1. Boiler Information:				
Boiler identification	EU6.AB (Aux Boiler)			
Manufacturer	Rentech			
Date manufactured (month/year)				
Date construction commenced (month/year)	January 2019			
Date installed (month/year)	October 2021			
Rated design heat input capacity (million Btu per hour)	296.2			
Rated steam production capacity (pounds per hour)	200,000			
Primary fuel type	Natural Gas			
Max. fuel quantity used per hour (include units)	289,100 scf/hr			
Max. fuel quantity used per year (include units)	253.3MMscf/yr			
If oil is used, sulfur content (% by wt.)				
Secondary fuel type	None			
Max. fuel quantity used per hour (include units)				
Max. fuel quantity used per year (include units)				
If oil is used, sulfur content (% by wt.)				
Stack identification	AuxBoil			
Stack height (feet)	100 ft			
Stack gas flow rate at maximum load (dscf/minute)				
Control device(s) identification from AQ300	CD.SCR6, CD.OC6			
Continuous monitoring systems	Yes			

2. Describe how the boilers(s) is operated. (Refer to instructions for guidance)

Auxiliary boiler will be used to produce steam for liquefaction train startup. Emission controls include SCR and a CO catalyst.

RENTECH

Proposal To:

BLACK & VEATCH

For:

Jordan Cove LNG[SM]

Auxiliary Boiler 189980.67.6150 - Located in Coos Bay, OR
Rentech Proposal No.: DFB-DTB-4983-CY-16-R0

Boilers for people who know and care

TO: Black & Veatch Corporation July 8, 2016
11401 Lamar Avenue
Overland Park, KS 66211

Attn: Venkoba Sah Pawar Narayana Sah, P.E

Based upon the request for an auxiliary boiler to be installed in the Jordan Cove LNG facility, located in Coos Bay, Oregon, RENTECH is pleased to furnish our proposal for:

ONE (1) 200,000 LB/HR, FULLY ASSEMBLED, "D-STYLE", Watertube BOILER, with BURNER, ECONOMIZER, FAN, SELECTIVE CATALYTIC REDUCTION, STACK, TRIM, and LADDERS & PLATFORMS to be designed and built in accordance with the requirements of Section I of the ASME Boiler and Pressure Vessel Code and described in the following pages.

Page No.

RENTECH is offering a ***completely custom boiler*** system, based on the specification provided.

Thank you for your interest in doing business with **RENTECH BOILER SYSTEMS, INC.** We look forward to providing a prompt response to all of your questions, attention to all details, and a top quality boiler. Please don't hesitate to contact me if you have any questions.

Sincerely,

Clayton Young

PROPOSAL SUMMARY

With over 500 boilers installed in 25 different countries it is no wonder that more than ever people who need steam are turning to ***RENTECH Boiler Systems, Inc***. Each RENTECH boiler is custom designed by our engineers and built by a team of our experienced employees to perform efficiently and safely in its unique application. We offer excellent technical solutions to the unique needs of our customers for steam with a focus on custom design and service, competitive prices, and ***reliable delivery schedules***. You will benefit from the years of combined experience of our employees in the boiler industry.

1. **Reliability and Availability**: We understand that these boilers will form a critical part of the steam system for the facility and that reliability is key. **This reliability is evident in RENTECH's 5-year parts and labor warranty covering the design and workmanship of the boiler pressure parts.**

2. **Life Expectancy:** Rentech understands that users are looking for the best possible quality and craftsmanship. This translates directly into an extended life expectancy of the installed equipment.

3. **Emissions:** We understand that providing an environmentally friendly boiler is critical to any new installation today.

Every boiler manufactured by RENTECH Boiler Systems is ***custom engineered***, giving us the flexibility to assure that the equipment fits your needs rather than ***forcing*** your needs into a ***pre-designed boiler model***.

RENTECH Solution:

The following are features that we have included in this proposal to meet specific requirements for this boiler project:

1. We have proposed a boiler with a conservative furnace design, as noted in the below discussion regarding furnace heat release rate. This design assures that the equipment will fit your needs, minimize emissions and provide the longest life expectance possible.

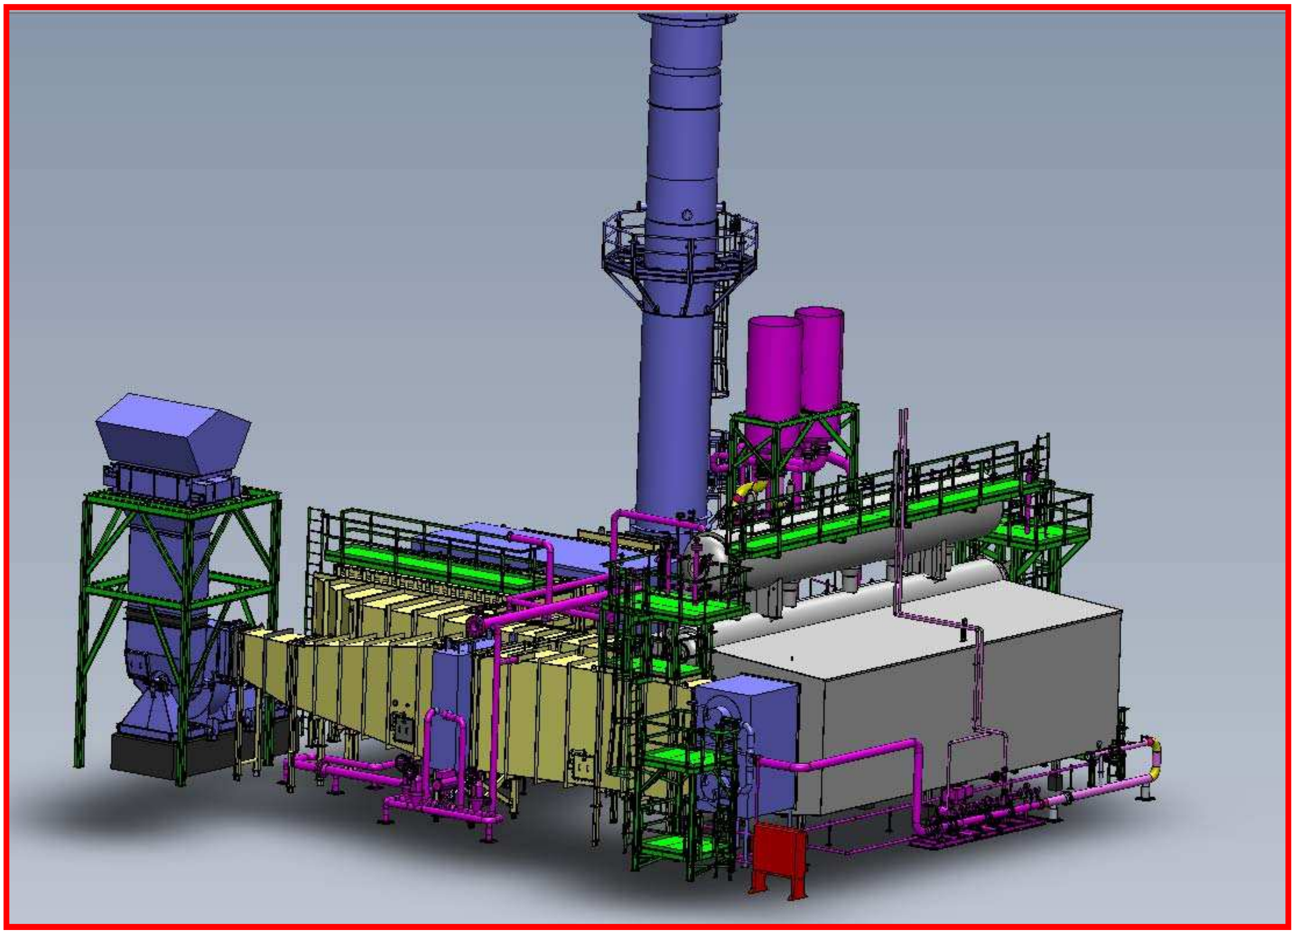
2. This design maximizes the shop fabrication of the boilers.

3. We have offered a 100% membrane wall construction furnace for this boiler, including the front and rear walls. This design is essential in minimizing the need for refractory in the furnace. Rentech's headered wall construction in the furnace assures that furnace gas seals do not fail due to high furnace temperatures and refractory failure.

This will significantly reduce downtime and maintenance cost over the life of the equipment.

4. Rentech will pre-fit all structural steel including ladders and platforms in our shop. Once they are assembled, photos will be taken and they will be disassembled for shipment. This added process is unique to Rentech and we have found will significantly save on field fit-up issues which could result in costly delays.

5. Rentech will utilize 3-D modeling in the engineering and design of your system. This will significantly improve fit up accuracy and avoid costly field modifications.



*Example of 3-D modeling software with entire boiler system.

TECHNICAL DISCUSSION

To meet your process and mechanical requirements, we are pleased to offer one (1), **100% membrane wall construction**, D-Type watertube boiler. The boiler has been designed for natural gas firing and will have a design pressure of **875 psig**. The unit will generate 200,000 lbs/hr of superheated steam at 740 psig and 725°F while firing NG. This is assuming the feedwater is supplied at **281°F**. Please refer to the attached Data Sheets for performance at the design conditions.

The boiler will be designed with ***complete membrane wall construction of the furnace***, including the front wall. This design minimizes the need for refractory and refractory seals, even in the corners. By minimizing the refractory, ***faster start-ups are possible***. Slow ramp-up time required to sustain the refractory at a constant temperature is not necessary. Of course, ***the absence of refractory rules out the possibility for cracking and crumbling*** problems that traditionally are associated with refractory in packaged boilers. The water-cooled front and rear walls also allow the furnace to operate at a lower temperature, which helps to reduce the formation of NO_x.

RADIANT FURNACE

The furnace section of the proposed boilers is of ***100% membrane wall design*** and is constructed of ***2.0"OD x 0.135"MW ERW SA-178A*** tubes on 4" centers. The tubes are connected by ¼" x 2**"** carbon steel membranes to form a totally water cooled enclosure, including the front and rear walls. This design avoids the traditional problems that package boilers have with firebrick and refractory maintenance. Membrane walls will be constructed as multiple tube panels maximizing machine welding and eliminating a fin to fin weld between tubes**.** The membrane wall construction is unique in that it utilizes a headered construction, which

Rentech Boiler Systems, Inc.
Abilene Office: 5025A E. Business 20 • Abilene, TX 79601 • Phone: 325-672-3400 • Fax: 325-672-9996
Lincoln Office: 145 North 46th Street • Lincoln, NE 68503 • Phone: 325-672-3400 Fax: 402-474-4243

eliminates the need for, and traditional problems associated with gas seals in the corners of the furnace. Our competition would utilize steel box seals at the locations where one furnace wall joins another. These gas seals require the use of refractory or ceramic fiber to protect them from the high temperatures in the furnace. Problems with gas seal failures arise over time as the refractory or ceramic fiber fails, exposing the gas seals to 2,000°F temperatures. ***With RENTECH'S headered wall design, the water cooled header forms the corners. It simply cannot fail by overheating.***

The furnace will have two observation ports located on each side wall to allow for viewing the flame in the furnace. The front of the furnace can be viewed through ports located on the burner. The rear wall of the furnace will have a davited 15"x18" access door, with a 9" refractory lining.

FURNACE DATA

Item	Units	Natural Gas
Furnace Dimensions	Ft – in	Height: 10'-9" ; Width: 7'-7"; Length: 38'-6"
Total Heat Input	MMBtu/Hr	269.3
Furnace Volume	Ft^3	3,125
Flat Projected Furnace Surface	Ft^2	1,549
Volumetric Heat Release Rate	$Btu/Hr\text{-}ft^3$	84,856
Square Foot Heat Release Rate	$Btu/Hr\text{-}ft^2$	171,164

Notes:

- Volumetric Heat Release Rate = Total Heat Input (includes all losses from the boiler) at MCR / Actual Furnace Volume Available for Combustion (This would exclude any volume occupied by a radiant superheater if such a design were offered). The heat input is a known value and will change depending on unit efficiency and fuel fired. The furnace volume is simply a calculation of the open volume in the furnace. This results in a value in $Btu/Hr\text{-}ft^3$.
- Square Foot Heat Release Rate = Total Heat Input at MCR / Flat Projected Furnace Heating Surface. The Flat Projected Furnace Heating Surface is the heating in the furnace not taking into account the curvature of the tubes. If one were to look at the furnace membrane wall, it a square foot of Flat Projected Heating Surface would simple be a 1 foot by 1 foot square.

CONVECTION TUBES

The convection tubes are ***2.0"OD x 0.135"MW ERW SA-178A*** and attach to the drums by rolling. Each tube hole will be serrated and carefully cleaned and polished just prior to tube installation. The ends of each tube will also be polished just prior to installation.

Please refer to the attached Mechanical Data for details of the convection section tube layout. This tube layout was specifically selected to meet your process and space requirements.

Rentech performs an acoustic analysis on all sections of the boiler at various loads to determine if longitudinal, vertical baffles are required to eliminate problems associated with acoustic vibration. Rentech will include these when necessary.

DRUMS

The steam drum is 54" ID and approximately 41'-0" in length, seam to seam. This combination of diameter and length has been optimized for the capacity of the boiler. This steam drum will allow the boiler to react to load swings while reducing the likelihood of excess moisture carryover or nuisance trips due to high or low water level. The drum is provided with primary belly pan and chevrons to assure that steam leaving the drum contains less than 1.0 PPM TDS carryover. Any steam purity guarantee will not include vaporous silica carryover. All other drum internal piping is also included as needed to make the unit operational. Each steam drum head will have a 12"X16" elliptical manway with davited cover, to provide access for inspection.

The lower drum will be 26" ID. The mud drum is complete with bottom blowdown connections to allow for the proper intermittent blowdown of solids that accumulate in the bottom of the drums. The mud drum will have two 12" X 16" elliptical manways. The boiler is supported from grade on channel saddles. It will be fixed on the burner end and the other end will free to slide and accommodate thermal expansion

DOWNCOMERS

Two unheated downcomers are included, one located at either end of the steam drum. They will stabilize the drum level during rapid changes in firing rate without the use of conventional convection tubes being used as downcomers. The downcomers also support the steam drum to reduce stresses on the tubes.

SUPERHEATER

The superheater is an inverted loop, fully drainable, type design. It will be constructed as a separate module and shop hydrostatically tested prior to installation in the boiler. The superheater will be located behind the division wall and behind the screen tubes so that it will be protected from direct radiation.

This is a single stage superheater with a desuperheater downstream the main steam outlet that uses boiler feedwater as a cooling medium. This two stage superheater will provide a guaranteed constant steam temperature of 725°F (+/- 10°F) over the operating range of 50% to 100% MCR.

BURNER

RENTECH is offering a single ZEECO Free Jet low NO_x burner for the auxiliary boiler. The maximum emission levels, **NOT using FGR**, from the burner when firing natural gas from 25% to 100% MCR, with all concentrations corrected to 3% oxygen, on a dry basis:

NOx	35 ppm
CO	50 ppm

The following scope related to the burner is included:

One (1) Zeeco Free Jet burner for a total of 1 boiler, each consisting of the following:

1. Zeeco non-insulated front plate, equipped with:
    a. Zeeco register assembly fabricated with carbon steel
    b. Zeeco carbon steel removable center equipped with center-fired gas gun assembly equipped with stainless steel tip assembly and swirler
    c. Two (2) sight ports
    d. One (1) **Fireye** scanner with swivel mount and 10m cable
2. Zeeco staged gas firing assembly equipped with carbon steel gas ring
3. Zeeco refractory throat tile, one (1) per burner

Zeeco ZA2 Igniter

One (1) ZA2 igniter constructed out of CS, equipped with:

1. One (1) spark electrode
2. One (1) ionization sensing rod
3. One (1) high tension direct spark rod
4. One (1) Ignition transformer and ionization amplifier to provide the spark and flame detection signals
5. One (1) three foot long stainless steel flexible hose for gas supplied to the igniter
6. One (1) six foot long HT/ionization cable to connect the ignition transformer and the ionization amplifier to the igniter lance

Windbox

1. Zeeco standard construction windbox non-insulated, fabricated with ¼" A36 steel plate including distribution baffles as required per the Zeeco Physical Air Flow Modeling study.
2. Windbox Mounted Devices
    a. **Three (3)** purge air and combustion air proving transmitter
    b. **Three (3)** High steam drum pressure transmitter
    c. NEMA 4X junction box(es) for devices and scanners

Valve Trains for Free Jet burner

1. Natural gas
    a. One (1) pressure gauge with isolation valve
    b. Six (6) pressure transmitters, **three (3)** low and **one (3)** high pressure
    c. Two (2) automatic safety shutoff valves
    d. One (1) automatic vent valve
    e. One (1) manual vent valve
    f. One (1) manual shutoff valve
    g. Two (2) flow control valves (CFG and outer ring)
    h. Two (2) pressure gauges with isolation valves (CFG and outer ring)
    i. Two (2) flex hoses (CFG and outer ring)

Igniter for the Free Jet burner

a. Two (2) manual shutoff valves
b. One (1) inlet wye strainer
c. One (1) pressure regulating valve
d. Two (2) automatic safety shutoff valves
e. One (1) automatic vent valve
f. Two (2) pressure gauges with isolation valves
g. One (1) flex hose

Components for Natural Gas Train

a. One (1) manual shutoff valve
b. One (1) wye strainer
c. One (1) pressure gauge with isolation valve
d. One (1) pressure regulating valve
e. One (1) manual vent valve
f. One (1) gas flow meter

Rentech Boiler Systems, Inc.
Abilene Office: 5025A E. Business 20 • Abilene, TX 79601 • Phone: 325-672-3400 • Fax: 325-672-9996
Lincoln Office: 145 North 46th Street • Lincoln, NE 68503 • Phone: 325-672-3400 Fax: 402-474-4243

General Construction and Wiring for Rack Mounted Valve Trains

1. Basic instrument air system comprised of **three (3)** low pressure transmitter (VT mounted), one pressure gauge, and individual component hand valves
2. Conduit and wire electrical (vs. cable and tray)
3. Base Valve Train Construction:
   a. Piping 2" and under shall be A-106 seamless pipe, schedule 80, socket welded end connections, 3000lb fittings
   b. Piping 2 ½" and larger will be A-106 seamless pipe, schedule 40, CL150 flanged or butt welded connections
   c. All valve rack lifting lugs 100% dye penetration inspection testing
   d. Bolts shall be ASTM A-193 Grade B7 – Zinc Plated
   e. Nuts shall be ASTM A-194 Grade 2H – Zinc Plated
   f. Flat-washer: (2) per Stud, (1) per bolt, Type F436 – Zinc Plated
   g. Gaskets shall be Garlock Blue-Gard 3000, 1/16" thick, or equal
4. NEMA 4X junction box(es)

FD FAN

An arrangement #7, 1780 rpm API 673 draft fan with a **600 HP** motor drive has been included for the auxiliary boiler. The fan being offered is an **Airfoil** design to help with efficiency of the fan and to decrease the required motor HP. Mechanical dampers, air silencer and the necessary air inlet ducting supports are also included.

Test block for the fan and drives is based on 110% of volumetric flow and 121% of static pressure. Fan performance is summarized below

Fan Blade Type		**Airfoil**	
Fan Model		***A55S-5875***	
Condition	Units	Test Block	Max Fire Case
Inlet Volume Flow Rate	acfm	58,948	51,215
Inlet Temperature	°F	105	80
Inlet Density	lb/ft³	0.0703	0.0736
Inlet Total Pressure	in.wg	0.00	0.00
Outlet Static Pressure	in.wg	42.60	35.20
Fan Static Pressure Rise	in.wg	42.60	35.20
Fan Speed	rpm	1,780	1,780
Power Consumption	HP	538	428
Approximate VIV Angle	°	90	43

NOTE - The fan will also include a **forced oil lubrication system**, designed per API-614. This system will ensure the bearings on the fan and motor are cooled for equipment longevity.

ECONOMIZER

A horizontal gas flow economizer has been included for each boiler. The tubes are horizontal and fully drainable, finned with 6 fins/in, 0.75" H x 0.05" W and serrated fins.

The economizer casing inner casing is ¼" carbon steel, and is gas tight and externally insulated with mineral fiber block insulation and lagged to match the boiler.

SCR & CO SYSTEM

This proposal includes a standard medium temperature **SCR catalyst** system for to reduce NOx emissions from the burner. The system is designed to utilize 19% aqueous ammonia as a reagent in the SCR process.

NOx emissions will be reduced as depicted in the following table:

	From Burner	SCR Outlet
NO_x, ppm	35 ppm	2 ppm

SCR CATALYST DESCRIPTION	
SCR Catalyst Manufacturer	Cormetech CM-21™
Catalyst Type	Homogeneous Honeycomb
Active Catalyst Material	Ti-V-W
Catalyst Flow Passage (pitch)	2.1 mm
Gas Flow	Horizontal
Module Arrangement	14 X 12.75
Flue Gas Maldistribution at Inlet to Catalyst:	
Velocity	+/- 15% RMS normal
Temperature	+/- 20°F
N_3 to NO_x Molar Ratio	+/- 10% RMS normal
Number of SCR Modules	4
Total SCR Catalyst Weight	2,400 lbs.
Guarantee Life	43,800 hours
Ammonia Slip	10 ppmvdc @ 3% O_2

An **ammonia package control unit (APCU)** is included with dilution components for aqueous ammonia per the following:

- Stainless steel structural skid base with lifting and grounding lugs
- Two regenerative blowers, one primary and one secondary, rated at 130 SCFM @ 42"WC, Electric motor rated 460/3/60, 3 HP, IEEE-841, 1.15 SF; inlet filter/silencers are included.
- Stainless steel dilution air line with expansion joints, check valves, automated damper vale assemblies, pressure gauges with a block and bleed valve, orifice flange assembly with a manifold/flow transmitter
- Two 100 kW 480/3/60 immersion heaters, one primary and one secondary, housed in stainless steel pipe, with type K thermocouples on each circuit. Vertical down flow; insulated and jacketed. Stainless steel piping downstream of the heaters will include expansion joints, automated damper valve assemblies, and a thermocouple/thermo well assembly with a temperature transmitter.
- One upward flow, stainless steel vertical vaporizer with internal mixing element and injection nozzle. The outlet stainless steel piping will have a thermocouple/thermo well assembly with a temperature transmitter.
- Class 150 stainless steel aqueous ammonia line, including manual isolation valves, duplex strainers with a common differential pressure gauge, a Micro Motion Coriolis mass meter, automated isolation ball valve assemblies with open/close limit switches, pressure gauges with block and bleed valves, a Fisher/Baumann flow control valve with a globe valve bypass, and a flex line to the injection nozzle
- Class 150 stainless steel instrument air header with manual isolation valves, a pressure switch, and a pressure gauge w/block and bleed valve to provide actuation of pneumatic valves
- NEMA 4X junction box for the termination of analog and discrete instrumentation
- NEMA 4X heater power panel containing components for modulated heater control and safety interlocks; with PLC based Compact Logix, I/O modules for control, and a 10" color touch screen; includes an A/C unit and Z purge.

Ammonia will be injected into the flue gas via distribution manifold header and an ammonia injection grid (AIG). The distribution manifold header consists of one header with an inlet intake and take off branches. Each branch contains a manual gate valve, orifice plate, and Dwyer Capsuhelic pressure gage for balancing flow. The ammonia injection grid consists of assemblies with three 3" lances per assembly. A total of twenty one stainless steel lances are provided.

- CFD modeling of the flue gas flow path and AIG has been included.

An **Allen Bradley PLC system** is included and is housed in a NEMA 4X enclosure located on APCU skid. It will consist of the following:

- Compact Logix PLC platform
- Redundant processors
- I/O modules for control of SCR system
- 10" color touch screen with sun shade

Rentech Boiler Systems, Inc.
Abilene Office: 5025A E. Business 20 • Abilene, TX 79601 • Phone: 325-672-3400 • Fax: 325-672-9996
Lincoln Office: 145 North 46th Street • Lincoln, NE 68503 • Phone: 325-672-3400 Fax: 402-474-4243

This proposal includes a standard medium temperature **CO catalyst** system for to reduce carbon monoxide emissions from the burner from 50 ppm down to 4 ppm, a destruction of 91.76%.

BOILER AND BURNER CONTROLS

Zeeco will provide a new Burner Management System (BMS) utilizing a redundant Allen Bradley Control Logix processors. The BMS will control the automatic sequencing during light off of the burner on Natural Gas and continuously monitor all safety interlocks to ensure safe firing of the boiler. If a hazardous situation does occur, the BMS will shut down the boiler automatically. A Control Narrative and SAMA Diagram showing the Combustion Control System Logic will be provided (to be programmed into the DCS by others).

Zeeco will provide all new hardware which will be mounted inside a NEMA 12 Free Standing enclosure. A 12" Red Lion HMI will be mounted on the door. The enclosure is not rated for any hazardous areas and must be installed in an unclassified climate controlled area. The BMS shall not be provided with any provisions for Intrinsically Safe instrumentation as Zeeco's standard is Ex d and Ex e.

The BMS can be controlled with the HMI or remotely through the DCS. "First Out" and alarm conditions will be displayed locally as well as annunciated to the DCS. Alarm and Indication communication with the DCS shall be done over redundant Fiber Optic Ethernet (using 1756-EN2F modules); permissives and control will be done through dry contacts.

A programming laptop with the latest version of Studio 5000 and the HMI software will be provided.

Rentech Boiler Systems, Inc.
Abilene Office: 5025A E. Business 20 • Abilene, TX 79601 • Phone: 325-672-3400 • Fax: 325-672-9996
Lincoln Office: 145 North 46th Street • Lincoln, NE 68503 • Phone: 325-672-3400 Fax: 402-474-4243

Notes:

- BMS shall meet all the latest NFPA 85 2015 standards
- The BMS is engineered utilizing an external safety watchdog timer to continuously monitor the PLC for processor faults.
- All critical PLC Input and Outputs shall be continuously monitored for faults during operation.
- Programming and Screen development for HMI screens.
- All BMS outputs shall be fused. Terminals will be Phoenix Contact.
- All digital I/O (switches, valves, etc.) shall be 24 VDC.
- Technical control package will include the following documents:
    a) BMS Panel Arrangement
    b) BMS Electrical Equipment List
    c) BMS Electrical Wiring Schematics
    d) BMS Sequence of Operations
    e) BMS Boolean Diagrams
    f) CCS Control Narrative
    g) CCS SAMA Diagram
    h) I/O List
    i) Install (Hook Up) Diagrams
    j) DCS Communication Map
    k) Utility Consumption List
    l) HMI Screen Shots
    m) Certifications for Hazardous Area

BMS Exceptions:

- Loop Drawings (Information will be presented in the wiring diagrams)
- Interconnect Drawings
- Cause and Effect Drawings (Information is better presented as Booleans)
- SAT Procedure
- The BMS will not accept any pneumatic (3-15 PSIG) signals.
- A Blower will not be installed in the BMS panel.
- A printer will not be provided.

STACK

Individual single wall freestanding stacks, extending to 100' above grade are included. The stack diameter is 72" at the discharge, sized for a discharge velocity of 50 ft/sec with both boilers operating at 100% MCR.

One 360° x 3'- 6" OSHA approved test platform will be included to access the test ports. Expanded metal personnel protection will be provided, 6' - 0", at the test platform, and behind the caged ladder.

DUCTWORK

The boiler outlet transition (SCR inlet), SCR and CO catalyst housing, SCR outlet (economizer inlet) and economizer outlet transition will be fabricated of 0.25" carbon steel material, stiffened as required. All ductwork will be insulated and lagged prior to shipment. Access doors will be provided.

BOILER TRIM AND INSTRUMENTATION

The boiler trim included in the base pricing is itemized on the trim list. Boiler trim appurtenances and instrumentation will be crated and shipped for safe delivery to site where it will be mounted by end user and/or his site contractor. Wiring in the field is supplied by others.

PIPING

We have included the piping as indicated in the above scope table. All piping supplied by RENTECH will analyzed for stresses and will come with the necessary supports to properly carry the loads. Field welds will be required to complete the feedwater piping installation.

Rentech Boiler Systems, Inc.
Abilene Office: 5025A E. Business 20 • Abilene, TX 79601 • Phone: 325-672-3400 • Fax: 325-672-9996
Lincoln Office: 145 North 46th Street • Lincoln, NE 68503 • Phone: 325-672-3400 Fax: 402-474-4243

INSULATION, LAGGING, AND PAINTING

The mud drum, excluding the drum heads, and all of the walls of the unit will be insulated with 3-4" mineral fiber insulation and protected with steel lagging. The roof of the furnace will be covered with steel casing. The steam drum, excluding the heads, will be insulated and lagged with steel. The drum heads will be provided with removable insulation covers. Exterior surfaces that will not be insulated will be cleaned and painted with one coat of inorganic zinc primer. Vendor supplied equipment will receive their standard paint application. Piping components, ductwork interior and surfaces that will be insulated will not be painted.

FIELD SERVICE

All field service is available at the below per diem rates.

Rentech Boiler Systems, Inc.
Abilene Office: 5025A E. Business 20 • Abilene, TX 79601 • Phone: 325-672-3400 • Fax: 325-672-9996

PERFORMANCE GUARANTEES

The performance of the packaged boiler is guaranteed as detailed below:

Fuel Fired		**Natural Gas**	
DESCRIPTION	**UNITS**		
System Performance			
Steam Flow (Net)	lb/hr	200,000	
Steam Pressure	PSIG	740	
Steam Quality @ Drum Outlet	%	0.05	
System Efficiency	**%**	**83.01**	
Emissions			
NOx	ppm	2	
CO	ppm	4	

Notes:

1. System performance guarantees are at 100% MCR only.
2. Feedwater temperature to boiler is 281°F.
3. Ambient temperature is 80°F.
4. The blowdown rate is as defined in the attached Predicted Operating Performance Tables.
5. Feedwater analysis must meet suggested Water Quality Limits per latest edition of ASME.
6. Boiler performance will be measured by a performance test based upon the principles of ASME PTC 4.1. Testing is to be by others.
7. The steam conditions are at the Rentech terminal points.
8. Emission guarantees are from 25% to 100% MCR.

