be indirectly affected (1,586 acres of high NRF/NRF habitat, 1,388 acres of dispersal only habitat, and 1,352 acres of capable habitat). The Pacific Connector Pipeline Project would remove 442 acres from LSRs , of which 379 acres is NSO habitat or capable of becoming NSO habitat (approximately 69 acres of high NRF, 93 acres of NRF [includes about 9 acres of "post-fire" NRF], 71 acres of dispersal only habitat, and 146 acres of capable habitat).

Potential direct effects on NSOs would include the following: (1) removal of a known nest tree during the entire breeding season (March 1 through September 30), and (2) human and noise disturbance due to ROW clearing and construction during the breeding period, including noise due to blasting and helicopter support during construction, and smoke from prescribed burnings. Potential indirect effects include the following: (1) removal or modification of suitable NRF habitat, dispersal habitat, and habitat that would be capable, over the life of the Project, to achieve dispersal or NRF habitat characteristics but for the Project's effects within LSR, Riparian Reserves, or NSO home ranges; (2) habitat fragmentation; and (3) other indirect effects that occur due to Project-related increases in edge habitat and loss of interior forest habitat, including increased predation, increased competition, and effects on prey utilized by NSOs. HDD and DP activities are not anticipated to disturb nesting NSO because noise associated with this work would attenuate to ambient levels before reaching NSO sites.

Pacific Connector would minimize effects on NSO habitat using the BMPs for crossing forested lands described in section 4.4 of this EIS. Pacific Connector would reduce effects on NSO habitat by replanting conifer trees outside of the 30-foot-wide maintenance corridor on certain federal lands and non-federal lands. However, replanted trees may be harvested from non-federal lands or federal lands slated for timber harvest (i.e., Matrix lands and Harvest Land Base), and if allowed to grow would provide minimal benefit to NSOs because it would take 80 years at a minimum to restore replanted forests to suitable habitat conditions. Timber removal would occur outside the entire NSO breeding season (March 1 through September 30) within 0.25 mile of NSO activity centers, and as a result, no nest trees within activity centers would be removed during the NSO nesting period, and disturbance or disruption would also be reduced. Additionally, Pacific Connector would install the pipeline within 0.25 mile of activity centers after the critical breeding period (after July 15). However, activities from pipeline construction during the late breeding period (July 16 through September 30) could disrupt or disturb NSO at 10 NSO activity centers within 0.25 mile of the pipeline ROW, and construction activities off the ROW would occur during the entire breeding season and could disturb NSO at two known activity centers located 0.25 mile of pipeline project components, if NSO are present.

For operations and maintenance activities, Pacific Connector would not conduct vegetation maintenance activities within 0.25 mile of NSO activity centers during the entire breeding season (March 1–September 30) to minimize disturbance and disruption to NSO. Other operations and maintenance activities may occur within the breeding season. Mitigation projects such as snag creation projects proposed by the Forest Service to meet LRMP objectives would benefit NSO.

Below is a determination of effects summary for the NSO and critical habitat. More details will be provided in the pending BA.

The Project **may affect** NSOs because:

- suitable habitat is available within the Provincial Analysis Area;[138] and
- NSO pairs and resident singles have been located within the Provincial Analysis Area during survey efforts.

The Project is **likely to adversely affect** NSOs for the following reasons:

- Noise from blasting during pipeline construction within 0.25 mile of NSO sites during the late breeding season would occur and could increase the risk of predation to fledglings that are generally not as able to escape as adults during the latter part of the breeding season.
- Construction of the Pacific Connector Pipeline Project would remove approximately 517 acres of high NRF and NRF habitat (including 26 acres of "post fire NRF" within the 2015 Stouts Creek fire area) within the provincial analysis area. This would result in effects on nest patches, core areas, and home ranges of known, best location, and Pacific Connector-assumed owls, some of which are currently below thresholds needed to sustain NSOs. Once suitable NRF habitat is reduced or modified in NSOs' home ranges, there is an increased likelihood that NSOs remaining in the Project area would be subject to:
  - displacement from nesting areas;
  - concentration into smaller, fragmented areas of suitable nesting habitat that may already be occupied;

[138] The Provincial Analysis Area includes the extent of the following potential Project effects: 1) habitat removal or modification, and 2) disturbance/disruption of NSO during the breeding season

  - increased interspecific (with barred owls) and intraspecific competition for suitable nest sites and forage;
  - decreased survival due to increased predation and/or limited resource (forage) availability; and
  - diminished reproductive success for nesting pairs.
- Construction of the Pacific Connector Pipeline Project would remove and modify high NRF, NRF, dispersal only, and capable habitat for NSOs throughout the Project area, including removal of habitat within the home range of 97 NSOs, 58 of which are currently below sustainable threshold levels of suitable habitat for continued persistence in their home range and/or core area.
- Construction of the Pacific Connector Pipeline Project would bring one NSO core area (best location activity center affected by 2015 Stouts Creek fire) below the 50 percent NRF threshold, and two NSO home range (known activity centers, one of which was affected by the 2015 Stouts Creek fire) below the 40 percent NRF threshold (best location activity center).

The Project **may affect** NSO critical habitat because:

- the Project would occur within designated NSO critical habitat; and
- the Project would affect habitat within designated critical habitat areas.

The Project is **likely to adversely affect** NSO critical habitat because:

- The proposed action would remove or potentially downgrade PBFs in critical habitat sub-units ORC-6, KLE-1, KLE-2, KLE-3, KLE-4, KLE-5, and ECS-1 as defined in the Final Rule designating critical habitat for the NSO (FWS 2012b).

As described above, construction of the pipeline (including access road use, helicopter use, and blasting), as well as pipeline operations and maintenance, would occur within the NSO breeding season and within 0.25 mile of NSO activity centers. These activities would disturb or disrupt NSOs and interfere with essential nesting behaviors during the entire breeding season. Therefore, to reduce these effects during the breeding season, we have recommended that Pacific Connector adhere to FWS-recommended timing restrictions within threshold distances of NSO activity centers (FWS 2016c; see recommendation above in the MAMU section).

Given the anticipated avoidance of disturbance and disruption to NSO during the breeding season per inclusion of the recommendation above into the proposed action (i.e., implementation of distance and timing restrictions, without exception), noise and visual effects on breeding NSO as a result of construction would be minimized. However, there would be a loss of future breeding opportunities due to the removal of suitable habitat during construction, as there would be less suitable habitat available for nesting. Additionally, the quality of the remaining habitat would be reduced due to habitat fragmentation and the addition of edge along the pipeline corridor. Habitat loss and modification, whether to nesting, roosting or foraging habitats, due to forest clear-cutting has been the primary factor causing declines of the NSO (FWS 1992c). Habitat losses and habitat fragmentation have indirect effects that can affect survival and reproduction of NSOs. Jordan Cove has indicated an interest in working with the FWS to discuss possible mitigation and conservation measures but has not proposed compensatory mitigation. In the absence of mitigation other than avoidance and minimization, the Project would result in long-term negative effects on this threatened species.

4.6.1.3 Fish

In this section, we summarize the listing status, life history, and presence and determination of Project action effects on the federally listed fish species and their critical habitat that could be affected by the Project. The species addressed include the Coho Salmon-Southern Oregon/Northern California Coast ESU, Coho Salmon-Oregon Coast ESU, North American Green Sturgeon–Southern DPS, Eulachon–Southern DPS, Lost River sucker, and shortnose sucker. Project effects on waterbodies are described in section 4.3 of this EIS. Minimization measures are currently proposed to reduce effects on threatened and endangered fish species. Overall, the types, methods, and magnitude of effects on listed fish species are represented by those presented for fish in general as presented earlier in section 4.5 of this EIS.

Coho Salmon-Southern Oregon/Northern California Coast ESU (Federal Threatened Species, State Sensitive Species)

The Southern Oregon/Northern California Coast (SONCC) ESU coho salmon was listed as a threatened species on June 28, 2005, between Punta Gorda, California, and Cape Blanco, Oregon (70 FR 37160). It includes all naturally spawning populations as well as three artificial propagation programs, of which one, the Cole Rivers Hatchery (ODFW stock #52) located on the Rogue River, is within the Project area.

Critical habitat for the SONCC ESU was designated in May 5, 1999 (74 FR 24249) and includes the accessible reaches of all rivers (including water, substrate, and adjacent riparian zone of estuarine and riverine reaches) between the Mattole River in California and the Elk River in Oregon. The Pacific Connector pipeline route would cross designated critical habitat within waterbodies of the Upper Rogue HUC (17100307) below Lost Creek, Willow Creek, and Fish Lake Dams.

Major rivers, estuaries, and bays known to support coho salmon within the range of the SONCC ESU include the Rogue River, Smith River, Klamath River, Mad River, Humboldt Bay, Eel River, and Mattole River (NMFS 1999), two of which (i.e., the Rogue and Klamath Rivers) are within the Project area although this ESU is currently prevented from accessing the potential Project-affected Klamath River areas due to dam passage barriers downstream.

Direct and indirect effects on SONCC Coho salmon are not expected within the marine analysis area. Coho salmon can avoid acoustic effects from LNG carriers during transit. Potential oil and gas spills from LNG carriers in the marine analysis area are highly unlikely to occur; even if LNG spilled or leaked, it would turn to vapor and would not mix with water, and vessel response plans required to address accidental spills of LNG and other petroleum products onboard would be implemented. Effects within the riverine analysis area are expected from in-water construction activities resulting in short-term increased sediment levels that would be stressful to fish, short-term benthic food source reduction, temporary migration impedance, short-term terrestrial/riparian habitat modifications, and limited long-term reduction in LWD sources. Limited fish mortality would also occur from fish salvage.

Below is the determination of effects summary for SONCC Coho Salmon ESU and critical habitat; see the details in our pending BA.

The Project **may affect** coho salmon in the SONCC ESU because:

- several stages and activities of coho salmon (upstream adult migration, juvenile rearing, and juvenile out-migration) are expected to occur at various locations in the riverine analysis area during construction and operation of the proposed action.

The Project is **likely to adversely affect** Coho salmon in the SONCC ESU for the following reasons:

- Juveniles would be exposed to elevated TSS concentrations during standard dry open-cut construction (fluming or dam-and-pump) for 2 to 5 hours. Such an exposure could cause injury, a short-term reduction in both feeding rate and feeding success, and minor physiological stress.
- A site crossing failure while dry open-cut construction is underway could result in elevated TSS concentrations for six hours while repair of failed isolation structures occurs, which could cause moderate habitat degradation injury, a short-term reduction in both feeding rate and feeding success, impaired fish homing, and possibly major physiological stress.
- Literature-based estimates of suspended sediment effects from pipeline construction on severity of ill effect (SEV) scores suggest typical dry crossing methods could result in SEVs of 4 and 6 for Coho salmon within a few hundred feet (e.g., 150 to 500 feet) below the crossing, which may include factors ranging from short-term reduction in feeding to moderate physiological stress. If failure of sealing occurs, SEV scores for coho salmon could be as high as 8, which may include habitat degradation, major physiological stress, and long-term reduction in feeding rate or success.
- Construction-induced blasting at 13 streams (4 at streams known to contain coho) could cause mortality to fish by rupturing swim bladders, but active fish removal from area prior to blasting would reduce risk of occurrence.
- Fish salvage would occur for some dry stream crossings as discussed in Pacific Connector's *Fish Salvage Plan*.[139] Capture and handling constitutes a taking under ESA and subjects coho salmon to injury and mortality.
- Lack of LWD is a limiting factor in most streams within range of SONCC coho salmon. Removal of mid-seral riparian forest (40 to 80 years old) would have long-term effects on recruitment of LWD, and removal of LSOG forest (80 years old or older) would have permanent effects on recruitment of LWD because planted conifers would not attain those age classes within the 50-year life of the Project, plus the ongoing loss of trees within the 30-foot-wide maintance corridor.

The Project **may affect** designated critical habitat for coho salmon in the SONCC ESU because:

- the Pacific Connector pipeline crosses designated critical habitat within waterbodies of the Upper Rogue HUC (17100307) below the Lost Creek, Willow Creek, and Fish Lake Dams.

[139] Appendix L of Pacific Connector's POD filed with the FERC in January 2018.

The Project is **likely to adversely affect** designated critical habitat for coho salmon in the SONCC ESU for the following reasons:

- a failure of dry open-cut crossing could cause moderate or more severe habitat degradations in some crossing areas;
- increases in turbidity are expected to temporarily affect the water quality downstream from stream crossing sites during construction;
- food resources would potentially be affected over the short term by dry open-cut and diverted open-cut construction methods that would remove substrate and benthos at crossing sites;
- freshwater migration corridors would potentially be affected over the short term by dry open-cut and diverted open-cut construction methods that would create temporary barriers to in-stream movements; and
- approximately 17 acres of native riparian vegetation (forest, wetlands, unaltered, and nonforested habitats) and altered habitat would be removed during construction within riparian zones associated with designated critical habitat. Adverse effects on riparian zones associated with critical habitat would be long term or permanent depending on whether mid-seral riparian forests (7 acres) or LSOG riparian forests (2 acres) are removed.

Coho Salmon-Oregon Coast ESU (Federal Threatened Species, State Sensitive Species)

This Coho salmon ESU was first proposed for listing on July 25, 1995 (60 FR 38011) and subsequently listed as threatened on June 20, 2011 (76 FR 35755). The Oregon Coast ESU includes all naturally spawned populations of coho in Oregon coastal streams south of the Columbia River and north of Cape Blanco, including the Cow Creek (ODFW stock #37) coho salmon hatchery program (NMFS 1995). Critical habitat for Oregon Coast coho salmon was designated on February 11, 2008 (73 FR 7816) and includes water, substrate, and adjacent riparian zones of estuaries and rivers within the range of the Oregon Coast ESU. There are three subbasins that coincide with the Project: South Umpqua Subbasin (HUC 17100302) and Coquille Subbasin (HUC 17100305), which are crossed by the Pacific Connector pipeline; and Coos Subbasin (HUC 17100304), which includes the Coos Bay estuary where the LNG terminal, slip, navigation channel improvements, and HDD portion of the Pacific Connector pipeline route would be located contain critical habitat watersheds. Within these subbasins are eight fifth-field watersheds crossed that contain designated critical habitat. Life stage requirements of coho salmon, within freshwater habitats in the Oregon Coast ESU, are expected to be similar to those described above for Coho salmon in the SONCC ESU.

Coho salmon would be expected to avoid acoustic effects from LNG carriers during transit of marine areas, and no substantial adverse oil and gas marine spills from LNG carriers are expected. Short-term adverse effects on coho salmon in the estuarine analysis area would result from locally increased turbidity from dredging activities and LNG carrier propeller wash and ship wake, causing avoidance and short-term reduction in food supply. Entrainment and impingement of coho salmon could occur in LNG carriers' cooling water intake port during LNG carrier loading and possibly dredging. Acoustic effects would likely cause at least avoidance during LNG terminal construction. Habitat modification would occur from all dredging activity and restoration activities at the Kentuck project site. Suspended sediment released accidentally during HDD construction across Coos Bay and the Coos River would also result in elevated sediment levels.