Performance Parameter Reference Top

Parameters Reference: DM9600 - 08

PERFORMANCE DEFINITIONS

PERFORMANCE DEFINITIONS DM9600

APPLICATION:
Engine performance tolerance values below are representative of a typical production engine tested in a calibrated dynamometer test cell at SAE J1995 standard reference conditions. Caterpillar maintains ISO9001:2000 certified quality management systems for engine test Facilities to assure accurate calibration of test equipment. Engine test data is corrected in accordance with SAE J1995. Additional reference material SAE J1228, J1349, ISO 8665, 3046-1:2002E, 3046-3:1989, 1585, 2534, 2288, and 9249 may apply in part or are similar to SAE J1995. Special engine rating request (SERR) test data shall be noted.

PERFORMANCE PARAMETER TOLERANCE FACTORS:
Power +/- 3%
Torque +/- 3%

Exhaust stack temperature +/- 8%
Inlet airflow +/- 5%
Intake manifold pressure-gage +/- 10%
Exhaust flow +/- 6%
Specific fuel consumption +/- 3%
Fuel rate +/- 5%
Specific DEF consumption +/- 3%
DEF rate +/- 5%
Heat rejection +/- 5%
Heat rejection exhaust only +/- 10%
Heat rejection CEM only +/- 10%

Heat Rejection values based on using treated water.

Torque is included for truck and industrial applications, do not use for Gen Set or steady state applications.

On C7 - C18 engines, at speeds of 1100 RPM and under these values are provided for reference only, and may not meet the tolerance listed.

These values do not apply to C280/3600. For these models, see the tolerances listed below.

C280/3600 HEAT REJECTION TOLERANCE FACTORS:
Heat rejection +/- 10%
Heat rejection to Atmosphere +/- 50%
Heat rejection to Lube Oil +/- 20%
Heat rejection to Aftercooler +/- 5%

TEST CELL TRANSDUCER TOLERANCE FACTORS:

Torque +/- 0.5%
Speed +/- 0.2%
Fuel flow +/- 1.0%
Temperature +/- 2.0 C degrees
Intake manifold pressure +/- 0.1 kPa

OBSERVED ENGINE PERFORMANCE IS CORRECTED TO SAE J1995 REFERENCE AIR AND FUEL CONDITIONS.

REFERENCE ATMOSPHERIC INLET AIR
FOR 3500 ENGINES AND SMALLER
SAE J1228 AUG2002 for marine engines, and J1995 JAN2014 for other engines, reference atmospheric pressure is 100 KPA (29.61 in hg), and standard temperature is 25deg C (77 deg F) at 30% relative humidity at the stated aftercooler water temp, or inlet manifold temp.

FOR 3600 ENGINES
Engine rating obtained and presented in accordance with ISO 3046/1 and SAE J1995 JANJAN2014 reference atmospheric pressure is 100 KPA (29.61 in hg), and standard temperature is 25deg C (77 deg F) at 30% relative humidity and 150M altitude at the stated aftercooler water temperature.

MEASUREMENT LOCATION FOR INLET AIR TEMPERATURE
Location for air temperature measurement air cleaner inlet at stabilized operating conditions.

REFERENCE EXHAUST STACK DIAMETER
The Reference Exhaust Stack Diameter published with this dataset is only used for the calculation of Smoke Opacity values displayed in this dataset. This value does not necessarily represent the actual stack diameter of the engine due to the variety of exhaust stack adapter options available. Consult the price list, engine order or general dimension drawings for the actual stack diameter size ordered or options available.

REFERENCE FUEL
DIESEL
Reference fuel is #2 distillate diesel with a 35API gravity;
A lower heating value is 42,780 KJ/KG (18,390 BTU/LB) when used at 29 (84.2), where the density is 838.9 G/Liter (7.001 Lbs/Gal).

GAS
Reference natural gas fuel has a lower heating value of 33.74 KJ/L (905 BTU/CU Ft). Low BTU ratings are based on 18.64 KJ/L (500 BTU/CU FT) lower heating value gas. Propane ratings are based on 87.56 KJ/L (2350 BTU/CU Ft) lower heating value gas.

ENGINE POWER (NET) IS THE CORRECTED FLYWHEEL POWER (GROSS) LESS EXTERNAL AUXILIARY LOAD
Engine corrected gross output includes the power required to drive standard equipment; lube oil, scavenge lube oil, fuel transfer, common rail fuel, separate circuit aftercooler and jacket water pumps. Engine net power available for the external (flywheel) load is calculated by subtracting the sum of auxiliary load from the corrected gross flywheel out put power. Typical auxiliary loads are radiator cooling fans, hydraulic pumps, air compressors and battery charging alternators. For Tier 4 ratings additional Parasitic losses would also include Intake, and Exhaust Restrictions.

ALTITUDE CAPABILITY
Altitude capability is the maximum altitude above sea level at standard temperature and standard pressure at which the engine could develop full rated output power on the current performance data set.

Standard temperature values versus altitude could be seen on TM2001.

When viewing the altitude capability chart the ambient temperature is the inlet air temp at the compressor inlet.

Engines with ADEM MEUI and HEUI fuel systems operating at conditions above the defined altitude capability derate for atmospheric pressure and temperature conditions outside the values defined, see TM2001.

Mechanical governor controlled unit injector engines require a setting change for operation at conditions above the altitude defined on the engine performance sheet. See your Caterpillar technical representative for non standard ratings.

REGULATIONS AND PRODUCT COMPLIANCE
TMI Emissions information is presented at 'nominal' and 'Potential Site Variation' values for standard ratings. No tolerances are applied to the emissions data. These values are subject to change at any time. The controlling federal and local emission requirements need to be verified by your Caterpillar technical representative.

Customer's may have special emission site requirements that need to be verified by the Caterpillar Product Group engineer.

Emissions Data

EMISSIONS VALUES ARE TAILPIPE OUT WITH AFTERTREATMENT. VALUES SHOWN AS ZERO MAY BE GREATER THAN ZERO BUT WERE BELOW THE DETECTION LEVEL OF THE EQUIPMENT USED AT TIME OF MEASUREMENT.

CATERPILLAR EMISSIONS CERTIFIED ENGINES TESTED WITHIN EPA SPECIFIED TEST CONDITIONS, AND USING TITLE 40 CFR PART 1065 TEST PROTOCOL, MEET THE NEW SOURCE PERFORMANCE STANDARDS. POTENTIAL SITE VARIATION DATA ACCOUNT FOR PRODUCTION ENGINE AND SYSTEM VARIABILITY IN ADDITION TO MEASUREMENT VARIABILITY FOR TYPICAL FIELD TEST METHODS AS DESCRIBED IN DM1176. THIS DATA ASSUMES SITE CORRECTIONS FOR AMBIENT HUMIDITY TO 75 GRAINS, AND STANDARD CONDITIONS OF 25 C (77 F) AIR TO TURBO TEMPERATURE AND 152.4 M (500 FT) ALTITUDE. GUIDANCE ON HUMIDITY CORRECTION METHODS ARE AVAILABLE IN TITLE 40 CFR SECTION 1065.670. FOR APPLICATIONS WITH GEOGRAPHIC OR AMBIENT CONDITIONS BEYOND THESE PUBLISHED VALUES, CONSULT CATERPILLAR (APPLICATION SUPPORT CENTER) FOR ADDITIONAL VARIABILITY INFORMATION.

Facility Name: JCEP LNG Terminal Project Permit Number:

Engine Information

1.	Device ID Number	EU9.EG (Backup Gen Engines)
2.	Existing or future?	Future
3.	Date construction commenced	January 2019
4.	Date installed/completed	October 2021
5.	Special controls (if applicable)	Tier 2
6.	Manufacturer	Caterpillar
7.	Date manufactured	
8.	Maximum rating (MMbtu/hr for turbines, Hp for others)	1,214, each
9.	Control device(s) (yes/no)	No
	If yes, enter the identification number(s)	
10.	Description of device:	

Two Caterpillar C27 SR5 800 eKW diesel-fired emergency backup engine generators.

Operating Schedule

11.	Projected maximum hours/day	2
12.	Projected maximum hours/year	200

Fuel Information

13. Fuel usage:	a. Type	b. Hourly usage	c. Annual usage
Primary	ULSD	57.3 gal/hr	11,460 gal
Back-up			
Other			

Stack Information

14.	Exit height (ft)	13
15.	Exit diameter (ft)	0.67
16.	Design flowrate (dscf/min)	6011.7 acfm

Monitoring Information

17. Monitoring equipment			
fuel flow (y/n)		recorder? (y/n)	
engine load (y/n)		recorder? (y/n)	
other (specify)	Hour meter	recorder? (y/n)	Yes

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
2015 MODEL YEAR
CERTIFICATE OF CONFORMITY
WITH THE CLEAN AIR ACT OF 1990

OFFICE OF TRANSPORTATION AND AIR QUALITY
ANN ARBOR, MICHIGAN 48105

Certificate Issued To: **Caterpillar Inc.**
(U.S. Manufacturer or Importer)

Certificate Number: FCPXL27.0NZS-005

Effective Date: 07/01/2014

Expiration Date: 12/31/2015

Byron J. Bunker, Division Director
Compliance Division

Issue Date: 07/01/2014

Revision Date: N/A

Model Year: 2015
Manufacturer Type: Original Engine Manufacturer
Engine Family: FCPXL27.0NZS

Mobile/Stationary Indicator: Stationary
Emissions Power Category: 560<kW<=2237
Fuel Type: Diesel
After Treatment Devices: No After Treatment Devices Installed
Non-after Treatment Devices: Electronic Control, Engine Design Modification

Pursuant to Section 111 and Section 213 of the Clean Air Act (42 U.S.C. sections 7411 and 7547) and 40 CFR Part 60, and subject to the terms and conditions prescribed in those provisions, this certificate of conformity is hereby issued with respect to the test engines which have been found to conform to applicable requirements and which represent the following engines, by engine family, more fully described in the documentation required by 40 CFR Part 60 and produced in the stated model year.

This certificate of conformity covers only those new compression-ignition engines which conform in all material respects to the design specifications that applied to those engines described in the documentation required by 40 CFR Part 60 and which are produced during the model year stated on this certificate of the said manufacturer, as defined in 40 CFR Part 60.

It is a term of this certificate that the manufacturer shall consent to all inspections described in 40 CFR 1068 and authorized in a warrant or court order. Failure to comply with the requirements of such a warrant or court order may lead to revocation or suspension of this certificate for reasons specified in 40 CFR Part 60. It is also a term of this certificate that this certificate may be revoked or suspended or rendered void *ab initio* for other reasons specified in 40 CFR Part 60.

This certificate does not cover engines sold, offered for sale, or introduced, or delivered for introduction, into commerce in the U.S. prior to the effective date of the certificate.

Caterpillar is leading the power generation marketplace with Power Solutions engineered to deliver unmatched flexibility, expandability, reliability, and cost-effectiveness.

Specifications

Generator Set Specifications	
Minimum Rating	680 ekW
Maximum Rating	800 ekW
Voltage	208 to 600
Frequency	60 Hz
Speed	1800 RPM

Generator Set Configurations	
Emissions/Fuel Strategy	Low Fuel Consumption, U.S. EPA Certified for Stationary Emergency Use Only (Tier 2 Nonroad Equivalent Emission Standards)

Engine Specifications		
Engine Model	C27 ATAAC, V-12, 4-Stroke, Water-Cooled Diesel	
Compression Ratio	16.5:1	
Aspiration	TA	
Governor Type	Adem™A4	
Fuel System	MEUI	
Bore	137.2 mm	5.4 in
Displacement	27.03 L	1649.47 in³
Stroke	152.4 mm	6 in

Benefits And Features

Cat Diesel Engine

- Reliable, rugged, durable design
- Field-proven in thousands of applications worldwide
- Four-stroke-cycle diesel engine combines consistent performance and excellent fuel economy with minimum weight

Generator

- Matched to the performance and output characteristics of Cat engines
- Industry leading mechanical and electrical design
- Industry leading motor starting capabilities
- High Efficiency

Cat EMCP Control Panel

The EMCP controller features the reliability and durability you have come to expect from your Cat equipment. EMCP4 is a scalable control platform designed to ensure reliable generator set operation, providing extensive information about power output and engine operation. EMCP4 systems can be further customized to meet your needs through programming and expansion modules.

Seismic Certification

- Seismic Certification available.
- Anchoring details are site specific, and are dependent on many factors such as generator set size, weight, and concrete strength.
- IBC Certification requires that the anchoring system used is reviewed and approved by a Professional Engineer
- Seismic Certification per Applicable Building Codes: IBC 2000, IBC 2003, IBC 2006, IBC 2009, CBC 2007, CBC 2010
- Pre-approved by OSHPD and carries an OSP-0321-10 for use in healthcare projects in California

Design Criteria

The generator set accepts 100% rated load in one step per NFPA 110 and meets ISO 8528-5 transient response.

UL 2200 / CSA - Optional

- UL 2200 listed packages
- CSA Certified
- Certain restrictions may apply.
- Consult with your Cat® Dealer.

Single-Source Supplier

Fully prototype tested with certified torsional vibration analysis available

World Wide Product Support

Cat Dealers provide extensive post sale support including maintenance and repair agreements. Cat dealers have over 1,800 dealer branch stores operating in 200 countries. The Cat® SOSSM program cost effectively detects internal engine component condition, even the presence of unwanted fluids and combustion by-products.

Standard Equipment

Air Inlet

- Air Cleaner

Cooling

- Package mounted radiator

Exhaust

- Exhaust flange outlet

Fuel

- Primary fuel filter with integral water separator
- Secondary fuel filter
- Fuel priming pump

Generator

- Matched to the performance and output characteristics of Cat engines
- Load adjustment module provides engine relief upon load impact and improves load acceptance and recovery time
- IP23 Protection

Power Termination

- Bus Bar

Control Panel

- EMCP 4 Genset Controller

General

- Paint - Caterpillar Yellow except rails and radiators gloss black

Optional Equipment

Exhaust

- Exhaust mufflers

Generator

- Anti-condensation heater
- Excitation: [ ] Permanent Magnet Excited (PM) [ ] Internally Excited (IE)
- Oversize and premium generators

Power Termination

- Circuit breakers, UL listed
- Circuit breakers, IEC compliant

Control Panels

- EMCP (4.2) (4.3) (4.4)
- Generator temperature monitoring & protection
- Load share module
- Digital I/O module
- Remote monitoring software

Mounting

- Rubber anti-vibration mounts
- Spring-type vibration isolator
- IBC isolators

Starting/Charging

- Battery chargers
- Oversize batteries
- Jacket water heater
- Heavy-duty starting system
- Charging alternator
- Air starting motor with control and silencer

General

- The following options are based on regional and product configuration:
- Seismic Certification per applicable building codes: IBC 2000, IBC 2003, IBC 2006, IBC 2009, CBC 2007
- UL 2200 package
- EU Certificate of Conformance (CE)
- CSA Certification
- EEC Declaration of Conformity
- Enclosures: sound attenuated, weather protective
- Automatic transfer switches (ATS)
- Integral & sub-base fuel tanks
- Integral & sub-base UL listed dual wall fuel tanks

Heat Rejection to Aftercooler	162 kW	9235 Btu/min
Heat Rejection to Atmosphere from Engine	110 kW	6240 Btu/min
Heat Rejection to Atmosphere from Generator	40 kW	2292 Btu/min

Alternator[2] See Generator Data		

Emissions (Nominal)[3]		
NOx	2580.0 mg/Nm^3	5.2 g/hp-hr
CO	115.1 mg/Nm^3	0.2 g/hp-hr
HC	12.5 mg/Nm^3	0.0 g/hp-hr
PM	9.7 mg/Nm^3	0.0 g/hp-hr

DEFINITIONS AND CONDITIONS

1. For ambient and altitude capabilities consult your Cat dealer. Air flow restriction (system) is added to existing restriction from factory.

2. UL 2200 Listed packages may have oversized generators with a different temperature rise and motor starting characteristics. Generator temperature rise is based on a 40° C ambient per NEMA MG1-32.

3. Emissions data measurement procedures are consistent with those described in EPA CFR 40 Part 89, Subpart D & E and ISO8178-1 for measuring HC, CO, PM, NOx. Data shown is based on steady state operating conditions of 77° F, 28.42 in HG and number 2 diesel fuel with 35° API and LHV of 18,390 btu/lb. The nominal emissions data shown is subject to instrumentation, measurement, facility and engine to engine variations. Emissions data is based on 100% load and thus cannot be used to compare to EPA regulations which use values based on a weighted cycle.

C27 ACERT
800 ekW/ 1000 kVA/ 60 Hz/ 1800 rpm/ 480 V/ 0.8 Power Factor

Rating Type: STANDBY

Emissions: U.S. EPA Certified for Stationary Emergency Use Only (Tier 2 Nonroad Equivalent Emission Standards)

Applicable Codes and Standards:
AS1359, CSA C22.2 No100-04, UL142,UL489, UL869, UL2200,
NFPA37, NFPA70, NFPA99, NFPA110, IBC, IEC60034-1, ISO3046, ISO8528,
NEMA MG1-22,NEMA MG1-33, 2006/95/EC, 2006/42/EC, 2004/108/EC.

Note: Codes may not be available in all model configurations. Please consult your local Cat Dealer representative for availability.

STANDBY: Output available with varying load for the duration of the interruption of the normal source power. Average power output is 70% of the standby power rating. Typical operation is 200 hours per year, with maximum expected usage of 500 hours per year.

Ratings are based on SAE J1349 standard conditions. These ratings also apply at ISO3046 standard conditions

Fuel Rates are based on fuel oil of 35º API [16º C (60º F)] gravity having an LHV of 42 780 kJ/kg (18,390 Btu/lb) when used at 29º C (85º F) and weighing 838.9 g/liter (7.001 lbs/U.S. gal.). Additional ratings may be available for specific customer requirements, contact your Cat representative for details. For information regarding Low Sulfur fuel and Biodiesel capability, please consult your Cat dealer.

Performance Parameter Reference

Parameters Reference:DM9600-08
PERFORMANCE DEFINITIONS

PERFORMANCE DEFINITIONS DM9600

APPLICATION:
Engine performance tolerance values below are representative of a typical production engine tested in a calibrated dynamometer test

cell at SAE J1995 standard reference conditions. Caterpillar maintains ISO9001:2000 certified quality management systems for engine test Facilities to assure accurate calibration of test equipment. Engine test data is corrected in accordance with SAE J1995. Additional reference material SAE J1228, J1349, ISO 8665, 3046-1:2002E, 3046-3:1989, 1585, 2534, 2288, and 9249 may apply in part or are similar to SAE J1995. Special engine rating request (SERR) test data shall be noted.

PERFORMANCE PARAMETER TOLERANCE FACTORS:

Power	+/- 3%
Torque	+/- 3%
Exhaust stack temperature	+/- 8%
Inlet airflow	+/- 5%
Intake manifold pressure-gage	+/- 10%
Exhaust flow	+/- 6%
Specific fuel consumption	+/- 3%
Fuel rate	+/- 5%
Specific DEF consumption	+/- 3%
DEF rate	+/- 5%
Heat rejection	+/- 5%
Heat rejection exhaust only	+/- 10%
Heat rejection CEM only	+/- 10%

Heat Rejection values based on using treated water.

Torque is included for truck and industrial applications, do not use for Gen Set or steady state applications.

On C7 - C18 engines, at speeds of 1100 RPM and under these values are provided for reference only, and may not meet the tolerance listed.

These values do not apply to C280/3600. For these models, see the tolerances listed below.

C280/3600 HEAT REJECTION TOLERANCE FACTORS:

Heat rejection	+/- 10%
Heat rejection to Atmosphere	+/- 50%
Heat rejection to Lube Oil	+/- 20%
Heat rejection to Aftercooler	+/- 5%

TEST CELL TRANSDUCER TOLERANCE FACTORS:

Torque	+/- 0.5%
Speed	+/- 0.2%
Fuel flow	+/- 1.0%
Temperature	+/- 2.0 C degrees
Intake manifold pressure	+/- 0.1 kPa

OBSERVED ENGINE PERFORMANCE IS CORRECTED TO SAE J1995 REFERENCE AIR AND FUEL CONDITIONS.

REFERENCE ATMOSPHERIC INLET AIR
FOR 3500 ENGINES AND SMALLER
SAE J1228 AUG2002 for marine engines, and J1995 JAN2014 for other engines, reference atmospheric pressure is 100 KPA (29.61 in hg), and standard temperature is 25deg C (77 deg F) at 30% relative humidity at the stated aftercooler water temp, or inlet manifold temp.

FOR 3600 ENGINES
Engine rating obtained and presented in accordance with ISO 3046/1 and SAE J1995 JANJAN2014 reference atmospheric pressure is 100 KPA (29.61 in hg), and standard temperature is 25deg C (77 deg F) at 30% relative humidity and 150M altitude at the stated aftercooler water temperature.

MEASUREMENT LOCATION FOR INLET AIR TEMPERATURE
Location for air temperature measurement air cleaner inlet at stabilized operating conditions.

REFERENCE EXHAUST STACK DIAMETER
The Reference Exhaust Stack Diameter published with this dataset is only used for the calculation of Smoke Opacity values displayed in this dataset. This value does not necessarily represent the actual stack diameter of the engine due to the variety of exhaust stack adapter options available. Consult the price list, engine order or general dimension drawings for the actual stack diameter size ordered or options available.

REFERENCE FUEL
DIESEL
Reference fuel is #2 distillate diesel with a 35API gravity;
A lower heating value is 42,780 KJ/KG (18,390 BTU/LB) when used at 29 (84.2), where the density is 838.9 G/Liter (7.001 Lbs/Gal).

GAS
Reference natural gas fuel has a lower heating value of 33.74 KJ/L (905 BTU/CU Ft). Low BTU ratings are based on 18.64 KJ/L (500 BTU/CU FT) lower heating value gas. Propane ratings are based on 87.56 KJ/L (2350 BTU/CU Ft) lower heating value gas.

ENGINE POWER (NET) IS THE CORRECTED FLYWHEEL POWER (GROSS) LESS EXTERNAL AUXILIARY LOAD
Engine corrected gross output includes the power required to drive standard equipment; lube oil, scavenge lube oil, fuel transfer, common rail fuel, separate circuit aftercooler and jacket water pumps. Engine net power available for the external (flywheel) load is calculated by subtracting the sum of auxiliary load from the corrected gross flywheel out put power. Typical auxiliary loads are radiator cooling fans, hydraulic pumps, air compressors and battery charging alternators. For Tier 4 ratings additional Parasitic losses would also include Intake, and Exhaust Restrictions.

ALTITUDE CAPABILITY
Altitude capability is the maximum altitude above sea level at standard temperature and standard pressure at which the engine could develop full rated output power on the current performance data set.

Standard temperature values versus altitude could be seen on TM2001.

When viewing the altitude capability chart the ambient temperature is the inlet air temp at the compressor inlet.

Engines with ADEM MEUI and HEUI fuel systems operating at conditions above the defined altitude capability derate for atmospheric pressure and temperature conditions outside the values defined, see TM2001.

Mechanical governor controlled unit injector engines require a setting change for operation at conditions above the altitude defined on the engine performance sheet. See your Caterpillar technical representative for non standard ratings.

REGULATIONS AND PRODUCT COMPLIANCE
TMI Emissions information is presented at 'nominal' and 'Potential Site Variation' values for standard ratings. No tolerances are applied to the emissions data. These values are subject to change at any time. The controlling federal and local emission requirements need to be verified by your Caterpillar technical representative.

Customer's may have special emission site requirements that need to be verified by the Caterpillar Product Group engineer.

STANDARD FEATURES

Generator Monitoring	• Voltage (L-L, L-N) • Current (Phase) • Average Volt, Amp, Frequency • kW, kVAr, kVA (Average, Phase, %) • Power Factor (Average, Phase) • kW-hr, kVAr-hr (total) • Excitation voltage and current (with CDVR) • Generator stator and bearing temp (with optional module)
Generator Protection	• Generator phase sequence • Over/Under voltage (27/59) • Over/Under frequency (81 O/U) • Reverse Power (kW) (32) • Reverse Reactive Power (kVAr) (32RV) • Overcurrent (50/51)
Engine Monitoring	• Coolant temperature • Oil pressure • Engine speed (RPM) • Battery voltage • Run hours • Crank attempt and successful start counter • Enhanced engine monitoring (with electronic engines)
Engine Protection	• Control switch not in auto (alarm) • High coolant temp (alarm and shutdown) • Low coolant temp (alarm) • Low coolant level (alarm) • High engine oil temp (alarm and shutdown) • Low, high, and weak battery voltage • Overspeed • Overcrank
Control	• Run / Auto / Stop control • Speed and voltage adjust • Local and remote emergency stop • Remote start/stop • Cycle crank
Inputs & Outputs	• Two dedicated digital inputs • Six programmable digital inputs • Six programmable form A dry contacts • Two programmable form C dry contacts • Two digital outputs
Communications	• Primary and accessory CAN data links • RS-485 annunciator data link • Modbus RTU (RS-485 Half duplex)
Language Support	Arabic, Bulgarian, Chinese, Czech, Danish, Dutch, English, Estonian, Finnish, French, German, Greek, Hungarian, Icelandic, Italian, Latvian, Lithuanian, Japanese, Norwegian, Polish, Portuguese, Romanian, Russian, Slovak, Slovene, Spanish, Swedish, Turkish
Environmental	• Control module operating temperature: -40°C to 70°C • Display operating temperature: -20°C to 70°C • Humidity: 100% condensing 30°C to 60°C • Storage temperature: -40°C to 85°C • Vibration: Random profile, 24-1000 Hz, 4.3G rms

MISCELLANEOUS PROCESS OR DEVICE

Facility Name: JCEP LNG Terminal Project   Permit Number:

Process Information

1. ID Number	EU10.GC (Gas Conditioning)
2. Descriptive name	Acid Gas Thermal Oxidizer
3. Existing or future?	Future
4. Date commenced	January 2019
5. Date installed/completed	October 2021

6. Description of process:

The Gas Conditioning train includes a system for mercury removal via sulfur impregnated activated carbon, carbon dioxide (CO2) and acid gas removal via an amine system, and dehydration via a molecular sieve adsorbent system. A thermal oxidizer combusts the acid gas from the amine process.

Operating Schedule

7. Seasonal or year-round?	Year-round
8. Batch or continuous operation?	Continuous
9. Projected maximum hours/day	24
10. Projected maximum hours/year	8,760

11. Process/device capacity:	Short term capacity		Annual usage	
Raw materials	Amount	Units	Amount	Units
Pipeline Natural Gas	50,000	MMBtu/hr		
Products				
Fuel Gas	3,905	lb/hr		
Acid Gas	124,710	lb/hr		
Flash Gas	1.276	lb/hr		

12. Control devices(s) (yes/no) Yes

If yes, provide the ID number and complete and attached the applicable series AQ300 form(s).

Zeeco Proposal No. 2016-03002IN-01 Rev. 0

Gentlemen:

Thank you for your continued interest in Zeeco. We appreciate this opportunity to provide a technical description/proposal for the equipment described in the above referenced inquiry.

The attached proposal describes the specific operating conditions and mechanical features of the combustion equipment. The design and materials of construction have been chosen to maximize on-line time and operational life while minimizing the capital cost of the equipment. In addition, the proposed equipment is in accordance with our understanding of data sheets and specifications.

Zeeco has unique capabilities and experience in delivering large incineration systems. The experience lists attached to our proposal include incinerators larger than those in this proposal, and we have experience with large gas-gas heat exchangers with waste gas as the heated media. We can provide *in-house* Computational Fluid Dynamics (CFD) modeling for the purpose of fluid flow analysis, gas mixing, and temperature profiles inside the incinerator chamber, and dynamic vortex shedding, and standing-wave analysis to avoid vibration problems in the preheaters. Zeeco has a license and engineers with experience using FEM software to analyze natural frequency problems. Zeeco can do in-house 3D modeling using Autodesk Inventor software.

Again, we appreciate the opportunity to provide our quotation in full accordance with your requirements. After you have had an opportunity to review our proposal, should you have any questions or require additional information, please contact me using the contact information noted below.

Sincerely,

P. M. Pickard

Peter Pickard
Senior Applications Engineer

TABLE OF CONTENTS

1.0 INTRODUCTION

Zeeco, Inc. has been designing and manufacturing burners, flares, incinerators, air preheaters, and combustion systems for world wide use since 1980. Zeeco, Inc., headquartered in the Tulsa, Oklahoma area, is privately held by a family who has successfully designed, developed and supplied combustion equipment for over 80 years.

Zeeco's Engineering Staff offers over 1,000 years of experience in the development, design, and testing of Combustion Systems. Zeeco has the proven skills and innovative abilities to design a practical and environmentally friendly combustion system to thermally treat virtually any industrial waste. This learned "art" gained by research and design efforts which are refined by testing and field experience has been implemented in the process plants of numerous industries throughout the world.

From project planning through design, procurement, manufacturing, installation, and even start-up, Zeeco, Inc. will provide project management and support as deemed necessary. It is our world class HANDS ON type design skills, quality products, experienced staff, and especially our responsiveness to our customers needs that truly set Zeeco apart from our competition.

Quality. Our customers expect it; we demand it.

4.0 DESIGN SUMMARY

4.1 Site Conditions

Wind Loading Code	ASCE/SEI 7-10
Maximum Hourly Sustained Peak Wind (Design)	150mph
3 second gust	183 mph
Occupancy category	IV
Importance factor	1.0
Exposure category	C
Wind Topographic Factor	1.0
Seismic Loading Code	ASCE/SEI 7-10 and IBC 2010
FERC Seismic Structural Category	II
Site classification	D
Importance factor (seismic loads) for structures (I)	1.5
Importance factor for Systems/Components (Ip)	1.5
Occupancy category	IV
Ss	1.50g
S1	1.00g
SDS	1.00g
SD1	1.00g
Site location	Coos Bay, Oregon
Elevation	Unknown
Atmospheric Pressure	Unknown
Ambient Temperature	Unknown
Electrical Area Classification	Class 1, Division 2, Group C & D

4.2 Waste Stream Summary – See attached excerpt from the spec

4.3 Process Summary

Case Name:	Max Case
FLOW RATE:	**lb/hr**
Acid Gas	124,710
Flash Gas	1276
Fuel Gas	3905
Combustion air	108,251
TOTAL, lb/hr	**238,142**
HEAT RELEASE:	**MMBtu/hr**
Acid Gas	1
Flash Gas	22
HP Fuel Gas	79
TOTAL, MMBtu/hr	**102**
Incinerator Temperature, ^{o}F	1600
Residence time, seconds	1
Flue Gas Mole Weight	34.29
FLUE GAS COMPOSITION:	**mol %**
CO_2	44.84
H_2O	10.05
N_2	42.39
O_2	2.72*
SO_2	< 10 ppm
TOTAL Flue Gas, mol %	**100**

*3% O2 on dry basis

4.4 Utilities

Instrument air, psig	60
Instrument air, usage	15 SCFM
Max Fuel gas usage, lb/hr	3905
Fuel gas at burner, psig	15
Connected HP for combustion air fan	50 at 480 volts, 3ph, 60 hz

4.5 System Performance

Emissions @ Stack Conditions	Guaranteed, less than:
VOC	99.9% DRE
NOx	< 50 ppm
CO	< 50 ppm
SO2	3.22 lb/hr
Correction basis for above	3% O2, dry volume

These values are understood to apply only when the system is operated in accordance with the operating conditions stipulated in the design summary and for the waste(s) stipulated in the design basis sections of this proposal and when the system is operated according to Zeeco's instructions.

Special note regarding SO2 emissions:
According to Zeeco calculation, the SO2 content in the flue gas at maximum condition is 3.43 lb/hr instead of 3.22 lb/hr. Zeeco assumes that JGC does not want to add an SO2 scrubber in order to account for a small difference in calculated SO2 quantity. Therefore, Zeeco is willing to guarantee the SO2 emission provided that it is understood that Zeeco will not be required to make any equipment modification if the SO2 emissions are exceeded. This is because there is nothing in the burner/thermal oxidizer that can be changed in order to reduce SO2 emissions. SO2 emissions are a direct result of the sulfur content in the feed gas. The only way to decrease the emissions without a change in feed condition is to add a scrubber which would roughly double or triple the cost of the system.

5.0 EQUIPMENT DESCRIPTION

5.1 Thermal Oxidizer

One (1) vertical, up-fired thermal oxidizer/stack designed to operate at 1600°F with excess air to ensure complete combustion of the waste gas combustible components. Each Incinerator has the following features:

- Nominal 9'-6" OD x 85 feet tall from grade
- ASME Section VIII, Div 1 design
- ASME STS-1
- No hydrotest
- No Code stamp
- Shell material SA-516-70N carbon steel
- 1/8" corrosion allowance
- Designed to be supported by concrete tabletop foundation (by others)
- All Carbon Steel External Surfaces Sandblasted SSPC-SP6
- Thermal shroud 360 degree carbon steel galvanized 26 gauge (panels ship loose for field assembly)
- Ladders and Platforms are provided to sampling port elevation
- 360 degree sample port platform
- Connections per GA Drawing
- Refractory lining per refractory schedule shown on GA drawing
- Refractory material is shipped loose for field installation by others
- Top 10'-0" of stack shell is 316 stainless steel
- Damping pad
- Stainless steel rain cap for protection of refractory at stack exit
- Assembly designed to ship as one piece, approximately 60 feet long
- Flanged burner connection
- Oregon PE stamped applicable documents

5.2 Burner

One (1) Zeeco Combination Waste Gas, Flash Gas and Fuel Gas Burner is offered per system and has the following features:

- 110 MMBtu/hr maximum fuel gas heat release (includes 10% safety factor)
- Zeeco AR/GS pilot for burner ignition
- High Energy Electric Spark Ignition System
- A-36 carbon steel construction
- See additional information about pilots here: http://www.zeeco.com/incinerators/incinerators-pilots.php

5.4 Combustion Air Fans

Two (2) Combustion Air Fans (one 100% installed spare) are offered and have the following features and preliminary design details:

Case	Mass Flow, lb/hr	Outlet Static Press., in WC	Power, BHP
Test Block	26,231	7.3	46
Operating Case	23,846	6.0	34

Preliminary design details:

- API 560 Design, Annex E
- Direct drive
- Fan antifriction bearings, grease lube
- Coupling guard
- Nameplate - Quantity per fan (1)
- A-36 or equivalent housing construction
- Paint Specification; Manufacturer's standard
- Motor drive: 50 HP, 3600 RPM, TEFC, 460 V / 3 phase / 60 Hz electric motor

5.5 Instrumentation & Controls

Zeeco scope of supply is depicted on the attached P&ID and includes the following:

- Fuel gas skid with valves, instruments and wiring
- Local control panel with pushbuttons and lights
- Ship loose instrumentation and valves as shown on P&ID
- Designed for analog control to be in customer's DCS
- Logic control hardware for burner management function, such as a PLC is NOT included.
- Cause and effect diagrams
- Logic diagrams
- Process control narrative descriptions of control loops

State of Oregon Department of Environmental Quality

Facility Name: JCEP LNG Terminal Project

Permit Number:

Process Information

1. ID Number	EU11.MPGF (Multipoint Ground Flares)
2. Descriptive name	Warm and Cold Flares
3. Existing or future?	Future
4. Date commenced	January 2019
5. Date installed/completed	October 2021
6. Description of process:	

Warm and cold ground flares used to burn gas released from the process during emergencies or while purging equipment in preparation for maintenance. Each flare system has seven stages with 2 pilots per stage. Together these warm and cold flare lines comprise a multi-point ground flare (MPGF) where the array of burners is arranged in a grid surrounded by barrier walls.

Operating Schedule

7. Seasonal or year-round?	Year-round
8. Batch or continuous operation?	Continuous (pilot and purge gas)
9. Projected maximum hours/day	24
10. Projected maximum hours/year	8,760

11. Process/device capacity:	Short term capacity		Annual usage	
Raw materials	Amount	Units	Amount	Units
Pilot Gas	1.82	MMBtu/hr	15,943	MMBtu/yr
Purge Gas	0.31	MMBtu/hr	2,715.6	MMBtu/yr
Products				
NA				

12. Control devices(s) (yes/no): No

If yes, provide the ID number and complete and attached the applicable series AQ300 form(s).

Facility Name: JCEP LNG Terminal Project

Indicate which of the following categorically insignificant activities are present at the facility by placing an "X" in the "Yes" or "No" column.

Yes	No	Type of activity — Categorically Insignificant Activities
✓		Constituents of a chemical mixture present at less than 1 percent by weight of any chemical or compound regulated under divisions 200 through 268 excluding divisions 248 and 262 of this chapter, or less than 0.1 percent by weight of any carcinogen listed in the U.S. Department of Health and Human Service's Annual Report on Carcinogens when usage of the chemical mixture is less than 100,000 pounds/year
✓		Evaporative and tail pipe emissions from on-site motor vehicle operation
	✓	Distillate oil, kerosene, gasoline, natural gas or propane burning equipment, provided the aggregate expected actual emissions of the equipment identified as categorically insignificant do not exceed the de minimis level for any regulated pollutant, based on the expected maximum annual operation of the equipment. If a source's expected emissions from all such equipment exceed the de minimis levels, then the source may identify a subgroup of such equipment as categorically insignificant with the remainder not categorically insignificant. The following equipment may never be included as categorically insignificant: A. Any individual distillate oil, kerosene or gasoline burning equipment with a rating greater than 0.4 million Btu/hour; B. Any individual natural gas or propane burning equipment with a rating greater than 2.0 million Btu/hour
	✓	Distillate oil, kerosene, gasoline, natural gas or propane burning equipment brought on site for six months or less for maintenance, construction or similar purposes, such as but not limited to generators, pumps, hot water pressure washers and space heaters, provided that any such equipment that performs the same function as the permanent equipment, must be operated within the source's existing PSEL
✓		Office activities
✓		Food service activities
✓		Janitorial activities
✓		Personal care activities
✓		Grounds keeping activities, including, but not limited to building painting and road and parking lot maintenance
✓		On-site laundry activities
	✓	On-site recreation facilities
✓		Instrument calibration
✓		Maintenance and repair shop
	✓	Automotive repair shops or storage garages;
✓		Air cooling or ventilating equipment not designed to remove air contaminants generated by or released from associated equipment
✓		Refrigeration systems with less than 50 pounds of charge of ozone depleting substances regulated under Title VI, including pressure tanks used in refrigeration systems but excluding any combustion equipment associated with such systems
✓		Bench scale laboratory equipment and laboratory equipment used exclusively for chemical and physical analysis, including associated vacuum producing devices but excluding research and development facilities

Yes	No	Type of activity
✓		Temporary construction activities
	✓	Warehouse activities
	✓	Accidental fires
✓		Air vents from air compressors
✓		Air purification systems
✓		Continuous emissions monitoring vent lines
	✓	Demineralized water tanks
	✓	Pre-treatment of municipal water, including use of deionized water purification systems
	✓	Electrical charging stations
	✓	Fire brigade training
✓		Instrument air dryers and distribution
	✓	Process raw water filtration systems
	✓	Pharmaceutical packaging
✓		Fire suppression
	✓	Blueprint making
✓		Routine maintenance, repair, and replacement such as anticipated activities most often associated with and performed during regularly scheduled equipment outages to maintain a plant and its equipment in good operating condition, including but not limited to steam cleaning, abrasive use, and woodworking
✓		Electric motors
✓		Storage tanks, reservoirs, transfer and lubricating equipment used for ASTM grade distillate or residual fuels, lubricants, and hydraulic fluids
✓		On-site storage tanks not subject to any New Source Performance Standard (NSPS), including underground storage tanks (UST), storing gasoline or diesel used exclusively for fueling of the facility's fleet of vehicles
✓		Natural gas, propane, and liquefied petroleum gas (LPG) storage tanks and transfer equipment
✓		Pressurized tanks containing gaseous compounds
	✓	Vacuum sheet stacker vents
✓		Emissions from wastewater discharges to publicly owned treatment works (POTW) provided the source is authorized to discharge to the POTW, not including on-site wastewater treatment and/or holding facilities
	✓	Log ponds
✓		Storm water settling basins
✓		Fire suppression and training
	✓	Paved roads and paved parking lots within an urban growth boundary
✓		Hazardous air pollutant emissions in fugitive dust from paved and unpaved roads except for those sources that have processes or activities that contribute to the deposition and entrainment of hazardous air pollutants from surface soils
✓		Health, safety, and emergency response activities

Yes	No	Type of activity
	✓	Emergency generators and pumps used only during loss of primary equipment or utility service due to circumstances beyond the reasonable control of the owner or operator, or to address a power emergency, provided that the aggregate horsepower rating of all stationary emergency generator and pump engines is not more than 3,000 horsepower. If the aggregate horsepower rating of all stationary emergency generator and pump engines is more than 3,000 horsepower, then no emergency generators and pumps at the source may be considered categorically insignificant
✓		Non-contact steam vents and leaks and safety and relief valves for boiler steam distribution systems
✓		Non-contact steam condensate flash tanks
✓		Non-contact steam vents on condensate receivers, deaerators and similar equipment
✓		Boiler blow down tanks
	✓	Industrial cooling towers that do not use chromium-based water treatment chemicals
	✓	Ash piles maintained in a wetted condition and associated handling systems and activities
	✓	Uncontrolled oil/water separators in effluent treatment systems, excluding systems with a throughput of more than 400,000 gallons per year of effluent located at the following sources: A. Petroleum refineries; B. Sources that perform petroleum refining and re-refining of lubricating oils and greases including asphalt production by distillation and the reprocessing of oils and/or solvents for fuels; or C. Bulk gasoline plants, bulk gasoline terminals, and pipeline facilities
✓		Combustion source flame safety purging on startup
	✓	Broke beaters, pulp and repulping tanks, stock chests and pulp handling equipment, excluding thickening equipment and repulpers
	✓	Stock cleaning and pressurized pulp washing, excluding open stock washing systems
	✓	White water storage tanks

Oregon Department of Environmental Quality

Land Use Compatibility Statement

State of Oregon Department of Environmental Quality

What is a land use compatibility statement?

A LUCS is a form developed by DEQ to determine whether a DEQ permit or approval will be consistent with local government comprehensive plans and land use regulations.

Why is a LUCS required?

DEQ and other state agencies with permitting or approval activities that affect land use are required by Oregon law to be consistent with local comprehensive plans and have a process for determining consistency. DEQ activities affecting land use and the requirement for a LUCS may be found in Oregon Administrative Rules (OAR) Chapter 340, Division 18.

When is a LUCS required?

A LUCS is required for nearly all DEQ permits and certain approvals of plans or related activities that affect land use prior to issuance of a DEQ permit or approval. These permits and activities are listed in section 1.D on p. 2 of this form. A single LUCS can be used if more than one DEQ permit or approval is being applied for concurrently.

Permit modifications or renewals also require a LUCS when any of the following applies:

1. Physical expansion on the property or proposed use of additional land;
2. Alterations, expansions, improvements or changes in method or type of disposal at a solid waste disposal site as described in OAR 340-093-0070(4)(b);
3. A significant increase in discharges to water;
4. A relocation of an outfall outside of the source property; or
5. Any physical change or change of operation of an air pollutant source that results in a net significant emission rate increase as defined in OAR 340-200-0020.

How to complete a LUCS:

Step	Who Does It?	What Happens?
1	Applicant	Applicant completes Section 1 of the LUCS and submits it to the appropriate city or county planning office.
2	City or County Planning Office	City or county planning office completes Section 2 of the LUCS to indicate whether the activity or use is compatible with the acknowledged comprehensive plan and land use regulations, attaches written findings supporting the decision of compatibility, and returns the signed and dated LUCS to the applicant.
3	Applicant	Applicant submits the completed LUCS and any supporting information provided by the city or county to DEQ along with the DEQ permit application or approval request.

Where to get help:

For questions about the LUCS process, contact the DEQ staff responsible for processing the permit or approval. DEQ staff may be reached at 1-800-452-4011 (toll-free, inside Oregon) or 503-229-5630. For general questions, please contact DEQ land use staff listed on our Land Use Compatibility Statement page online.

***CULTURAL RESOURCES PROTECTION LAWS**: Applicants involved in ground-disturbing activities should be aware of federal and state cultural resources protection laws. ORS 358.920 prohibits the excavation, injury, destruction, or alteration of an archeological site or object or removal of archeological objects from public and private lands without an archeological permit issued by the State Historic Preservation Office. 16 USC 470, Section 106, National Historic Preservation Act of 1966 requires a federal agency, prior to any undertaking, to take into account the effect of the undertaking that is included on or eligible for inclusion in the National Register. For further information, contact the State Historic Preservation Office at 503-378-4168, ext. 232.*

SECTION 1 - TO BE COMPLETED BY APPLICANT	
1A. Applicant Name: Jordan Cove Energy Project, L.P.	1B. Project Name: JCEP LNG Terminal Project
Contact Name: Rose Haddon	Physical Address: Jordan Cove Road
Mailing Address: Suite 500, 5615 Kirby	City, State, Zip: Unincorporated Coos County, OR
City, State, Zip: Houston, TX 77005	Tax Lot #: Not yet partitioned
Telephone: 713-400-2834	Township: T25S Range: R13W Section: 5
Tax Account #:	Latitude: 43.434024 N
	Longitude: 124.243219 W

1C. Describe the project, include the type of development, business, or facility and services or products provided (attach additional information if necessary):

Jordan Cove Energy Project is a natural gas liquefaction and export terminal in Coos County, Oregon to serve overseas markets around the Pacific Rim. Natural gas will be delivered to the terminal by pipeline from the Malin hub located in southern Oregon. The liquefaction and export facility will have an LNG production capacity of 7.8 mtpa. The facility will be developed on approximately 265 acres of industrial-zoned land owned by affiliates of JCEP.

1D. Check the type of DEQ permit(s) or approval(s) being applied for at this time.

- ☐ Air Quality Notice of Construction
- ☑ Air Contaminant Discharge Permit *(excludes portable facility permits)*
- ☐ Air Quality Title V Permit
- ☐ Air Quality Indirect Source Permit
- ☐ Parking/Traffic Circulation Plan
- ☐ Solid Waste Land Disposal Site Permit
- ☐ Solid Waste Treatment Facility Permit
- ☐ Solid Waste Composting Facility Permit (includes Anaerobic Digester)
- ☐ Conversion Technology Facility Permit
- ☐ Solid Waste Letter Authorization Permit
- ☐ Solid Waste Material Recovery Facility Permit
- ☐ Solid Waste Energy Recovery Facility Permit
- ☐ Solid Waste Transfer Station Permit
- ☐ Waste Tire Storage Site Permit
- ☐ Pollution Control Bond Request
- ☐ Hazardous Waste Treatment, Storage, or Disposal Permit
- ☐ Clean Water State Revolving Fund Loan Request
- ☐ Wastewater/Sewer Construction Plan/Specifications *(includes review of plan changes that require use of new land)*
- ☐ Water Quality NPDES Individual Permit
- ☐ Water Quality WPCF Individual Permit *(for onsite construction-installation permits use the DEQ Onsite LUCS form)*
- ☐ Water Quality NPDES Stormwater General Permit *(1200-A, 1200-C, 1200-CA, 1200-COLS, and 1200-Z)*
- ☐ Water Quality General Permit *(all general permits, except 600, 700-PM, 1700-A, and 1700-B when they are mobile.)*
- ☐ Water Quality 401 Certification for federal permit or license

1E. This application is for: ☐ Permit Renewal ☑ New Permit ☐ Permit Modification ☐ Other:

SECTION 2 - TO BE COMPLETED BY CITY OR COUNTY PLANNING OFFICIAL

Instructions: Written findings of fact for all local decisions are required; written findings from previous actions are acceptable. For uses allowed outright by the acknowledged comprehensive plan, DEQ will accept written findings in the form of a reference to the specific plan policies, criteria, or standards that were relied upon in rendering the decision with an indication of why the decision is justified based on the plan policies, criteria, or standards.

2A. The project proposal is located: ☐ Inside city limits ☐ Inside UGB ☐ Outside UGB

2B. Name of the city or county that has land use jurisdiction (the legal entity responsible for land use decisions for the subject property or land use):

SECTION 2 - TO BE COMPLETED BY CITY OR COUNTY PLANNING OFFICIAL	
Applicant Name:	**Project Name:**

2C. Is the activity allowed under Measure 49 (2007)? ☒ No, Measure 49 is not applicable ☐ Yes; if yes, then check one:

☐ Express; approved by DLCD order #:

☐ Conditional; approved by DLCD order #:

☐ Vested; approved by local government decision or court judgment docket or order #:

2D. Is the activity a composting facility?
☒ No ☐ Yes; Senate Bill 462 (2013) notification requirements have been met.

2E. Is the activity or use compatible with your acknowledged comprehensive plan as required by OAR 660-031?
Please complete this form to address the activity or use for which the applicant is seeking approval (see 1.C on the previous page). If the activity or use is to occur in multiple phases, please ensure that your approval addresses the phases described in 1.C. For example, if the applicant's project is described in 1.C as a subdivision and the LUCS indicates that only clearing and grading are allowed outright but does not indicate whether the subdivision is approved, DEQ will delay permit issuance until approval for the subdivision is obtained from the local planning official.

☐ The activity or use is specifically exempt by the acknowledged comprehensive plan; explain:

☐ **Yes**, the activity or use is pre-existing nonconforming use allowed outright by *(provide reference for local ordinance)*:

☐ **Yes**, the activity or use is allowed outright by *(provide reference for local ordinance)*:

☒ **Yes**, the activity or use received preliminary approval that includes requirements to fully comply with local requirements; findings are attached.

☐ **Yes**, the activity or use is allowed; findings are attached.

☐ **No**, see 2.C above, activity or use allowed under Measure 49; findings are attached.

☐ **No**, *(complete below or attach findings for noncompliance and identify requirements the applicant must comply with before compatibility can be determined)*:
Relevant specific plan policies, criteria, or standards:

Provide the reasons for the decision:

Additional comments (attach additional information as needed):

NOTICE OF ADOPTION

August 31, 2016

Re: Coos County Planning Department File No. HBCU-15-05/FP-15-09
Final Decision and Order No. 16-08-071PL

On August 30, 2016, the Board of Commissioners Adopted Final Decision and Order No. 16-08-071PL in the matter of approving conditional use application for Jordan Cove Energy Project L.P. file Numbers HBCU-15-05/FP-15-09.

The final decision and order that was adopted can be found on the Coos County Planning Department webpage at:
http://www.co.coos.or.us/Departments/Planning/2015Applications.aspx.

The adoption of these final decisions and orders can be appealed to the Land Use Board of Appeals (LUBA), pursuant to ORS 197.830 to 197.845, by filing a Notice of Intent to Appeal within 21 days of the date of the final decision and order. For more information on this process, contact LUBA by telephone at 503-373-1265, or in writing at 775 Summer St. NE #330, Salem, Oregon 97301.

All documents related to this file are available for inspection, at no cost, in the Planning Department located at 225 North Adams Street, Coquille, Oregon. Copies may be purchased at a cost of 50 cents per page.

If you have any questions, please contact the Planning Department by telephone at (541) 396-7770, or visit the Planning Department at 225 North Adams Street, Coquille, Oregon, Monday through Friday, 8:00 AM - 5:00 PM (closed Noon - 1:00 PM).

Exit Temperature (˚F)	(1)	243	1,600	330	1832	ambient	948.3	873.6	952.5

Notes:
(1) Provided by KBJ.
(2) Engines are required to combust fuel with 15 ppm sulfur or less per 40 CFR 60 Subpart IIII.
(3) Site-specific data provided by KBJ.

Table 3. Natural Gas Turbines Potential Emissions
Jordan Cove Energy Project L.P. - Emission Inventory
Coos Bay, Oregon
Scenario: 4000 hours 100% load DB, 4760 hours 100% load no DB

Pollutant		Emission Factor			Hourly Emissions per Unit [a] (lb/hr)	Annual Emissions [b] (tons/yr)
Criteria Pollutants						
NO_X	100% Load - DB fired	3.8	lb/hr	(1)	3.75	81.99
	100% Load - DB unfired	3.7	lb/hr			
CO	100% Load - DB fired	4.6	lb/hr	(1)	4.47	97.82
	100% Load - DB unfired	4.4	lb/hr			
SO_2	100% Load - DB fired	1.64	lb/hr	(1), (2)	1.61	35.19
	100% Load - DB unfired	1.58	lb/hr			
VOC	100% Load - DB fired	1.7	lb/hr	(1)	1.49	32.72
	100% Load - DB unfired	1.3	lb/hr			
$PM/PM_{10}/PM_{2.5}$	100% Load - DB fired	5.4	lb/hr		5.13	112.26
	100% Load - DB unfired	4.9	lb/hr	(1)		
H_2SO_4	100% Load - DB fired	1.10	lb/hr	(1)	1.08	23.61
	100% Load - DB unfired	1.06	lb/hr			
NH_3	100% Load - DB fired	3.5	lb/hr	(1)	3.45	75.43
	100% Load - DB unfired	3.4	lb/hr			
Lead		---		(3)	---	---
CO_2e		---		(4)	59,053	1,292,706
CO_2	100% Load - DB fired	60,218	lb/hr	(1)	58,990	1,291,320
	100% Load - DB unfired	57,958	lb/hr			
CH_4		0.001	kg/MMBtu	(5)	1.155	25.293
N_2O		0.0001	kg/MMBtu	(5)	0.116	2.529
Hazardous Air Pollutants						
Acetaldehyde - Turbine		4.0E-05	lb/MMBtu	(6)	2.0E-02	4.4E-01
Acrolein - Turbine		6.4E-06	lb/MMBtu	(6)	3.2E-03	7.1E-02
Benzene - Turbine		1.2E-05	lb/MMBtu	(6)	6.1E-03	1.3E-01
Benzene - Duct Burner		2.1E-03	lb/MMscf	(7)	4.3E-05	4.3E-04
1,3-Butadiene - Turbine		4.3E-07	lb/MMBtu	(6)	2.2E-04	4.7E-03
Dichlorobenzene - Duct Burner		1.2E-03	lb/MMscf	(7)	2.5E-05	2.5E-04
Ethylbenzene - Turbine		3.2E-05	lb/MMBtu	(6)	1.6E-02	3.5E-01
Formaldehyde - Turbine		1.0E-04	lb/MMBtu	(8)	5.0E-02	1.1E+00
Formaldehyde - Duct Burner		7.5E-02	lb/MMscf	(7)	1.6E-03	1.6E-02
Hexane - Duct Burner		1.8E+00	lb/MMscf	(7)	3.7E-02	3.7E-01
Naphthalene - Turbine		1.3E-06	lb/MMBtu	(6)	6.6E-04	1.4E-02
Naphthalene - Duct Burner		6.1E-04	lb/MMscf	(7)	1.3E-05	1.3E-04
PAH - Turbine		2.2E-06	lb/MMBtu	(6)	1.1E-03	2.4E-02
PAH - Duct Burner		8.9E-05	lb/MMscf	(7)	1.8E-06	1.8E-05
Propylene Oxide - Turbine		2.9E-05	lb/MMBtu	(6)	1.5E-02	3.2E-01
Toluene - Turbine		1.3E-04	lb/MMBtu	(6)	6.6E-02	1.4E+00
Toluene - Duct Burner		3.4E-03	lb/MMscf	(7)	7.0E-05	7.0E-04
Xylenes - Turbine		6.4E-05	lb/MMBtu	(6)	3.2E-02	7.1E-01
Arsenic		2.0E-04	lb/MMscf	(3)	1.1E-04	2.4E-03
Beryllium		1.2E-05	lb/MMscf	(3)	6.6E-06	1.4E-04
Cadmium		1.1E-03	lb/MMscf	(3)	6.1E-04	1.3E-02
Chromium		1.4E-03	lb/MMscf	(3)	7.7E-04	1.7E-02
Cobalt		8.4E-05	lb/MMscf	(3)	4.6E-05	1.0E-03

Pollutant	Emission Factor		Hourly Emissions per Unit [(a)] (lb/hr)	Annual Emissions [(b)] (tons/yr)
Manganese	3.8E-04 lb/MMscf	(3)	2.1E-04	4.6E-03
Mercury	2.6E-04 lb/MMscf	(3)	1.4E-04	3.1E-03
Nickel	2.1E-03 lb/MMscf	(3)	1.2E-03	2.5E-02
Selenium	2.4E-05 lb/MMscf	(3)	1.3E-05	2.9E-04
Total HAPs			**0.25**	**5.06**
Maximum Individual HAP				**1.44**

Calculations:

(a) Hourly Emissions (lb/hr) = [Emission Factor for 100% load (lb/hr)] x [Time at 100% load (%) / 100] + [Emission Factor for 75% load (lb/hr)] x [Time at 75% load (%) / 100]

Hourly Emissions (lb/hr) = [Emission Factor (kg/MMBtu)] x [Heat Rate (MMBtu/hr)] x [2.20462 (lb/kg)]

Hourly Emissions (lb/hr) = [Emission Factor (lb/MMBtu)] x [Heat Rate (MMBtu/hr)]

Hourly Emissions (lb/hr) = [Emission Factor (lb/MMscf)] x [Heat Rate (MMBtu/hr)] / [Fuel Heat Content (MMBtu/MMscf)]

Hours at 100% load DB fired (%) =	4000	(9)
Hours at 100% load DB unfired (%) =	4760	(9)
Turbine Maximum Heat Rate (MMBtu/hr) =	504.4	(10)
Duct Burner Maximum Heat Rate (MMBtu/hr) =	19.7	(10)
Maximum Heat Rate (MMBtu/hr) =	524.1	(10)
Fuel Heat Content (Btu/scf) =	952	(11)

(b) Annual Emissions (tons/yr) = [Hourly Emissions (lb/hr)] x [Turbine Hours of Operation (hr/yr) - Startup/Shutdown Hours (hr/yr)] x [Number of Units] / [2,000 (lb/ton)]

Annual Emissions (tons/yr) = [Hourly Emissions (lb/hr)] x [Duct Burner Hours of Operation (hr/yr)] x [Number of Units] / [2,000 (lb/ton)]

Number of Units =	5	(9)
Duct Burner Hours of Operation (hr/yr) =	4,000	(12)
Turbine Hours of Operation (hr/yr) =	8,760	(9)
Startup/Shutdown Hours (hr/yr) =	3.8	(13)

Notes:

(1) Emission estimates provided by manufacturer.

(2) SO_2 emissions include assumptions of 20 percent by volume oxidation rate in CO catalyst and 3 percent by volume oxidation rate in SCR.

(3) AP-42, Chapter 1.4, Table 1.4-4. Emission Factors for Metals from Natural Gas Combustion, July 1998. Note emission factor for lead is ND as indicated in AP-42, Chapter 3.1-2a, Table 3.1, Emission Factors for Criteria Pollutants and Greenhouse Gases from Stationary Gas Turbines.

(4) Carbon dioxide equivalent, global warming potentials; CO_2 = 1, CH_4 = 25, N_2O = 298.

(5) Emission Factors from Table C-2 to Subpart C of 40 CFR Part 98 - Default CH_4 and N_2O Emission Factors for Various Types of Fuel.

(6) AP-42, Chapter 3.1, Table 3.1-3. Emission Factors for Hazardous Air Pollutants from Natural Gas-Fired Stationary Gas Turbines, April 2000.

(7) AP-42, Chapter 1.4, Table 1.4-3. Emission Factors for Speciated Organic Compounds from Natural Gas Combustion, July 1998. HAP emission factors used for Duct Burners.