Effects within the riverine analysis area primarily from in-water construction activities would include short-term increased sediment levels causing fish stress, reduced short-term benthic food supplies, temporary migration impedance, terrestrial/riparian habitat modifications, and limited long-term reduction in LWD sources. Limited mortality from fish salvage would also occur.

Below is the determination of effects summary for Oregon Coast Coho Salmon ESU and critical habitat; see our pending BA for details.

The Project **may affect** coho salmon in the Oregon Coast ESU because:

- several stages and activities of coho salmon (upstream adult migration, juvenile rearing, and juvenile out-migration) are expected to occur at various locations in the riverine analysis area during construction and operation of the proposed action;
- several stages and activities of coho salmon (juveniles, adults) are expected to occur within the estuarine analysis area during construction and operation of the proposed action; and
- juvenile and adult coho salmon area expected to occur within the marine analysis area during operation of the proposed action.

The Project is **likely to adversely affect** coho salmon in the Oregon Coast ESU for the following reasons:

- Short-term increase in noise associated with in-water or nearwater pile driving at various temporary construction activities throughout the bay may cause disturbance and physical injury to Oregon Coast coho if they are in proximity to the noise during construction.
- Some juvenile coho may be subject to localized entrainment by dredging associated with the access channel and Navigation Reliability Improvements, as well as ongoing maintenance dredging.
- Local short-term increases in suspended sediment in Coos Bay from in-water construction, particularly during dredging of Jordan Cove terminal access channel and navigation channel widening, may result in behavioral effects on rearing coho salmon juveniles with physiological consequences that may affect growth and survival.
- Short-term effects on the benthic community and potential food resources for Oregon Coast coho would result from dredging the proposed marine waterway modifications in Coos Bay.
- Installation of the proposed pipeline beneath Coos Bay and the Coos River using HDD construction would avoid effects on coho unless an inadvertent return of drilling fluid occurred. An inadvertent return would temporarily increase sedimentation and turbidity and likely result in behavioral avoidance of the affected area.
- Individual Coho salmon may be directly affected by local restoration activities at the Kentuck project due to short-term construction-related increases in turbidity, in-water work, and isolation measures.
- Water intakes by LNG carriers at the Jordan Cove terminal berth during engine cooling operations could entrain or impinge juvenile salmon.
- Dredging of the Jordan Cove terminal access channel in Coos Bay in the short term could remove eelgrass and benthic community that provide potential food resources and rearing habitat for Oregon Coast Coho salmon;

- Removing eelgrass from donor stocks in the bay to develop the Eelgrass Mitigation site may reduce cover and food sources for rearing juvenile coho salmon in the short term:
- Exposure to TSS concentrations during dry open-cut construction (fluming or dam-and-pump) for 2 to 6 hours could potentially cause minor physiological stress (increased coughing rate and/or increased respiration rate) in juvenile coho salmon.
- A site crossing failure while dry open-cut construction is underway could result in elevated TSS concentrations for six hours while repair of failed isolation structures could cause moderate habitat degradation, impaired homing by fish, moderate to major physiological stress, and, in very limited areas, reduced growth and reduced fish density.
- Literature-based estimates of suspended sediment effects from pipeline construction on SEV scores suggest typical dry crossing methods could result in SEVs between 4 and 6 for coho salmon within a few hundred feet (e.g., 150 to 500 feet) below the crossing, which may include factors ranging from short-term reduction in feeding to moderate physiological stress. If failure of sealing occurs, SEV scores for coho salmon could be as high as 8, which may include habitat degradation, major physiological stress, and long-term reduction in feeding rate or success.
- Blasting at 22 streams (12 known or assumed to have Coho salmon at the crossing) could cause mortality to fish by rupturing swim bladders but active fish removal from the area prior to blasting would reduce risk of occurrence.
- Fish salvage would occur within isolated construction sites, possibly when adult and juvenile coho salmon are present. Coho salmon are considered vulnerable to electrofishing, subject to injury and mortality. Seining, electrofishing, and handling during salvage may adversely affect Oregon Coast coho salmon.
- Lack of LWD is a limiting factor in most streams within range of Oregon Coast coho salmon. Removal of mid-seral riparian forest (40 to 80 years old) would have long-term effects on recruitment of LWD, and removal of LSOG forest (80 years old or older) would have permanent effects on recruitment of LWD because planted conifers would not attain those age classes within the 50-year life of the Project, plus the ongoing loss of trees within the 30-foot-wide maintance corridor.

The Project **may affect** designated critical habitat for coho salmon in the marine analysis area, the estuarine analysis area, and the riverine analysis area for the Oregon Coast ESU because:

- construction and operation of the Project would occur in or cross designated critical habitat within waterbodies of the Coos, Coquille, and South Umpqua subbasins.

The Project is **likely to adversely affect** proposed critical habitat for coho salmon in the Oregon Coast ESU for the following reasons:

- dredging of the Jordan Cove terminal access channel in Coos Bay and marine waterway modifications could remove eelgrass and benthic community that are potential food resources and rearing habitat for Oregon Coast coho salmon;
- increases in turbidity are expected to temporarily affect the water quality downstream from stream crossing sites during construction;
- TSS concentrations generated during dry open-cut construction and potential failure of isolation structures would adversely affect freshwater habitats by changing coho habitat preferences (SEV = 3) or causing moderate habitat degradations (SEV = 7 or 8);

- a failure of dry open-cut crossing lasting up to 6 hours could cause moderate or more habitat degradations in some streams;
- food resources would potentially be affected over the short term by dry open-cut and diverted open-cut construction methods that would remove substrate and benthos at crossing sites;
- freshwater migration corridors would potentially be affected over the short-term by dry open-cut and diverted open-cut construction methods that would create temporary barriers to in-stream movements; and
- approximatedly 88 acres of native riparian vegetation (forest, wetlands, and nonforested habitats) and altered habitat would be removed during construction within riparian zones associated with designated critical habitat associated with waterbodies within range of Oregon Coast coho ESU. Adverse effects on riparian zones associated with critical habitat would be long term or permanent depending on whether mid-seral riparian forests (14 acres) or LSOG riparian forests (4 acres) are removed.

North American Green Sturgeon – Southern Distinct Population Segment (Federal Threatened Species, State Sensitive-Critical Species)

On January 23, 2003 (NMFS 2003), NMFS determined that the North American green sturgeon comprises two DPSs that qualify as species under the ESA: (1) a northern DPS consisting of populations in coastal watersheds northward of and including the Eel River in California; and (2) a southern DPS consisting of coastal and Central Valley populations south of the Eel River, with the only known spawning population in the Sacramento River. On April 7, 2006, NMFS listed the southern DPS as federally threatened under the ESA, including spawning populations of green sturgeon south of the Eel River, principally the Sacramento River spawning population (71 FR 17757). Designated critical habitat extends from U.S. marine waters to 110 meters depth (360 feet) or 60 fathoms from Monterey Bay, California, north to Cape Flattery, Washington, including the Strait of Juan de Fuca (74[195] FR 52300 [October 9, 2009]). Critical habitat includes three components that are occupied by and are essential to different life stages of green sturgeon: (1) freshwater riverine systems, (2) estuarine areas, and (3) nearshore marine waters. No rivers in Oregon were included in the listing. However, many estuaries were part of the critical habitat proposal in Washington, Oregon, and California. Estuaries in Oregon proposed for inclusion were the Columbia River estuary, Winchester Bay, Yaquina Bay, Nehalem Bay, and Coos Bay. Large numbers of this green sturgeon DPS are within Coos Bay. Subadults and adults may occupy Coos Bay for feeding, optimization of growth, and thermal refuge, and the Bay supplies oversummer habitat. Similarly, coastal marine waters 110 meters deep or less. The North American green sturgeon (both northern and southern DPSs) occurs within Coos Bay and its adjacent waterbodies (Israel and May 2007) and is considered abundant in the bay (73 [174] FR 52084 [September 8, 2008]). This fish may also occur in the lower portions of the Coos River.

Green sturgeons spawn every three to five years in deep pools in large, turbulent river mainstems, generally from March through July (Tracy 1990; Moyle et al. 1992). Little is known about sturgeon feeding, but some studies have found that adults and juveniles feed on benthic invertebrates including shrimp, mollusks, amphipods, and even small fish (Moyle et al. 1992; Radtke 1966). Natural reproduction in this estuary is considered low (Wagoner et al. 1990). The Coos River system is not considered to provide suitable spawning habitat for green sturgeon (Whisler et al. 1999). Green sturgeon, likely less than three years of age, may utilize both shallow and deep-water habitats within the estuarine area, though there is no information relating individual occurrence to DPS membership. Green sturgeon may also occur in bottom areas along the LNG carrier transit route, in waters mostly less than 110 meters deep, which would be primarily only during entry and exit of the vessels as they would travel in deeper water during transit between ports.

Direct and indirect effects on green sturgeon in the southern DPS are not expected within the marine analysis area. Green sturgeon might detect noise from LNG carriers but would be able to avoid adverse effects from noise. Potential oil and gas spills from LNG carriers in the marine analysis area are unlikely to affect aquatic resources because they are highly unlikely to occur; if LNG spilled or leaked, it would turn to vapor, would not mix with water, and would not contaminate surface water; and vessel response plans required to address accidental spills of LNG and other petroleum products onboard would be implemented. Effects on green sturgeon in the estuarine analysis area include acoustic effects such as avoidance during terminal construction, increased turbidity sedimention affecting benthic food sources from dredging activities, bed and bank erosion from LNG carrier propeller wash and ship wake, loss of forage from removal of eelgrass and shallow water habitat, and elevated suspended sediment released from an accidental drilling mud release during HDD construction across Coos Bay and the Coos River. Effects within the riverine analysis area include increased turbidity and sedimentation causing short-term avoidance and food source reduction from in-water construction activities on Stock Slough.

Below is the determination of effects summary for the Southern DPS of green sturgeon and critical habitat. Details will be provided in our pending BA.

The Project **may affect** green sturgeon (Southern DPS) because:

- adult and/or subadult green sturgeon may occur within the estuarine analysis area during construction and operation of the proposed action;
- adult and/or subadult green sturgeons may occur within the marine analysis area during operation of the proposed action; and
- the proposed action may affect potential food resources and water quality during the short-term construction period and maintenance dredging within the estuarine analysis area.

The Project is **likely to adversely affect** green sturgeon (Southern DPS) because:

- short-term increase in noise generated from in-water and nearshore pile driving at various temporary construction sites throughout the bay may cause disturbance and physical injury to green sturgeon if individuals are in proximity to the noise during construction;
- exposure to TSS concentrations during dry open-cut construction (fluming or dam-and-pump) could potentially cause minor physiological stress, a short-term reduction in feeding rate, and short-term reduction in feeding success in the Stock Slough estuarine stream/river channel crossed by the pipeline if present there at the time of construction;
- on a localized basis, the proposed action may affect migratory and feeding behavior, potential food resources, and water quality (TSS) during the short-term construction period and periodic maintenance dredging within the estuarine analysis area;
- bottom disturbance from Project construction, navigation channel widening, and maintenance dredging may reduce the abundance and diversity of benthic food supply within Coos Bay; and

- short-term increased turbidity could cause avoidance in Coos Bay or lower Coos River HDD if frac-out were to occur.

The Project **may affect** critical habitat for green sturgeon (Southern DPS) because:

- Project activities would occur within portions of the Coos Bay estuary, Stock Slough, and coastal marine waters, which have been designated as critical habitat;

The Project is **likely to adversely affect** critical habitat for the southern DPS of green sturgeon because:

- bottom disturbance from Project construction, navigation channel widening, and maintenance dredging may disrupt local food supply and habitat usability within Coos Bay; and
- suspended sediment produced during dry open-cut crossing Stock Slough could affect water quality in freshwater riverine critical habitat.

Eulachon – Southern Distinct Population Segment (Federal Threatened, No State Status)

On March 18, 2010, the NMFS published in the Federal Register the final rule to list the southern DPS of the Pacific eulachon as threatened under the ESA (75 FR 13012 [March 18, 2010]). The NMFS has identified the eulachon southern DPS as those populations which spawn in rivers south of the Nass River in British Columbia, Canada, to and including the Mad River in California (NMFS 2008c). The southern DPS has been further segregated into four subareas: Klamath River, Columbia River, Fraser River, and British Columbia coastal rivers south of the Nass River (NMFS 2008c). A total of 16 distinct regions in Washington, Oregon, and California have been designated as critical habitat for Pacific eulachon (76 FR 65323 [October 20, 2011]). No part of the Project or its effects would occur within waterbodies included in the eulachon critical habitat designation.

Adult Pacific eulachon usually spend three to five years in saltwater before returning to freshwater to spawn from late winter though early summer in rivers (74 FR 10857 [March 13, 2009]). Fertilized eggs adhere to river bottoms and shortly after hatching, the larvae are carried downstream and dispersed by estuarine and ocean currents (74 FR 10857 [2009]). No recent spawning runs have been documented for the Coos River, although some may have occurred historically and have recently been found in Winchester Creek, a major tributary to South Slough that enters Coos Bay near the ocean (Willson et al. 2006; Wagoner et al. 1990, NMFS 2018b).

Little is known about the use of marine waters by eulachon and, due to paucity of sampling, little specific information exists on eulachon distribution off the U.S West Coast, including Oregon (Gustafson et al. 2010). Larvae and young juveniles become widely distributed in coastal waters, with fish found mostly at depths up to 15 meters (171 feet) but sometimes as deep as 182 meters (597 feet; Hay and McCarter 2000). Larger rearing fish have been reported to be in the near benthic habitats in open marine waters of the continental shelf between 20 and 150 meters (66 to 492 feet) deep (Barraclough 1964 as cited in Gustafson et al. 2010).

Adults and juveniles commonly forage at moderate depths (15 to 182 meters [50 to 600 feet]) in inshore waters, feeding on zooplankton, primarily eating crustaceans (Hay and McCarter 2000). Adults are found rarely in Coos Bay (64 FR 66601 [1999]), but have been reported to utilize both shallow and deep habitats in the estuary (64 FR 66601 [1999]). A 1971 report (Cummings and Schwartz 1971) noted their distribution only in the outer 7 miles of Coos Bay. Detailed larvae and juvenile fish sampling in Coos Bay over a 3.5-year period (1998-2001) found no eulachon (Miller and Shanks 2005). More recently, pelagic Tucker trawl samples over a 17-month period found larvae and small juveniles of a close relative, surf smelt, but no eulachon near the proposed terminal in Coos Bay (Shanks et al. 2011). However, given the limited survey effort and highly variable presence of eggs and larvae, eulachon occurrence in Coos Bay could not be ruled out (Storch and Van Dyke 2014).