(8) California Air Resource Board (CARB) emission inventory for NG turbine.

(9) Percentage of time at specific loads, number of units, and hours of operation provided by KBJ.

(10) Maximum heat rate at 100% load with duct burners provided by manufacturer (see Table 13).

(11) Provided by KBJ.

(12) Provided by KBJ.

(13) KBJ estimates 12 startup per year at 10 minutes per startup and 12 shutdowns per year at 9 minutes per shutdown. See Table 4 for additional startup and shutdown calculations.

Table 4. Natural Gas Turbines Startup/Shutdown Potential Emissions
Jordan Cove Energy Project L.P. - Emission Inventory
Coos Bay, Oregon

Pollutant	Startup Emission Factor per Event		Shutdown Emission Factor per Event		Emissions per Startup Event [a] (lb)	Emissions per Shutdown Event [a] (lb)	Annual Emissions [b] (tons/yr)

Flaring of Excess Boil off gas generated during gas up of the LNG carrier each time it returns to LNG transportation service following a drydock overhaul period (when the entire cargo system needs to be fully warmed up and gas freed) is expected to occur at the JCLNG terminal for up to 4 ships per year. The operational assumption is 50% of the gas up volume would be recovered and 50% flared. A worst-case scenario would be flaring of 100% of the gas. Inert gas and methane are routed to the marine flare for combustion.

Calculations:

(a) Hourly Emissions (lb/hr) = [Annual Emissions (tons/yr)] x [2000 lbs/ton)] / [Number of gas up events/year] / [Duration of flaring for event (hours/event)]

Average tanker size hull gas relief (LNG tonnes/ship) =	355.7	(9)
Average flared gas -Turbulent mixing (MMBtu/ship, LHV) =	22,264	(9)
Duration of turbulent event flaring (hours/event) =	30	(9)
Number of turbulent events per year (ships/year) =	1	(9)
Average flared gas - Laminar mixing (MMBtu/ship, LHV) =	19,619	(9)

Duration of non-turbulent event flaring (hours/event) =	18.52	(9)
Number of non-turbulent events per year (ships/year) =	2	(9)
Average flared gas per year (MMBtu/year) =	61,502	
Average duration of event flaring (hours/event) =	22.37	(9)
Fuel Heat Content (Btu/scf) =	877	(9)
Conversion of SO_2 to H_2SO_4 (percent) =	5	(4)
Molecular Weight S (lb/lb-mole) =	32	
Molecular Weight SO_2 (lb/lb-mole) =	64	
Molecular Weight H_2SO_4 (lb/lb-mole) =	98	

(b) Annual Emissions (tons/yr) = [Flared gas per year (MMBtu/yr)] x [Emission factor (lb/MMBtu)] / [2,000 lb/ton]

Annual Emissions (ton/yr) = [S Content (grains/scf)] x [Molecular Weight SO_2 (lb/lb-mole)] / [Molecular Weight S (lb/lb-mole) x [Flared gas (MMBtu/yr)/ Flared Gas HHV (Btu/scf)* 1,000,000 Btu/MMBtu] / [7000 (grains/lb)] x [1 - Conversion of SO_2 to H_2SO_4 (percent)]

Annual Emissions (ton/yr) = [Emission Factor (µg/L)] / [1,000,000 (µg/g)] x [0.00220462 (lb/g)] x [28.317 (L/ft ^{3})] x [10.6 (ft ^{3} exhaust/ft ^{3} fuel)] x [Flared gas (MMBtu/yr) / Flared Gas HHV (Btu/scf) * 1,000,000 Btu/MMBtu]

Annual Emissions (ton/yr) = [SO_2 Annual Emissions (ton/yr)] x [Conversion of SO_2 to H_2SO_4 (percent)] x [Molecular Weight H_2SO_4 (lb/lb-mole)] / [Molecular Weight SO_2 (lb/lb-mole)]

Annual Emissions (tons/yr) = [Emission Factor (lb/MMscf)] x [Flared Gas (MMBtu/yr) / [Flared gas HHV (Btu/scf)] / [2,000 lb/ton]

Annual Emissions (ton/yr) = [Emission Factor (kg/MMBtu)] x [Flared Gas (MMBtu/yr)] x [2.20462 (lb/kg)] / [2,000 (lb/ton)]

Notes:

(1) AP-42, Chapter 13.5, Table 13.5-1. THC and Soot Emissions Factors for Flare Operations, October 1996. PM emission factor is for lightly smoking flare.

(2) AP-42, Chapter 13.5, Table 13.5-2. VOC and CO Emissions Factors for Flare Operations, October 1996.

(3) Sulfur content of 0.01 grains per scf provided by KBJ.

(4) Assume conversion of SO_2 to SO_3 of 5 percent by volume as provided by KBJ.

(5) AP-42, Chapter 1.4, Table 1.4-2. Emission Factors for Criteria Pollutants and Greenhouse Gases from Natural Gas Combustion, July 1998. Note lead is a HAP and is included in the HAP total.

(6) Carbon dioxide equivalent, global warming potentials; CO_2 = 1, CH_4 = 25, N_2O = 298.

(7) Emission Factors from Tables C-1 and C-2 to Subpart C of 40 CFR Part 98 - Default CO_2, CH_4 and N_2O Emission Factors for Various Types of Fuel.

(8) Ventura County Air Pollution Control District.

(9) Information provided by JCLNG for gas up/cool down procedures. Ship vapor (14% CO_2, 84% N_2, 2% O_2) is displaced with LNG. When hydrocarbon is detected it is sent to the flare. When the gas contains less than 50 ppm CO_2 it is sent to be used as fuel gas. Two scenarios were supplied, with and without turbulence for the gas up procedure. The scenario with the greater emissions (turbulence) is included. During the cool down procedure all gas is sent to the fuel gas system.

Table 13. Fugitive Potential Emissions
Jordan Cove Energy Project L.P. - Emission Inventory
Coos Bay, Oregon

Pollutant	Annual Emissions (tons/yr)			
	LNG Tank	Equipment Leaks	Total	
Criteria Pollutants				
NO_X	---	---	---	
CO	---	---	---	
SO_2	---	---	---	
VOC	0.114	7.87	7.98	(1)

CH_4	23.06	501.52	524.58	(1)
N_2O	---	---	---	
Hazardous Air Pollutants				
N-Hexane [(a)]	2.5E-02	1.75	1.77	(4)
Total HAPs			**1.77**	
Maximum Individual HAP			**1.77**	

Calculations:
(a) Annual Emissions (tons/yr) = [VOC Hourly Emissions (tons/yr)] x [N-Hexane/CO_2 Content (mass %)] / [VOC Content (mass %)]

N-Hexane Content (mass %) =	0.31	(4)
VOC Content (mass %) =	1.38	(4)

Notes:
(1) The tank size is the same as in the original permit application. Therefore, the tons/yr emissions for the tanks are from original permit application. See Table 17 for the Equipment Leak Emission calculations.
(2) Carbon dioxide equivalent, global warming potentials; CO_2 = 1, CH_4 = 25
(3) Carbon dioxide emissions are based on a gas composition of 0.36 mol percent VOC and 0.11 mol percent CO_2. See KBJ fuel gas composition provided in Zeeco flare quote.
(4) N-Hexane emissions are based on a fuel gas composition provided by KBJ.

APPENDIX C

NSPS SUBPART Db APPLICABILITY SUMMARY

Type B State New Source Review Application

Jordan Cove LNG Terminal
Jordan Cove Energy Project, LP
125 Central Avenue, Suite 380
Coos Bay, Oregon 97240

September 2017

Table C-1 40 CFR Part 60 Subpart Db Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units	
	Auxiliary Boiler
Applicability §60.40b(a) and (j)	(a) The affected facility to which this subpart applies is each steam generating unit that commences construction, modification, or reconstruction after June 19, 1984, and that has a heat input capacity from fuels combusted in the steam generating unit of greater than 29 megawatts (MW) (100 million British thermal units per hour (MMBtu/hr)). (j) Any affected facility meeting the applicability requirements under paragraph (a) of this section and commencing construction, modification, or reconstruction after June 19, 1986 is not subject to subpart D (Standards of Performance for Fossil-Fuel-Fired Steam Generators, §60.40).
Sulfur dioxide (SO_2) Standards §60.42b(k)(2)	Units firing only gaseous fuel with a potential SO_2 emission rate of 140 ng/J (0.32 lb/MMBtu) heat input or less are exempt from the SO_2 emissions limit in §60.42b(k)(1).
Particulate Matter (PM) Standards §60.43b	PM standards do not apply to units combusting only natural gas.
Nitrogen Oxides (NO_X) Standards §60.44b (h), (i), and (l)(1)	Do not discharge into the atmosphere any gases that contain NO_X in excess of 0.20 lb/MMBtu heat input determined on a 30-day rolling average basis. This standard applies at all times including periods of startup, shutdown, or malfunction. Based on the calculated heat release rate (design heat capacity divided by furnace volume), the auxiliary boiler has a high heat release rate. (See attachment for calculation).
Monitoring §60.48b(b), (e), (f)	Install, calibrate, maintain, and operate a continuous emission monitoring system (CEMS) for measuring NO_x and O_2 (or CO_2) emissions discharged to the atmosphere, and record the output of the system. When NO_X emission data are not obtained because of CEMS breakdowns, repairs, calibration checks and zero and span adjustments, emission data will be obtained by using standby monitoring systems, Method 7 or 7A, or other approved reference methods to provide emission data for a minimum of 75 percent of the operating hours in each steam generating unit operating day, in at least 22 out of 30 successive steam generating unit operating days.
Recordkeeping §60.45b(k), §60.48b(b), and §60.49b(d)(1), (g), (h), (o), (p), and (r)	1) Record and maintain records of the amounts of natural gas combusted during each day and calculate the annual capacity factor for the reporting period. The annual capacity factor is determined on a 12-month rolling average basis with a new annual capacity factor calculated at the end of each calendar month. [§60.49b(d)] 2) Obtain and maintain fuel receipts (such as a current, valid purchase contract, tariff sheet, or transportation contract) from the fuel supplier that certify that the gaseous fuel meets the definition of natural gas and has a potential SO_2 emission rate of 140 ng/J (0.32 lb/MMBtu) heat input or less. [§60.45b(k) and §60.49b(r)] 3) Record the NO_x and O_2 (or CO_2) output of the CEMS. [§60.48b(b)] 4) For each auxiliary boiler operating day, record: a) Calendar date; b) The average hourly NO_X emission rates (expressed as NO_2) (ng/J or lb/MMBtu heat input) measured or predicted; c) The 30-day average NO_X emission rates (ng/J or lb/MMBtu heat input) calculated at the end of each steam generating unit operating day from the measured or predicted hourly NO_X emission rates for the preceding 30 steam generating unit operating days; d) Identification of the steam generating unit operating days when the calculated

Table C-1 40 CFR Part 60 Subpart Db Standards of Performance for Industrial-Commercial-Institutional Steam Generating Units	
	Auxiliary Boiler
	30-day average NO_X emission rates are in excess of the NO_X emissions standards, with the reasons for such excess emissions as well as a description of corrective actions taken; e) Identification of the steam generating unit operating days for which pollutant data have not been obtained, including reasons for not obtaining sufficient data and a description of corrective actions taken; f) Identification of the times when emission data have been excluded from the calculation of average emission rates and the reasons for excluding data; g) Identification of "F" factor used for calculations, method of determination, and type of fuel combusted; h) Identification of the times when the pollutant concentration exceeded full span of the CEMS; i) Description of any modifications to the CEMS that could affect the ability of the CEMS to comply with Performance Specification 2 or 3; and j) Results of daily CEMS drift tests and quarterly accuracy assessments as required under appendix F, Procedure 1 of 40 CFR Part 60. 5) Submit excess emission reports for any excess emissions that occurred during the reporting period. 6) Calculate a new annual capacity factor at the end of each calendar month (12-month rolling average). 7) Records shall be maintained for a period of two years following the date of the record.
Reporting §60.49b(a), (i), (r), (v), and (w)	1) Submit a notification of the date of initial startup and include the following: k) The design heat input capacity of the auxiliary boiler; l) Identification of the fuel to be combusted (natural gas); and m) Annual capacity factor anticipated for the auxiliary boiler based on all fuels fired. 2) Submit performance test data from the initial performance test and performance evaluation of the CEMS. 3) Submit reports containing the information above in Recordkeeping, paragraph 4. Reports shall be submitted to the Administrator certifying that only natural gas that is known to contain insignificant amounts of sulfur were combusted in the auxiliary boiler during the reporting period. 4) Submit written reports semi-annually (every six months). All reports submitted to the Administrator must be postmarked by the 30^{th} day following the end of the reporting period. 5) Quarterly electronic records of CEMS data or excess emissions reports may be submitted in lieu of semi-annual written reports.
Performance Test §60.46b(c), (e)(1) and (3)	Initial Compliance Test: Use the CEMS to monitor NO_X for 30 successive steam generating unit operating days. The 30-day average emission rate is used to determine compliance with the NO_x emission standards. The 30-day average emission rate is calculated as the average of all hourly emissions data recorded by the monitoring system during the 30-day test period. Following the initial compliance test, determine compliance with the NO_x standards on a continuous basis through the use of a 30-day rolling average emission rate. A new 30-day rolling average emission rate is calculated each steam generating unit operating day as the average of all of the hourly NO_x emission data for the preceding 30 steam generating unit operating days.

Jordan Cove
40 CFR 60 Subpart Db
Appendix C

Annual Capacity Factor

$$\text{Annual Capacity Factor} = \frac{\text{Actual Heat Input from Fuel}}{\text{Potential Heat Input to Boiler at 8,760 hr/yr}}$$

Actual Heat Input from Fuel								
Annual fuel consumption rate =	296.20	MMBtu/hr	x	876	hr/yr	=	259,471.20	**MMBtu/yr**

Potential Heat Input to Boiler at 8,760 hr/yr								
Potential heat input to boiler =	296.2	MMBtu/hr	x	8,760	hr/yr	=	**2,594,712.0**	**MMBtu/yr**

Annual Capacity Factor								
Annual Capacity Factor =	259,471	MMBtu/yr	/	2,594,712	MMBtu/yr	=	0.10	10%

Jordan Cove Energy Project is not taking a federally enforceable limit on the annual capacity factor of 10%.

Heat Release Rate

$$\text{Heat Release Rate} = \frac{\text{Boiler Design Heat Input Capacity}}{\text{Furnace Volume}}$$

Heat Release Rate								
Heat Release Rate =	296.2	MMBtu/hr	/	3,125	ft3	=	**94,784.0**	**Btu/hr-ft^3**

High Heat Release Rate is defined as a heat release rate greater than 70,000 Btu/hr-ft^3

Notes:

Heat input from fuel =	1024.6	Btu/scf
Project operating hours =	876	hr/yr
Boiler heat input capacity =	296.2	MMBtu/hr
Furnace volume (boiler specification sheet) =	3,125	ft^3

Re: Jordan Cove Energy Project L.P.
Jordan Cove LNG Terminal, Coos Bay, Oregon
Type B State New Source Review Dispersion Modeling Protocol

Dear Mr. Allen,

On behalf of Jordan Cove Energy Project, L.P., SLR International Corporation (SLR) is submitting a dispersion modeling protocol for a proposed Type B State New Source Review (NSR) permit modification application for the Jordan Cove LNG terminal located in Coos Bay, Oregon. Jordan Cove was issued the Prevention of Significant Deterioration (PSD) Air Contaminant Discharge Permit (ACDP) 06-0118-ST-01 on June 16, 2015. A technical permit modification application will be submitted to incorporate changes for the final design of the facility. Included in the protocol are:

- Project description and background
- Emissions data
- Regulatory applicability for a Type B State New Source Review project
- Methodology proposed for demonstrating compliance with the NAAQS and PSD increments in Class II areas
- Methodology proposed for addressing PSD Class I area requirements
- Methodology proposed for assessment of the potential for $PM_{2.5}$ and ozone secondary formation

Under separate cover Jordan Cove is submitting a White Paper on PSD applicability for LNG terminals to summarize research and findings on applicability and determinations for permitting of other LNG projects nationally.

The air quality analysis will be performed following approval of this protocol. After submission of the air permit modification application to DEQ, a copy of the complete application will be included in the FERC application Resource Report 9 (RR9) as an appendix. A version of the RR9 is being submitted to FERC this month which includes dispersion modeling results for a preliminary analysis performed to inform the design process. Those results will be replaced in a future RR9 version with the final air quality analysis results, when available.

We look forward to receiving your approval on the proposed methodologies contained within the dispersion modeling protocol. If you have questions, please contact Jason Reed at (970) 999-3970 or Meagan Masten at (541) 280-9099.

Sincerely,
SLR International Corporation

1. INTRODUCTION

Jordan Cove Energy Project, L.P. (JCEP) plans to construct and operate a natural gas liquefaction and export facility (LNG Terminal or Project) located on the bay side of the North Spit of Coos Bay, Oregon. The LNG Terminal will include five gas-fired turbine-driven compressors, an auxiliary boiler, emergency fire water booster pumps, backup engine generators, a thermal oxidizer, and three flares. Standard Air Contaminant Discharge Permit (ACDP) No. 06- 0118-ST-01 was issued for the Project, but due to facility design changes, a permit modification is sought. This dispersion modeling protocol proposes the analysis methodologies for the Standard ACDP Technical Modification application. An illustration of the area is provided in Figure 1-1 and an illustration of the site layout is provided in Figures 1-2A and 1-2B.

The LNG Terminal is located in Coos County, Oregon, which is in attainment or unclassified for all pollutants. The proposed Jordan Cove LNG Project has the potential to emit nitrogen oxides (NO_X), volatile organic compounds (VOC), carbon monoxide (CO), sulfur dioxide (SO_2), particulate matter (PM), particulate matter less than 10 micrometers (PM_{10}), particulate matter less than 2.5 micrometers ($PM_{2.5}$), and sulfuric acid mist (H_2SO_4) above Oregon Significant Emission Rates (SERs) but below the Prevention of Significant Deterioration (PSD) threshold of 250 tons per year.[1] Therefore, a Type B State New Source Review (NSR) air quality impact analysis will be conducted for CO, SO_2, PM_{10}, $PM_{2.5}$ and NO_X.

The air quality impact analysis will be conducted to demonstrate that predicted ambient air concentrations from NO_X, CO, SO_2, PM_{10}, and $PM_{2.5}$ emissions comply with the National Ambient Air Quality Standards (NAAQS) and PSD Increments, as they apply to Class I and Class II areas. The purpose of this modeling protocol is to obtain approval from the Oregon Department of Environmental Quality (DEQ) for the proposed modeling inputs and methodologies. NAAQS and PSD Increment modeling methodologies will follow DEQ and United States Environmental Protection Agency (EPA) modeling guidance as further described in this document.[1]

[1] OAR 340-224-0010(1)(a)(A) and 340-224-0010(2)(b)(A)

2. PROJECT DESCRIPTION

Jordan Cove Energy Project, L.P. (JCEP) is proposing to construct and operate a natural gas liquefaction and export facility (LNG Terminal or Project), located on the bay side of the North Spit of Coos Bay, Oregon. The Project would include a facility capable of liquefying natural gas and storing the liquefied natural gas (LNG) for export. Once completed, the Project facilities would be placed in service and natural gas would be delivered to the LNG Terminal via the proposed Pacific Connector Gas Pipeline, which would connect the Project with existing interstate natural gas pipeline systems.

Natural gas received at the LNG Terminal would be cooled into liquid form and stored in two 160,000 cubic meter (m^3) full-containment LNG storage tanks. The Project facilities would have the capability to allow export of 7.8 million metric tons per annum (MMTPA) via LNG carriers.

JCEP is proposing to utilize the following equipment at the LNG terminal:

- Five (5) combined-cycle natural gas turbines with duct burners
- One (1) Auxiliary boiler
- Three (3) liquefaction area fire pumps
- Four (4) emergency generators
- One (1) thermal oxidizer
- Three (3) flares

LNG carrier (LNGC) emissions are not part of the stationary source, but LNGC emissions and downwash will be included in the cumulative source emissions modeling as competing sources.

2.1 SOURCE EMISSION RATES

The potential annual emission rates for each criteria air pollutant from each source are shown in Table 2-1. The EPC contractor, KBJ, has completed the pre-FEED design stage of the project and is currently developing the detailed facility design.

Table 2-1 Stationary Source Criteria Air Pollutant Potential Emissions

Unit	PM/PM_{10}/ $PM_{2.5}$ (tpy)	SO_2 (tpy)	NO_X (tpy)	CO (tpy)	VOC (tpy)	H_2SO_4 (tpy)	Pb (tpy)	CO2e (tpy)
Turbines (with 4000 hours DB)	112.26	35.19	81.99	97.82	32.72	23.61	--	1,292,706
Turbines Startup/Shutdown	0.11	4.4E-03	0.23	0.73	0.10	--	--	188
Thermal Oxidizer	3.59	19.84	63.25	38.50	1.12	--	2.4E-04	624,730
Auxiliary Boiler	2.47	0.36	0.96	1.16	0.67	2.4E-01	6.4E-05	15,193
Fire-Water Pumps	9.0E-02	2.1E-03	1.59	0.80	4.5E-02	1.6E-04	2.1E-05	241
Generators	0.09	1.1E-02	4.81	0.49	0.13	8.7E-04	1.1E-04	1,280
Flares	0.36	3.7E-02	0.80	3.64	7.74	2.8E-03	6.8E-06	2,077
Gas Up	1.12	0.16	2.09	9.50	17.53	1.3E-02	2.1E-05	4,351
Fugitives	--	--	-	--	7.98	--	--	13,116
AIE	1.00	1.00	1.00	1.00	1.00	0.70		
Total Emissions	121.1	56.6	156.7	153.7	69.0	24.6	4.6E-04	1,953,883

Note: The LNGC emissions are not included in this table because they are not subject to federal or state stationary source permitting regulations.

2.2 REGULATORY APPLICABILITY

The LNG terminal was permitted as a PSD source under ACDP No. 06- 0118-ST-01 in 2015. The facility design included six 70 megawatt (MW) combined-cycle gas turbines to be operated at the South Dunes Power Plant. The Project was classified as a 'fossil fuel-fired steam electric plant of more than 250 million BTU/hour heat input.' Electricity was to be generated at the South Dunes Power plant to power the facility.

With the change in design to remove the power plant from the LNG Terminal, the source operations no longer fall within any of the listed 28 source categories, and the applicable PSD threshold is 250 tons per year of any regulated pollutant, excluding GHGs.[2]

The Project will have a fossil fuel-fired boiler capacity in excess of 250 MMBtu per hour heat input. One of the designated source categories for purposes of identifying Federal Major Sources is "fossil fuel fired boilers, or combination thereof, totaling more than 250 million BTU per hour heat input." Therefore, the fossil fuel-fired boiler must be evaluated to determine if it constitutes a Federal Major Source.[3]

Consistent with EPA guidance, the boiler is evaluated independently of the facility as a whole based on the boiler being a "nested source" or "source within a source." EPA guidance recognizes that listed source categories can exist within an unlisted source category. However, the presence of a listed source category does not make the entire facility subject to the 100 tpy threshold. As EPA has explained:

> In other words, a source subject to the 100 TPY applicability test that emits greater than 100 TPY is subject to the PSD requirements even if that source is located within a facility for which the primary activity is subject to a 250 TPY applicability threshold and emits less than 250 TPY. In this situation, only the source that exceeds its applicability threshold is subject to PSD, not the entire facility.[4]

This guidance means that the fossil fuel-fired boiler is subject to the 100 tpy PSD threshold while the parent facility is subject to the 250 tpy threshold. Emissions from the auxiliary boiler will not exceed 100 tpy. The auxiliary boiler is only planned to operate for up to 10 percent of any given year, except during the first year of facility commissioning. The auxiliary boiler emissions are compared to the PSD threshold in Table 2-2.

---

2 *See* White Paper on applicability of the Federal Major Source categories to LNG Facilities.
3 The duct burners on the turbines do not meet the definition for 'boiler' in EPA's NSPS rules. Therefore, the auxiliary boiler is the only unit to consider against the 250 MMBtu/hr threshold.
4 March 24, 1995, letter from EPA Region 3 to Henry Nickel on behalf of Consolidation Coal Company.

Table 2-2 Auxiliary Boiler Emissions Comparison to PSD Threshold

Source	NOX (tpy)	CO (tpy)	SO_2 (tpy)	VOC (tpy)	$PM_{10}/PM_{2.5}$ (tpy)
Auxiliary Boiler	0.96	1.16	0.36	0.67	2.47
Federal Major Source Threshold	100	100	100	100	100
PSD?	No	No	No	No	No

Jordan Cove does not need to request that DEQ impose a 99 tpy limit on emissions of any of the criteria pollutants from the fossil fuel-fired boiler at the facility. The auxiliary boiler PTE is below 100 tpy for all criteria pollutants. Because the criteria pollutant potential to emit from the fossil fuel-fired boiler will be limited to less than 100 tpy, the fossil fuel-fired boiler is not a Federal Major Source.

PSD only applies to a Federal Major Source. Because LNG terminals are not within any of the 28 listed source categories in OAR 340-200 0020(55), the Jordan Cove LNG Terminal emissions must be compared to the 250 tpy threshold to determine whether it is a Federal Major Source. As shown in Table 2-1, the potential to emit of the plant as a whole will be limited to less than 250 tpy for each regulated pollutant.

As neither the facility as a whole nor the fossil fuel-fired boiler qualifies as a Federal Major Source, the Jordan Cove LNG terminal is not subject to PSD program requirements. The project is subject to Type B State NSR requirements.

2.3 POLLUTANTS TO BE EVALUATED

JCEP is located in Coos County, which is currently designated as attainment or unclassified for all criteria pollutants. Because the project does not fall under any of the 28 categories of named sources in OAR-340-200-0020(66)(c), the applicable threshold for being considered a Federal Major Source is 250 tons per year of any individual regulated pollutant, excluding GHG. As shown in Table 2-1, the project does not have the potential to emit more than 250 tons of any one of these pollutants. Therefore, the Project is not a Federal Major Source. However, since the potential emissions of PM_{10}, $PM_{2.5}$, NOx, CO, SO_2, H_2SO_4, VOC, and GHG are greater than the Oregon SER, the proposed project is subjected to Type B State NSR and must meet the requirements of OAR 340-224-0270, *Requirement for Sources in Attainment and Unclassified Areas*.

The dispersion modeling analysis will therefore include an evaluation of PM_{10}, $PM_{2.5}$, CO, NO_X, SO_2, and VOC emissions to demonstrate compliance with their respective significance levels, NAAQS and PSD Increments, as applicable. The sulfuric acid mist is included in the $PM_{2.5}$ emission rates and not evaluated individually. VOC, SO_2, and NOx are considered precursors for pollutants ozone and $PM_{2.5}$ and will be evaluated using the latest federal modeling guidance for pollutants with secondary formation as described further in Section 4.

2.4 SOURCE LOCATION

The area surrounding the facility (within 3 kilometers) consists mainly of forested areas, sand dunes, and water bodies to the east, north, and west of the site with some industrial use along the bay to the south. The residential area of North Bend as well as North Bend Municipal Airport (currently known as the Southwest Oregon Regional Airport) is located to the south of the facility. Approximately 90 percent of the land uses within 3 kilometers of the facility consist of water, forest/undeveloped areas and sand dunes.

The graded elevation of the proposed facility site will vary from 30 to 60 feet above mean sea level (MSL). Topography proximate of the facility is relatively flat with elevations ranging from MSL to 160 feet above MSL within 1 kilometer of the site. To the east of the site lies some rolling terrain with hill top elevations ranging up to approximately 600 feet above MSL.

The proposed facility will be located at approximately 43.434024° North Latitude, 124.243219° West Longitude, North American Datum 1983 (NAD83). The approximate Universal Transverse Mercator (UTM) coordinates of the proposed facility are 399,383 meters Easting, 4,809,765 meters Northing, in Zone 10, NAD83.

2.5 STACK PARAMETERS

2.5.1 COMBUSTION TURBINES

JCEP proposes to use five (5) combustion turbines, each equipped with duct burner. The five turbines would be direct compressor-driver turbines located in the Ingram Yard area of the project. Each turbine is rated at 504.4 MMBtu/hr with an additional duct burner heat input of 19.7 MMBtu/hr, for a total input (HHV) of 524.1 MMBtu/hr per turbine. Twelve startups at 10 minutes per startup and twelve shutdowns at 9 minutes per shutdown will be modeled for each unit. Normal, full load operation is assumed for the remainder of the year. Additional information regarding the turbine parameters is shown in Table 2-3 and Table 2-4.

For the annual emissions, the modeled emission rate was determined by developing a weighted emission factor that encompasses the following operating scenarios to be encountered over the year:

- 8,760 hours of operation at full load and 42°F with 4,000 hours of duct burner firing
- 8,760 hours of operation at full load and 42°F without duct burner firing

From the scenarios and operating times discussed above, a weighted emission factor for the entire year of operation can be obtained. This weighted emission factor is then used over the entire year, minus the hours in which the turbine is in startup or shutdown, to determine the total annual emissions.

Table 2-3 Turbine Parameters with Duct Burner Firing

Stack Parameters				Potential Emission Rates			
Temperature (°F)	Velocity (ft/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
243	71	10	119	3.8	5.4	1.64	4.6

Table 2-4 Turbine Parameters without Duct Burner Firing

Stack Parameters				Potential Emission Rates			
Temperature (°F)	Velocity (ft/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
243	71	10	119	3.7	4.9	1.58	4.4

2.5.2 AUXILIARY BOILER

The natural gas-fired auxiliary boiler, with the maximum hourly heat input capacity of 269 MMBtu/hr, will be utilized during turbine startups. Total time of operation is conservatively estimated as 876 hours per year. Potential maximum hourly emissions and stack parameters for the auxiliary boiler are provided in Table 2-5 below.