Direct and indirect effects on eulachon in the southern DPS are not expected within the marine analysis area. Eulachon might detect noise from LNG carriers, but would be able to avoid adverse effects from noise. Potential oil and gas spills from LNG carriers in the marine analysis area are unlikely to affect aquatic resources because they are highly unlikely to occur; if LNG spilled or leaked, it would turn to vapor, would not mix with water, and would not contaminate surface water; and vessel response plans required to address accidental spills of LNG and other petroleum products onboard would be implemented. Effects on eulachon in the estuarine analysis area include increased turbidity from dredging activities and LNG carrier propeller wash and ship wake causing avoidance and reduced food supply, increased suspended sediment should an HDD construction failure occur in Coos Bay or the Coos River, entrainment and impingement in LNG carriers' water intake ports, acoustic effects including avoidance during terminal construction, habitat modification from dredging, and restoration activities at the Kentuck project site.

Below is the determination of effects summary for Pacific eulachon (Southern DPS) and critical habitat. Details will be provided in our pending BA.

The Project **may affect** Pacific eulachon (Southern DPS) because:

- Pacific eulachon may be present within the estuarine analysis area during construction and operation of the Project;
- Pacific eulachon may occur within the marine analysis area during operation of the proposed action;

The Project is **likely to adversely affect** Pacific eulachon (Southern DPS) because:

- Bottom disturbance and suspended sediment from Project construction, navigation channel widening, and maintenance dredging may affect the abundance and diversity of potential benthic and pelagic food resources, water quality, and suspended sediment during the short-term duration of these actions within the estuarine analysis area.
- Short-term increase in noise generated from the MOF land-based pile driving and in-water pile driving in various Coos Bay estuarine analysis areas may cause physical injury to individual eulachon at a limited distance during construction.
- Although eulachon would be rare in Coos Bay, and their large size would allow most to be able to avoid the LNG carrier cooling water intake, some limited number could be entrained during dredging and vessel loading in the bay.

The Project would have **no effect** on critical habitat for the Pacific eulachon (Southern DPS) because no designated critical habitat is present within the areas affected by the Project.

Lost River Sucker (Federal Endangered Species, State Endangered Species)

The Lost River sucker was listed as a federally endangered species on July 18, 1988, because of a variety of factors including loss of habitat and access to historical range, overfishing, degraded water quality, lack of adaquate recruitment, inadequate regulatory mechanisms, and a variety of other reasons resulting in declining populations (FWS 1988). Lost River sucker critical habitat was originally proposed in 1994 (59 FR 61744) but that proposal was never finalized. In 2011, a revised critical habitat designation was proposed and ultimately finalized in December 11, 2012 (77 FR 73739). Designated critical habitat for the Lost River sucker includes two units: the Upper Klamath Lake Unit and Lost River Basin Unit

The present distribution of the Lost River sucker includes Upper Klamath Lake and its tributaries, Clear Lake Reservoir and its tributaries, Tule Lake and the Lost River, the Klamath River, and Copco, Iron Gate, and John C. Boyle Reservoirs with no substantial change since listing (Reclamation 2007, 2012; FWS 2007d). They have also been found in Tule Lake (Reclamation 2012; FWS 2007d, 2013d). Critical habitat that could potentially be affected by construction of the Pacific Connector pipeline includes the Klamath River.

In the Upper Klamath Lake watershed, the Lost River sucker spawning runs are primarily limited to Sucker Springs in Upper Klamath Lake, and the Sprague and Williamson Rivers. Spawning runs also occur in the Wood River and in Crooked Creek in this watershed. In the Project vicinity, Lost River suckers spawn in the Lost River and are present in John C. Boyle Reservoir, downstream from the pipeline crossing at river mile (RM) 225 (NRC 2004). In addition to collections of Lost River suckers in John C. Boyle Reservoir, ORBIC (2012) cites records of collections in Lake Ewauna and in the Lost River Diversion Channel connecting the Klamath River (at RM 249.8) to the Lost River at the Lost River Diversion Dam, approximately 10 river miles downstream from the Pacific Connector pipeline crossing of the Lost River at RM 9.5.

The Pacific Connector pipeline route would cross Lost River (MP 212.07) 7.6 miles upstream of the known spawning area downstream of Anderson–Rose Dam, using a dry, open-cut method during low flows that coincide with the ODFW instream construction window extending from July 1 through March 31.

Spawning occurs within limited areas of the Lost River (FWS 2013d; Reclamation 2012), and occasional individuals have been found in this stream (NMFS and FWS 2013), which suggests it is possible that Lost River sucker occurs at the Pacific Connector pipeline crossing of Lost River at MP 212.07 during the non-spawning period. An additional 31 dry open-cut small intermittent stream crossings could also contain Lost River suckers as surveys have not been conducted for their presence.

Potential effects on the Lost River sucker are associated with pipeline stream crossings. These effects include the release of drilling mud from Klamath River HDD potential frac-out as well as potential entrainment or entrapment of fish, and increased turbidity and suspended sediment in occupied stream affecting fish avoidance and benthic food supply. Pacific Connector would install a temporary flowing stream crossing by lifting or spanning a structure from a bank so that equipment does not enter flowing waters. However, if it is not possible to do this safely, only equipment necessary to install the bridge would cross the stream. This would cause some limited short-term bottom benthic disruption and possibly elevated suspended sediment. Adults and juveniles subject to fish salvage associated with the Lost River crossing could be injured or killed if electrofishing is used, and stressed if seining is used. Incidental take of a Lost River sucker is possible, but salvage operations would follow Pacific Connector's *Fish Salvage Plan* which describes netting methods (e.g., beach seining, dip netting) that would be used before using electrofishing. There are additional salvage methods that have been specifically developed for these listed suckers to further reduce the potential effects of salvage (see the Klamath Project Operations Biological Opinion [Reclamation 2008] consistent with Reclamation's *Handling Guidelines for Klamath Basin Suckers).*

Below is the determination of effects summary for Lost River sucker and critical habitat. Details will be provided in our pending BA.

The Project **may affect** Lost River suckers because:

- Lost River suckers occur within the Upper Klamath River subbasin and Lost River subbasin, which would be affected during construction of the proposed action.

The Project is **likely to adversely affect** Lost River suckers because:

- Lost River suckers could occur in 19 waterbodies crossed by dry open-cut construction in the Lake Ewauna-Klamath River watershed and in 13 waterbodies west of MP 214.38 (including the Lost River) crossed in the Mills Creek-Lost River watershed and be indirectly affected by elevated suspended sediment levels, streambank erosion and stability, and aquatic nuisance species introductions; and
- fish salvage during the crossing of 31 ditches crossed by dry-open cuts and the Lost River crossing could result in injuring or killing of Lost River suckers if electroshocking is used, and stressing fish if seining is used.

The Project **may affect** designated critical habitat for the Lost River sucker because:

- there is a low risk of HDD failure during crossing of the Klamath River, resulting in a frac-out that releases drilling mud into the river.

However, the Project is **not likely to adversely affect** designated critical habitat for the shortnose sucker because:

- HDD crossing methods would avoid critical habitat in the Klamath River;
- the potential for hydraulic fracture during HDD drilling is so unlikely as to be discountable; and
- in the event of released bentonite, corrective actions would contain and temporally limit drill mud volumes.

Shortnose Sucker (Federal Endangered Species, State Endangered Species)

The shortnose sucker was listed as a federally endangered species on July 18, 1988 (FWS 1988). The final rule to list the shortnose sucker as endangered suggested several reasons for their decline, including the construction of dams, water diversions, overfishing, competition and predation by exotic species, water quality problems associated with timber harvest, removal of riparian vegetation, livestock grazing, lack of adaquate recruitment, inadequate regulatory mechanisms and agricultural practices. Shortnose sucker critical habitat was originally proposed in 1994 (59 FR 61744) but that proposal was never finalized. In 2011, a revised critical habitat designation was proposed and ultimately finalized in December 11, 2012 (77 FR 73739). Designated critical habitat for the shortnose sucker includes two units: the Upper Klamath Lake Unit and Lost River Basin Unit. The Klamath River is the only critical habitat for the shortnose sucker crossed by the pipeline or potentially affected by any Project actions.

Currently, shortnose suckers are present in upper Klamath Lake and tributaries, Lost River, Clear Lake Reservoir, the Klamath River, and three large Klamath reservoirs (Keno, Copco, and possibly Iron Gate Reservoirs) with no substantial change since listing (Reclamation 2007, 2012). They have also recently been found in Tule Lake and Gerber Reservoir (Reclamation 2012; FWS 2007d, 2013e).

Shortnose suckers live in lakes and spawn in rivers, streams or springs associated with the lake habitats, generally from early February through mid-April. After hatching, larval suckers migrate out of spawning substrates, which are usually gravels or cobbles, and drift downstream into lake habitats from early May to mid-June (FWS 1988, 1993b). The shortnose sucker is known to migrate out of Tule Lake to spawn in the Lost River below Anderson–Rose Dam about 7.6 miles downstream from the Lost River crossing. Therefore, the Pacific Connector pipeline would cross the Lost River where shortnose suckers could be present.

Potential effects on the shortnose sucker are associated with pipeline stream crossings. These effects include the release of drilling mud from Klamath River HDD potential frac-out as well as potential entrainment or entrapment of fish, and increased turbidity and suspended sediment affecting fish avoidance and benthic food sources in occupied streams, and fish being injured or killed during fish salvage efforts. Pacific Connector would install temporary flowing stream crossing by lifting or spanning a structure from a bank so that equipment does enter flowing waters. However, if it is not possible to do this safely, only equipment necessary to install the bridge would cross the stream. This would cause some limited, short-term bottom benthic disruption and possibly elevated suspended sediment. Adults and juveniles subject to fish salvage within the isolated construction site at the Lost River could be injured or killed if electroshocking is used and stressed if seining is used. Pacific Connector has included guidelines noted above under the Lost River sucker section in their *Fish Salvage Plan* that would be used near listed suckers. However, despite these measures, it is still possible that shortnose suckers could be killed by salvage operations and modifications to these plans may be needed to reduce this risk (see the Lost River Sucker section above).

Spawning occurs within limited areas of the Lost River (FWS 2013d; Reclamation 2012), and occasional individuals have been found in this stream region (NMFS and FWS 2013), suggesting it is possible that shortnose sucker could occur at the Pacific Connector pipeline crossing of Lost River at MP 212.07 during the non-spawning period. An additional 31 dry open-cut small intermittent stream crossings cannot be ruled out completely from potentially having shortnose sucker present because surveys have not been conducted for their presence.

The Project **may affect** shortnose suckers because:

- shortnose suckers occur within the Upper Klamath River subbasin and Lost River subbasin, which would be affected during construction of the proposed action.

The Project is **likely to adversely affect** shortnose suckers because:

- there is a possibility that shortnose suckers could occur within the Lost River when it would be crossed by the Pacific Connector pipeline and may be affected by elevated suspended sediment;
- shortnose suckers could occur in 19 waterbodies crossed by dry open-cut construction in the Lake Ewauna-Klamath River watershed and in 13 waterbodies west of MP 214.38 (including the Lost River) crossed in the Mills Creek-Lost River watershed and be indirectly affected by elevated suspended sediment levels, streambank erosion and stability, and aquatic nuisance species introductions; and
- adults and juveniles subject to fish salvage within the isolated construction site at 31 ditches crossed by dry-open cuts and the Lost River could be affected if electroshocking is used and stressed if seining is used.

The Project **may affect** designated critical habitat for the shortnose sucker because:

- there is a low risk of HDD failure during crossing of the Klamath River, resulting in a frac-out that releases drilling mud into the river.

However, the Project is **not likely to adversely affect** designated critical habitat for the shortnose sucker because:

HDD crossing methods would avoid critical habitat in the Klamath River;

- the potential for hydraulic fracture is so unlikely as to be discountable; and
- in the event of released bentonite during an HDD crossing, corrective actions would contain and temporally limit drill mud volumes.

4.6.1.4 Amphibians and Reptiles

Oregon Spotted Frog (Federally Threatened Species, Critical Habitat, State Sensitive-Critical)

On August 29, 2014, FWS listed the Oregon spotted frog as threatened (79 FR 51657). Critical habitat for the Oregon spotted frog was finalized in May 2016 and includes critical habitat in Oregon (Units 7 through 14; 81 FR 29335). This species is almost always found in or near a perennial body of water that includes zones of shallow water and abundant emergent or floating aquatic plants, which the frogs use for basking and escape cover (Corkran and Thoms 1996; FWS 2013f). The closest designated critical habitat unit to the Project is CHU 14 – Upper Klamath, which consists of 262 acres of lakes and creeks in Klamath and Jackson Counties and is currently occupied by Oregon spotted frogs (1 FR 2933). The Buck Lake population within CHU 14 is the closest occurrence of Oregon spotted frogs to the Project. This site includes seasonally wetted areas adjacent to the western edge of Buck Lake encompassing Spencer Creek downstream due west of Forest Service Road 46, three unnamed springs, and Tunnel Creek (81 FR 29335).

Oregon spotted frogs at Buck Lake have been consistently monitored from 2012 to 2016, along with other populations in the Oregon Cascades (Adams et al. 2017). Observations of frogs at two sites in Buck Lake and one in Tunnel Creek (both in CHU 14) indicate some variability in counts for each of several life stages but adults and larva or juveniles were found each year. Spencer Creek upstream of Buck Lake is almost equally subdivided into Buck Marsh, closest to Clover

Creek Road, and Buck Meadow, closest to Buck Lake (Lerum 2012). Buck Marsh is fed by several springs with evidence of beaver activity, and Buck Meadow is a pasture that often floods in the spring but does not stay flooded long enough to provide Oregon spotted frog breeding habitat. Further, soils in Buck Marsh are dense, possibly compacted by past heavy livestock use, and provide little water infiltration. Neither Buck Marsh nor Buck Meadow currently provide habitat for Oregon spotted frogs (Lerum 2012). Riparian vegetation is sparse and is unlikely to support beaver occupancy that could help to create suitable habitat (Lerum 2012).

The Project would cross Spencer Creek on the north side of Clover Creek Road, approximately 6,400 feet upstream from the CHU 14 at Buck Lake and pass within 280 feet of critical habitat in Spencer Creek downstream of Buck Lake. Potential effects on Oregon spotted frogs include changes to habitat quality and acoustic. Conservation measures proposed by Pacific Connector to minimize construction and operation effects on waterbodies and riparian zones would apply to Oregon spotted frogs.

Spencer Creek upstream of Buck Lake is not currently suitable habitat for Oregon spotted frogs and is unlikely to become suitable habitat and support Oregon spotted frogs at the time of construction. Clover Creek road separates the ROW from Spencer Creek downstream of Buck Lake so sediment from the construction ROW is not expected to enter Spencer Creek.

The Project **may affect** Oregon spotted frogs because:

- the Pacific Connector pipeline route would cross Spencer Creek, which is hydrologically connected to Buck Lake which is occupied by the frog; and
- the Pacific Connector pipeline route is within 280 feet of Spencer Creek and would cross tributaries to Spencer Creek downstream of Buck Lake, which is occupied by the Oregon spotted frog.

However, the Project **is not likely to adversely affect** Oregon spotted frogs for the following reasons:

- Buck Lake is approximately 6,400 feet downstream from where the pipeline route would cross Spencer Creek. Suspended sediment generated by the proposed action is expected to remain in the water column for 1,450 feet downstream from the construction site.
- Suspended sediment resulting from the crossing of Spencer Creek would pass through Buck Marsh, which Oregon spotted frogs do not currently inhabit. If the Oregon spotted frog does occur in Buck Marsh at the time of pipeline construction, conservation measures would limit potential effects due to acoustic shock, introduction of non-native species and/or disease, fuel and chemical spills, and herbicides.
- Future presence of Oregon spotted frogs in the Spencer Creek upstream of Buck Lake at the time of construction is extremely unlikely and considered to be discountable.
- Although the ROW occurs as close as 280 feet from Spencer Creek downstream of Buck Lake, they are not hydrologically connected because Clover Creek road separates the ROW from Spencer Creek; BMPs and erosion control measures should prevent sediment from the construction ROW from entering Spencer Creek.

The Project **may affect** designated critical habitat for the Oregon spotted frog because:

- the Pacific Connector pipeline route would be within 280 feet of proposed critical habitat within Spencer Creek downstream of Buck Lake.

The Project **is not likely to adversely affect** designated critical habitat for the Oregon spotted frog because:

- the designated critical habitat within 280 feet of the pipeline is not hydrologically connected to the ROW because it is separated by Clover Creek Road; and
- test water from the proposed hydrostatic discharge site at MP 169.52 is not expected to reach the critical habitat in Spencer Creek or Buck Lake, so effects on PBFs from changes in hydrology or introduction of nonnative species from the Project are discountable.

Sea Turtles

Four federally listed sea turtles potentially occur near the Project: green sea turtles, leatherback sea turtle, olive ridley sea turtle, and loggerhead sea turtle. All four species are federally threatened and state endangered.

Green sea turtles have been sighted from Baja California to southern Alaska, but most commonly occur from San Diego south (NMFS 2007a). Green turtles primarily use three types of habitat: oceanic beaches (for nesting), convergence zones in the open ocean, and benthic feeding grounds in coastal areas (NMFS 2007a). Reports of stranding suggest that the green turtle is a frequent visitor to the coast of California. Based on this data, green turtles are likely infrequent, transient visitors to the Oregon Coast, but may occasionally be found in the marine analysis area.

The leatherback sea turtle is the most common sea turtle in United States waters north of Mexico (NMFS and FWS 1998), and numerous sightings have been documented off the Oregon Coast. Adult leatherback turtles are highly migratory and available information indicates that eastern Pacific migratory corridors exist along the west coast of the United States (NMFS and FWS 1998). The west coast of the United States may represent some of the most important foraging habitat in the world for the leatherback turtle (NMFS and FWS 1998). Despite occasional reports of leatherbacks sighted at sea, and a growing database documenting their incidental catch in coastal and pelagic fisheries, there are very few areas where the species is routinely encountered. Exceptions include Monterey Bay, California (NMFS and FWS 1998). These data suggest that leatherback sea turtles would be present in the marine analysis area in higher densities relative to other sea turtle species, but still in low densities overall.

At-sea occurrences of olive ridley sea turtles in waters under United States jurisdiction are limited to the west coast of the continental United States and Hawaii, where the species is rare, but possibly increasing. During feeding migrations, olive ridley turtles may disperse into waters off the Pacific west coast as far north as Oregon (FWS 2013g). Based on sightings off the Oregon coast, olive ridley turtles may occasionally occur in the marine analysis area.

Loggerhead sea turtles occupy three different ecosystems during their lives—the terrestrial zone, the oceanic zone, and the neritic zone (NMFS 2007b). In the United States, occasional sightings are reported from the coasts of Washington and Oregon, but most records are of juveniles off the coast of California (NMFS 2007b). The potential importance of Oregon waters and the marine analysis area to loggerhead turtles is unknown, although two loggerhead turtles have been reported stranded in Oregon and Washington since the beginning of 1997 through 2007 (NMFS 2008d).

Direct effects of the proposed action include injury and/or mortality due to ship-strikes, underwater ship noise, and potential adverse effects from a vessel spill or ship release of LNG and fire at sea. Spills and/or release could indirectly affect federally listed sea turtles by affecting forage species. Below is a determination of effects summary for the federally listed sea turtles and critical habitat. More details will be provided in the pending BA.

The Project **may affect** federally listed sea turtles because:

- these sea turtles may occur within the marine analysis area during operation of the proposed action;
- the proposed action would increase shipping traffic (LNG carriers) within the marine analysis area; and
- the continental U.S. Pacific Coast provides important foraging habitat for leatherback turtles.

However, the Project is **not likely to adversely affect** federally listed sea turtles because:

- ship strike on sea turtles would be highly unlikely;
- Jordan Cove would provide a ship strike avoidance measures package to LNG carrier operators transporting cargo from the terminal that consists of multiple measures to avoid striking marine mammals, which should also benefit sea turtles;
- The FERC does not have authority over the LNG carrier; however, the independent carrier operators would be required to follow all Coast Guard requirements regarding the operation of LNG carriers including carrier speeds;
- noise produced by LNG carriers would contribute to overall noise levels within the marine analysis area en route to the Port of Coos Bay and effects of ship noise on sea turtles could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise (NMFS 2016c, NMFS 2017b, NMFS 2018c), but would not exceed existing background ship noise levels and would not cause injury; and
- given vessel design, on-board spill kits, safety records, and implementation of Coast Guard recommendations, it is not likely that there would be a major ship spill of hazardous materials that may adversely affect water quality or aquatic species. Fuel released at sea, if any, would be in small enough quantities that potential effects on listed sea turtles would be discountable, especially given the low density of sea turtles within the marine analysis area.

No critical habitat has been designated or proposed for the olive ridley or loggerhead sea turtles. Critical habitat was established for the green turtle on Culebra Island, Puerto Rico, on September 2, 1998 (NMFS 1998); however, no critical habitat for green sea turtles occurs on the U.S. Pacific Coast, and the Project would therefore have no effect on designated critical habitat for the green turtle.

The Project **may affect** designated critical habitat for the leatherback turtle because:

- Critical habitat coincides with nearshore waters in the marine analysis area through which LNG carriers would transit to Coos Bay and the LNG terminal.

However, the Project is **not likely to adversely affect** designated critical habitat for the leatherback turtle because:

- LNG carriers and the Jordan Cove LNG Project are not likely to contribute oil, fuel, lubricants, or other contaminants to critical habitat to the extent that would adversely affect the occurrence of prey species, primarily jellyfish, of sufficient condition, distribution, diversity, and abundance to support individual as well as population growth, reproduction and development (PBF 1); and
- disturbance of benthic habitats within Coos Bay due to dredging would be of sufficiently short duration and small scale relative to the area available for settlement of larvae of the scyphozoan prey species within Area 2 that effects on PBF 1 would be unmeasurable and would therefore be discountable.

4.6.1.5 Invertebrates

Vernal Pool Fairy Shrimp (Federally Threatened Species with Critical Habitat, No State Status)

Vernal pool fairy shrimp were listed as threatened under the ESA on September 19, 1994 (FWS 1994a). This crustacean inhabits vernal pools, or seasonal wetlands that fill with water during fall and winter rains, in California and southwestern Oregon. The vernal pool fairy shrimp was identified relatively recently (in 1990) and was not discovered in Jackson County, Oregon until 1998 (FWS 2005s). As a result, it is possible that additional locations for the species will be found in Oregon in the future (FWS 2005a). Suitable vernal pool habitat occurs within and adjacent to Project facilities, some of which has not been surveyed. Additionally, a proposed pipe storage yard is in the Burrill Lumber industrial yard adjacent to the vernal pool fairy shrimp critical habitat unit VERFS 3A. Potential effects on vernal pool fairy shrimp and critical habitat include possible disturbance to pools from driving or storing equipment or pipes near or on pools or wetlands, and alteration of hydrology. Although nine vernal pools within the ROW between MPs 145.3 and 145.4 are outside the known range for vernal pool fairy shrimp, the vernal pools may provide suitable habitat for the species because the pools occur within the appropriate soils type (Agate-Winlo) for vernal pool fairy shrimp, occur near (i.e., within 8.2 miles of) the known and relatively recently (1998) expanded range of the species, and the species' absence has not been confirmed. Based on the relatively recent expansion of the known range of this species and the presence of potentially suitable habitat (including soil type) that has not been surveyed, there is potential for this species to be present within the ROW and be affected by pipeline construction.

These effects would be minimized through avoidance and minimization measures. Specifically, Pacific Connector has indicated they would avoid using areas within yards that may contain vernal pool fairy shrimp and, if this species is noted during survey efforts, they would implement proper sedimentation control barriers to minimize potential effects on the species. Below is a determination of effects summary for the vernal pool fairy shrimp and critical habitat. More details will be provided in the pending BA.

The Project **may affect** vernal pool fairy shrimp for because:

- Potentially suitable habitat for vernal pool fairy shrimp has been identified near four proposed Jackson County pipe storage yards, as well as within and adjacent to the pipeline ROW between MPs 145.30 and 145.40.

The Project is **likely to adversely affect** vernal pool fairy shrimp because:

- Effects on vernal pool fairy shrimp are possible due to the Project's crossing of potentially suitable, unsurveyed habitat within the pipeline ROW between MPs 145.30 and 145.40 (within Agate-Winlo soils).

The Project **may affect** vernal pool fairy shrimp critical habitat because:

- the Project occurs adjacent to designated vernal pool fairy shrimp critical habitat; and
- the Project may affect suitable habitat within designated critical habitat adjacent to the Project.

However, the Project is **not likely to adversely affect** vernal pool fairy shrimp critical habitat because:

- Although the proposed Burrill Lumber pipe yard occurs within 250 feet of designated vernal pool fairy shrimp critical habitat unit (VERFS 3A), it is separated from the critical habitat unit by Agate Road, which is a two-lane paved road that acts as a barrier to hydrologic connectivity that is considered a definitive boundary to the area of effects.
- Burrill Lumber pipe yard has been previously disturbed, and additional surface disturbances and/or soil compaction by heavy machinery from use within Burrill Lumber pipe storage yard should be minimal. Also, Agate Road is located between Burrill Lumber pipe yard and critical habitat unit VERFS 3A, which is raised and paved, and would serve as an existing barrier between the pipe yard and critical habitat unit. Therefore, use of the Burrill Lumber pipe storage yard is not expected to adversely modify geographic, topographic, and edaphic features potentially within 250 feet of the yard that support systems of hydrologically interconnected pools, swales, and other ephemeral wetlands and depressions within the matrix of surrounding uplands (PBF 2).
- Proposed conservation measures would reduce the potential for increased sediment mobilization, increased fugitive dust, and the potential spread of invasive species to suitable vernal pool habitats.

4.6.1.6 Plants

A botanical analysis area applies to the extent of Project-related effects on listed plant species. The botanical analysis area for this Project extends to 98 feet (30 meters) each side of the pipeline project (i.e., construction ROW, TEWAs, UCSAs, rock source and disposal sites, proposed storage yards, and aboveground facilities) as well as the footprint for the Jordan Cove LNG Project. The botanical analysis area, in general, includes the area surveyed for sensitive and listed plant species (at least 100 feet from habitat removal on federal lands and at least 50 feet from habitat removal on non-federal, private lands) and distance that indirect effects on plants would be expected. Surveys are incomplete in areas of potential habitat along the pipeline route where landowner permission was denied. Pacific Connector would survey these areas after the Project is certificated, but before construction begins (i.e., if the Project is approved and Pacific Connector gains access using eminent domain proceedings under Section 7h of the NGA). Pacific Connector identified unsurveyed areas that may contain suitable habitat for listed species, as will be discussed in our pending BA.

Pacific Connector has developed a *Federally-listed Plant Conservation Plan* to address how avoidance, minimization, propagation, restoration, and other conservation measures would be applied to protect listed plant species, as well as how potential effects on unsurveyed lands would be addressed. For example, if populations of listed plant species are identified where surveys were previously denied, Pacific Connector would apply mitigation measures that have been developed for surveyed lands to minimize and avoid effects on these species including (1) minor alignment or route adjustments; (2) narrowing or necking-down the construction ROW; or (3) eliminating or removing a portion of a TEWA or UCSA (depending on where new populations of these species were identified). Additional construction measures that would be implemented in areas that contain listed plants to minimize and avoid effects on these species, if they occur, include the following measures listed below.

- The construction ROW and TEWAs would be surveyed and flagged to clearly mark the limits of construction disturbance (i.e., clearing/grading).
- Where feasible, the EI would monitor the survey and flagging efforts and would provide additional protective buffers or neckdowns to ensure protection of adjacent plant populations or provide additional avoidance. The EI would consult with Pacific Connector's Chief Inspector and the construction contractor during construction to determine where additional buffer protections or neckdowns could be accommodated without affecting construction safety.
- Known plant populations adjacent to the construction ROW or other plants populations identified during preconstruction surveys would be protected by a safety fence and silt fence to ensure these plants are not inadvertently affected by Project activities.
- BMPs outlined in Pacific Connector's *Air, Noise and Fugitive Dust Control Plan*[140] to minimize wind erosion and fugitive dust emissions during construction and restoration activities would be implemented. Water would be used to control fugitive dust along the construction ROW (no Dustlok® would be used within 150 feet of any listed plants). Only enough water would be sprayed to control the dust or to reach the optimum soil moisture content to create a surface crust; no runoff would be generated.
- Equipment would be inspected and cleaned of potential noxious weed seed or plant parts consistent with the requirements of Pacific Connector's *Integrated Pest Management Plan*.
- Topsoil salvaging would occur within affected populations after species-specific seed, bulb, or whole plant salvage has occurred. The salvaged topsoil would be returned to its original location during restoration.
- During restoration, all areas would be regraded as closely as possible to the original contours to ensure preconstruction drainage patterns are not affected.

[140] Appendix B in Pacific Connector's POD filed with the FERC in January 2018,

- The construction ROW would be restored to its original contours and reseeded with an appropriate seed mixture recommended by FWS prior to the following growing season.
- When feasible, Pacific Connector would collect and bag seeds and/or bulbs of affected listed plants and provide these seeds and/or bulbs to a suggested repository. Upon FWS approval, the collected seeds would be replanted within or adjacent to the construction ROW on suitable federal lands where future protection can be managed or on private lands where a conservation easement has been acquired.
- Construction activities would occur in the fall and winter outside the critical growing, flowering, and seeding periods.
- Wetland mats would be used in travel areas in saturated soil areas to minimize soil rutting and soil compaction and protect existing plants that may be present.

The *Federally-listed Plant Conservation Plan* includes specific mitigation plans for Applegate's milk-vetch, Gentner's fritillary, Kincaid's lupine, and Cox's mariposa-lily. In addition, the Forest Service has developed mitigation measures/requirements related to their ROW Grant that may also indirectly benefit listed plant species (see chapter 2 of this EIS and appendix F).

Below is a discussion of each federally-listed plant species that could be affected by the Project. The mitigation measures discussed above would apply to all federally-listed plants discussed in this section.