Table 2-5 Auxiliary Boiler Stack Parameters and Emissions

Stack Parameters				Potential Emission Rates			
Temperature (°F)	Velocity (ft/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
330	49	6	100	2.18	5.63	0.83	2.66

2.5.3 OXIDIZER

The thermal oxidizer will be used to combust acid gas from the hydrogen sulfide removal process. The unit will have a maximum heat rate of 110 MMBtu/hr and operate 8,760 hours per year. Potential emissions and stack parameters for the thermal oxidizer are provided in Table 2-6 below.

Table 2-6 Oxidizer Stack Parameters and Emissions

Stack Parameters				Potential Emission Rates			
Temperature (°F)	Velocity (ft/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
1,600	42	9.5	131	14.44	0.82	4.53	8.79

2.5.4 FLARES

Three (3) separate flares will be used to handle gas relieved during emergency upset conditions. The design has warm and cold flares (a combined multi-point ground flare) and a marine flare (enclosed ground flare). However, emissions are not evaluated for emergency upset conditions because of the unpredictability and rarity of this occurrence. Emissions from the continuous operation of the pilot and purge gas on each flare will be included in the dispersion modeling.

If an LNG tanker arrives which requires cooling of the hull prior to LNG loading, hull gas must be vented. The inert gas and some methane is routed to the marine flare and combusted. Due to the intermittent nature of LNG gas up of warm interted LNGC events, the annualized emissions will be used in the dispersion modeling analysis. The stack parameters and potential hourly emissions for the flares are provided in Table 2-7 below for the marine flare. The gas-up annual emissions will also be included with this source.

Table 2-7 Marine Flare Stack Parameters and Emissions

Stack Parameters				Potential Emission Rates			
Temperature (K)	Velocity (m/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
ambient	negligible	45	100	0.04	0.017	0.0017	0.17

The flare parameters and potential hourly emissions for the multi-point ground flare, modeled as an area source, are provided in Table 2-8 below.

Table 2-8 Ground Flare Parameters and Emissions

Flare Parameters		Potential Emission Rates			
Area of Enclosure	Enclosure Height	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
259 ft x 227 ft	85 ft	0.14	0.065	0.0067	0.66

2.5.5 FIRE WATER PUMPS

Three (3) 700 hp fire water pumps will be placed in the liquefaction area. These pumps are expected to operate less than 1 hour per short-term period for reliability testing and maintenance and no more than 200 hours per year per pump. Stack parameters and potential hourly emissions for each fire water pump are provided in Table 2-9 below. Due to their intermittent nature, the annualized emissions will be used in the dispersion modeling analysis.

Table 2-9 Fire Water Pumps Stack Parameters and Emissions

Stack Parameters				Potential Emission Rates			
Temperature (°F)	Velocity (ft/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
948.3	193	0.67	18	5.31	0.30	0.0071	2.68

2.5.6 GENERATORS

JCEP proposes a total of four generators at the site. There will be two different types of generators at the site. Two of the generators will be black start generators and rated at 4,376 hp each, and the other two generators will be backup generators and rated at 1,214 hp each. Annual operation is not expected to exceed 200 hours per year per generator. Stack parameters and potential hourly emissions for the generators are provided in Tables 2-10 and 2-11 below. Due to their intermittent nature, the annualized emissions will be used in the dispersion modeling analysis.

Table 2-10 1,214 hp Backup Generator Stack Parameters and Emissions

Stack Parameters				Potential Emission Rates			
Temperature (°F)	Velocity (ft/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
952.5	287	0.67	13	16.63	0.19	0.012	1.42

Table 2-3 4,376 hp Black Start Generator Stack Parameters and Emissions

Stack Parameters				Potential Emission Rates			
Temperature (°F)	Velocity (ft/sec)	Stack Diameter (ft)	Stack Height (ft)	NO_X (lb/hr)	$PM_{10}/PM_{2.5}$ (lb/hr)	SO_2 (lb/hr)	CO (lb/hr)
873.6	177	1.67	13	7.43	0.23	0.044	1.04

3. CLASS II AIR QUALITY ANALYSIS

This section discusses the modeling methodology that will be used to demonstrate compliance with the NAAQS and PSD Increments in Class II Areas. The air dispersion modeling analysis will be organized into two tiers: a Significant Impact Analysis and a Full Impact Analysis. The techniques used in the air dispersion modeling analysis will be consistent with the modeling protocol discussion held on March 13, 2017 with Oregon DEQ, current EPA modeling guidelines, OAR 340, and other agency guidance as applicable.[5,6]

3.1 MODEL SELECTION AND INPUTS

SLR will use the latest version of the AERMOD modeling system (currently version 16216r) to perform the Class II analysis. AERMOD is the official guideline model for short-range (i.e., <50 km) analyses recommended in 40 CFR 51 Appendix W. Since the land use in a 3 km radius surrounding the proposed facility is rural in nature, the rural option will be used. All other model settings will be set to their default values.

3.1.1 UTM COORDINATE SYSTEM

The Coos Bay area of western Oregon is located in UTM Zone 10. All emission points, building, and receptor locations will be converted to UTM coordinates in Zone 10, North American Datum of 1983. Table 3-1 summarizes the coordinates and elevation of all emission sources included in the modeling.

[5] Code of Federal Regulations, Title 40-Protection of Environment, Part 51, Appendix W, January 17, 2017.

[6] The contents of a modeling analysis were discussed with Phil Allen (Oregon DEQ) on March 13, 2017 in Portland, Oregon. The methodology and inputs described herein are based on that discussion.

Table 3-1 Stationary Source UTM Coordinates

Source ID	Source Description	UTM Easting (meters)	UTM Northing (meters)	Elevation (meters)
Turb1	Turbine 1	397644.88	4809333.42	14

3.1.2 METEOROLOGICAL DATA

The surface data to be used in the analysis will be the five most-recent complete years of data collected at the Southwest Oregon Regional Airport (call sign KOTH), located at 43.419°N, 124.243°W, which is approximately 2 km southeast of the project site. The meteorological sensors at KOTH are Automated Weather Observing System (AWOS III)[7], which does not collect 1- or 5-minute data for use in the analysis. Upper air data from McNary Field in Salem, OR (44.92°N, 123.02°W) will also be used, which is approximately 197 km northeast of the project site. The period of meteorological data to be used is January 1, 2012 to December 31, 2016.

As detailed in the prior modeling assessment as part of the Prevention of Significant Deterioration (PSD) application, the surface meteorological data collected at the Southwest Regional Airport is temporally and spatially representative of the project location and areas of concern.[8] A topographic map with both the project site and the location of the AWOS instruments is provided in Figure 1-1. A windrose of the meteorological data is provided in Figure 3-1.

[7] https://www.faa.gov/air_traffic/weather/asos/?state=OR
[8] Jordan Cove Energy Project, L.P. PSD Air Permit Application, TRC, May 2013.

Since the instrumentation is a standard AWOS system, it does not collect atmospheric turbulence data for input into AERMET/AERMOD. As a result, this dataset meets the criteria for use of the AJD_u* model option[9], which is contained within the latest AERMET/AERMOD models as default, if invoked. SLR will review the processed meteorological datasets and will document and justify the use of this model option if it is invoked.

3.1.3 LAND COVER ANALYSIS

A land cover analysis will also be conducted to define the surface characteristics (surface albedo, Bowen ratio, and roughness length) for input into stage 3 of AERMET. The EPA-provided AERSURFACE program (version 13016) will be run with 1992 National Land Cover Data 1992 (NLCD92)[10] to generate surface characteristics for the area surrounding the meteorological site. The inputs to AERSURFACE are provided in Table 3-2 below. Figure 3-2 shows a plot of the NLCD92 data for the area surrounding the facility.

Table 3-2 Summary of AERSURFACE Inputs

Parameter	Value
Surface roughness study radius	1 km
Bowen ratio and albedo study region	10 km by 10 km
Vary by sector?	Yes, 12 sectors, each 30 degrees in width.
Temporal Resolution	Summer: June, July, August Autumn: September, October, November Winter: December, January, February Spring: March, April, May
Continuous snow-cover most of the winter?	No
Is the site near an airport?	Yes
Is the site an arid region?	No
Surface Moisture	TBD on a monthly basis

3.1.4 DOMAIN AND RECEPTOR GRIDS

Ground-level concentrations will be calculated within a nested, Cartesian receptor grid. The nested grids will cover an area extending up to 30 km from the proposed facility, but truncated over the Pacific Ocean. The grids will be defined as follows:

1) receptors spaced every 25 m along the facility fenceline;
2) receptors spaced every 25 m that extend 100 m from the facility fenceline;
3) receptors spaced every 100 m that extend from 100 m to 3 km;

[9] From the preamble to Title 40-Protection of Environment, Part 51, Appendix W, January 17, 2017 "the model performance and diagnostic evaluations strongly support the finding that the ADJ_U* option provides for an appropriate adjustment to the surface friction velocity parameter when standard National Weather Service (NWS) airport meteorological data".
[10] http://www.mrlc.gov/nlcd92_data.php

4) receptors spaced every 250 m that extend from 3 km to 5 km;
5) receptors spaced every 500 m that extend from 5 km to 20 km; and
6) receptors spaced every 1,000 m that extend from 20 km to 30 km.

The locations of the fenceline receptors and near-field gridded receptors are shown in Figure 3-3. Figure 3-4 illustrates the receptor grid out to 30 km. If the maximum concentration is predicted at any receptor in the coarse grids (greather than 100 m spacing) and is within 75% of an ambient standard, then, a refined grid with 100 m receptor spacing will be centered on the "hot spot".

3.1.5 TERRAIN DATA

Significant grading of the existing site is expected; therefore the graded elevations of the sources, buildings, fenceline and any ambient air receptors will be based on project-supplied information. For those areas outside of the graded area, terrain elevations for the receptors within the modeling domain will be taken from National Elevation Dataset (NED) terrain data using AERMAP (version 11103). All receptors, graded or not, will be run through AERMAP in order to obtain the appropriate scale heights. The NED data will be at a 1/3 arcsecond resolution, which translates into a resolution of approximately 10 meter spacing for the terrain.

3.1.6 DOWNWASH AND GEP STACK HEIGHT ANALYSIS

The effects of plume downwash will be considered for all stationary point sources. The effects of plume downwash will also be considered for the marine carriers when considered for the multisource modeling. Direction-specific building dimensions will be calculated using the current version of the EPA-approved Building Profile Input Program (BPIPPRM Version 04274). The site layout, dimensions and heights will be obtained from facility drawings. In addition to calculating direction-specific building dimensions, the BPIPPRM program also calculates the Good Engineering Practice (GEP) stack height. All facility stack heights will be checked to verify that they are within the GEP stack height limit.

3.2 BASELINE AIR QUALITY AND SIGNIFICANCE ANALYSIS

The first step in the air quality impact analysis will be to model the proposed project emissions and compare the maximum modeled concentrations to the applicable significant impact levels (SILs), provided in Table 3-3 below.[11] Comparison to these thresholds is used to determine the scope of the modeling analysis by pollutant/averaging period. However, use of the SILs in a tiered modeling analysis first requires an assessment of the background concentration relative to the ambient air quality standards i.e., the headroom; as well as recent emission changes in the nearby area. The headroom analysis (ambient standard minus background value with the difference compared to the SIL) is provided in Table 3-3 and demonstrates sufficient headroom to support the use of the SILs as protective of air quality. For this analysis, the NW AIRQUEST database was used as representative background data for the area. The NW AIRQUEST

[11] U.S. EPA, Office of Air Quality Planning and Standards, Guidance for PM2.5 Permit Modeling, May 20, 2014. This guidance describes the vacation of the $PM_{2.5}$ SILs and SMC for use in permitting analyses. However, the SILs in Table 3-1 are provided in OAR 340-200-0020(163) and will be used in this analysis based on an assessment of the headroom.

project used air quality observations and archived CMAQ model data from daily air quality forecast models from Idaho, Oregon, and Washington to compute the design values on a 12-km grid for the period of 2009-2011. The values were obtained from the grid cell representative of the proposed facility location (latitude 43.434, longitude -124.2538). The 2009 – 2011 NW AIRQUEST data are the most recent data available.

With regard to second criteria for using the SILs, SLR has reviewed the past three National Emission Inventory releases for years 2008, 2011, and 2014 for Coos County, Oregon to assess recent changes in local emission changes.[12] The emission summaries for the area are shown in Table 3-4 and reveal generally flat levels of emissions in the area, which indicates the NW AIRQUEST background values for the area should be considered temporally and spatially representative. It is noted that there is an increase in primary PM_{10} emission in 2014 over 2011; review of the data indicates there was a substantial increase (+8,000 tons) in 'miscellaneous' PM_{10} emissions in 2014.

[12] The Tier 1 summaries consolidate the emission inventory sectors into 14 main categories and can be summarized by county. https://www.epa.gov/air-emissions-inventories/national-emissions-inventory-nei

Table 3-3 Applicable Class II Significant Thresholds, Ambient Standards, and Headroom Analysis

Pollutant	Averaging Period	Applicable Thresholds	Applicable Standards[3]		NW AIRQUEST Background Data ($\mu g/m^3$)	Headroom ($\mu g/m^3$) [2] / Is Headroom > SIL?
		Class II SILs[1] ($\mu g/m^3$ or as noted)	NAAQS ($\mu g/m^3$ or as noted)	Class II PSD Increment ($\mu g/m^3$)		
SO_2	1-hour	8.0	196	--	3.1	193 / Yes
	3-hour	25.0	1,300	512	2.9	1,297 / Yes
	24-hour	5.0	262	91	2.9	259 / Yes
	Annual	1.0	52	20	1.1	51 / Yes
NO_2	1-hour	8.0	188	--	16	172 / Yes
	Annual	1.0	100	25	1.9	98 / Yes
CO	1-hour	2,000	40,000	--	755	39,245 / Yes
	8-hour	500	10,000	--	591	9,409 / Yes
Ozone	8-hour	1 ppb	70 ppb	--	46	24 / Yes
PM_{10}	24-Hour	1.0	150	30	35	115 / Yes
	Annual	0.20	--	17	--	--
$PM_{2.5}$	24-hour	1.2	35	9	9.9	25 / Yes
	Annual	0.2 | 0.3	12	4	6.7	5 / Yes

(1) OAR 340-200-0020(163) All SILS are based on the first highest concentration at any one location. For ozone, the SIL is proposed by EPA in Revised August 18, 2016 Guidance on Significant Impact Levels for Ozone and Fine Particulates in the Prevention of Significant Deterioration Permitting Program. For $PM_{2.5}$, the 0.2 $\mu g/m^3$ value is also from the August 18, 2016 guidance.

(2) Headroom values represent NAAQS minus NW AIRQUEST background data; the result is compared to the SILs for an assessment if the headroom is greater the SIL.

(3) The form of the standards are as defined in OAR 340-202

Table 3-4 Summary of Recent National Emission Inventories in Coos County, Oregon

Pollutant (tons/year)	2008	2011	2014
CO	104,684	103,304	94,009
NO_x	3,381	3,048	2,491
Primary PM_{10}	14,097	13,452	21,148
Primary $PM_{2.5}$	7,937	8,074	7,971
SO_2	572	558	513
VOC	41,783	38,850	44,262

3.2.1 OPERATING SCENARIOS

The potential operating scenarios for the turbines include normal operation and SU/SD. The support equipment will be held constant for both turbine scenarios. The scenario will include the following:

- Normal operation - where the turbine operates in normal mode (full load) for the entire period (short-term); and
- SU/SD mode - where the turbine undergoes start-up for a portion of the period (e.g., 10 minutes) and operates in normal mode for the remainder of the period (short-term).

The annual emissions scenario will include the total emissions from the expected number of startups and shutdowns plus normal operation for the remainder of the year. Any other project non-baseload source will also be considered in the development of modeled scenarios.

3.3 TIER I: PROJECT SIGNIFICANCE ANALYSIS

As noted above, the first step in the air quality impact analysis will be to model the proposed project scenarios with the worst-case equipment and compare the maximum modeled concentrations to the applicable Class II SILs. If the maximum modeled concentrations for a pollutant/averaging time are less than the applicable SILs, then no additional modeling is required for that pollutant/averaging period. If the maximum modeled concentrations for a pollutant/averaging time are equal to or above the SIL, then a tier 2 analysis for NAAQS and Class II PSD increment compliance is required for that pollutant/averaging time. This modeling step is also used to determine the Source Impact Area (SIA) of the proposed source, by pollutant/averaging period. The SIA is any location with a predicted concentration equal to or above the SIL, defined for each pollutant and averaging period. In the event that there are no predicted significant impacts, the SIA is zero. Once the SIA is determined, it will be provided to DEQ in order for the offsite source inventory to be updated, if needed.

3.4 TIER 2: REFINED ANALYSIS

For those pollutants/averaging periods shown to have a significant impact, a refined air quality analysis will be conducted to demonstrate compliance with the NAAQS and Class II PSD increments. The same project operating scenario/equipment configuration used in the SIL analysis will be combined with the DEQ-provided competing source inventory as defined following OAR 340-225. In addition, LNGC emissions will be included in the cumulative impact analyses, similar to the prior modeling demonstration. For the NAAQS analysis, background air quality concentrations will be added to the project and competing source inventory modeled impacts; background will not be added for the increment analysis. The background values shown in Table 3-3 will be used for the NAAQS analysis.

3.5 CHEMICAL TRANSFORMATION

3.5.1 NO_2 FORMATION

The modeling analysis will follow the tiered approach described in the latest EPA guidance:

- The first Tier will assume a full, 100% conversion of NO_x to NO_2.
- If needed, the second tier will utilize the ambient ratio method (ARM2) method implemented and documented per EPA guidance.
- If needed, the third tier will utilize the Ozone Limiting Method (OLM) or Plume Volume Molar Ratio Method (PVMRM) implemented and documented per EPA guidance.

3.5.2 $PM_{2.5}$ AND OZONE FORMATION

In consultation with DEQ, the draft EPA guidance on addressing secondary formation of $PM_{2.5}$ and ozone will be used to develop a project-specific evaluation of the potential impacts from these VOC, SO_2, and NOx.[13,14] Project emissions will be compared to the information provided in the EPA guidance for Maximum Emission Rates for Precursors (MERPs). This EPA guidance is based on a suite of photochemical modeling runs across the continental U.S. designed to assess secondary ozone and $PM_{2.5}$ formation from various, hypothetical sources. These runs were used to establish modeled responses to precursor emissions, which can be used to determine:

- emission thresholds below which insignificant secondary formation is expected to occur and
- secondarily-formed downwind concentrations of ammonium sulfate, ammonium nitrate or ozone from emitted precursors.

The first step of the guidance is to compare Project emissions to the emission thresholds. Since the Project emits more than one precursor pollutant, an additional calculation is needed to account for the combined effect of the precursors. This is accomplished by adding ratios (project emissions divided by an emission threshold) for each precursor together. If the

[13] Guidance on the Development of Modeled Emission Rates for Precursors (MERPs) as a Tier 1 Demonstration Tool for Ozone and PM2.5 under the PSD Permitting Program, December 2016.

[14] Distribution of the EPA's modeling data used to develop illustrative examples in the draft Guidance on the Development of Modeled Emission Rates for Precursors (MERPs) as a Tier 1 Demonstration Tool for Ozone and PM2.5 under the PSD Permitting Program, February, 2017.

combined ratios of the precursors are greater than one, then significant secondary formation is possible and needs to be quantified.

The second use of the guidance allows for quantification of the secondary formation. Since the EPA modeling was for a limited number of sources, several inputs were varied by EPA to obtain more robust model responses. The inputs that were varied include stack height and parameters, precursor emission levels, and inherently based on the source's location, regional emissions and geophysical characteristics (i.e., climate, terrain, proximity to other large sources or cities). If the quantification of secondary effects is required, Appendix A of the EPA guidance will be reviewed to find a source-impact relationship that is representative of the Project. Representativeness will be determined by stack parameters, emission levels, local/regional emissions, and geophysical environment.

Table 3-5 compares the lowest (most conservative) ozone emission threshold values for NOx and VOCs in the Western U.S to Project emissions. Since both NOx and VOC are emitted, the combined effect is accounted for as shown in Table 3-5. Following the draft EPA guidance, since the sum of the combined ratios (project emissions/emission threshold value) for each precursor is less than a value of 1, significant ozone concentrations will not be generated from the Project.

Table 3-5 Summary of MERPs Analysis for Ozone

Precursor	Project Emissions (tpy)	8-hr O3 MERP (tpy) [1]	Ratio of Project Emissions to Daily Ozone MERP	Sum of Ratios
NOx	155.0	184	0.84	0.91
VOC	72.5	1,049	0.07	

[1] These are the most conservative (lowest) MERP values for ozone in the Western U.S. as summarized in the February 23, 2017 memorandum.

A similar analysis for daily and annual $PM_{2.5}$ is shown in Tables 3-6 and 3-7, respectively. The approach for secondary $PM_{2.5}$ formation from NOx and SO_2 emissions is the same as ozone, but $PM_{2.5}$ also needs to include direct $PM_{2.5}$ impacts as modeled in AERMOD.[15] As shown in Tables 3-6 and 3-7, insignificant secondary formation is expected to occur for both daily and annual $PM_{2.5}$. However, if Project direct $PM_{2.5}$ impacts (i.e., modeled in AERMOD) are above the significant impact level, then the reported $PM_{2.5}$ will include the expected secondary formation using representative modeled responses in Appendix A of the EPA guidance as discussed further below.

[15] Total $PM_{2.5}$ is the sum of direct $PM_{2.5}$ plus secondary $PM_{2.5}$. Direct $PM_{2.5}$ emissions and downwind impacts are modeled in AERMOD. The secondary formation of Project NOx and SO_2 emissions into $PM_{2.5}$ is crux of the MERPs guidance.

While the lowest (most conservative) emission thresholds are useful for screening project emissions, they are not necessarily representative of potential secondary formation due to Project emissions. For instance, the sources with the lowest SO_2 and NOx emission thresholds are in interior California, which is not representative of the climatology or source environment of the proposed Project. Furthermore, both of these sources were modeled with 'low' source heights (release height of 1 m), which is not representative of Project sources.

The summarized modeling results for 24-hour average concentrations of secondary formation for precursor SO_2 and NOx in Appendix A of the modeling guidance was further reviewed. The data was sorted to only include:

- sources located in Oregon or Washington (considered to be more representative of climate at the Project site);
- Precursor emissions of 500 tpy (similar in magnitude, yet conservative, to Project emissions); and
- And 'high' stack heights (similar to Project sources).

The results of this analysis are summarized in Table 3-8. Taking the two highest modeled responses, 0.15 $\mu g/m^3$ and 0.24 $\mu g/m^3$ for NOx and SO_2, respectively, the combined potential secondary formation from Project emissions is 0.39 $\mu g/m^3$.

Table 3-6 Summary of MERPs Analysis for Daily $PM_{2.5}$

Precursor	Project Emissions (tpy)	Daily $PM_{2.5}$ MERP (tpy) [1]	Ratio of Project Emissions to Daily $PM_{2.5}$ MERP	Sum of Ratios
Direct $PM_{2.5}$	AERMOD			0.34
NOx	155.0	1,075	0.14	
SO_2	40.2	210	0.19	

[1] These are the most conservative (lowest) MERP values for ozone in the Western U.S. as summarized in the February 23, 2017 memorandum.

Table 3-7 Summary of MERPs Analysis for Annual $PM_{2.5}$

Precursor	Project Emissions (tpy)	Annual $PM_{2.5}$ MERP (tpy) [1]	Ratio of Project Emissions to Annual $PM_{2.5}$ MERP	Sum of Ratios
Direct $PM_{2.5}$	AERMOD			0.07
NOx	155.0	2,289	0.05	
SO_2	40.2	3,184	0.02

4. CLASS I AIR QUALITY ANALYSIS

Federal Class I areas are afforded the highest level of protection under the Clean Air Act. As such, the Class I area analysis for Type B State NSR projects includes the assessment of ambient impacts in terms of pollutant concentrations. The model inputs and scenarios described in Section 3 will be used for the Class I analyses for all Class I areas located within 200 km from the project location (provided in Table 4-1 below).

Table 4-1 Distance to Class I Areas

Class I Area	State	Distance (km)
Crater Lake National Park	OR	165
Redwood National Park	CA	177
Kalmiopsis Wilderness Area	OR	110
Diamond Peak Wilderness Area	OR	165
Three Sisters Wilderness Area	OR	178

There are no Class I areas within 50 km of the project.

4.1 Q/D SCREENING ANALYSIS

An air quality related values (AQRV) analysis is not required for a Type B State NSR project, but is required as part of other regulatory requirements the Project will be required to meet.[16] Therefore for consistency and informational purposes a Q/D calculation for regional haze and deposition will be used to screen for the air quality related values (AQRVs).[17] The screening analysis is based on distance from the source to the Class I area and the annualized daily emissions of AQRV-impacting pollutants. If the Q/D analysis results are less than or equal to the screening factor of 10, then FLM agencies do not require any further Class I AQRV impact analyses from those sources.

Using the emissions summarized in Table 2-1 for the visibility impairing pollutants of NOx, SO_2, PM, and H_2SO_4 the calculated Q value is 327.6. Using the shortest distance, D, from Table 4-1 above, the Q/D value is calculated to be 2.98, which is below the threshold value of 10.

4.2 CLASS I SIGNIFICANCE ANALYSIS

An assessment of project impacts in comparison to the Class I significant impact level for the Class I PSD increments will be run using AERMOD as a screening tool. Receptors will be

[16] The 2017 FERC analysis requirements specify that visibility impacts at Class I areas must be considered.
[17] U.S. Forest Service – Air Quality Program, National Park Service – Air Resources Division, U.S. Fish and Wildlife Service – Air Quality Branch, *Phase I Report of the Federal Land Managers' Air Quality Related Values Workgroup (FLAG)- Revised*, Section 3.2. October 2010.

placed at a distance of 50 km from the project in arcs that will be located to capture plume impacts in the direction of each Class I area. The elevation of the receptors will be based on the actual elevation of each receptor location as determined by AERMAP and standard NED data. Results from the screening modeling will be compared to the Class I SILs defined in the OAR and proposed by EPA, which are listed in Table 4-2, below. Similar to the Class II analyses, direct $PM_{2.5}$ impacts from AERMOD at 50 km will be added to the representative secondary formation discussed in Section 3.5.2, if applicable.

If Project impacts are above the Class I SILs then a qualitative approach will be developed to demonstrate that Project impacts will be less than the Class I SILs at the actual distance of the Class I areas.

Table 4-2 Class I Significant Impact Levels and PSD Increments

Pollutant	Averaging Period	OAR Class I SILs(1) (μg/m³)	EPA Class I SILs(2) (μg/m³)	Class I Increments(3) (μg/m³)

Subject: **Applicability of the Prevention of Significant Deterioration Enumerated Source Categories to Natural Gas Liquefaction Facilities**

This paper addresses whether natural gas liquefaction facilities are, per se, within one of the 28 source categories listed in the Clean Air Act ("CAA" or "the Act") that are subject to the Prevention of Significant Deterioration ("PSD") program if they emit 100 tons per year or more of a regulated pollutant. This paper also summarizes recent permits issued to natural gas liquefaction facilities in the United States, and discusses whether, and on what basis, the relevant state agencies evaluated whether the facility was subject to the PSD program.

A. Summary

As further discussed below, LNG liquefaction facilities are not, per se, within one of the 28 source categories listed in the CAA that are subject to the PSD program if they emit 100 tons per year ("tpy") or more of a regulated pollutant. In its regulations and guidance documents, EPA has not concluded that LNG liquefaction facilities are per se within one of the 28 source categories listed in the Act. A review of recent permitting decisions for other LNG liquefaction facilities has reached the same conclusion.

B. Background

Under the CAA, certain facilities are subject to the PSD program if they emit, or have the potential to emit, one hundred tpy or more of any air pollutant.[1] Other sources not specifically listed in the CAA are subject to the PSD program if they emit, or have the potential to emit, two hundred and fifty tpy or more of any air pollutant.[2] The 28 source categories that are subject to the 100 tpy limit are listed in the Act and its implementing regulations.[3]

The list of 28 source categories included in the Act and its implementing regulations was derived from a list that EPA included in an early PSD rulemaking. In 1974, before Congress amended the Clean Air Act to include the PSD program, EPA issued a final rule that established an early version of the PSD program.[4] In that final rule, EPA included a list of 18 source

---

[4] 39 Fed. Reg. 42,510 (Dec. 5, 1974).

categories that would be subject to the early PSD program.[5] When Congress amended the Clean Air Act in 1977 to include the PSD program, it relied on the list of 18 sources included in EPA's earlier rule and added ten additional sources to that list.

The 28 source categories listed in the Act and in EPA's PSD regulations are not clearly defined in the statute or regulations. EPA has acknowledged this and has explained that where a facility does not clearly fall into any of the 28 categories, the facility should consult the definitions in EPA's New Source Performance Standards ("NSPS") regulations to determine whether the facility is a listed source.[6] EPA has also clarified the meaning of many of the 28 source categories in guidance documents.

C. Listed Source Categories

As described in more detail below, under the Act, EPA regulations, and EPA guidance documents, LNG liquefaction facilities have not per se been considered to be included under one of the 28 listed source categories for purposes of PSD applicability. An analysis of certain listed source categories is presented below. The remaining source categories would not apply to LNG liquefaction facilities.