Applegate's Milk-vetch (Federally Endangered Species, State Endangered Species)

FWS listed Applegate's milk-vetch (*Astragalus applegatei*) as endangered on July 28, 1993 (FWS 1993c). This species has a narrow range, known only in the Lower Klamath Basin (the plain containing Lower Klamath Lake), near the city of Klamath Falls in southern Oregon. It was believed to be extinct until its rediscovery in 1983 and at the time of listing was only known from two extant sites. Applegate's milk-vetch grows in flat-lying, seasonally moist, alkaline soils with underlying clay hardpans. The species' habitat was historically characterized by sparse, native bunchgrasses and patches of bare soil, allowing for some seed dispersal by wind. Today, dense coverage of the habitat by introduced grasses and weeds means seed dispersal is highly localized, with most seedling establishment found adjacent to mature plants (FWS 1998b). Continued destruction, modification, and/or curtailment of its habitat or range due to urban and commercial development, and loss of habitat through competition with non-native weeds, are the principal threats to the survival of the species (FWS 2009a).

The Pacific Connector Project is located within known and historic Applegate's milk-vetch range between MPs 191.20 to 214.30. The "Collins Tract site," which is located within and adjacent to the botanical analysis area between approximately MP 195.3 and MP 196.7, contains 19 sub-populations of Applegate's milk-vetch, several of which were discovered by FWS and SBS during surveys conducted for Pacific Connector. This area was revisited in 2018 and no new sites were documented. Pacific Connector has revised its proposed route slightly in this area to avoid direct effects on the plants identified in 2008 within the Collins Tract site. Survey efforts of the pipeline route subsequent to these initial survey efforts in 2007 and 2008 have not identified any additional plants; however, Pacific Connector has not surveyed all potential habitat. Additionally, in 2009, the FWS and The Nature Conservancy documented 1,260 plants within and adjacent to the proposed Klamath Falls Memorial Drive 2 pipe storage yard, in an area that has not been surveyed for the Project (ORBIC 2017a).

The route has been relocated to avoid known populations of Applegate's milk-vetch as well as suitable habitat found during surveys conducted during summer 2008; therefore, no direct effects on known plants in those sites are expected. Additionally, Pacific Connector would resurvey the Klamath Falls Memorial Drive 2 pipe storage yard prior to construction and avoid the use of the proposed yard within 30 meters of known and documented Applegate's milk-vetch plants. Project surveys of all suitable habitat have not been completed for this species; therefore, additional plants could potentially be encountered and affected by the Project. Measures to reduce impacts on unidentified plants are included in the *Applegate's Milk-vetch Mitigation Plan*; however, the FWS has indicated it may require additional mitigation for these potential impacts as part of their BO (including additional survey, seed collection, and salvage requirements). Below is a determination of effects summary for Applegate's milk-vetch and critical habitat. More details will be provided in the pending BA.

The Project **may affect** Applegate's milk-vetch because:

- suitable habitat is available within the botanical analysis area; and
- individual plants have been located within the analysis area during survey efforts.

The Project is **likely to adversely affect** Applegate's milk-vetch because:

- approximately 175.3 acres of potential suitable habitat that has not been surveyed occurs within the botanical analysis area along the pipeline route, which includes 77 acres within the pipeline ROW; therefore, it is possible that unidentified plants occur within the construction ROW and workspace;
- surface disturbance and excavation would occur within potentially suitable habitats and could impact unidentified plants (including in areas where surveys have not been completed); and
- indirect effects, including potential changes in hydrology and soil characteristics, introduction and spread of invasive plants and noxious weeds, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust, could impact documented or suspected plants and habitat outside the construction ROW, but within 30 meters of the Project pipeline.

Critical habitat has not been designated for Applegate's milk-vetch.

Gentner's Fritillary (Federally Endangered Species, State Endangered Species)

FWS listed Gentner's fritillary (*Fritillaria gentneri*) as endangered on December 10, 1999 (FWS 1999). Gentner's fritillary is found in small, scattered locations in the Rogue and Klamath River watersheds in Jackson and Josephine Counties in Oregon (FWS 2003c; 2016d). This species is highly localized, with populations occurring within a 30-mile radius of Jacksonville Cemetery in Jacksonville, Oregon (FWS 2003c). Since the 2003 publication of the recovery plan, nine new Gentner's fritillary populations (approximately 131 flowering plants within 1.6 acres) have been detected outside of the four recovery unit boundaries (FWS 2016d). It is difficult to census populations of Gentner's fritillary because this species does not flower every year and individuals can remain dormant for one or more years underground.

Gentner's fritillary is often found on the edge of dry woodland and forests where the overstory can be dominated by Oregon white oak, madrone, Douglas-fir, and ponderosa pine; it also occurs in open chaparral and grassland environments. It occurs at a wide range of elevations, from 1,000 to 5,100 feet, and is usually associated with shrubs that provide protection from the wind and sun (FWS 2003c).

The Pacific Connector Project crosses the plant's range between approximately MP 113 through MP 155. Surveys for Gentner's fritillary have occurred within suitable habitat near the pipeline from 2007 through 2018. Surveys are expected to continue to complete recommended second year survey efforts, where necessary. Additionally, surveys will be initated in other areas that receive survey permission. Since 2007, survey efforts have identified Gentner's fritillary individuals in five locales: (1) approximately 0.38 mile north of MP 128.0 near Indian Creek and 50 feet below a four-wheel drive road; (2) 21 feet from TEWA 128.01-W; (3) 100 feet from proposed access road EAR-128.05; (4) near MP 129.1 approximately 54 feet from TEWA 128.96-N; and (5) within 21 feet of TEWA 142.07-N near MP 142.1. Of these five sites, three are located within the analysis area. Direct impacts on known individuals of Gentner's fritillary would be avoided; however, unidentified *Fritillaria* plants near MP 142.1 that could be Gentner's fritillary occur within the pipeline ROW and would be impacted if a reroute of the pipeline alignment is not implemented (additional details to be provided in our pending BA). Additionally, unidentified *Fritillaria* plants near MP 129 that could be Gentner's fritillary occur within the analysis area and could be indirectly affected.

Additionally, Project surveys of all suitable habitat have not been completed for Gentner's fritillary; therefore, additional plants could potentially be encountered and affected by the Project. The FWS will require two-year protocol surveys in unsurveyed, potentially suitable habitat and in suitable habitat where surveys are older than 10 years. However, indirect impacts on known individuals could be eliminated with minor modifications to the construction ROW. Therefore, **we recommend that:**

- **<u>Prior to end of the draft EIS comment period</u>, Pacific Connector should file with the Secretary revised alignment sheets that eliminate or relocate TEWA 128.01-W, TEWA 128.96-N, TEWA 142.07-N. and EAR-128.05.**

Below is the determination of effects summary for Gentner's fritillary; more details will be provided in our pending BA.

The Project **may affect** Gentner's fritillary because:

- suitable habitat is available within the analysis area; and
- individual plants have been located within the analysis area during survey efforts.

The Project is **likely to adversely affect** Gentner's fritillary because:

- approximately 240.9 acres of potential suitable habitat that has not been surveyed occurs within the botanical analysis area along the pipeline route, which includes 50.4 acres within the pipeline ROW; therefore, it is possible that unidentified plants occur within the construction ROW and workspace;

- *Fritillaria* spp. have been identified within and adjacent to areas that would be affected by the Project;
- Gentner's fritillary can remain dormant underground for one year or longer, does not flower every year, and has been documented to not flower for several years; therefore, it is possible that protocol surveys conducted for the Project did not locate this species; and
- indirect effects, including potential changes in hydrology and soil characteristics, introduction and spread of invasive plants and noxious weeds, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust, could impact documented or suspected plants and habitat outside the construction ROW, but within 30 meters of the Project pipeline.

Critical habitat has not been designated for Gentner's fritillary.

Western Lily (Federally Endangered Species, State Endangered Species)

FWS listed the western lily (*Lilium occidentale*) as endangered on August 17, 1994 (FWS 1994b). This lily is currently known from 23 small populations in freshwater marshes and swamps, early successional fens (bogs), coastal scrub and prairie, openings in coastal, Sitka spruce–dominated coniferous forests, as well as other poorly drained soils along the coast of southern Oregon and northern California (FWS 2009b). Western lilies have an extremely restricted distribution, and only occur along the coast within 4 miles of the Pacific Ocean. Occurrences within the Coos Bay area are reported to occur in Blacklock soils; however, it also grows in soils that are well drained that have a substancial layer of organic soil (SHN 2013c).

The closest known western lily occurrence in relation to the Project is approximately 1 mile south of the Myrtlewood Off-site Park & Ride at the Hauser Bog (ORBIC 2017b). However, the Myrtlewood Off-site Park & Ride is located completely in the paved parking lot and does not contain suitable habitat for the western lily. There are no other known occurrences within two miles of the Project (ORBIC 2017b). There are no records of western lily north of Hauser, and the FWS typically considers Hauser the northern extent for the species along the Oregon coast.

Surveys for western lily within potential habitat in the analysis area (i.e., poorly drained bogs with acidic organic soils and within six miles of the coast below 300 feet elevation) were conducted between 2006 and 2017 (SHN 2013c; SBS 2008a, 2012, 2013, 2014, 2017a). Jordan Cove conducted surveys at the LNG terminal site in 2006, 2012, and 2013 and surveys were conducted by SBS for Pacific Connector between 2007 and 2017. No occurrences of western lily were detected during these surveys, and only limited areas of potential suitable habitat were identified. More details will be provided in our pending BA.

Although no plants were identified in the area that would be affected by the Project and potential occurrence of this species in this area is low, surveys of all potential habitat in the area have not been completed for this species; therefore, western lily could potentially be encountered and affected by the Project. Additionally, this species is difficult to detect when not flowering, and surveys may overlook western lily juveniles or vegetative adults, especially non-flowering individuals growing within dense vegetation (FWS 2008b). Below is the determination of effects summary for western lily and critical habitat.

The Project **may affect** the western lily because:

- known populations occur within 1 mile of the botanical analysis area; and
- potential suitable habitat is available within the analysis area.

The Project is **not likely to adversely affect** the western lily because:

- surveys of potential western lily habitat at the Jordan Cove site and associated facilities and along the pipeline route did not document western lily and potential suitable habitat within the botanical analysis area is limited;
- surveys in potentially suitable habitat would occur prior to ground-disturbing activities; if plants are identified, conservation measures developed to avoid or minimize effects on any documented plants would be implemented; and
- consultations with the FWS would be reinitiated if this species is found to be present in the area and effects cannot be avoided.

Critical habitat has not been designated for the western lily.

Large-Flowered Meadowfoam (Federally Endangered Species, State Endangered Species)

The large-flowered meadowfoam (*Limnanthes pumila* ssp. *grandiflora*) was federally listed as endangered on November 7, 2002 (FWS 2002b). It is an endemic species restricted mostly to the Agate Desert area in the Rogue River Valley of southern Oregon. It grows on the wetter, inner edges of vernal pools at elevations between 1,220 and 1,540 feet. The plant is capable of self-fertilization and self-pollination. In the Rogue River Valley, large-flowered meadowfoam is often found in the same vernal pool habitats as Cook's lomatium (*Lomatium cookii*) and the vernal pool fairy shrimp.

In 2010, FWS designated eight CHUs (5,840 acres) for the large-flowered meadowfoam in the Agate Desert complex in Jackson County, Oregon. Two of the units designated are shared by the designated habitat for Cook's lomatium. All designated CHUs are currently occupied (or expected to be occupied; FWS 2010b). Within the vicinity of White City, Oregon, where multiple pipe storage yards would be located, CHUs RV6 (6A through 6H) and RV8 have been designated. Industrial parks surround all units. Unit RV6C is across an existing paved road from the Burrill Lumber pipe storage yard, and Unit RV6D is 590 feet northeast of this pipe storage yard. RV8 is over 1.8 miles west of the proposed Rogue Aggregates and the other three pipe storage yards.

Botanical surveys were conducted within identified suitable habitat for this species where access was permitted, during the flowering season in April 2007. In 2007, survey efforts documented approximately 36 large-flowered woolly meadowfoam plants approximately 850 to 1,165 feet east of the proposed Burrill Lumber pipe storage yard. Additionally, ORBIC (2017a) has reported several other subpopulations of large-flowered woolly meadowfoam (approximately 16,200 plants) near proposed pipe storage yards, including within the Ken Denman State Game Management Preserve across an existing paved road east of the Burrill Lumber pipe storage yard.

No surveys have been permitted within Avenue F & 11th Street and WC Short pipe storage yards; however, off-site observations identified approximately 0.48 acre of highly modified, low-quality vernal pool habitat within 250 feet of the Avenue F & 11th Street and WC Short pipe yards. This area is associated with active industrial sites or previously disturbed industrial areas and is not expected to provide high-quality vernal pool habitat or support individuals of large-flowered woolly meadowfoam. Additionally, no direct or indirect effects on potential vernal pool habitat are expected from use of the Avenue F & 11th Street and WC Short pipe storage yards.

The Project **may affect** large-flowered woolly meadowfoam because:

- the pipeline occurs near occupied, large-flowered woolly meadowfoam habitat.

The Project is **not likely to adversely affect** large-flowered woolly meadowfoam because:

- surveys of potentially suitable habitat at proposed pipe storage yards in Jackson County and along the Project did not document large-flowered woolly meadowfoam plants;
- the 0.48-acre of unsurveyed potential habitat within the Avenue F and 11th and WC Short pipe storage yards consists of low-quality vernal pool habitat within active industrial sites or previously disturbed industrial areas and is unlikely to contain large-flowered woolly meadowfoam;
- Pacific Connector would avoid using portions of the pipe storage yards within 250 feet (indirect effect) of this species or potentially suitable vernal pool habitat;
- effects on suitable habitat are likely to be discountable to the point where no meaningful measurement, detection, or evaluation of effects would be possible (i.e., effects would not reach a level where individual plants would be lost);
- sedimentation barriers would be used, as appropriate, to prevent run-off and changes in hydrology;
- conservation measures have been developed to avoid or minimize effects on any plants identified during surveys prior to construction; and
- construction of the pipeline is not expected to adversely modify hydrology in nearby suitable habitat areas within 250 feet of proposed pipe storage yards.

The Project **may affect** designated critical habitat for large-flowered woolly meadowfoam because:

- the Project occurs adjacent to large-flowered woolly meadowfoam critical habitat.

The Project is **not likely to adversely affect** large-flowered woolly meadowfoam critical habitat because:

- Construction of the pipeline is not expected to adversely modify designated critical habitat areas within 250 feet of pipeline components (i.e., subunit RV6C); existing features (i.e., paved Agate Road) and proposed conservation measures would provide sufficient protection from adjacent development and invasive plant and noxious weed sources; and

- The Burrill Lumber pipe yard is hydrologically disconnected from subunit RV6D due to topography (flow is away from RV6D) and distance (greater than 590 feet) and is hydrologically isolated from subunit RV6C by the raised Agate Road.

Cook's Lomatium (Federally Endangered Species, State Endangered Species)

Cook's lomatium was listed as federally endangered on November 7, 2002 (FWS 2002b). Its range is on seasonally wet soils limited to two areas: (1) along vernal pools in the Agate Desert area of the Rogue River Valley, Jackson County, and (2) in seasonally wet serpentine-derived grassland meadows, sloped mixed-conifer forest openings, and and along roadsides edges in shrub dominated plant communities or adjacent to meadows within the Illinois River Valley area near Cave Junction, Josephine County. The Jackson County populations occur along the margins and bottoms of vernal pool habitats within a 20,510-acre landform known as the Agate Desert. The plant flowers from late March to May and is pollinated entirely by insects. In the Rogue River Valley, Cook's lomatium is often found in the same vernal pool habitats as the large-flowered meadowfoam and the vernal pool fairy shrimp.

In 2010, the FWS designated 16 units (6,289 acres) of critical habitat for the Cook's lomatium, including three CHUs in Jackson County, totaling 2,282 acres. Two of the designated units in Jackson County are shared by the designated habitat for large-flowered woolly meadowfoam. All designated CHUs are currently occupied (FWS 2010b). CHUs RV6 (A, F, G, and H) and RV8 have been designated within the vicinity of White City, Oregon, where multiple pipe storage yards would be located. Industrial parks surround these units. CHUs RV6A and RV6H are located approximately 0.5 mile south and 0.8 mile southeast, respectively, of the Avenue F & 11th Street and WC Short pipe storage yards.

Four pipe storage yards, Burrill Lumber, WC Short, Avenue F & 11th Street, and Rogue Aggregates, occur within the Agate Desert near White City in proximity to known occupied vernal pools. No vernal pool habitat or individuals of Cook's lomatium were observed during surveys of the Burrill Lumber and Rogue Aggregates pipe storage yards, and no potential vernal pools were located within 250 feet of the Burrill Lumber pipe storage yard. Although the layout for the Rogue Aggregates pipe storage yard has been reconfigured since surveys in 2007, unsurveyed portions do not contain suitable soil types for Cook's lomatium. Several patches of Cook's lomatium have been documented in the Denman Wildlife Management Area and Agate Desert Preserve, 0.5 mile south of the Avenue F & 11th Street and WC Short pipe storage yards (Friedman 2006, ORBIC 2017a). Surveys have not been conducted within the Avenue F & 11th Street and WC Short pipe storage yards because access has not been granted; however, based on aerial photography and off-site observation in April 2018, Avenue F and 11th and WC Short pipe storage yards do not appear to contain suitable habitat for Cook's lomatium. A long drainage ditch running along the northern edge of the Avenue F and 11th pipe storage yard, which could provide low-quality habitat for Cook's lomatium, was observed during these off-site surveys.

Below is the determination of effects summary for Cook's lomatium and critical habitat; more details will be provided in our pending BA.

The Project **may affect** Cook's lomatium because:

- suitable, occupied habitat is available within the vicinity of the Project.

The Project is **not likely to adversely affect** Cook's lomatium because:

- surveys of suitable habitat at pipe storage yards in Jackson County and along the pipeline did not document Cook's lomatium;

- Pacific Connector would avoid using portions of pipe storage yards within 250 feet of high-quality vernal pool habitat, as well as areas with potential vernal pool habitat;
- effects on suitable habitat are likely to be discountable to the point where no meaningful measurement, detection, or evaluation of effect would be possible (i.e., effect would not reach a level where individual plants would be affected);
- sedimentation barriers would be used, as appropriate, to prevent run-off and changes in hydrology;
- conservation measures have been developed to avoid or minimize effects on any plants identified during surveys prior to pipeline construction;
- known sites within the vicinity of the Project are farther than 0.5 mile from pipe storage yards; and
- unsurveyed habitat is low-quality vernal pool habitat located over 0.25 mile from known sites with no apparent hydrologic connectivity.

The Project would have **no effect** on designated Cook's lomatium critical habitat because:

- the pipeline is over 0.5 mile from the nearest critical habitat subunit RV6A; and
- the proposed action is not expected to adversely modify habitat areas that provide buffer protection from adjacent development and weed sources, continuous nonfragmented habitat, and intact hydrology (PBFs 1 and 4).

Kincaid's Lupine (Federally Threatened Species, State Threatened Species)

Kincaid's lupine was listed as federally threatened on January 25, 2000 (FWS 2000b). It is a long-lived perennial herb inhabiting native prairies and foothills (FWS 2000b). In Douglas County, Oregon, it occupies sites that are more shaded, occurring in areas with tree (i.e., Douglas-fir, California black oak, Pacific madrone, ponderosa pine, incense cedar, hairy manzanita, and poison oak) and shrub canopy cover of 50 to 80 percent (FWS 2006f). About 600 acres have been designated as critical habitat for this species; however, all of these designated habitats are located outside of areas that would be disturbed by the Project.

The pipeline is located within known or historical Kincaid's lupine range between MPs 46.8 and 99.3. Multiple populations of lupine have been identified in the Project's botanical analysis area within Douglas County, including 11 sites within 2.5 miles of the pipeline (ORBIC 2017a). Surveys in 2007 identified three populations of Kincaid's lupine in the vicinity of the pipeline: 1) within and adjacent to the construction ROW on private land between approximately MPs 57.84 and 57.92; 2) on private land near MP 59.60 (approximately 300 feet north of MP 59.60; 67 and 222 feet to the north and west of TEWA 59.30-N; and approximately 40 and 85 feet to the south and west of EAR 59.62); and 3) and on private land within the construction ROW and along proposed access roads between MPs 96.48 to 96.90.

Pacific Connector has modified the pipeline route to avoid the population located within the construction ROW between MP 57.84 and MP 57.92. No direct impacts are anticipated to the population near MP 59.60, as plants are located at least 67 feet from pipeline facilities. The two sites, near MP 57.84-57.92 and 59.60, were revisited in 2017, and both populations appeared to be stable or slightly increasing (SBS 2017b).

Pacific Connector also modified the construction ROW between MP 96.48 and 96.90 to avoid direct impacts on the Kincaid's lupine individuals identified during surveys in 2007. Additionally, the population between MP 96.48 and 96.90 was burned during the 2015 Stouts Creek fire. This population was revisited in 2016 to determine the affect of the fire, associated fire-suppression activity, and subsequent logging activities. Kincaid's lupine was observed in only 2 of the original 28 subpopulations documented in the area during surveys in 2007, and no viable plants were observed in the pipeline ROW or within proposed access roads (SBS 2016). Although no plants were relocated along the construction ROW between MP 96.48 and 96.90 in 2016, it is possible that construction of the pipeline and use of access roads could affect this population if plants resprout in this area. Pacific Connector would conduct additional surveys within the Stouts Creek fire area (MP 96.48 to 96.9) prior to ground disturbance.

No additional plants have been documented in other areas of the pipeline route, where access was granted, during subsequent surveys. However, not all suitable habitats within the Project area have been surveyed to date, indicating that additional unknown populations may be present within areas that could be affected by the Project. If other Kincaid's lupine populations are identified during additional surveys, Pacific Connector would implement applicable mitigation measures, such as necking down the construction right-of way, excluding a portion of an identified TEWA or pipe storage yard, and erecting a protective fence or barrier, to avoid or minimize impacts on newly observed populations. Persisting subpopulations at MPs 96.48 to 96.9 would be flagged/fenced to minimize potential disturbance.

The Project could affect unknown populations of Kincaid's lupine within and adjacent to the pipeline ROW. The *Federally-listed Plant Conservation Plan* contains a Kincaid's Lupine Mitigation Plan that specifically addresses mitigation that would be implemented for Kincaid's lupine; however, the FWS may require additional mitigation for these potential impacts as part of their BO (including additional survey, seed collection, and salvage requirements). Below is the determination of effects summary for Kincaid's lupine and critical habitat.

The Project **may affect** Kincaid's lupine because:

- suitable habitat is present within the analysis area; and
- individual plants have been located within the analysis area during survey efforts.

The Project is **likely to adversely affect** Kincaid's lupine because:

- approximately 991.6 acres of potential suitable habitat that has not been surveyed occurs within the botanical analysis area along the pipeline route, which includes 448.7 acres within the pipeline ROW; therefore, it is possible that unidentified plants occur within the construction ROW and workspace;
- surface disturbance and excavation would occur within potentially suitable habitats, and could impact unidentified plants (including in areas where surveys have not been completed);
- indirect effects, including potential changes in hydrology and soil characteristics, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust, could impact documented or suspected plants and habitat outside of the construction ROW, but within 30 meters of the Project pipeline and along access roads; and

- trenching activities associated with the pipeline could affect below-ground stems, and the expected effect to extant plants is unknown.

The Project would have **no effect** on Kincaid's lupine critical habitat because:

- the pipeline does not occur within designated Kincaid's lupine critical habitat.

Rough Popcornflower (Federally Endangered Species, State Endangered Species)

The rough popcornflower was federally listed as endangered on January 25, 2000 (FWS 2000c). It is found in seasonal wet meadows or wet prairies in poorly drained clay or silty clay loam soils at elevations ranging from 100 to 900 feet. This plant occurs mostly on private lands in the Umpqua River drainage near Sutherlin and Yoncalla in northern Douglas County (FWS 2003d). As of 2010, there were 14 extant populations of rough popcornflower distributed from Yoncalla Creek near Rice Hill, south to Sutherlin Creek near Wilbur, of which five populations have been introduced (FWS 2010c). Six populations are considered protected and have a documented occupancy of at least 5,000 plants (FWS 2010c).

The closest known occurrences of rough popcornflower to the Project include multiple subpopulations approximately 1.7 miles north of the Winchester pipe storage yard and 17.5 miles north of the pipeline ROW at MP 68 (ORBIC 2017a, 2017c). Surveys for rough popcornflower have been conducted in potential habitat between MPs 51.7 and 67.0. To date, no individuals of rough popcornflower have been documented during surveys. However, Pacific Connector has not been granted access to approximately 99.83 acres of potentially suitable rough popcornflower habitat within the analysis area, the majority of which is associated with the Winchester pipe storage yard.

Due to the potential for the plant to occur within areas of potential habitat that have not been surveyed by Pacific Connector and may be disturbed by construction activities, the Project may affect rough popcornflower. Below is the determination of effects summary for rough popcornflower and critical habitat.

The Project **may affect** rough popcornflower because:

- populations occur near a pipe storage yard; and
- potential suitable habitat might be present within the 98-foot (30-meter) botanical analysis area.

The Project is **not likely to adversely affect** rough popcornflower because:

- where access has been granted, surveys for the Project have not documented individuals of rough popcornflower; surveys in potentially suitable habitat identified within the Winchester pipe storage yard would occur prior to ground-disturbing activities; if plants are identified, Pacific Connector would not use either the pipe storage yard or portions of the yard where plants are documented;
- surveys within potential habitat along the pipeline ROW would occur prior to ground disturbing activities; if any plants are identified, conservation measures developed to avoid or minimize effects on documented plants would be implemented; and
- consultation with the FWS would be reinitiated if this species is found to be present in the area and effects cannot be avoided.

Critical habitat has not been designated for rough popcornflower.

4.6.1.7 Conclusions and Recommendations for Threatened and Endangered Species

Based on informal consultations with the FWS and NMFS, 34 federally listed and proposed species were identified as potentially occurring near the Project. The FERC would only authorize the Project to proceed if the FWS' and NMFS' BOs find the Project, as described, would not jeopardize the continued existence of listed species or result in the destruction or adverse modification of designated critical habitat. Further, to ensure compliance with the ESA, **we recommend that:**

- **Jordan Cove and Pacific Connector <u>should not begin construction until</u>:**
  - **a. the Commission staff completes formal consultations with the NMFS and FWS; and**
  - **b. Jordan Cove and Pacific Connector have received written notification from the Director of OEP that construction and/or implementation of conservation measures may begin.**

4.6.2 State-Listed Threatened or Endangered Species

In addition to species that are federally threatened or endangered, there are 13 species designated as threatened or endangered by the State of Oregon that could potentially occur in the area affected by the Project (table 4.6.2-1).

TABLE 4.6.2-1

State-Listed Species Potentially Occurring in the Area Affected by the Proposed Project

Species	FWS Status	ODFW Status	Portion of the Project Area Where Species Potentially Occur
Mammals			
Kit fox *Vulpes macrotis*	None	Threatened	Pacific Connector Pipeline
Gray Whale *Eschrichtius robustus* (Eastern North Pacific stock)	Delisted	Endangered	LNG carrier transit in the waterway, Navigation Reliability Improvements Dredge Areas
Birds			
California brown pelican *Pelecanus occidentalis*	None	Endangered	Navigation Reliability Improvements Dredge Areas, Jordan Cove terminal
Plants			
Pink sand verbena *Abronia umbellata* ssp. *Breviflora*	Species of Concern	Endangered	Jordan Cove terminal
Point Reyes bird's-beak *Cordylanthus maritimum* ssp. palustre (*C. maritimus* ssp. *palustris*)	Species of Concern	Endangered	Jordan Cove terminal; Pacific Connector pipeline
Wayside aster *Eucephalis vialis* (*Aster vialis*)	Species of Concern	Threatened	Pacific Connector pipeline
Peck's milk-vetch *Astragalus peckii*	None	Threatened	Pacific Connector pipeline
Pumice grape-fern *Botrychium pumicola*	None	Threatened	Pacific Connector pipeline
Cox's mariposa-lily *Calochortus coxii*	Species of Concern	Endangered	Pacific Connector pipeline
Umpqua mariposa-lily *Calochortus umpquaensis*	Species of Concern	Endangered	Pacific Connector pipeline

TABLE 4.6.2-1

State-Listed Species Potentially Occurring in the Area Affected by the Proposed Project

Species	FWS Status	ODFW Status	Portion of the Project Area Where Species Potentially Occur
Dwarf woolly meadowfoam *Limnanthes pumila ssp. pumila*	Species of Concern	Threatened	Pacific Connector pipeline
Silvery phacelia *Phacelia argentea*	Species of Concern	Threatened	Jordan Cove terminal Pacific Connector pipeline
Wolf's evening primrose *Oenothera wolfii*	None	Threatened	Jordan Cove terminal

4.6.2.1 Mammals

Kit Fox (No ESA Status, State Threatened Species)

The kit fox reaches its northern limit in southern Oregon. In Oregon, it is found in arid desert valleys dominated by halophytic plants like greasewood and shadscale, intermingled with sagebrush. Although the Project may affect suitable kit fox habitat, the expected distribution of this species does not include the Project area. Because kit foxes have not been recently observed within the area affected by the Project (ORBIC 2017a), the Project is not expected to affect this species.