1. Fuel Conversion Plants

Nothing in the Act, EPA regulations or EPA Guidance suggest that an LNG liquefaction facility is a "fuel conversion plant" for purposes of PSD applicability. The Act, the PSD regulations, and the NSPS regulations do not define "fuel conversion plant." However, EPA has explained in guidance that a facility is a "fuel conversion plant" if it changes the state (e.g., solid to gas) or form (e.g., coal gasification, oil shale processing, conversion of waste to fuel gas and processes saw dust into pellets) of a fuel.[7] However, even if a facility changes the state of a fuel (e.g., liquid to gas), it is not a fuel conversion plant if the change requires only minimal processing.[8]

EPA has specifically considered whether LNG vaporization facilities are "fuel conversion plants" for purposes of PSD applicability. In a 2003 guidance document, EPA examined whether a facility that converted LNG into natural gas was a "fuel conversion plant" under the PSD program.[9] EPA explained that, while the facility did change the state of the fuel (liquid to gas), it did so with only minimal processing.[10] EPA stated that the facility was not a "fuel conversion plant" because converting LNG into natural gas could be done "without the need for

[9] *Id*.
[10] *Id*.

chemical or process change that generally occurs at other sources that EPA considers as 'fuel conversion plants' (e.g., coal gasification, oil shale processing, conversion of municipal waste to fuel gas, processing of sawdust into pellets) under the PSD rules."[11]

For the same reasons described by EPA in its 2003 guidance, an LNG liquefaction facility (converting natural gas to liquid) is not a "fuel conversion plant." Like converting LNG to natural gas, converting natural gas to LNG does not require significant chemical or process changes. Both LNG vaporization facilities and LNG liquefaction facilities rely on changing the temperature of the fuel to convert it from one state to another, and neither requires any other chemical or process changes. As a result, like an LNG vaporization facility, an LNG liquefaction facility would not be considered a "fuel conversion plant" for purposes of PSD applicability.

2. Petroleum Storage and Transfer Facility

Nothing in the Act, EPA regulations or EPA Guidance suggest that an LNG liquefaction facility is a "petroleum storage and transfer facility" for purposes of PSD applicability. The Act, the PSD regulations, and the NSPS regulations do not define "petroleum storage and transfer facility." The NSPS regulations do, however, define "petroleum" as "the crude oil removed from the earth and the oils derived from tar sands, shale, and coal."[12] EPA has further stated that a facility that stores or transfers gasoline is not considered a "petroleum storage and transfer facility."[13] In its guidance, EPA explained that "it is our determination that the named category [petroleum storage and transfer facility] was limited to crude oil and not its refined products."[14] Because an LNG liquefaction facility does not store "petroleum," it is not a "petroleum storage and transfer facility" for purposes of PSD applicability.

3. Petroleum Refinery

Nothing in the Act, EPA regulations or EPA Guidance suggest that an LNG liquefaction facility is a "petroleum refinery" for purposes of PSD applicability. Neither the Act nor the PSD regulations define "petroleum refinery." The NSPS regulations define "petroleum refinery" as "any facility engaged in producing gasoline, kerosene, distillate fuel oils, residual fuel oils, lubricants, asphalt (bitumen) or other products through distillation of petroleum or through redistillation, cracking or reforming of unfinished petroleum derivatives. A facility that produces only oil shale or tar sands-derived crude oil for further processing at a petroleum refinery using only solvent extraction and/or distillation to recover diluent is not a petroleum refinery."[15] An LNG liquefaction facility does produce petroleum products through distillation, cracking or reforming. Because an LNG liquefaction facility does not meet the definition of "petroleum refinery" under the NSPS regulations, it is not a "petroleum refinery" for purposes of PSD applicability.

[14] *Id*.
[15] 40 CFR § 60.101a.

4. Fossil Fuel-Fired Steam Electric Plant

Nothing in the Act, EPA regulations or EPA Guidance suggest that an LNG liquefaction facility is a "fossil fuel-fired steam electric plant" for purposes of PSD applicability. The Act, the PSD regulations, and the NSPS regulations do not define "fossil fuel-fired steam electric plant." However, EPA's initial PSD program and the legislative history of the Act indicate that this source category was intended to cover large electric power plants, not LNG liquefaction facilities even if electricity is produced.

As described above, the list of 28 source categories in the CAA and in the current PSD regulations was derived from a list that EPA established in an earlier version of the PSD program. In the Federal Register notices promulgating that earlier rule, EPA explained that the list of source categories was intended to include the largest emitters in the nation.[16] In the proposed rule, EPA stated that the listed source categories "account for approximately 30 percent of the particulate matter and 75 percent of the sulfur dioxide emitted" each year.[17] Similarly, in a technical support document that was part of the PSD rulemaking, EPA stated that the listed source categories were "the largest present emitters of SO2 and [total suspended particulates] on a nationwide basis."[18] At the time of EPA's initial rulemaking in 1974, there were few (if any) operating LNG liquefaction facilities. There is nothing in EPA's supporting documents which suggests that EPA intended to regulate under this category LNG liquefaction facilities.

Further, rulemaking documents confirm that the source category "fossil fuel-fired steam electric plant" was intended to cover large power plants. In a technical support document prepared as part of the PSD rulemaking, EPA repeatedly refers to "fossil fuel-fired steam electric power plants" when discussing various aspects of the rule.[19] While the regulations remove the term "power" in the list of covered sources, this rulemaking document confirms that EPA understood this category to cover what are commonly thought of as electric power plants.

Similarly, the legislative history of the 1977 amendments to the CAA, which formalized the PSD program, indicate that the source category "fossil fuel-fired steam electric plant" was understood to cover large electric power plants. In Congressional debate over the proposed amendments, the representatives repeatedly discuss the impact of the proposed amendments on the construction of large power plants.[20]

While EPA has issued a few short guidance documents describing the meaning of "fossil fuel-fired steam electric plant," it has not found that LNG liquefaction plants are part of this source category. In a 1987 applicability determination, EPA concluded that certain equipment that was ancillary to a gas turbine should be considered when determining whether the turbine

---

[16] 38 Fed. Reg. 18,986, 18,989 (July 16, 1973); U.S. EPA, TECHNICAL SUPPORT DOCUMENT – EPA REGULATIONS FOR PREVENTING THE SIGNIFICANT DETERIORATION OF AIR QUALITY, EPA-450/2-75-001 (Jan. 1975) [hereinafter "Technical Support Document"].

[19] *See* e.g., Technical Support Document at 34 (emphasis added).
[20] *See* e.g., 123 Cong. Rec. 18,154 (June 9, 1977).

satisfied the 250 mmbtu heat input requirement for this source category.[21] EPA did not, however, describe the facility in which the turbine was located or describe whether and why the facility was considered a "fossil fuel-fired steam electric plant." EPA only addressed the narrow issue of what ancillary equipment should be considered when calculating the heat input of a "fossil fuel-fired steam electric plant."[22] Similarly, in a 1993 applicability determination, EPA concluded that gas turbine combined cycle cogeneration plants could be considered "fossil fuel-fired electric plants," but did not discuss whether that determination extended to combined cycle cogeneration plants at LNG liquefaction facilities.[23] In a 1978 applicability determination, EPA concluded that a steam generating unit that produced electricity could be considered a "fossil fuel-fired steam electric plant" even if it was not part of a large power plant.[24] This determination from almost forty years ago, however, does not address whether gas turbines used to drive compressors that do not directly generate electricity would be considered "fossil fuel-fired steam electric plants." The applicability determination was also issued when there were very few, if any, LNG liquefaction facilities in the United States and does not address whether LNG liquefaction facilities are considered part of this source category.

Finally, turbines used at LNG liquefaction facilities are used to drive compressors for refrigeration and do not produce electric output through the shaft work to drive generators. Therefore the turbines do not produce electricity and would not be considered a "fossil fuel-fired steam <u>electric</u> plant" for purposes of PSD applicability. As a result, an LNG liquefaction facility would not be considered a "fossil fuel-fired steam electric plant" for purposes of PSD applicability.

5. <u>Fossil-Fuel Boilers and LNG Gas Turbines with Duct Burners</u>

Nothing in the Act, EPA regulations or EPA Guidance suggest that gas turbines with duct burners at an LNG liquefaction facility qualify as "fossil-fuel boilers" for purposes of PSD applicability. Neither the Act nor the PSD regulations define "fossil fuel boilers of more than [250 mmbtu] per hour heat input." However, the NSPS regulations define "boiler" as "any enclosed device that extracts useful energy in the form of steam."[25] The term boiler does not include "duct burners." In contrast, a duct burner is "a device that combusts fuel and that is placed in the exhaust duct from another source, such as a stationary gas turbine, internal combustion engine, kiln, etc., to allow the firing of additional fuel to heat the exhaust gases before the exhaust gases enter a heat recovery steam generating unit."[26] When a duct burner is connected to and part of a combined cycle gas turbine, it is considered part of the gas turbine

---

[24] Letter from Director, U.S. EPA Division of Stationary Source Enforcement to Thomas W. Devine, Chief, U.S. EPA Region I Air Branch (Feb. 13, 1978, *available at* https://www.epa.gov/sites/production/files/2015-07/documents/m021378.pdf.
[25] 40 C.F.R. §§ 60.561, 60.611, 60.661.
[26] 40 C.F.R. § 60.41Da.

and is regulated as part of the turbine under NSPS Subpart KKKK, and is explicitly exempted from the NSPS requirements for boilers.[27],[28]

To the extent that an LNG liquefaction facility uses a combined cycle gas turbine with an attached duct burner to drive the refrigeration compressor and also has a fossil-fuel fired boiler on site, the heat input capacity of the duct burner is not combined with the boiler to determine whether the 250 mmbtu heat input threshold is met. As described above, a duct burner is not a boiler and should not be considered when determining the heat input of the boiler. Similarly, if the duct burner is not even attached to the boiler, it would be inappropriate to consider the heat input of the duct burner when determining PSD applicability with respect to the boiler. As a result, an LNG liquefaction facility using gas turbines with duct burners to drive refrigeration compressors would not be considered a "fossil-fuel boiler" for purposes of PSD applicability.

6. Sulfur Recovery Plants

Nothing in the Act, EPA regulations or EPA Guidance suggest that gas treatment systems at an LNG liquefaction facility qualify as "sulfur recovery plants" for purposes of PSD applicability. Neither the Act nor the PSD regulations define "sulfur recovery plants." Under EPA's NESHAPs regulations a "*Sulfur recovery unit*" means "a process unit that recovers elemental sulfur from gases that contain reduced sulfur compounds and other pollutants, usually by a vapor-phase catalytic reaction of sulfur dioxide and hydrogen sulfide. This definition does not include a unit where the modified reaction is carried out in a water solution which contains a metal ion capable of oxidizing the sulfide ion to sulfur, e.g., the LO-CAT II process."[29] Similarly, sulfur recovery as defined by AP-42 refers to the conversion of hydrogen sulfide to elemental sulfur.[30] Gas treatment systems at LNG liquefaction facilities treat the natural gas to reduce hydrogen sulfide followed by a carbon dioxide removal process using a primary amine process to remove CO_2 and a dehydration system to remove water and mercury. The remaining acid gas is typically sent to a thermal oxidizer for combustion. Elemental sulfur is not recovered. Because the gas treatment systems at an LNG liquefaction facility do not recover sulfur, an LNG liquefaction facility is not a "sulfur recovery plant" for purposes of PSD applicability.

7. Chemical Process Plants

Nothing in the Act, EPA regulations or EPA Guidance suggest that an LNG liquefaction facility is a "chemical process plant" for purposes of PSD applicability. The Act, the PSD regulations, and the NSPS regulations do not define "chemical process plant." Chemical process plants are described in the SIC manual, and cited in EPA applicability determination, as "establishments producing basic chemicals, and establishments manufacturing products by predominantly chemical processes." The SIC manual notes these facilities manufacture three general classes of products: "(1) basic chemicals, such as acids, alkalines, salts, and organic chemicals; (2) chemical products to be used in further manufacture, such as synthetic fibers, plastics materials, dry colors and pigments; and (3) finished chemical products to be used for

[27] 40 C.F.R. § 60.4305(a).
[28] Note that duct burners installed on turbines not subject to NSPS Subpart KKKK can be subject to other NSPS regulations but have not been considered to be "boilers" as is referenced in the PSD listed source category.
[29] 40 C.F.R. § 63.1579.
[30] AP-42, Section 8.13 (7/93, reformatted 1/95).

ultimate consumption, such as drugs, cosmetics, and explosives."[31] The purpose of a LNG liquefaction facility is to liquefy natural gas by refrigeration, not manufacture the types of chemicals described above. Liquefying natural gas is not a process included in the list described in the SIC manual. For these reasons, an LNG liquefaction facility would not be considered a "chemical process plant" for purposes of PSD applicability.

D. LNG Facility Permit Review

As described above, an LNG liquefaction facility does not, per se, fall within one of the 28 source categories listed in the Act. Several permitting authorities have recently reached the same conclusion and found that LNG liquefaction facilities are not listed sources subject to the 100 tpy threshold for purposes of the PSD program. The discussion below examines PSD permits that were recently issued to LNG liquefaction facilities and confirms that the permitting authorities did not treat the LNG liquefaction facilities as being within one of the 28 listed source categories. No permitting decisions have been located that reached a different conclusion.

1. <u>Port Arthur LNG, LLC, TX, Permit Numbers 131769, PSDTX1456, and GHGPSDTX134</u>

Port Arthur LNG, LLC received a PSD permit on February 17, 2016 for the proposed construction and operation of a natural gas liquefaction and export terminal near Port Arthur, Jefferson County and the Sabine Pass in Southeast Texas. The proposed liquefaction plant will consist of two liquefaction trains, each capable of producing 5.0 MMTPA of LNG. Each LNG train will consist of one propane and one mixed refrigeration compression turbine and an Acid Gas Removal Unit.

The facility will be located in Jefferson County, which is classified as an attainment or unclassified area for all criteria pollutants. The major source threshold of 250 tpy was used for the PSD applicability of this project.

2. <u>Golden Pass Products LLC, TX, Permit Numbers 116055 and PSDTX1386</u>

Golden Pass Products, LLC received a PSD permit on January 16, 2015 for the proposed construction and operation of a natural gas liquefaction and export plant near the Sabine Pass in Southeast Texas. The proposed liquefaction plant will consist of three liquefaction trains. Each train will consist of two gas-fired refrigeration compressor turbines equipped with heat recovery steam generating units.

The facility will be located in Jefferson County, which is classified as an attainment or unclassified area for all criteria pollutants. The major source threshold of 250 tpy was used for the PSD applicability of this project.

---

[31] Letter dated August 8, 1997 from Carla E. Pierce, Chief, Operating Source Section, U.S. EPA Air & Radiation Technology Branch, to Chun-chi S. Liu, Mecklenburg County Department of Environmental Protection

3. Corpus Christi Liquefaction Stage III, LLC, TX, Permit Numbers 139479, PSDTX1496, and GHGPSDTX157

Corpus Christi Liquefaction Stage III, LLC received a PSD permit on February 14, 2017 for the proposed construction and operation of two new LNG trains, including 12 natural gas compressor turbines, at a preexisting facility in San Patricio County, TX. The original construction at the facility (Permits 70741 and PSDTX1038) was for an LNG import terminal, while the proposed new trains are for natural gas compression. Since the construction is to occur at a pre-existing facility, the permit application was considered under the "major modification" rules and is not relevant for determining whether a new LNG liquefaction facility is one of the 28 listed source categories.

4. Freeport LNG Pretreatment Facility, TX, Permit Numbers 100114, N150, and PSDTX1282

Freeport LNG Development, L.P. received a PSD permit on March 24, 2015 to construct and operate a natural gas liquefaction plant at the site of an existing LNG import terminal near Freeport, Texas. Since the liquefaction plant is proposed at a pre-existing facility, the permit application was considered under "major modification" rules and is not relevant for determining whether a new LNG liquefaction facility is one of the 28 listed source categories.

5. Elba Island LNG Terminal, GA, Permit 4922-051-0003-V-05-0

Kinder Morgan, Inc. proposed to construct the Elba Liquefaction Terminal, an LNG export terminal, at the site of a pre-existing LNG import terminal in Chatham County, Georgia near the city of Savannah. Because the liquefaction terminal was proposed at a pre-existing facility, the permit application was considered a "major modification" and is not relevant for determining whether a new LNG liquefaction facility is one of the 28 listed source categories.

However, the facility's most recent Title V Renewal Application Review (dated April 21, 2014) explains that the facility is not within one of the 28 listed source categories and that the 250 tpy standard is the appropriate standard to use in determining whether the facility is a Federal Major Source for PSD purposes. According to the renewal application, the facility had been subject to the 100 tpy standard at one time because its combined boiler capacity was greater than 250 MMBtu/hr. However, because the combined boiler capacity at the time of the Title V renewal had dropped below 250 MMBtu/hr, the 100 tpy standard no longer applied. This is significant because it confirms that there was nothing other than the boiler capacity that caused the facility to be designated as one of the 28 listed sources.

6. Sabine Pass LNG Terminal, LA, Permit PSD-LA-703(M3, M4, M5)

Sabine Pass LNG has been granted several modifications to its existing PSD permit to allow the construction of natural gas liquefaction facilities at a pre-existing LNG vaporization facility in Johnsons Bayou, Louisiana. The M3 modification of the permit (December 6, 2011) permitted construction of four natural gas liquefaction trains, consisting of 24 compressor turbines, two generator turbines, two generator engines, flares, acid gas vents, and fugitives. The M4 modification of the permit (March 22, 2013) allowed several changes to the proposed four liquefaction trains. The M5 modification of the permit (June 3, 2015) allowed construction of two additional liquefaction trains, to be similar to the initial four trains.

Since the liquefaction trains were constructed at a pre-existing facility, the application was considered a "major modification" and is not relevant for determining whether a new LNG liquefaction facility is one of the 28 listed source categories.

APPENDIX E

MODEL INPUT SUMMARY

(1) The tug emissions are included in all 1-hour scenarios, along with one of the individual activities below.
These are combined with the ODEQ competing sources, and the project sources (either the normal scenario or SUSD scenario), to come up with the 1-hour scenarios for full impact runs.

(2) Four surrogate tugboat sources and 68 surrogate vessel sources are used to represent the motion of these vessels.
Each surrogate tug is assigned 1/4 of the total tug emissions, and each surrogate vessel 1/68 of the total vessel emissions.

Appendix G – LNG Carriers

The fleet of LNG vessels expected to call at the JCEP terminal consists of both vessels that have boiler/steam turbine driven (ST) propulsion systems, as well as vessels powered by duel-fuel diesel-electric (DFDE) propulsion. Further, each type of vessel may be operated on either natural gas or fuel oil. For the DFDE ships, however, operation on oil versus operation on natural gas was confined to different activities during the ship's call. Therefore, three vessel emissions scenarios were created in order to determine worst-case air emissions calculations and associated air quality impacts:

- ST vessels operating on oil
- ST vessels operating on natural gas
- DFDE ships

JCEP expects up to 120 LNG vessel calls per year. For the purposes of the modeling, in each of the three scenarios, it is assumed that all of the 120 vessel calls will be of ships of the same propulsion and fuel type.

The LNG vessel call activities can be divided into the following activities and operating periods per visit. These activity times are not dependent on the ship or fuel type. As can be seen in table F-1 the activities in total will last 29 hours per vessel call.

Emission rates for different activities during the ship's call are developed from the emission factors shown in Table F-2, and the amount of power expected to be consumed during that particular activity. As the emission factors are in a g/kWh basis, and the power will vary depending on activity, the emission rates (on a mass per unit time basis) will vary depending on the activity in which the ship is engaged.

If a ship is engaged in a particular activity for the full averaging period, than the full mass per unit time rate is used for modeling of that activity. If a ship is engaged for the activity for a portion of the averaging period, then the mass per unit time emission factor is weighted by the proportion of the activity time to the time of the averaging period. For example, for an activity that takes four hours, the full mass per unit time emission rate calculated will be used for 1-hour averaging periods (as the activity time is longer than that averaging period), but one-sixth of the full mass per unit time emission rate will be used for 24-hour averaging periods (as the four hours of activity time is one-sixth of the averaging period).

The emission factors are shown in Table F-2. The mass per unit time emission calculations for each of the three types of ships are shown in Tables F-3 through F-5, respectively. The emission rates by pollutant and averaging period for model input are shown in Tables F-6 through F-8, respectively. Vessel source locations and stack parameters are shown in Tables F-9 through F-11, respectively.

In addition to the activities at and in the immediate vicinity of the terminal, the emissions of the ship's transit of the channel and near-shore open water are considered by setting up 68 sources along the geographic track of arriving and departing ships. The transit emission rates are used for these surrogate sources, with the emissions divided equally over the 68 surrogate sources.

In addition to the LNG vessels, tugboats will also be deployed in operation at the JCEP LNG terminal. The worst-case scenario involves use of one tugboat. Since the tugboat will be maneuvering around the ship during the worst case, the tugboat is represented as a series of four surrogate sources in the channel adjacent to the ship dock, with one-quarter of the total tugboat emissions assigned to each surrogate source. The tugboat emissions are shown in Table F-12, and stack parameters and location information of the tugboat are detailed in Table F-13.

Marine vessel emissions scenario summaries for the annual, 24-hour, and 1-hour averaging periods are shown in Tables F-14 through F-16.

Table G-1. LNG Vessel Activities and Operating Periods per Visit		
Category	Activity	Time (hours)

Table G-12. Tugboat Emissions Information[1]							
Pollutant	Emission Factor (g/kWh)	Tug Emissions per Port Call (kg)	Emission Factors for Modeling (per surrogate source, g/s)[1]				
			1-hour	3-hour	8-hour	24-hour	Annual
NO_x[2]	1.80E+00	72	2.38E-01	N/A	N/A	N/A	5.70E-04
CO[3]	3.35E+00	134	4.42E-01	N/A	4.42E-01	N/A	N/A
PM[2]	6.00E-02	2	N/A	N/A	N/A	7.93E-03	1.90E-05
SO_2[3]	4.92E-01	20	6.50E-02	6.50E-02	N/A	6.50E-02	1.56E-04
VOC[2]	1.90E-01	8	N/A	N/A	N/A	N/A	N/A
CO_2[3]	7.06E+02	28183	N/A	N/A	N/A	N/A	N/A

Notes:
(1) Tug is represented as four surrogate sources to account for manuevering about the berthed ship.
(2) NOx, PM, and VOC emissions are EPA Marine Tier 4 standards (40 CFR Section 1042.1, Table 3)
(3) CO, SO2, and CO2 emission factors from AP42 Table 3.4-1. Sulfur content of fuel assumed 0.1%.
(4) Emissions per call calculated by multiplying emisison factor by 39942 kWh, the total energy expended per ship call. Rates determined by dividing total emissions by 1260 minutes operation per ship call. Emission rate for each surrogate source is one-quarter of the overall emission rate. Annual emissions based on 120 ship calls per year.

Tug Activities and Operating Times per Ship Call

Activity	Time (min)	Kw	Kw-Hour
Maneuvering Around Ship	1200	1902	38040
Maneuvering Around Ship/Easy Push	60	1902	1902
Total Tug Activity per LNG Ship Call	1260	1902	39942

Table F-13. Tugboat Stack and Location Information[1]						
Location			Stack Parameters

DESCRIPTION OF THE VESSEL

METHANE JULIA LOUISE
SHI – HULL 1745

1	**GENERAL**	
	Hull Number	1745
	Builder and Yard	Samsung Heavy Industries Co. Ltd. Korea
	Year Built	2010
	Flag	Bermuda
	Classification Society	American Bureau of Shipping
	Classification Notations	HA1 E, Liquefied gas carrier, Ship type 2G (Membrane tank, Maximum pressure 25 kPaG and Minimum Temperature -163ºC, Specific Gravity 500 kg/m^3), SH, FL(40), SH-DLA, SHCM, SFA(40), HM2+R, HAMS, NIBS, HACCU, UWILD, PMS including CMS, R2 without dual centralized fresh water cooling systems.
	Call Sign	ZCEB2
2	**PERFORMANCE STANDARDS**	
	Guaranteed Deadweight	80,700 metric tonnes at design draft of 11.5 meters
	Guaranteed Speed	19.75 knots at a draft of 11.5 meters and at propulsion shaft power of 20, 840 kW
	Guaranteed LNG Cargo Carrying Capacity	168,162.306 cubic meters at maximum allowable cargo tank fill ratio of 98.5% and reference temperature according to IGC Code 15.1.2-4
	Guaranteed Fuel Consumption	Maximum Continuous Rating (MCR): Approx 25,400kW X 86 RPM. Gas Operation: Specific energy consumption at MCR with main generation driven pumps of 7,410 kJ/kWh, with 1.0 g/kWh for pilot fuel Back Up Fuel Operation: Specific energy consumption at MCR with main generation driven pumps of 189 g/kWh Daily Fuel Oil Consumption of 124.9 metric tons per day of DO at MCR Daily fuel consumption of reliq plant 11.4 metric tons of DO per day Fuel Consumption shall be measured according to ISO 3046/1-1995, with lower calorific value of 42,700 kJ/kg of diesel oil.
	Guaranteed Boil-off Rate	0.15 per cent by volume per laden day.
	Cargo containment system type	Gaztransport & Technigaz (MARK III) Membrane

3	**DIMENSIONS**	
	Length Overall	291.066 meters
	Length between perpendiculars	279.000 meters
	Breadth (moulded)	45.000 meters
	Depth to upper deck (moulded)	26.000 meters
	Design Draft, moulded (in seawater of specific gravity of 1.025) :	11.500 meters
	Scantling Draft, moulded (in seawater of specific gravity of 1.025)	12.500 meters
	Air Draft	54.338 meters Ballast draught 9.72m
4	**TONNAGE**	
	Dead-weight tonnage on LNG loaded draught: (11.73m)	84,000 metric tonnes (at full cargo with density 470 kg/m3 plus 5050 m/t bunker, FW, lubs, etc).
	Light ship displacement	32,968.9 metric tonnes
	Displacement	119,094.1 metric tonnes (summer)
	Gross Tonnage	109,004 tons
	Net Tonnage	32,701 tons
	Suez Canal Gross Tonnage	113,005.56
	Suez Canal New Tonnage	101,642.68
5	**MACHINERY**	
	Main Propulsion Plant:	Dual Fuel Diesel Electric, Twin Shaft
	Electric Propulsion Motor Make and Type	Converteam, N3HXC 1000. Squirrel Cage Induction Motor x 2 Sets
	Horsepower (at MCR)	25,400 kW (12,700 kW x 2 sets)
	Normal Service Rating	20,840 kW
	Main Electrical Generating Plant:	
	Dual Fuel Generator Engines Make and Type	Wartsila 12V50DF x 3 sets Wartsila 6L50DF x 1 set
	Generators Make and Type	Converteam M4HXD 253-71 x 3 Sets Converteam M4HXD 253-58 x 1 Set
	Maximum Output	11,400 kW x 3 Sets 5,700 kW x 1 Set
	Auxiliary Boilers:	
	Make	Aalborg
	Type	Mission OS 5000
	Maximum Evaporation	5000 kg/h
	Number	2 Sets

6	**CARGO TANKS**	
	Number of Cargo Tanks	4
	Total Capacity 100% full	170,723.372 m^3
	Type of construction	GTT Mark III system (Membrane)
	Type of insulation	Rigid polyurethane foam with reinforcing glass fibre.
	Minimum Temperature	Minus 163 degrees Celsius
	Loading/filling restrictions	98.5% maximum filling limit
	100%Capacity at 25 ℃ of: • No. 1 tank • No. 2 tank • No. 3 tank • No. 4 tank	 26,995.4 m^3 47,904.6 m^3 47,906.1 m^3 47,917.3 m^3
	The Vessel's cargo tanks can be cooled down from ambient temperature to the loading condition (minus 130 degree Celsius mean temperature of cargo tanks) within ten hours.	
	Relief valve settings	25kPa gauge
	Loaded boil-off design rate	0.15 per cent by volume per laden day
7	**FRESH WATER**	
	Capacity of F.W. generators	30 Tonnes per Day x 2sets
	Capacity of Tanks:	
	Boiler Feed (Distilled Water) Fresh Water Drinking Water	63.6 m^3 495.5 m^3 Not applicable
8	**BUNKER CAPACITY**	
	Diesel Oil (100%)	824.0 m^3 (Storage and Service Tanks in Machinery Space)
	Fuel Oil (100%)	5,259.5 m^3 (Storage, Settling and Low Sulphur Tanks)
9	**WATER BALLAST**	
	Tank Capacity (100%)	62,933.4 m^3 (including peak tanks)
	Number and Capacity of water ballast pumps	3000 m^3/hr each X 3 sets
	The vessel is capable of loading/discharging ballast concurrent with cargo operations	Yes
10	**CARGO PUMPS**	
	Number	8 sets
	Type and Make	Single stage centrifugal submerged, Ebara International Corporation
	Rated Capacity of each Pump	1750 m^3/hr 160 MLC (specific gravity 0.5)
11	**SPRAY PUMPS**	
	Number	4 sets
	Type and Make	Single stage centrifugal submerged, Ebara International Corporation
	Rated capacity of each Pump	50 m^3/hr 145 MLC (specific gravity 0.5)

12	**FUEL GAS PUMPS**	
	Number	2 sets
	Type and Make	Single stage centrifugal submerged, Ebara International Corporation
	Rated capacity of each Pump	15 m^3/hr 215 MLC (specific gravity 0.5)
13	**CARGO INSTRUMENTATION**	
	Liquid Level Gauge Primary: Maker and Type Number per Tank Accuracy Measuring Range Secondary: Type and Maker Number per Tank Accuracy Measuring Range	 SAAB Marine Electronics AB, Radar Ullage Measurement 1 set ± 7.5 mm 0.026m to 26.52m Whessoe Total Automation, Float Type Ullage Measurement 1 set ± 7.5mm 0 to 54 m.
	Temperature Sensor Type Number per Tank Accuracy Measuring range	 Resistance temperature detectors 5 pairs ± 0.2 ℃ (between - 165℃ and - 145℃) Rising to + 1.5 ℃ at +50 ℃ From - 165 ℃ to + 50 ℃
	Pressure Sensor System Number per Tank Accuracy Measuring range	 1 set ± 1 % of span with deck temperature ranging between – 30^{0}C and +60^{0}C 800 - 1,400 mbar
14	**RE-LIQUEFACTION PLANT**	
	System Maker and Type	Hamworthy Gas Systems, Moss RS™ Mark I re-liquefaction system
	System Capacity	2500 kg/hr (including 500kg/hr flash gas)
	BOG Compressors	
	Type and Make Number and Capacity Discharge Pressure Suction Press. and Temperature	Cryostar, CM2-200 Horizontal, two stage centrifugal. Two sets, 6,699 m^3/h each 6.5 barA 1.03 barA / -120 ℃
	Compander Make and Type	 Atlas Copco, Model GT026N3D0+ET1135MS Three stage integral gear compressor with a single stage radial turbine.
	Cold Box	
	Make and Type	Fives Cryogenic, Counter-Flow Heat Exchanger
	Capacity	2,500 kg/hr