Gray Whale (Eastern North Pacific stock; Federal Delisted Species, State Endangered Species)

The gray whale is a large baleen whale that is distributed in the northern Pacific Ocean in western and eastern stocks. The eastern stock, found along the west coast of North America, was federally delisted on June 16, 1994 (59 FR 115), but remains state endangered in Oregon. The eastern Pacific stock feeds in the summer in the Chukchi Sea, the western Beaufort Sea, and the northern Bering Sea. They migrate south from November through early February to lagoons on the Pacific coast of central and southern Baja California. Northward migration occurs after the calving and breeding season, from early February to May. These whales have the longest known migration of any mammal. Gray whales feed on infaunal benthic species that are buried in sediments (Maser et al. 1981). Gray whales are federally protected under the MMPA.

Potential effects on gray whales include injury and/or mortality due to ship strikes, underwater ship noise, construction noise (including pile driving and dredging) and potential adverse effects from a ship fuel spill at sea. Spills could indirectly affect gray whales by impacting forage species. These potential effects would be similar to the effects on federally listed whales that are discussed above, except that gray whales migrate in coastal waters north and south parallel to the Pacific Coast, making them more susceptible to ship strikes in nearshore waters during migration.

According to the Oregon Parks and Recreation Department (OPRD 2007), gray whales are the most predominant whales seen along the Oregon coast. They migrate twice a year, in winter and spring, and about 200 of them feed along the coast during the summer months. Gray whales have on occasion entered Coos Bay beyond the Jordan Cove LNG Project site and have been seen in Coos Bay at about the same frequency as killer whales. Gray whales may be encountered along the LNG carrier transit route during their southern migration from November through early February or from early February to May during the northern migration. Based on data in Pacific waters between 1999 and 2003, gray whales are struck by ships at a rate of 1.2 whales annually (Angliss and Outlaw 2007). The increase in shipping traffic resulting from LNG carriers could cause an increase in the probability of whales being struck by ships, or of being disturbed during migration. Measures that Jordan Cove would implement to avoid or minimize effects on federally listed whales (see section 4.6.1.1) would serve to avoid or minimize effects on the gray whale.

4.6.2.2 Birds

California Brown Pelican (Federal Delisted Species, State Endangered Species)

The brown pelican was listed as a federally endangered species on June 2, 1970, within California, Oregon, Texas, and Washington states, as well as Central and South America (FWS 1970). It was delisted in December 2009 (FWS 2009c); however, Oregon still considers the brown pelican an endangered species under state law (ODFW 2017h).

The California brown pelican is a primarily coastal species, rarely seen inland or far out at sea (FWS 2005b). They feed mostly in shallow estuarine waters, normally staying within 20 miles of shore (FWS 2005b). Pelicans make extensive use of sand spits, offshore sand bars, and islets for nocturnal roosting and daily loafing, especially by non-breeders and during the non-nesting season (FWS 2005b).

Brown pelicans nest in colonies, mostly on small coastal islands in California (FWS 1985, 2007e). Brown pelicans generally breed between February and October and are most abundant in Oregon during post-breeding migration (FWS 2005b). In Oregon, numbers peak in late August through October and gradually decline from October through early November as birds move south (Gilligan et al. 1994). Since brown pelicans have wettable feathers, they return to land daily to roost and dry their feathers (FWS 2005b). Sand islands within three large estuaries in Oregon and Washington serve as primary night roosts (Jaques and O'Casey 2006 as cited in FWS 2007e). The total number of brown pelicans in Oregon in 2001 was estimated to be 6,095 (Marshall et al. 2003).

Brown pelicans are regularly seen in moderate numbers during the summer months in Coos Bay, and they also occur in small numbers in the winter (Contreras 1998). Coos Bay provides excellent habitat for this species. Brown pelicans were recorded foraging near the Project site more than 500 feet from the shore and loafing across the bay in moderate numbers daily during surveys in October 2012 (SHN 2012). The species was also observed during surveys conducted in 2005-2006 until early September (LBJ 2006). The Project site provides no nesting habitat for the brown pelican. Roosting and feeding sites have been documented within the Project area, although the last observation was in 1985. Roosting was reported on the north side of Coos Bay on a sunken jetty close to the Bay mouth and on a sand spit on the North Spit of Coos Bay, as well as on dredge spoil islands around MPs 3R through 4R (ORBIC 2017a).

In the past, California brown pelicans have been affected by human disturbances at nesting colonies and roosting habitats. Existing nesting and roosting habitats within the Coos Bay Estuary and Jordan Cove LNG Project area have not been documented. If they occur within the estuary during construction and operation of the proposed action, pelicans may be associated with on-shore fish-cleaning stations where they possibly feed on offal (Marshall et al. 2003). Existing fish-cleaning stations are present at the Empire Boat Ramp, Oceanside RV Park and Bastendorff Beach County Park, both in Charleston. Fish-cleaning could also occur at the Charleston Marina, California Street Boat Ramp, and BLM Boat Ramp, though they are not designated as such.

Noise and human activities associated with construction and operation of the Project are likely to be the only direct effect to brown pelicans if they occur within one or more of the Project's analysis areas. Jordan Cove is proposing construction of its access channel in Coos Bay during the ODFW recommended in-water work window between October 1 and February 15. This schedule would minimize effects on brown pelicans because there is a gradual decline in populations in Oregon as birds move south from October through early November (Gilligan et al. 1994). However, noise created by pile driving and construction in general is likely to affect brown pelicans if present and could disrupt brown pelican feeding behavior.

Brown pelicans that forage within the vicinity of the Jordan Cove LNG Project (i.e., the estuarine analysis area) could ingest low levels of contaminants through the food web that are re-suspended from dredging activities. However, sediments at the Jordan Cove LNG Project site and pipeline route within Coos Bay are not expected to contain levels of sediment contaminants that could adversely affect brown pelicans. Access channel dredging and maintenance dredging would not occur during the period of peak pelican abundance in the lower bay. Therefore, dredging activities would not substancially disrupt normal behavior patterns for brown pelicans.

Pacific Connector is proposing construction across Coos Bay using HDD construction in two segments (MP 0.12 to MP 1.11 and MP 1.40 to MP 3.09). It is possible that the brown pelican could be present within Coos Bay and its vicinity during the time of construction (see Contreras 1998). Therefore, noise and human activities associated with construction and operation of the pipeline are likely to affect brown pelicans as sources of disturbance and disruption if they are present and could disrupt brown pelican feeding behavior.

There is some evidence in the literature that high intensity continuous anti-collision lights on structures may result in an increased number of bird strikes, especially at night or during fog and overcast conditions. The number of strikes can apparently be reduced by strobe or blinking the anti-collision lights. The LNG storage tanks would not be illuminated with high intensity lighting. The intensity and number of lights would be limited to what is required for security and operations. With the low-intensity lighting to be used, the likelihood of adverse effects on brown pelicans from collisions with the LNG storage tanks is minimal.

Brown pelicans may be encountered during any portion of the LNG carrier transit route in the waterway. There is no evidence that pelicans are struck by current cargo ships using the Port.

During operation of the Pacific Connector pipeline, aerial inspection of the pipeline route would occur within the permanent ROW. Aerial inspections would generally occur during all times of year, although inspections would not affect nesting or breeding brown pelicans since they do not nest or breed within Coos Bay. Additionally, aerial inspection should not disturb migrating, roosting, or foraging brown pelicans since air traffic is a constant disturbance within Coos Bay from the existing North Bend airport.

The proposed action would create auditory and visual disturbances that are likely to cause foraging brown pelicans to temporarily avoid areas of high activity. The proposed action area does not contain existing nesting or roosting habitat and would not affect nesting or roosting individuals. As a result, the proposed action would temporarily affect foraging individuals but is not expected to affect nesting or roosting by brown pelicans

4.6.2.3 Plants

Pink Sand Verbena (Federal Species of Concern, State Endangered Species)

The historical range of pink sand verbena (*Abronia umbellata* ssp. *breviflora*) was from northern California to Vancouver British Columbia, Canada (ODA 2017c). Its present range is along coastal beach and foredune, predominantly from Cape Blanco (Curry County), southern Oregon to Point Reyes National Seashore in Marin County, California and sporadically along Oregon's northern and central coast. Pink sand verbena only inhabits the littoral sandy beach areas and unstabilized sand dunes of the coastal strip and usually occurs on beaches in fine sand between the high-tide line and the driftwood zone, and in areas of active sand movement below the foredune (ORBIC 2010). In the northern portion of its range, most populations of pink sand verbena occur on broad beaches and/or near the mouths of creeks and rivers.

Of the 12 reported occurrences in Oregon, only 2 have more than 50 plants; many of the populations consist of only one plant and will probably not persist. Two populations of pink sand verbena documented near the mouth of Coos Bay, contained approximately 300,000 plants when surveyd in 2012 (ORBIC 2017a). Approximately 15 miles north of the entrance to Coos Bay, 19 plants were documented in 1995 within a protected (public entry prohibited) snowy plover nesting area (ORBIC 2012). There are no known occurrences of pink sand verbena within two miles of the Jordan Cove Project area (ORBIC 2017a). No pink sand verbena plants have been reported within the Pacific Connector pipeline area (ORBIC 2006a) and the pipeline route would not affect coastal sand dune habitat; therefore, Pacific Connector has not conducted botanical surveys for this species and no incidental documentations of this species has occurred.

Jordan Cove identified suitable habitat for the plant along the eastern portion of the LNG terminal in areas of actively moving dunes and European beachgrass. However, surveys conducted at the Jordan Cove Project area in 2006, 2012, and 2013 did not locate any pink sand verbena plants (SHN 2006b, 2013c). As surveys conducted within the Jordan Cove Project area, as well as historic data, indicate that pink sand verbena is not present within the Project area, the Project is not expected to affect this species.

Point Reyes Bird's-beak (Federal Species of Concern, State Endangered Species)

Point Reyes bird's-beak (*Cordylanthus maritimum* ssp. *palustre* [*C. maritimus* ssp. *palustris*]) inhabits salt marshes along the coast, sometimes growing just above tidewater in wet areas. Its habitat requirements are specific: approximately 7.5 to 8.5 feet (2.28 to 2.59 meters) above mean lower low water, soil salinity of 34 to 55 parts per thousand, sandy substrate covered by 1 to 10 cm (0.39 to 3.93 inches) organic silt, and less than 30 percent bare soil in summer. Point Reyes bird's-beak occurs along the Pacific Coast from Tillamook County, Oregon, south to Santa Clara County, California. In Oregon, the species is restricted to Netarts Bay, Yaquina Bay, and Coos Bay, with most known occurrences located in Coos Bay. Within the counties crossed by the Project, Point Reyes bird's-beak is found in Coos County.

Several occurrences of Point Reyes bird's-beak are near both the Jordan Cove LNG Project and the Pacific Connector Pipeline Project. Populations with 1,000 to 10,000 plants are located along the margins of Coos Bay and on sand salt marshes near the edge of high water marks (ORBIC 2017a). Several occurrences of Point Reyes bird's-beak are near the Jordan Cove LNG Project, and this species is known to occur within the intertidal wetland between APCO Sites 1 and 2;

however, there is no suitable habitat on APCO Site 2 as this area is dominated by upland vegetation. This species also occurs outside the LNG terminal area along the west and southeast shoreline of the South Dunes site (ORBIC 2017a) and potential habitat for this species has also been observed along the shoreline south of the South Dunes site. Jordan Cove would conduct an additional survey in this area of potential habitat prior to construction.

The area affected by the Pacific Connector Pipeline Project is within the vicinity of documented populations of Point Reyes bird's-beak and the pipeline route would cross suitable habitat. Populations with 1,000 to 10,000 plants were located in 1982 and 1999 along the margins of Coos Bay approximately 260 feet south of TEWA 0.10 (HDD pull-back) and on sand salt marshes near the edge of high water marks on the west side of Haynes Inlet approximately 815 feet north of the Jordan Cove Meter Station near the proposed HDD across Coos Bay (ORBIC 2017a). These plants are farther than 100 feet from the pipeline route and should not be affected by construction. Surveys conducted for Pacific Connector in 2007 located one population of about 1,000 Point Reye's bird's-beak plants approximately 1.7 miles south of MP 1.7 (FERC 2009). Additional surveys occurred in 2017 along the pipeline route near MPs 0.3, 1.0, and 1.47 near the edge of high water marks where the pipeline HDD exits and enters land. Approximately 30 Point Reyes bird's beak plants were located at the margin of Coos Bay near MP 0.9, approximately 475 feet northwest of the construction right-of way and 700 feet west/northwest of TEWAs 1.09-N and 1.09-W. This portion of the pipeline would be constructed by HDD and should not affect plants observed at this location.

Point Reyes bird's-beak is found within and near the Jordan Cove and Pacific Connector Project areas; however, construction of the Project should not directly affect individual plants. Additionally, Pacific Connector has committed to protecting plants adjacent to the pipeline construction ROW through the appropriate installation of safety and silt fence as determined by Pacific Connector's EIs.

Wayside Aster (Federal Species of Concern, State Threatened Species)

The wayside aster's (*Eucephalis* [*Aster*] *vialis*) range is limited to central, southern, and western Oregon and the northern California state line (ORBIC 2010). About 100 populations are known, totaling fewer than 9,000 individuals. Most populations are centered in the southern Willamette Valley of Lane County or in southern Jackson and Josephine Counties, although a few populations exist in the adjacent counties of California (ORBIC 2010). None of the known populations are protected, and many populations are along roadsides and in areas of residential development. Wayside aster occurs in areas of natural and man-made disturbance, edges and openings in woodlands and forests, in second and old-growth, and in shaded roadsides.

Several populations of wayside aster plants have recently been documented within Douglas and Jackson Counties; however, except for one site discussed below, these records are more than 0.5 mile from the Pacific Connector Project area. Botanical surveys for this species in potential habitat have been conducted by Pacific Connector in Coos Bay, Roseburg, and Medford BLM Districts; Umpqua National Forest; and Jackson County. This species was documented in 2007 adjacent to a previously proposed existing access road that would require improvements; however, this road is no longer proposed for use as an access road. This site was revisited in 2009 and additional surveys were conducted within 0.25 mile of this site; however, no plants were located.

Although the species is documented near the Project, surveys conducted by Pacific Connector for the wayside aster did not detect this plant's presence. Construction of the pipeline, including the use of access roads, is not anticipated to affect this species.

Peck's Milk-vetch (Federal Species of Concern, State Threatened Species)

Peck's milk-vetch (*Astragalus peckii*) occurs east of the Cascades Mountain range. Most populations of Peck's milk-vetch are centered in three separate areas: one in north-central Deschutes County, another in north-central Klamath County, and the third in south-central Klamath County. These populations total about 300,000 individuals. The plant occurs in very dry sites, on loose, sandy soil or pumice, often in or along dry water courses, in sagebrush or rabbitbrush openings in ponderosa pine forests (in the south) or in western Juniper woodlands (in the north), and occasionally on barren flats.

Peck's milk-vetch has not been documented within the vicinity of the Project (ORBIC 2006a). No suitable habitat for Peck's milk-vetch occurs within the areas crossed by the pipeline route; therefore, Pacific Connector did not conduct botanical surveys for this species. As this species is not expected to occur along the pipeline route, it would probably not be affected by construction and operation of the Project.

Pumice Grape-Fern (No ESA Status, State Threatened Species)

This species is one of the rarest grape-ferns, and in Oregon is found only within the Crater Lake area and Paulina Mountains in Deschutes and Klamath Counties. Most known populations are found in fine pumice gravel at elevations above 7,800 feet (2,400 meters). It has also been located within frost pockets in lodgepole pine forests with bitterbrush, in areas with deep, sterile pumice. In Oregon, pumice grape-fern *(Botrychium pumicola*) is typically associated with Brewer's sedge and buckwheat (*Eriogonum* spp.) species (Eastman 1990; ORBIC 2010).

The Project is not located near known sites of this plant, and no suitable habitat for this plant occurs within the areas crossed by the pipeline route; therefore, Pacific Connector did not conduct botanical surveys for this species. As the pumice grape-fern is not expected to occur along the pipeline route, the Project would probably have no effect on this species.

Cox's Mariposa Lily (Federal Species of Concern, State Endangered Species)

The Cox's mariposa lily (*Calochortus coxii*) is endemic to serpentine and ultramafic soils and is limited to a small area (30 square meters) along a 10-mile serpentine ridge system in Douglas County, Oregon. All known populations are on serpentine soils, mostly on shady, north-facing, mesic sites near ridgelines, typically, growing in serpentine grasslands and forest margins. Population monitoring studies on BLM land from 2011 through 2015 demonstrated relatively high interannual variation in population estimates for Cox's mariposa lily. For example, 6,966 plants were observed in 2011, whereas 13,865 individuals were observed in 2012 (Gray and Bahm 2015). Populations are also known to occur on private lands; however, surveys haven't been conducted on private lands since the early 1990s (ORBIC 2017a; Aaron Roe, Botanist Roseburg BLM District, personal communication, February 1, 2019). Threats to this species include fire exclusion, encroachment by conifers, noxious weed invasion, logging, grazing, road construction, and off-highway vehicle recreational use (Gray and Bahm 2015; BLM and FWS 2004).

Based on existing data, the Pacific Connector pipeline route would cross one population between MP 74.1 and 75.0 on lands administered by the BLM Roseburg District (ORBIC 2017a). In 2012, surveys conducted by the BLM documented approximately 1,300 plants within and adjacent (within 100 meters) to the Project, with approximately 300 plants occurring in the construction ROW (BLM 2017c). However, modifications have been made to the pipeline route subsequent to these surveys. In 2018, surveys for Cox's mariposa lily were conducted during the flowering season on approximately 65 acres between MPs 74 and 75 of the revised pipeline route. The 2018 survey data are currently under review by the BLM. Additionally, there are approximately 45.3 acres of potential suitable Cox's mariposa lily habitat on private lands within the pipeline route that have not been surveyed.

Individuals of Cox's mariposa lily occur along the pipeline route; therefore, construction and operation of the Project would directly and indirectly affect this species and this species' habitat. In addition to the direct removal of individuals, construction of the pipeline would fragment approximately 0.9 mile of of suitable Cox's mariposa lily habitat. Potential indirect effects to documented or suspected plants and habitat include potential changes in hydrology and soil characteristics, alterations to vegetation cover and species composition of associated habitat, and effects from fugitive dust.

Pacific Connector has developed a Cox's mariposa lily specific mitigation plan (included as an attachment to the *Federally-Listed Plant Conservation Plan*[141]) to avoid and minimize potential effects on this species. As described in the mitigation plan, Pacific Connector would determine if site-specific neck-downs can be incorporated into the construction ROW to minimize direct effects on the population of Cox's mariposa lily between MPs 74 and 75. The construction ROW in this area utilizes the typical 95-foot width with TEWAs because of the steep and narrow ridgeline alignment; thus, neck-downs would be dependent on site-specific conditions and would be based on species presence and the work area requirements to ensure safe pipeline installation. Appropriate barriers would be installed along areas that contain this species to ensure that the mariposa lily populations in the vicinity are not affected by sediments and debris from the ROW. In locations where individual plants cannot be avoided by construction activities, plants would be salvaged during the late summer or fall after the growing season of the year preceding actual pipeline construction. Additional mitigation techniques that would be employed to protect these populations of Cox's mariposa lily include seed collection and bulb salvage, and site restoration and monitoring. However, there has not been any research on the effectiveness of seed collection and bulb salvage as mitigation techniques for this species. Based on comments provided by the BLM, the BLM may require additional mitigation measures for the Cox's mariposa lily as part of their review of the ROW application.

Umpqua Mariposa Lily (Federal Species of Concern, State Endangered Species)

The Umpqua mariposa lily (*Calochortus umpquaensis*) is known to occur within 17 localities; none of which are protected. This plant grows in both forests and meadows on serpentine soils at elevations below 2,500 feet, but it is the most vigorous in margins between forests and meadows. In southwestern Oregon, it is associated with a diverse array of plants, and it is found in diverse soils, aspects, and slopes.

[141] Appendix J to Pacific Connector's POD filed with the FERC in January 2018.

Several large populations of this plant (5,000 to 60,000-plus) have previously been documented approximately 1.3 and 2.5 miles east of the pipeline alignment near MP 99.55, adjacent to the Green Butte (EAR 102.30) and Callahan Creek (EAR 104.24) access roads. Pacific Connector conducted botanical surveys for this species between 2007 and 2017 in potential habitat within the vicinity[142] of the pipeline in lands administered by the Roseburg BLM District and Umpqua National Forest. In 2016, seven plants were observed adjacent to EAR 102.3 and 25 feet east of the Hatchet Quarry MP 102.3 Rock Source/Disposal Site near a previously (1992) documented population. Additionally, potential suitable habitat would also be crossed by the pipeline near the site where Cox's mariposa-lily was documented (MPs 74.08 to 75.02), although no individuals of Umpqua mariposa lily were observed during surveys conducted for the pipeline in this location.

Although, Umpqua mariposa lily individuals have been documented adjacent to EARs 102.30 and 104.24, no road improvements are necessary. Additionally, plants are separated from the access roads by topography and/or Callahan Creek; therefore, it is not expected that use of the existing access roads would directly or indirectly affect these populations. The population along EAR 102.30 and 25 feet east of the Hatchet Quarry MP 102.3 Rock Source/Disposal Site may be indirectly affected by the Pacific Connector Project; however, construction of the Project should not directly affect individual plants. Additionally, Pacific Connector has committed to protecting plants adjacent to the pipeline construction ROW through the appropriate installation of safety and silt fence as determined by Pacific Connector's EIs.

Dwarf Woolly Meadowfoam (Federal Species of Concern, State Threatened Species)

Dwarf woolly meadowfoam's (*Limnanthes pumila* ssp. *pumila*) range is restricted to two small protected areas, totaling about 2 square miles with at least 10,000 individuals (ORBIC 2010). Dwarf woolly meadowfoam inhabits small depressions in thin clay soil overlying old basalt at the edges of deep vernal pools, which are dry by mid-summer and generally exposed to full sunlight. The only known occurrences are on Table Rock in Jackson County (on Lower and Upper Table Rocks); which is over 12 miles southwest of the Pacific Connector pipeline and 1.4 to 2.4 miles north of four proposed Jackson County pipe storage yards (ORBIC 2006a).

Because the dwarf woolly meadowfoam is endemic to vernal pools at Table Rocks, Pacific Connector did not conduct botanical surveys for this species. Additionally, this species was not documented incidentally during survey efforts for other vernal pool–associated species conducted for the Project. As this species is not expected to occur along the pipeline route, it would probably not be directly affected by construction and operation of the Project.

Silvery Phacelia (Federal Species of Concern, State Threatened Species)

The silvery phacelia (*Phacelia argentea*) is known from 24 occurrences, totaling 15,000 individuals, along the coastline of Coos and Curry Counties and in adjacent northern California, Del Norte County (ORBIC 2010). In March 2015, a petition was submitted to the FWS to list the silvery phacelia as a threatened or endangered species (FWS 2015a); however, the petition was denied in 2015 due to lack of substantial information that this species was a listable entity (FWS 2015b). Silvery phacelia is the only phacelia growing along the coastline in open sand or on dunes

[142] Provided in Pacific Connector's Initial Response to the FERC staff's Environmental Information Request dated January 3, 2018, filed with the FERC on January 23, 2018.

along the south coast of Oregon. It inhabits sandy beach dunes and bluffs near the coast, and some partially-stabilized or unstabilized dunes.

Silvery phacelia has not been documented in the vicinity of the Project and the closest known plants are located more than 10 miles south of the entrance to the Coos Bay Estuary (ORBIC 2017a); however, suitable habitat for this species does exist at the LNG terminal area, in regions of active and semi-active dunes where the European beachgrass and the red fescue-salt rush herbaceous vegetation associations occur (see section 4.4 of this EIS). There is marginal habitat at the APCO Site and the meteorological station, although the European beachgrass in these areas is generally too dense to support this species. Surveys conducted by Jordan Cove have not detected this species (SHN 2006b, 2012) and, due to the lack of suitable habitat, botanical surveys for this species were not conducted along the pipeline route. Based on the lack of occurrences (from both historical data as well as surveys), it is not expected that the Project would affect this species.

Wolf's Evening Primrose (No ESA Status, State Threatened Species)

Wolf's evening primrose (*Oenothera wolfii*) occurs in well-drained sandy soils with adequate moisture in coastal bluff scrub, coastal prairie, roadsides, and coastal dune habitats from Curry County in southern Oregon to the northern California coast (Tibor 2001). This species is associated with a high disturbance regime and several occurrences in California are located along roadsides with sandy soil (CNDDB 2005 as cited in FERC 2015). Wolf's evening primrose is typically associated with low elevation coastal habitats, but there have been reported occurrences in lower montane coniferous forest in California, at elevations greater than 2,500 feet (Tibor 2001).

The closest known occurrence of Wolf's evening primrose to the Project is in Port Orford, Oregon, approximately 60 miles to the south of the Jordan Cove LNG terminal site; however, suitable habitat for this species is present at the LNG terminal site. There is marginal habitat at the APCO Site and the meteorological station, although the European beachgrass in these areas is generally too dense to support this species. Surveys conducted at the LNG terminal site did not detect the Wolf's evening primrose (SHN 2006b, 2012). Considering the lack of occurrences (based on historic and recent survey data), it is not expected that the Project would affect this species.

4.6.3 Other Special Status Species

In addition to the federal and state threatened, endangered, and proposed species described above, there are species that have been given special status designations by federal or state agencies and Indian tribes that could potentially occur in the Project area (see tables I-3, I-4, and I-5 in appendix I). The FWS and NMFS maintain a list of federal species of concern, which are species whose conservation standing is of concern but for which status information is still needed. The ODFW also assigns special status to fish and wildlife species that are not listed. State special status designations include sensitive and sensitive-critical (ORBIC 2016). Sensitive refers to fish and wildlife that are facing one or more threats to their populations and/or habitats. Species or taxa with a sensitive-critical subdesignation are sensitive species of particular conservation concern. Sensitive-critical species have current or legacy threats that are impacting their abundance, distribution, diversity, and/or habitat. They may decline to the point of qualifying for threatened or endangered status if conservation actions are not taken.

In addition to the threatened and endangered plant species described above, ODA designates candidate species for listing. ODA candidate species include any plant species designated for study by the director of ODA whose numbers are believed low or declining, or whose habitat is sufficiently threatened and declining in quantity and quality, so as to potentially qualify for listing as a threatened or endangered species in the foreseeable future (ODA 2017d).

4.6.3.1 U.S. Fish and Wildlife Service and National Marine Fisheries Service

The FWS (2006d, 2006e, 2013h, 2017c) and NMFS (2006) list 69 fish and wildlife species of concern that potentially occur in counties coinciding with the Project. The list of federal species of concern includes 14 mammals, 20 birds, 3 reptiles, 10 amphibians, 10 fish, and 12 invertebrates. These species, and expected habitat for each species, are listed in tables I-3 and I-4 in appendix I of this EIS. The FWS has noted that the Umpqua chub may be present in the Umpqua River, and this species is of concern because it has rapidly decreased in abundance. This species is discussed in detail in the BE (see appendix F.7 of this EIS).

The FWS lists one plant species as a federal candidate for listing, and 52 federal plant species of concern that potentially occur in counties coinciding with the Project. These species are listed in table I-5 in appendix I of this EIS, along with expected habitat for each species.

4.6.3.2 Oregon Department of Fish and Wildlife

The ODFW (2016) identified 71 state sensitive species that potentially occur in counties coinciding with the Project area, some of which (i.e., 37) are also considered federal species of concern. This list includes 15 mammals, 28 birds, 13 fish, 2 reptiles, and 13 amphibians. The ODFW does not assign special status for invertebrates. Tables I-3 and I-4 in appendix I provide the following information for each state special status species: expected habitat and documentation within each county, BLM district, and National Forest crossed by the Pacific Connector pipeline and vicinity.

Although the state sensitive species listed in tables I-3 and I-4 may occur in counties noted by FWS (2006d, 2006e) and ODFW (ORBIC 2006a, 2012), distributions and/or habitat associations of some preclude their potential occurrence in the area that would be affected by the Project.

4.6.3.3 Oregon Department of Agriculture

The ODA identified 41 candidates for listing that potentially occur in counties coinciding with the Project area, 26 of which are also federal species of concern. Descriptions of expected habitat, documented or suspected occurrences, and a description of potential Project effects on these special status species as a result of the Project are presented in table I-5 in appendix I.

4.6.3.4 Tribal Species of Concern

The CIT identified the following plant and animal species as species of concern. According to the CIT, this list is not comprehensive, but does represent the most significant and important traditional cultural plant and animal species that are found on the Coquille Forest and other Tribal lands. A more complete list and description of plant usage can be found in "Ethnobotany of the Coquille Indians". Significant and important plants include, but are not limited to:

- Trees (bark and wood): Port Orford cedar, western red cedar, Sitka spruce, big leaf maple, myrtle, red alder, madrone, Pacific yew.

- Shrubs (wood, nuts and berries): elderberry (*Sambucus* spp.), willows, hazel, vine maple, rhododendron, azalea (*Rhododendron* spp.), manzanita, ocean spray, Labrador tea (*Ledum* spp.), huckleberry, salal, thimbleberry, salmonberry, Oregon grape.
- Flowers and vines (roots and fiber): yarrow (*Achillea millefolium*), camas (*Camassia*), tiger lily (*Lilium columbianum*), columbine (*Aquilegia* spp.), various *Lomatium* and *Brodiaeas*, iris (*Iris* spp.), trailing blackberry (*Rubus ursinus*), yerba buena (*Clinopodium douglasii*), beargrass (*Xerophyllum tenax*).
- Wet Meadow/Riparian Plants: cattail, tule (*Schoenoplectus* spp.), various sedges and ferns, skunk cabbage, various mosses.
- Marine/Estuary: eelgrass, giant kelp (*Macrocystis* spp.), bull kelp (*Nereocystis luetkeana*), sea lettuce (*Ulva* spp.), surfgrass (*Phyllospadix* spp.).