15	**INERT GAS GENERATION**	
	Make and Type	Smit Gas Systems BV, Oil burning type with cooling and drying unit,
	Capacity	14000 Nm^3/hour
	Quality of Gas	O_2 - max 1% by volume CO_2 - max approx 14% by volume CO- max 100 ppm SO_x - max 1 ppm N_2 - balance Soot - complete absence (0 on Bacharach scale) Dew Point not more than -45 °C
16	**NITROGEN GENERATION**	
	Make and Type	Air Products AS, NC1.1-1816-WXP-130970 Ext.cab Membrane Separation Type.
	Capacity	130 Nm^3/h @ 97% N_2 x 2 sets
	Pressure Tank	32 m^3 x 10 bar g x 1 set
17	**GAS COMPRESSORS**	
	High Duty:	
	Make and Type	Cryostar, CM 400/55 Horizontal, single stage, centrifugal.
	Number and Capacity	Two sets 28,000 m^3/h each
	Discharge Pressure	2.0 barA,
	Suction Press. and Temp.	1.03 barA -140 °C
18	**CARGO VAPOURISERS**	
	Forcing Vapouriser Make, Type and Capacity	Cryostar, 34-UT-25/21-3.6, 5,500 kg/hr
	LNG Vapouriser Make, Type and Capacity	Cryostar, 65-UT-3838/34-5.6, 25,000 kg/hr
19	**DECK MACHINERY**	
	Winches: Number, Position, Type	Upper deck forward Combine Anchor Windlass and Mooring winch 2 sets x 30 Metric Tonnes x 15 m/min (winch) or x 57 Metric Tonnes x 9 m/min (windlass) for 110 meters chain in the water Total drums: 9 Mooring Winches 2 sets x 30 Metric Tonnes x 15 m/min Upper deck Aft Mooring Winches 5 sets x 30 Metric Tonnes x 15 m/min Total drums: 11
	Holding Power of Brakes	99.7 Metric Tonnes Type: Split Compact Electro Hydraulic Winch.
	Mooring Ropes Make and Type	Samson, Amsteel Blue

	Size and min. B.S. of Wires	40 mmΦ x 200 m, ISO/BS EN 919 MBS 128mt
	Whether Fitted with Tails, State Length, Material, Min. B.S.	Samson P-7 Grommet Mooring Line Pendant 56mmΦ x 11 m, 100% Polyester ISO/BS EN919 MBS 164mt
	Derrick, Cranes, etc.: Type and Capacity	Midships Hose Handling cranes : MacGregor x 2 Sets, Slewing single jib type, 5.0 metric tonnes SWL, minimum outreach 5.2 m, maximum outreach 26m Cargo Machinery crane: DMC x 1 set, slewing single jib type, SW L 6.0 tonnes, out reach min. 3,4 m max. 12 m. Provision cranes Stbd side – MacGregor,1 set, slewing single jib type, 10.0 metric tonnes SWL, minimum outreach 3.7m, maximum outreach 18.3m, hook travel 54m Port Side-MacGregor,1 set, slewing single jib type, 5.0 metric tonnes SWL, minimum outreach 3.7m, maximum outreach 18.3m, hook travel 54m
20	**NAVIGATION AND RADIO**	
	Navigation Aids	Make: Furuno Electric Co Ltd. Two sets X-band radar with Arpa One set S-band radar with Arpa Two sets Differential Global Positioning System navigator equipment One set Electronic Chart Display and Information System.
	Radio Equipment	Make: Furuno Electric Co Ltd One set GMDSS (area 3) Radio Equipment, One set radio station comprising 1 set MF/HF transmitter/receiver with radio telephone and DSC control unit , 1 set MH/HF DSC watch receiver, and I set remote distress message controller. One set Inmarsat C MES equipment One set Inmarsat F MES equipment
21	**OTHERS**	
	Bilge Oily Water Monitor	Make: Smart Cell– Bilge Type; Detection of light scatter across oily water sample. .
	Incinerator	Make Hyundai -Atlas Type: Forced draught package type, 500,000 kcal per hour
	Sewage Treatment Plant	Make: DVZ-Services GmBH. Type: DVZ-SKA-30 “BIOMASTER” Bio reaction and aeration system Capacity 3,450 ltr per day.

PROFORMA FORM C

DESCRIPTION OF THE VESSEL

SHI – HULL 1553-54-55-85-86-87-88

1.	**GENERAL**			
	1.1	Vessel Name and Hull Number	:	*To be named* Hull Number 1553-54-55-85-86-87-88
	1.2	Builder and Yard	:	Samsung Heavy Industries Geoje Island, Korea
	1.3	Year Built / delivered	:	2006-2008
	1.4	Containment System	:	Membrane Type GTT Mark 3
	1.5	Country of Registry	:	Bermuda
	1.6	Port of registration	:	Hamilton
	1.7	Classification Society		American Bureau of Shipping A1Ⓔ, Liquefied gas carrier, ship type 2G (Membrane tank, Maximum pressure 25 kPaG and Minimum Temperature - 163ºC, Specific Gravity 500 kg/m^3), SH, FL(40), SH-DLA, SHCM, SFA(40), HM2+R, AMS, NIBS, ACCU, UWILD, PMS including CMS.
			:	
2.	**DIMENSIONS, TONNAGE**			
	2.1	Length Overall	:	approx. 283 metres
	2.2	Length between Perpendiculars	:	270.0 metres
	2.3	Beam (moulded)	:	43.4 metres
	2.4	Depth to upper deck, moulded	:	26.0 metres
	2.5	Scantling Draft, moulded (in seawater of specific gravity of 1.025)	:	12.4 metres
	2.6	Design Draft, moulded (in seawater of specific gravity of 1.025)	:	11.4 metres
	2.7	Summer Draft (moulded)	:	Apprx. 12.0 metres
	2.8	Air Draft	:	max. 50.00 A/B with radar mast in lowered position and about 56.00m A/B with radar mast in raised position.
3.	**TONNAGE**			
	3.1	Deadweight at Design Draft, extreme	:	Apprx. 71,450 metric tonnes
		at Summer Draft, extreme	:	Apprx. 77,450 metric tonnes
	3.2	Lightweight	:	-
	3.3	Displacement at Summer Draft	:	-
	3.4	Gross Tonnage (International)	:	Apprx. 97,100 metric tonnes
	3.5	Net Register Tonnage	:	-
	3.6	Suez Canal Gross Tonnage	:	-
	3.7	Suez Canal Net Tonnage	:	-
4.	**MACHINERY**			
	4.1	Propelling Machinery,		

	Type and Make	:	Steam Turbine, Reversible Geared, Cross Compound, Steam Driven / Kawasaki Heavy Industries Limited
	Maximum Continuous Rating	:	39,500 PS @ 90 RPM
	Normal Service Rating	:	33,550 PS @ 86.9 RPM
4.2	Main Boilers		
	Type, Make and Number	:	Two Water tube, forced draft, marine boiler, Kawasaki Heavy Industries Limited
	Maximum Evaporation	:	Total 65 Te/h, each (incl. 4 Te/h desuperheated steam)
4.3	Electrical Generating Plan		
	Type, Maximum Output per	:	Two (2) sets of turbo generator, 4,312.5 kVA (3,450 kW), 6,600 VAC, 60 Hz, 3 Phase / Mitsubishi Heavy Industries Limited One (1) sets of diesel generator, 4,312.5 kVA (3,450 kW), 6,600 VAC, 60 Hz, 3 Phase / Wärtsilä One (1) set of emergency diesel generator, 1,062 kVA (850 kW), 450V AC, 60Hz, 3 Phase / STX--Cummins
4.4	Bow Thruster	:	Controllable Pitch Propeller (C.P.P.)
	Electric motor	:	2,500 kW, 6,600V
	No of blades	:	Four (4) (Ni-Al-Bronze)

5. OWNER GUARANTEE SPEEDS

The guarantee speed at the designed draft of 11.4m on even keel shall be not less than 20.2 knots with the main propulsion machinery running at an output of 30,910 PS under weather conditions not exceeding Beaufort 4.

6. FUEL CONSUMPTION RATE

At NCR	:	182.2 metric tonnes per day

Consumption rate based upon using fuel classified as RMH55 in accordance with ISO8217 (1996) and having a higher calorific value of 43 MJ/kg (10,280 kcal/kg).

7. CARGO TANKS

7.1	Total Capacity 98.5% full	:	142,950 cubic metres at maximum allowable cargo tank fill ratio of 98.5% and reference temperature according to IGC Code 15.1.2-4
7.2	Number of Cargo Tanks	:	4
7.3	Maximum S.G.	:	470 kg/m^3
7.4	Minimum Temperature	:	-163ºC
7.5	Normal Tank Operating Pressure	:	106 kPa absolute
7.6	Relief Valve Settings	:	25 kPa gauge
7.7	Capacity at -163°C 100% full	:	Apprx.145,130 m^3

No. 1 tank	:	22,040 m^3	No. 2 tank	:	42,760 m^3
No. 3 tank	:	42,,760 m^3	No. 4 tank	:	37,570 m^3

7.8 The Vessel's cargo tanks can be cooled down from ambient temperature to the loading condition in less than 10 hours (-130°C , mean temp. of cargo tanks).

8 CARGO LOADING AND DISCHARGE PERFORMANCE

(a) The ship shall be able to load the bulk of the cargo (exluding slow starting and topping off) through two (2) liquid manifolds in ***approximately 12 hours at pressure of 240 kPa(G)*** inboard of the manifold strainer.

(b) The ship shall be able to discharge the bulk cargo through three (3) liquid manifolds in approximately 12 hours (excluding slow starting and topping off) against a backpressure of 100 MLC measured inboard of the manifold strainer with cargo tanks at mid-level.

9. BOIL-OFF RATE

9.1	Guarantee Boil-off Rate	:	Not to exceed 0.15% per day

10. FRESH WATER

10.1	Capacity of F.W. generators	:	Two 60 T/d / Alfa-Laval
10.2	Capacity of Tanks		
	Boiler Feed	:	Apprx. 400 m^3
	Fresh Water	:	Apprx. 350 m^3

11. BUNKER CAPACITY

11.1	Fuel Oil (100%)	:	Apprx. 7,400 m^3
11.2	Gas Oil (100%)	:	Apprx. 100 m^3
11.3	Diesel Oil (100%)	:	Apprx. 300 m^3
		:	

12. WATER BALLAST

12.1	Tank Capacity (100%)	:	Apprx. 55,500 m^3
12.2	Number and Capacity of water ballast pumps	:	3 X 3,000 m^3/h at 30 mwc
12.3	The vessel is capable of loading/discharging ballast concurrent with cargo operations	:	Yes

13. CARGO PUMP

13.1	Number	:	8
13.2	Type and Make	:	Centrifugal, single stage, submerged / Ebara
13.3	Rated Capacity of each Pump	:	1,700 m^3/h at 155 mlc (S.G. 0.5)

14. SPRAY PUMP

14.1	Number	:	4
14.2	Type and Make	:	Centrifugal, submerged / Ebara
14.3	Rated Capacity of each Pump	:	50 m^3/h at 145 mlc (S.G. 0.5)

15. EMERGENCY CARGO PUMP

15.1	Number	:	1
15.2	Type and Make	:	Centrifugal, single stage, removable type / Ebara
15.3	Rated Capacity	:	550 m^3/h at 155 mlc (S.G. 0.5)

16. CARGO INSTRUMENTATION

16.1	Liquid Level Gauge		
	<u>Primary</u>		
	Type	:	Radar / Saab
	Number per Tank	:	1
	Accuracy	:	7.5 mm
	Measuring range	:	26.52 m

	Secondary		
	Type	:	Float / Whessoe
	Number per Tank	:	1
	Accuracy	:	7.5 mm
	Measuring range	:	26.52 m
16.2	Temperature Sensor		
	Type	:	High Accuracy
	Number per Tank	:	5 pair
	Accuracy	:	+0.2°C between -165°C and -145°C, rising to +1.5°C at +50°C
	Measuring range	:	-165°C to +50°C
16.3	Pressure Sensor System		
	Number per Tank	:	1
	Accuracy	:	+ 1% of span with deck temperature ranging between -30°C and +60°C
	Measuring range	:	800 - 1,400 mbar
16.4	Ship shore communication system	:	Fibre optic, intrinsically safe and pneumatic types

17. NITROGEN GENERATION

17.1	Type and Make	:	Membrane permeation type / Air Product AS
17.2	Capacity	:	2 off 100 Nm^3/h
17.3	Pressure Tank	:	6.5 bar g

18. INERT GAS GENERATION

18.1	Type and Make	:	Stoichiometric combustion of fuel oil / Smit Gas System
18.2	Capacity	:	14,000 Nm3/h inert gas or dry air
18.3	Quality of Gas	:	Dew point -45°C at 760 mmHg

O_2	: max. 1.0% by vol.
CO	: max. 100 ppm
SOx	: max. 10 ppm
NOx	: max. 100 ppm
Soot	: Bacharach 0
HC	: 0%
CO_2	: max. 14% by volume
Remainder	: N_2 , H_2 , Ar

19. GAS COMPRESSORS

19.1	High Duty		
	Type and Make	:	Horizontal, single stage centrifugal / Cyrostar
	Number and Capacity		2 off 26,000 m^3/h
	Discharge Pressure		200 kPa A
	Suction Press and Temp		-140°C, 103 kPa A
19.2	Low Duty		
	Type and Make	:	Horizontal, single stage centrifugal / Cyrostar
	Number and Capacity	:	2 off 8,000 m^3/h
	Discharge Pressure	:	200 kPa A
	Suction Press and Temp	:	-40°C, 106 kPa A

20. FORCING VAPORIZER

20.1	Capacity	:	7,000 kg/h from -163°C to -40°C / Cyrostar

21. DECK MACHINERY

21.1	Winches Number, Position, Type (incl. windlass)	:	4 for'd (2 combined with windlass) 5 aft, Electro-hydraulic self contained power pack, non auto-tension type mooring winches & windlasses / Kochs
21.2	Holding Power of Brake	:	80% of mooring line MBL (design) set at 60%
21.4	Size of Wires and whether fitted with Tails State Length, Material	:	Twenty-two (22) sets including two (2) spares, each 200 m long and 44 mm diameter of spectra rope or equivalent with each 11 m long nylon tail and a Tonsberg mooring link.
21.5	Derrick, cranes, etc. Type and Capacity	:	Electro-hydraulic driven single jib crane One (1) x 5.0 Te SWL at port aft and one (1) x 10.0 Te SWL at starboard aft. One (1) x 6.0 Te SWL for cargo machinery room Two (2) x 5.0 Te SWL at P&S manifold

22. NAVIGATION AND RADIO

22.1	Navigation Aids and Radio Equipment	:	VHF radio telephones GMDSS distress message controller Display units for radars (X and S-bands), ECDIS and conning display Auto pilot operating unit CCTV control station for mooring area camera and night vision camera UHF base station DGPS navigator Echo sounder recorder Master electric clock DGPS navigator Speed log main unit Navtex receiver Signal light control panel Loran-C receiver VHF radio telephone Inmarsat-B Inmarsat-C

23. OTHER

23.1	Bilge Oily Water Monitor	:	1 X 5 m^3/h (15 ppm)
23.2	Incinerator	:	1 X 500,000 kcal/h for solid garbage waste and sludge oil having flash point above 60°C
23.3	Sewage Treatment Plant	:	One (1) biological type for 45 persons

23.4 CCTV system with 11 cameras and monitors in wheelhouse, engine control room and cargo control room;
23.5 Loading computer including damage stability calculations;
23.6 Shipboard management system
23.7 Public address system
23.8 Master clock system
23.9 UHF onboard radio communication with 2 base stations, 1 base repeater station and twelve portable sets

APPENDIX H

CLASS I SCREENING AND Q/D ANALYSIS

Type B State New Source Review Application

Jordan Cove LNG Terminal
Jordan Cove Energy Project, LP
125 Central Avenue, Suite 380
Coos Bay, Oregon 97240

September 2017

All,

Here is the determination by Don Shepherd of the NPS that Jordan Cove will not have a significant impact on AQRVs for the NPS Class I areas. The USFS has not yet made their determination.

Subject: Re: FW: Additional information request

Hi Phil,

Based upon the new information provided by the applicant, we conclude that it is unlikely that the Jordan Cove Energy Project would have a significant impact upon Air Quality Related Values in any of our Class I areas.

We would appreciate it if OR DEQ would provide electronic copies of the complete/final permit application, staff analysis, draft permit, and public notice.

thanks,

Hi Phil, please see below for our response to Don Shepherd's request. Please let me know if there are any additional questions.

SLR has recalculated the Q value for the Jordan Cove Energy Project based on a worst-case 24 hour emission scenario for project emissions of PM, SO_2, NOx, and H_2SO_4 (see attached). Following FLAG 2010 guidance, the worst-case 24 hour emissions were assumed to persist for the entire year and then summed in order to calculate the ton per year emissions (Q). The worst-case daily emissions scenario includes the following assumptions:

- Each turbine undergoing a startup/shutdown with normal operation (with duct burners) thereafter;
- Continuous operation of the thermal oxidizer;
- Continuous operation of the auxiliary boiler;
- One hour of operation of each of the three fire water pumps;
- One hour of operation of each of the two backup generators;
- One hour of operation of each of the two black start generators;
- Continuous operation of the ground flare and the marine flare pilot and purge gas; and
- Continuous emissions from gas up (flaring of gas vented from incoming LNG tankers).

Based on this worst-case daily emissions scenario, the calculated Q value is 849 tons per year. Both Crater Lake National Park (NP) and Redwood NP are approximately 165 km from the facility, **resulting in a Q/D value of 5.1**. In the development of the worst-case scenario, it is noted that several of the sources are intermittent (e.g., startup/shutdowns, auxiliary boiler, firewater pumps, backup generators, black start generators, and gas up emissions), thus concurrent operation of these sources in the same day is extremely unlikely.

It should also be noted that the Q value quoted in the Jordan Cove Energy Project modeling protocol was provided for informational purposes only for the Type B state New Source Review application, since AQRV analyses are not required.

Hi Jason,

See below for email from Don Shepherd of the NPS requesting additional information for the Q/d calculation for Class I Area impacts. Please respond to me, and I will forward the revised information to both the NPS and USFS.

On a separate note, the inventory of competing sources will be sent later today by separate email.

Please contact me if you have questions. Thanks.

Subject: Jordan Cove Modeling Protocol and Q/d

Hello Phil,

Tonnie Cummings has asked me to respond to your request for comments on the modeling protocol for the Jordan Cove Energy Project.

Before i can give you a decision, i need clarification of how the "Q" value in the Q/d calculation was derived. Here is what the applicant says on page 21 of the application:

Using the emissions summarized in Table 2-1 for the visibility impairing pollutants of NOx, SO2, PM, and H2SO4 the calculated Q value is 327.6. Using the shortest distance, D, from Table 4-1 above, the Q/D value is calculated to be 2.98, which is below the threshold value of 10.

My concern regards Table 2.1 on page 3. According to the applicant:

The potential annual emission rates for each criteria air pollutant from each source are shown in Table 2-1. The EPC contractor, KBJ, has completed the pre-FEED design stage of the project and is currently developing the detailed facility design.

Instead of using annual average emissions, Q should be calculated based upon the maximum 24-emission rates of NOx, SO2, PM, and H2SO4, including start-ups and shut-downs. The maximum 24-hour emission rate should then annualized to yield a tpy value for Q. It is also important that the applicant provide its calculations and assumptions in deriving these emission rates.

Please feel free to contact me with any questions.

thanks,

Don Shepherd

Subject: RE: NPS Class I Area Determination

Hi Phil,

Given that the revised Q/D for Kalmiopsis – the closest Class I unit – is still < 10, Rick and I do not think Jordan Cove will have a significant impact for USFS Class I areas. Thank you for providing the feedback from Tonnie, Don, and others.

Best,

Jim

Cadmium		1.1E-03	lb/MMscf	(3)	6.1E-04	1.3E-02
Chromium		1.4E-03	lb/MMscf	(3)	7.7E-04	1.7E-02
Cobalt		8.4E-05	lb/MMscf	(3)	4.6E-05	1.0E-03

Pollutant	Emission Factor	Hourly Emissions per Unit [(a)] (lb/hr)	Annual Emissions [(b)] (tons/yr)
Manganese	3.8E-04 lb/MMscf (3)	2.1E-04	4.6E-03
Mercury	2.6E-04 lb/MMscf (3)	1.4E-04	3.1E-03
Nickel	2.1E-03 lb/MMscf (3)	1.2E-03	2.5E-02
Selenium	2.4E-05 lb/MMscf (3)	1.3E-05	2.9E-04
Total HAPs		**0.25**	**5.06**
Maximum Individual HAP			**1.44**

Calculations:

(a) Hourly Emissions (lb/hr) = [Emission Factor for 100% load (lb/hr)] x [Time at 100% load (%) / 100] + [Emission Factor for 75% load (lb/hr)] x [Time at 75% load (%) / 100]

Hourly Emissions (lb/hr) = [Emission Factor (kg/MMBtu)] x [Heat Rate (MMBtu/hr)] x [2.20462 (lb/kg)]

Hourly Emissions (lb/hr) = [Emission Factor (lb/MMBtu)] x [Heat Rate (MMBtu/hr)]

Hourly Emissions (lb/hr) = [Emission Factor (lb/MMscf)] x [Heat Rate (MMBtu/hr)] / [Fuel Heat Content (MMBtu/MMscf)]

Hours at 100% load DB fired (%) =	4000	(9)
Hours at 100% load DB unfired (%) =	4760	(9)
Turbine Maximum Heat Rate (MMBtu/hr) =	504.4	(10)
Duct Burner Maximum Heat Rate (MMBtu/hr) =	19.7	(10)
Maximum Heat Rate (MMBtu/hr) =	524.1	(10)
Fuel Heat Content (Btu/scf) =	952	(11)

(b) Annual Emissions (tons/yr) = [Hourly Emissions (lb/hr)] x [Turbine Hours of Operation (hr/yr) - Startup/Shutdown Hours (hr/yr)] x [Number of Units] / [2,000 (lb/ton)]

Annual Emissions (tons/yr) = [Hourly Emissions (lb/hr)] x [Duct Burner Hours of Operation (hr/yr)] x [Number of Units] / [2,000 (lb/ton)]

Number of Units =	5	(9)
Duct Burner Hours of Operation (hr/yr) =	4,000	(12)
Turbine Hours of Operation (hr/yr) =	8,760	(9)
Startup/Shutdown Hours (hr/yr) =	3.8	(13)

Notes:

(1) Emission estimates provided by manufacturer.
(2) SO_2 emissions include assumptions of 20 percent by volume oxidation rate in CO catalyst and 3 percent by volume oxidation rate in SCR.
(3) AP-42, Chapter 1.4, Table 1.4-4. Emission Factors for Metals from Natural Gas Combustion, July 1998. Note emission factor for lead is ND as indicated in AP-42, Chapter 3.1-2a, Table 3.1, Emission Factors for Criteria Pollutants and Greenhouse Gases from Stationary Gas Turbines.
(4) Carbon dioxide equivalent, global warming potentials; CO_2 = 1, CH_4 = 25, N_2O = 298.
(5) Emission Factors from Table C-2 to Subpart C of 40 CFR Part 98 - Default CH_4 and N_2O Emission Factors for Various Types of Fuel.
(6) AP-42, Chapter 3.1, Table 3.1-3. Emission Factors for Hazardous Air Pollutants from Natural Gas-Fired Stationary Gas Turbines, April 2000.
(7) AP-42, Chapter 1.4, Table 1.4-3. Emission Factors for Speciated Organic Compounds from Natural Gas Combustion, July 1998. HAP emission factors used for Duct Burners.
(8) California Air Resource Board (CARB) emission inventory for NG turbine.
(9) Percentage of time at specific loads, number of units, and hours of operation provided by KBJ.
(10) Maximum heat rate at 100% load with duct burners provided by manufacturer (see Table 13).
(11) Provided by KBJ.
(12) Provided by KBJ.
(13) KBJ estimates 12 startup per year at 10 minutes per startup and 12 shutdowns per year at 9 minutes per shutdown. See Table 4 for additional startup and shutdown calculations.

Flaring of Excess Boil off gas generated during gas up of the LNG carrier each time it returns to LNG transportation service following a drydock overhaul period (when the entire cargo system needs to be fully warmed up and gas freed) is expected to occur at the JCLNG terminal for up to 4 ships per year. The operational assumption is 50% of the gas up volume would be recovered and 50% flared. A worst-case scenario would be flaring of 100% of the gas. Inert gas and methane are routed to the marine flare for combustion.

Calculations:

(a) Hourly Emissions (lb/hr) = [Annual Emissions (tons/yr)] x [2000 lbs/ton)] / [Number of gas up events/year] / [Duration of flaring for event (hours/event)]

Average tanker size hull gas relief (LNG tonnes/ship) =	355.7	(9)
Average flared gas -Turbulent mixing (MMBtu/ship, LHV) =	22,264	(9)
Duration of turbulent event flaring (hours/event) =	30	(9)
Number of turbulent events per year (ships/year) =	1	(9)
Average flared gas - Laminar mixing (MMBtu/ship, LHV) =	19,619	(9)

Duration of non-turbulent event flaring (hours/event) =	18.52	(9)
Number of non-turbulent events per year (ships/year) =	2	(9)
Average flared gas per year (MMBtu/year) =	61,502	
Average duration of event flaring (hours/event) =	22.37	(9)
Fuel Heat Content (Btu/scf) =	877	(9)
Conversion of SO_2 to H_2SO_4 (percent) =	5	(4)
Molecular Weight S (lb/lb-mole) =	32	
Molecular Weight SO_2 (lb/lb-mole) =	64	
Molecular Weight H_2SO_4 (lb/lb-mole) =	98	

(b) Annual Emissions (tons/yr) = [Flared gas per year (MMBtu/yr)] x [Emission factor (lb/MMBtu)] / [2,000 lb/ton]

Annual Emissions (ton/yr) = [S Content (grains/scf)] x [Molecular Weight SO_2 (lb/lb-mole)] / [Molecular Weight S (lb/lb-mole) x [Flared gas (MMBtu/yr)/ Flared Gas HHV (Btu/scf)* 1,000,000 Btu/MMBtu] / [7000 (grains/lb)] x [1 - Conversion of SO_2 to H_2SO_4 (percent)]

Annual Emissions (ton/yr) = [Emission Factor (µg/L)] / [1,000,000 (µg/g)] x [0.00220462 (lb/g)] x [28.317 (L/ft^3)] x [10.6 (ft^3 exhaust/ft^3 fuel)] x [Flared gas (MMBtu/yr) / Flared Gas HHV (Btu/scf) * 1,000,000 Btu/MMBtu]

Annual Emissions (ton/yr) = [SO_2 Annual Emissions (ton/yr)] x [Conversion of SO_2 to H_2SO_4 (percent)] x [Molecular Weight H_2SO_4 (lb/lb-mole)] / [Molecular Weight SO_2 (lb/lb-mole)]

Annual Emissions (tons/yr) = [Emission Factor (lb/MMscf)] x [Flared Gas (MMBtu/yr) / [Flared gas HHV (Btu/scf)] / [2,000 lb/ton]

Annual Emissions (ton/yr) = [Emission Factor (kg/MMBtu)] x [Flared Gas (MMBtu/yr)] x [2.20462 (lb/kg)] / [2,000 (lb/ton)]

Notes:

(1) AP-42, Chapter 13.5, Table 13.5-1. THC and Soot Emissions Factors for Flare Operations, October 1996. PM emission factor is for lightly smoking flare.

(2) AP-42, Chapter 13.5, Table 13.5-2. VOC and CO Emissions Factors for Flare Operations, October 1996.

(3) Sulfur content of 0.01 grains per scf provided by KBJ.

(4) Assume conversion of SO_2 to SO_3 of 5 percent by volume as provided by KBJ.

(5) AP-42, Chapter 1.4, Table 1.4-2. Emission Factors for Criteria Pollutants and Greenhouse Gases from Natural Gas Combustion, July 1998. Note lead is a HAP and is included in the HAP total.

(6) Carbon dioxide equivalent, global warming potentials; CO_2 = 1, CH_4 = 25, N_2O = 298.

(7) Emission Factors from Tables C-1 and C-2 to Subpart C of 40 CFR Part 98 - Default CO_2, CH_4 and N_2O Emission Factors for Various Types of Fuel.

(8) Ventura County Air Pollution Control District.

(9) Information provided by JCLNG for gas up/cool down procedures. Ship vapor (14% CO_2, 84% N_2, 2% O_2) is displaced with LNG. When hydrocarbon is detected it is sent to the flare. When the gas contains less than 50 ppm CO_2 it is sent to be used as fuel gas. Two scenarios were supplied, with and without turbulence for the gas up procedure. The scenario with the greater emissions (turbulence) is included. During the cool down procedure all gas is sent to the fuel gas system.

Table 13. Fugitive Potential Emissions
Jordan Cove Energy Project L.P. - Emission Inventory
Coos Bay, Oregon

Pollutant	Annual Emissions (tons/yr)			
	LNG Tank	Equipment Leaks	Total	
Criteria Pollutants				
NO_X	---	---	---

N_2O	---	---	---	
Hazardous Air Pollutants				
N-Hexane [(a)]	2.5E-02	1.75	1.77	(4)
Total HAPs			**1.77**	
Maximum Individual HAP			**1.77**	

Calculations:

(a) Annual Emissions (tons/yr) = [VOC Hourly Emissions (tons/yr)] x [N-Hexane/CO_2 Content (mass %)] / [VOC Content (mass %)]

N-Hexane Content (mass %) =	0.31	(4)
VOC Content (mass %) =	1.38	(4)

Notes:

(1) The tank size is the same as in the original permit application. Therefore, the tons/yr emissions for the tanks are from original permit application. See Table 17 for the Equipment Leak Emission calculations.

(2) Carbon dioxide equivalent, global warming potentials; CO_2 = 1, CH_4 = 25

(3) Carbon dioxide emissions are based on a gas composition of 0.36 mol percent VOC and 0.11 mol percent CO_2. See KBJ fuel gas composition provided in Zeeco flare quote.

(4) N-Hexane emissions are based on a fuel gas composition provided by KBJ.

All,

Here is the determination by Don Shepherd of the NPS that Jordan Cove will not have a significant impact on AQRVs for the NPS Class I areas. The USFS has not yet made their determination.

Phil

Subject: Re: FW: Additional information request

Hi Phil,

Based upon the new information provided by the applicant, we conclude that it is unlikely that the Jordan Cove Energy Project would have a significant impact upon Air Quality Related Values in any of our Class I areas.

We would appreciate it if OR DEQ would provide electronic copies of the complete/final permit application, staff analysis, draft permit, and public notice.

thanks,

Subject: RE: Additional information request

Hi Phil, please see below for our response to Don Shepherd's request. Please let me know if there are any additional questions.

SLR has recalculated the Q value for the Jordan Cove Energy Project based on a worst-case 24 hour emission scenario for project emissions of PM, SO_2, NOx, and H_2SO_4 (see attached). Following FLAG 2010 guidance, the worst-case 24 hour emissions were assumed to persist for the entire year and then summed in order to calculate the ton per year emissions (Q). The worst-case daily emissions scenario includes the following assumptions:

- Each turbine undergoing a startup/shutdown with normal operation (with duct burners) thereafter;
- Continuous operation of the thermal oxidizer;
- Continuous operation of the auxiliary boiler;
- One hour of operation of each of the three fire water pumps;
- One hour of operation of each of the two backup generators;
- One hour of operation of each of the two black start generators;
- Continuous operation of the ground flare and the marine flare pilot and purge gas; and
- Continuous emissions from gas up (flaring of gas vented from incoming LNG tankers).

Based on this worst-case daily emissions scenario, the calculated Q value is 849 tons per year. Both Crater Lake National Park (NP) and Redwood NP are approximately 165 km from the facility, **resulting in a Q/D value of 5.1**. In the development of the worst-case scenario, it is noted that several of the sources are intermittent (e.g., startup/shutdowns, auxiliary boiler, firewater pumps, backup generators, black start generators, and gas up emissions), thus concurrent operation of these sources in the same day is extremely unlikely.

It should also be noted that the Q value quoted in the Jordan Cove Energy Project modeling protocol was provided for informational purposes only for the Type B state New Source Review application, since AQRV analyses are not required.

Subject: Additional information request

Hi Jason,

See below for email from Don Shepherd of the NPS requesting additional information for the Q/d calculation for Class I Area impacts. Please respond to me, and I will forward the revised information to both the NPS and USFS.

On a separate note, the inventory of competing sources will be sent later today by separate email.

Please contact me if you have questions. Thanks.

Subject: Jordan Cove Modeling Protocol and Q/d

Hello Phil,

Tonnie Cummings has asked me to respond to your request for comments on the modeling protocol for the Jordan Cove Energy Project.

Before i can give you a decision, i need clarification of how the "Q" value in the Q/d calculation was derived. Here is what the applicant says on page 21 of the application:

Using the emissions summarized in Table 2-1 for the visibility impairing pollutants of NOx, SO2, PM, and H2SO4 the calculated Q value is 327.6. Using the shortest distance, D, from Table 4-1 above, the Q/D value is calculated to be 2.98, which is below the threshold value of 10.

My concern regards Table 2.1 on page 3. According to the applicant:

The potential annual emission rates for each criteria air pollutant from each source are shown in Table 2-1. The EPC contractor, KBJ, has completed the pre-FEED design stage of the project and is currently developing the detailed facility design.

Instead of using annual average emissions, Q should be calculated based upon the maximum 24-emission rates of NOx, SO2, PM, and H2SO4, including start-ups and shut-downs. The maximum 24-hour emission rate should then annualized to yield a tpy value for Q. It is also important that the applicant provide its calculations and assumptions in deriving these emission rates.

Please feel free to contact me with any questions.

thanks,

Don Shepherd

Subject: RE: NPS Class I Area Determination

Hi Phil,

Given that the revised Q/D for Kalmiopsis – the closest Class I unit – is still < 10, Rick and I do not think Jordan Cove will have a significant impact for USFS Class I areas. Thank you for providing the feedback from Tonnie, Don, and others.

Best,

Jim

SUMMARY

At the request of Jordan Cove Energy Project, L.P. (JCEP), SLR International Corporation (SLR) has conducted baseline ambient sound level monitoring for the proposed natural gas liquefaction and liquefied natural gas (LNG) export facility (LNG Terminal).

This report presents the results of the sound level measurements for the JCEP Project area. The measurement results are summarized in the table below.

Summary of Long-Term Baseline Sound Level Measurement Data

Receptor	Distance to Receptor, Miles	Direction	Measurement Duration(1) HH:MM	Daytime(2) L_{eq}, dBA	Nighttime(3) L_{eq}, dBA	Ambient L_{dn}, dBA
NSA 1	1.3	South	29:48	51.7	43.9	**52.7**
NSA 2	2.2	East	32:39	62.7	57.5	**65.2**
NSA 3	1.3	Northeast	32:03	57.9	40.3	**56.3**
REC 1	0.7	West	31:50	51.1	48.3	**55.2**

(1) The Measurement Duration represents the total duration of valid data, when the wind speed was less than 6.6 m/s.

(2) Daytime is 7:00 a.m. until 10:00 p.m.

(3) Nighttime is 10:00 p.m. until 7:00 a.m. the next day.

1. INTRODUCTION

At the request of Jordan Cove Energy Project, L.P. (JCEP), SLR International Corporation (SLR) has conducted baseline ambient sound level monitoring for the proposed natural gas liquefaction and liquefied natural gas (LNG) export facility (LNG Terminal). The facility site is located on the bay side of the North Spit of Coos Bay, Oregon. This report presents the results of the sound level measurements for the JCEP Project area.

2. ENVIRONMENTAL SOUND LEVEL CRITERIA

2.1 FEDERAL

The environmental sound level contributions from the proposed equipment at this facility are subject to the FERC noise regulation governing interstate gas transmission compressor stations and LNG facilities. The FERC noise regulation is receptor based, and limits LNG facility noise contributions to no more than 55 dB(A) day-night average (L_{dn}) or, equivalently, no more than a continuous 48.6 dB(A) at the surrounding noise sensitive areas (NSAs) such as schools, hospitals, or residences.

2.2 STATE AND LOCAL

The ODEQ noise standards are contained in OAR, Chapter 340, Division 35 – Noise Control Regulations. The OAR noise regulations are not directly applicable to the operational noise from the LNG Terminal site.

The City of North Bend has a noise ordinance that prohibits the “making of unnecessary noise,” but the ordinance has no specific numerical limits (North Bend City Code, Section 9.04.030). Daytime construction noise between the hours of 7 a.m. to 6 p.m. is exempt under the North Bend ordinance. The project is located in Coos County, but Coos County does not have a noise ordinance.

3. SOUND LEVEL SURVEY AND SITE ASSESSMENT

3.1 METHODOLOGY

A baseline ambient environmental sound level survey was conducted near the JCEP project area by Jessica Stark and Kellye Larsen of SLR on May 23 – 26, 2017. Sound level monitors were positioned near each receptor, as shown on the attached Figure 1 in order to measure environmental sound levels during daytime and nighttime hours. Over 72 hours’ worth of continuous sound measurement data were collected at each location. An averaging period with 1-hour samples was used. Sound levels were also simultaneously collected in terms of 60-second averages to capture shorter-term variations in sound levels. The sound meters were time synchronized with each other. Microphones were located approximately 5 feet above the ground and a windscreen was used.

3.2 NOISE SENSITIVE AREAS

A drawing showing the approximate distance and direction from the facility to the receptors is shown in the attached Figure 1 and summarized in Table 1. Distances are referenced from the center of the proposed liquefaction area. There were three NSAs identified. NSAs 1 and 2 represent residential communities consisting primarily of single family houses. NSA 3 was a campground and recreation area. A fourth recreational area was monitored and is referred to as REC 1.

Table 1: Summary of Pre-existing Noise Sensitive Areas

Receptor	Description	Direction to Receptor	Distance, miles
NSA 1	Residential	South	1.3
NSA 2	Residential	East	2.2
NSA 3	Campground	Northeast	1.2
REC 1	Recreational	West	0.7

3.3 MEASUREMENT EQUIPMENT

Sound level equipment used during the site survey included the following instruments:

- Larson Davis Model 831 SLM; Type 1; s/n 0001736, 0001737, and 0002443
- Brüel & Kjær Model 4231 Pure Tone Calibrator; Class 1; s/n 2240964

Equipment was field calibrated before and after measurement intervals. All instrumentation has current laboratory certification. Calibration certificates are attached.

3.4 WEATHER CONDITIONS

Weather station data (wunderground.com) for the North Bend Municipal Airport, North Bend, Oregon (KOTH) were used to determine ranges of environmental parameters during the monitoring period, as summarized in Table 2.

Table 2: Weather Data During the Monitoring Period

Date	May 23 – 26, 2017
Temperature	48 – 61° F
Relative Humidity	59 – 100%
Wind Direction	North & NNE
Wind Speed	0 – 33 mph
Sky Condition	Clear
Ground Condition	Damp

The wind was generally from the north (59% of the time) and north-northeast (12%) during the survey. The wind speed was 10 mph or less 36% of the time. There was no precipitation during the survey period.

3.5 DATA REDUCTION

ANSI S12.18 does not allow for sound level measurements during wind speeds greater than 5 m/s (11.2 mph). To account for the fact that data were collected at a height of 5 feet (1.5 m) above ground, and a typical weather station anemometer is located at a height of 10 m above ground, the wind speed threshold was adjusted for height using wind profile power law. Based on this equation, which corrects between wind speeds at different heights, a speed of 6.6 m/s (14.8 mph) at a height of 10 m was found to correspond to a speed of 5 m/s at a height of 1.5. Therefore, measurement data that were collected during periods with wind speed exceeding 6.6 m/s were excluded from analysis.

The wind speed exceeded this for 44 percent of the measurement duration. The monitored sound level data were processed to eliminate data from periods when wind speeds exceeded 6.6 m/s. The following tables show, for the respective receptors measuring locations, the data reduction including the total cumulative amount of measurement time used to determine the L_{dn} for each location.

3.6 MEASUREMENT RESULTS AND AMBIENT SOUND ENVIRONMENT

The 24-hour day-night average (L_{dn}) sound levels have been determined based on the data-reduced daytime and nighttime sound levels measured at the four monitoring positions. The results are shown in Table 7. Level versus time graphs are included in Appendix A.

Table 7: Summary of Long-Term Baseline Sound Level Measurement Data

Receptor	Distance to Receptor, Miles	Direction	Duration[(1)] HH:MM	Daytime[(2)] L_{eq}, dBA	Nighttime[(3)] L_{eq}, dBA	Ambient L_{dn}, dBA
NSA 1	1.3	South	29:48	51.7	43.9	**52.7**
NSA 2	2.2	East	32:39	62.7	57.5	**65.2**
NSA 3	1.3	Northeast	32:03	57.9	40.3	**56.3**
REC 1	0.7	West	31:50	51.1	48.3	**55.2**

(1) The Measurement Duration represents the total duration of valid data, when the wind speed was less than 6.6 m/s.

(2) Daytime is 7:00 a.m. until 10:00 p.m.

(3) Nighttime is 10:00 p.m. until 7:00 a.m. the next day.

Existing environmental noise sources present at NSA 1 included industrial noise from the nearby water treatment plant, airplane traffic at the nearby airport, and intermittent traffic noise on the neighborhood streets. Wind noise and frog vocalizations were also audible.

Environmental noise sources present at NSA 2 included vehicular traffic on the Highway 101 bridge and on nearby local roads. A helicopter in flight was also observed. Wind noise was also audible.

Environmental noise sources present at NSA 3 included a recreational vehicle power generator, all-terrain vehicles, and human activities including speech and shouts. Wind noise and frog vocalizations were also audible.

Environmental noise sources present at REC 1 included general traffic noise, an all-terrain vehicle, forest sounds, and high wind noise. Waves and frog noise were generally the dominant sound sources.

In addition to the reduced data, Table 8 show what the sound level was at each receptor without the wind speed data reduction. These data are just slightly higher than the wind speed corrected data. The wind speed corrected data will be used for any further analysis to be conservative.

Table 8: Summary of Baseline Sound Level Measurement Data Without Data Reduction

Receptor	Distance to Receptor, Miles	Direction	Duration HH:MM	Daytime[1] L_{eq}, dBA	Nighttime[2] L_{eq}, dBA	Ambient L_{dn}, dBA
NSA 1	1.3	South	72:24	52.8	46.0	**54.3**
NSA 2	2.2	East	72:35	63.3	57.3	**65.3**
NSA 3	1.3	Northeast	72:15	57.1	44.5	**56.3**
REC 1	0.7	West	72:12	52.3	49.4	**56.4**

(1) Daytime is 7:00 a.m. until 10:00 p.m.

(2) Nighttime is 10:00 p.m. until 7:00 a.m. the next day.

4. SUMMARY AND CONCLUSION

Sound level measurements were taken at the receptors around the proposed LNG Facility. The measurements show that the current ambient sound levels range from 53 to 65 dB(A) L_{dn}. High wind speeds were present during the survey and are typical for the coastal area. However, the data were processed so that only sound level data taken during periods when the wind speed was below 6.6 m/s were used to determine the day night average sound level at each site.

APPENDIX A

LEVEL VERSUS TIME GRAPHS FOR OVERNIGHT MONITORING

A graphical presentation of all of the monitoring data is included in this appendix. Each measurement position has four pages of graphs, the first is the full data set from May 23 to May 26, 2017 followed by individual daily graphs. The top section of each graph shows the 1-minute L_{eq}, represented by a solid blue line; the 1-hour L_{eq}, a stepped red line; and the 1-hour L_{90}, a stepped green line.

The bottom section of the graphs shows the frequency-based data. Sound frequency is plotted on the vertical axis and time on the horizontal axis. The color indicates the A-weighted sound pressure level at each frequency. The frequency data are useful for determining the presence of any tonal frequencies and helps to characterize the presence of specific noise emissions.

SOUND LEVEL EQUIPMENT CALIBRATION CERTIFICATIONS

(D)

Calibration Certificate

Certificate Number 2015007196

Customer:
The Modal Shop
3149 East Kemper Road
Cincinnati, OH 45241, United States

Model Number	831
Serial Number	0001736
Test Results	**Pass**
Initial Condition	AS RECEIVED same as shipped
Description	Larson Davis Model 831

Procedure Number	D0001.8378		
Technician	Ron Harris		
Calibration Date	30 Jul 2015		
Calibration Due	30 Jul 2016		
Temperature	23.27	°C	± 0.01 °C
Humidity	49.1	%RH	± 0.5 %RH
Static Pressure	86.98	kPa	± 0.03 kPa

Evaluation Method Tested electrically using PRM831 S/N 029412 and a 12.0 pF capacitor to simulate microphone capacitance. Data reported in dB re 20 μPa assuming a microphone sensitivity of 50.0 mV/Pa.

Compliance Standards Compliant to Manufacturer Specifications and the following standards when combined with Calibration Certificate from procedure D0001.8384:

IEC 60651:2001 Type 1	ANSI S1.4-2014 Class 1
IEC 60804:2000 Type 1	ANSI S1.4 (R2006) Type 1
IEC 61252:2002	ANSI S1.11 (R2009) Class 1
IEC 61260:2001 Class 1	ANSI S1.25 (R2007)
IEC 61672:2013 Class 1	ANSI S1.43 (R2007) Type 1

Issuing lab certifies that the instrument described above meets or exceeds all specifications as stated in the referenced procedure (unless otherwise noted). It has been calibrated using measurement standards traceable to the SI through the National Institute of Standards and Technology (NIST), or other national measurement institutes, and meets the requirements of ISO/IEC 17025:2005. **Test points marked with a ‡ in the uncertainties column do not fall within this laboratory's scope of accreditation.**

The quality system is registered to ISO 9001:2008.

This calibration is a direct comparison of the unit under test to the listed reference standards and did not involve any sampling plans to complete. No allowance has been made for the instability of the test device due to use, time, etc. Such allowances would be made by the customer as needed.

The uncertainties were computed in accordance with the ISO Guide to the Expression of Uncertainty in Measurement (GUM). A coverage factor of approximately 2 sigma (k=2) has been applied to the standard uncertainty to express the expanded uncertainty at approximately 95% confidence level.

The quality system is registered to ISO 9001:2008.

This calibration is a direct comparison of the unit under test to the listed reference standards and did not involve any sampling plans to complete. No allowance has been made for the instability of the test device due to use, time, etc. Such allowances will be made by the customer as needed.

The uncertainties were computed in accordance with the ISO Guide to the Expression of Uncertainty in Measurement (GUM). A coverage factor of approximately 2 sigma (k=2) has been applied to the standard uncertainty to express the expanded uncertainty at approximately 95% confidence level.

Certificate of Calibration

for

PRECISION INTEGRATING SLM

Manufactured by:	LARSON DAVIS
Model No:	831
Serial No:	0001737
Calibration Recall No:	26438

Submitted By:

Customer:	Eve MacPherson
Company:	SLR INTERNATIONAL CORPORATION
Address:	6001 SAVOY DRIVE
	HOUSTON TX 77036-332

The subject instrument was calibrated to the indicated specification using standards traceable to the National Institute of Standards and Technology or to accepted values of natural physical constants. This document certifies that the instrument met the following specification upon its return to the submitter.

West Caldwell Calibration Laboratories Procedure No. 831 LARS

Upon receipt for Calibration, the instrument was found to be:

Within (X)

tolerance of the indicated specification. See attached Report of Calibration.

West Caldwell Calibration Laboratories' calibration control system meets the requirements, ISO 10012-1 MIL-STD-45662A, ANSI/NCSL Z540-1, IEC Guide 25, ISO 9001:2008 and ISO 17025.

Note: With this Certificate, Report of Calibration is included.

Approved by:

Calibration Date: 29-Apr-16

[1] A concrete truck holds 10 cubic yards and a cubic yard is approximately 2 tons. Amounts delivered are based on truck deliveries.

[2] WRAP Fugitive Dust Handbook, Countess Environmental, September 2006, Section 3.4.1. Water and otherapproved dust suppressants would be used at construction sites.

Dust Control Efficiency = 50%

[3] WRAP Fugitive Dust Handbook, Table 3-2 "Recommended PM10 Emission Factors for Construction Operations", level 1, average conditions.

According to Section 3.3.1, "The PM2.5/PM10 ratio for fugitive dust from construction and demolition activities is 0.1based on the analysis conducted by MRI on behalf of WRAP."

PM_{10} Emission Factor = 0.11 tons/acre-month

$PM_{2.5}$ Emission Factor = 0.011 tons/acre-month

[4] AP-42 Table 11.12-2, Emission Factors for Concrete Batching, Uncontrolled

Aggregate Transfer = 0.0033 lb PM_{10}/ton of material, 1865 pounds aggregate per cubic yard of cement

Sand Transfer = 0.00099 lb PM_{10}/ton of material, 1428 pounds sand per cubic yard of cement

Weigh Hopper Loading = 0.00280 lb PM_{10}/ton of material (aggregate and sand)

Mixer Loading = 0.156 lb PM_{10}/ton of cement

Truck Loading = 0.310 lb PM_{10}/ton of cement

Total Emission Factor = 0.47017 lb PM_{10}/ton of cement

[5] Data does not include TPP/101, Kentuck Slough, and potential utilities installation.

[5] Terminal (Ingram Yard, South Dunes, Corridor, Berth), plus Roseburg.

APPENDIX F.9

Marine Vessel Inventory and Emission Calculations

The fleet of LNG vessels expected to call at the JCEP terminal consists of both vessels that have boiler/steam turbine driven (ST) propulsion systems, as well as vessels powered by duel-fuel diesel-electric (DFDE) propulsion. Further, each type of vessel may be operated on either natural gas or fuel oil. For the DFDE ships, however, operation on oil versus operation on natural gas was confined to different activities during the ship's call. Therefore, three vessel emissions scenarios were created in order to determine worst-case air emissions calculations and associated air quality impacts:

- ST vessels operating on oil
- ST vessels operating on natural gas
- DFDE ships

JCEP expects up to 120 LNG vessel calls per year. For the purposes of the modeling, in each of the three scenarios, it is assumed that all of the 120 vessel calls will be of ships of the same propulsion and fuel type.

The LNG vessel call activities can be divided into the following activities and operating periods per visit. These activity times are not dependent on the ship or fuel type. As can be seen in table F-1 the activities in total will last 29 hours per vessel call.

Emission rates for different activities during the ship's call are developed from the emission factors shown in Table F-2, and the amount of power expected to be consumed during that particular activity. As the emission factors are in a g/kWh basis, and the power will vary depending on activity, the emission rates (on a mass per unit time basis) will vary depending on the activity in which the ship is engaged.

If a ship is engaged in a particular activity for the full averaging period, than the full mass per unit time rate is used for modeling of that activity. If a ship is engaged for the activity for a portion of the averaging period, then the mass per unit time emission factor is weighted by the proportion of the activity time to the time of the averaging period. For example, for an activity that takes four hours, the full mass per unit time emission rate calculated will be used for 1-hour averaging periods (as the activity time is longer than that averaging period), but one-sixth of the full mass per unit time emission rate will be used for 24-hour averaging periods (as the four hours of activity time is one-sixth of the averaging period).

The emission factors are shown in Table F-2. The mass per unit time emission calculations for each of the three types of ships are shown in Tables F-3 through F-5, respectively. The emission rates by pollutant and averaging period for model input are shown in Tables F-6 through F-8, respectively. Vessel source locations and stack parameters are shown in Tables F-9 through F-11, respectively.

In addition to the activities at and in the immediate vicinity of the terminal, the emissions of the ship's transit of the channel and near-shore open water are considered by setting up 68 sources along the geographic track of arriving and departing ships. The transit emission rates are used for these surrogate sources, with the emissions divided equally over the 68 surrogate sources.

In addition to the LNG vessels, tugboats will also be deployed in operation at the JCEP LNG terminal. The worst-case scenario involves use of one tugboat. Since the tugboat will be maneuvering around the ship during the worst case, the tugboat is represented as a series of four surrogate sources in the channel adjacent to the ship dock, with one-quarter of the total tugboat emissions assigned to each surrogate source. The tugboat emissions are shown in Table F-12, and stack parameters and location information of the tugboat are detailed in Table F-13.

Marine vessel emissions scenario summaries for the annual, 24-hour, and 1-hour averaging periods are shown in Tables F-14 through F-16.

Table F-1. LNG Vessel Activities and Operating Periods per Visit

Category	Activity	Time (hours)
Transit	Arrival to Berth	2
	Transit Berth to Pilot Station	2
Hoteling	Berthing Vessel	1
	Berthed, Not Carrying Out Cargo Transfer	6
	Vessel warm up of main engine and departure preparation	2
	Unberthing time	1

Table F-12. Tugboat Emissions Information[1]							
Pollutant	Emission Factor (g/kWh)	Tug Emissions per Port Call (kg)	Emission Factors for Modeling (per surrogate source, g/s)[1]				
			1-hour	3-hour	8-hour	24-hour	Annual
NO_x[2]	1.80E+00	72	2.38E-01	N/A	N/A	N/A	5.70E-04
CO[3]	3.35E+00	134	4.42E-01	N/A	4.42E-01	N/A	N/A
PM[2]	6.00E-02	2	N/A	N/A	N/A	7.93E-03	1.90E-05
SO_2[3]	4.92E-01	20	6.50E-02	6.50E-02	N/A	6.50E-02	1.56E-04
VOC[2]	1.90E-01	8	N/A	N/A	N/A	N/A	N/A
CO_2[3]	7.06E+02	28183	N/A	N/A	N/A	N/A	N/A

Notes:
(1) Tug is represented as four surrogate sources to account for manuevering about the berthed ship.
(2) NOx, PM, and VOC emissions are EPA Marine Tier 4 standards (40 CFR Section 1042.1, Table 3)
(3) CO, SO2, and CO2 emission factors from AP42 Table 3.4-1. Sulfur content of fuel assumed 0.1%.
(4) Emissions per call calculated by multiplying emisison factor by 39942 kWh, the total energy expended per ship call. Rates determined by dividing total emissions by 1260 minutes operation per ship call. Emission rate for each surrogate source is one-quarter of the overall emission rate. Annual emissions based on 120 ship calls per year.

Tug Activities and Operating Times per Ship Call

Activity	Time (min)	Kw	Kw-Hour
Maneuvering Around Ship	1200	1902	38040
Maneuvering Around Ship/Easy Push	60	1902	1902
Total Tug Activity per LNG Ship Call	1260	1902	39942

Table F-13. Tugboat Stack and Location Information[1]						
Location			Stack Parameters			
UTM E (m)	UTM N (m)	Elevation (m)	Height (m)	Temp (K)	Velocity (m/s)	Diameter (m)
397485.0	4809200.0	0.0	10.7	801.0	61.8	0.3
397485.0	4809100.0	0.0	10.7	801.0	61.8	0.3

(1) The tug emissions are included in all 1-hour scenarios, along with one of the individual activities below.
The ship activities included in the source groups differ for the 1-hour NO2 and SO2 full impact modeling versus the 24-hour and annual full impact modeling for PM2.5 and PM10 and annual full impact modeling for NO2 because of the length of the ship calls at the Terminal and the time the ship is engaged in each activity during its call. For the 1-hour averaging periods, source groups include the emissions from one activity of the LNG tanker (transit, arrival to berth, departure from berth, berthing, berthed but not carrying out cargo transfer, berthed and carrying out cargo transfer, warmup and unberthing time." Each of these activities take at least one hour. Therefore, 1-hour source groups for marine vessels are designed to include one of these individual activities, in addition to the activities of the tugboats. For the 24-hour and annual averaging periods, relevant source groups include multiple activities from the LNG tanker in addition to the tugboats.

(2) Four surrogate tugboat sources and 68 surrogate vessel sources are used to represent the motion of these vessels.
Each surrogate tug is assigned 1/4 of the total tug emissions, and each surrogate vessel 1/68 of the total vessel emissions

LIST OF FIGURES

1 Scope

This document describes the basis, methodology, and results of acoustical modeling for the JCLNG project. It includes updated acoustical design and performance information that is consistent with the Acoustical BOD, along with acoustical calculation results in accordance with design standards.

2 Applicable Documents

2.1 SUPPORTING AND SUPPLEMENTAL DOCUMENTS

2.1.1 Supporting Documents

Supporting documents are those documents that are used in conjunction with this document.

Document Title	Document Number
1. Acoustical BOD	J1-000-MEC-BOD-KBJ-50002

2.1.2 Drawings

JCLNG Project Drawing Title	JCLNG Document Number
1. Overall Plot Plan	J1-000-TEC-PLT-KBJ-51000-01 (Proj. Dwg. No. 189980-0000-FG2000)
2. Liquefaction Plot Plan	J1-000-TEC-PLT-KBJ-51001-01 (Proj. Dwg. No. 189980-0000-FG2001)
3. Equipment Layout Liquefaction – Train #1	J1-000-PIP-PLT-KBJ-50002-01 (Proj. Dwg. No. 189980-0000-FM0011)

3 Codes and Standards

Codes and Standards to be used on the JCLNG Project are the latest version of the codes and standards identified in 189980-0000-FU0200 Applicable Code and Standards, including ISO 9613 for calculation of outdoor sound levels, unless otherwise noted therein.

4 Calculation Methodology

Calculations were completed in accordance with ISO 9613 methodology using DataKustik Cadna/A™ software (version 2017). Modeling configuration was as follows:

- Source-to-receiver search radius: 6 km
- Temperature: 10 °C
- Relative humidity: 70 percent
- Default ground absorption value, G: 0.50 ("mixed" ground)

ISO 9613 calculations inherently assume a downwind condition from all sources to all receivers, and a moderate temperature inversion akin to a clear, calm, nighttime condition. Effects of local topography were included via project site grading information and GIS terrain data. Water surfaces—i.e., Coos Bay—were included with G=0.0 ("hard" ground). Shielding from major project equipment and structures, including impermeable vapor barrier walls, was included. Shielding from off-site structures was not included. All other calculation parameters were default ISO 9613 values.

5 Model Input (Sources)

Equipment packages considered in the acoustical model are detailed in Table 5-1. Information is consistent with the referenced Acoustical BOD. Items not originally included in the Acoustical BOD, but considered for this updated analysis are as indicated in Table 5-1. Octave-band sound levels for equipment were included in the model, as shown in Table 5-2. The basis for octave-band sound levels was in-house data sources for similar equipment, or empirically calculated data adjusted to conform to project specifications and requirements. For reference, a 3-D view of the acoustical model is provided in Figure 5-1. Note that some sources that will not operate continuously, such as ground flares and tanker hoteling, were conservatively included in the model. No supplemental noise mitigation measures have been included in the model.

Table 5-1 JCLNG Project Equipment Broadband Sound Levels

Equipment Package	Qty	Sound Level Specification (L_p re 20 µPa)	Associated Sound Power Level (L_w re 1 pW)
Refrigerant compressor	5	95dBA @ 3 ft	112 dBA

Flare (max)	L_w	100	105	111	114	116	118	120	119	118
Engine noise	L_w	96	92	98	94	86	82	76	66	58

Note: L_w = sound power levels re 1 pW and L_p = sound pressure levels re 20 µPa. Sound levels are unweighted.

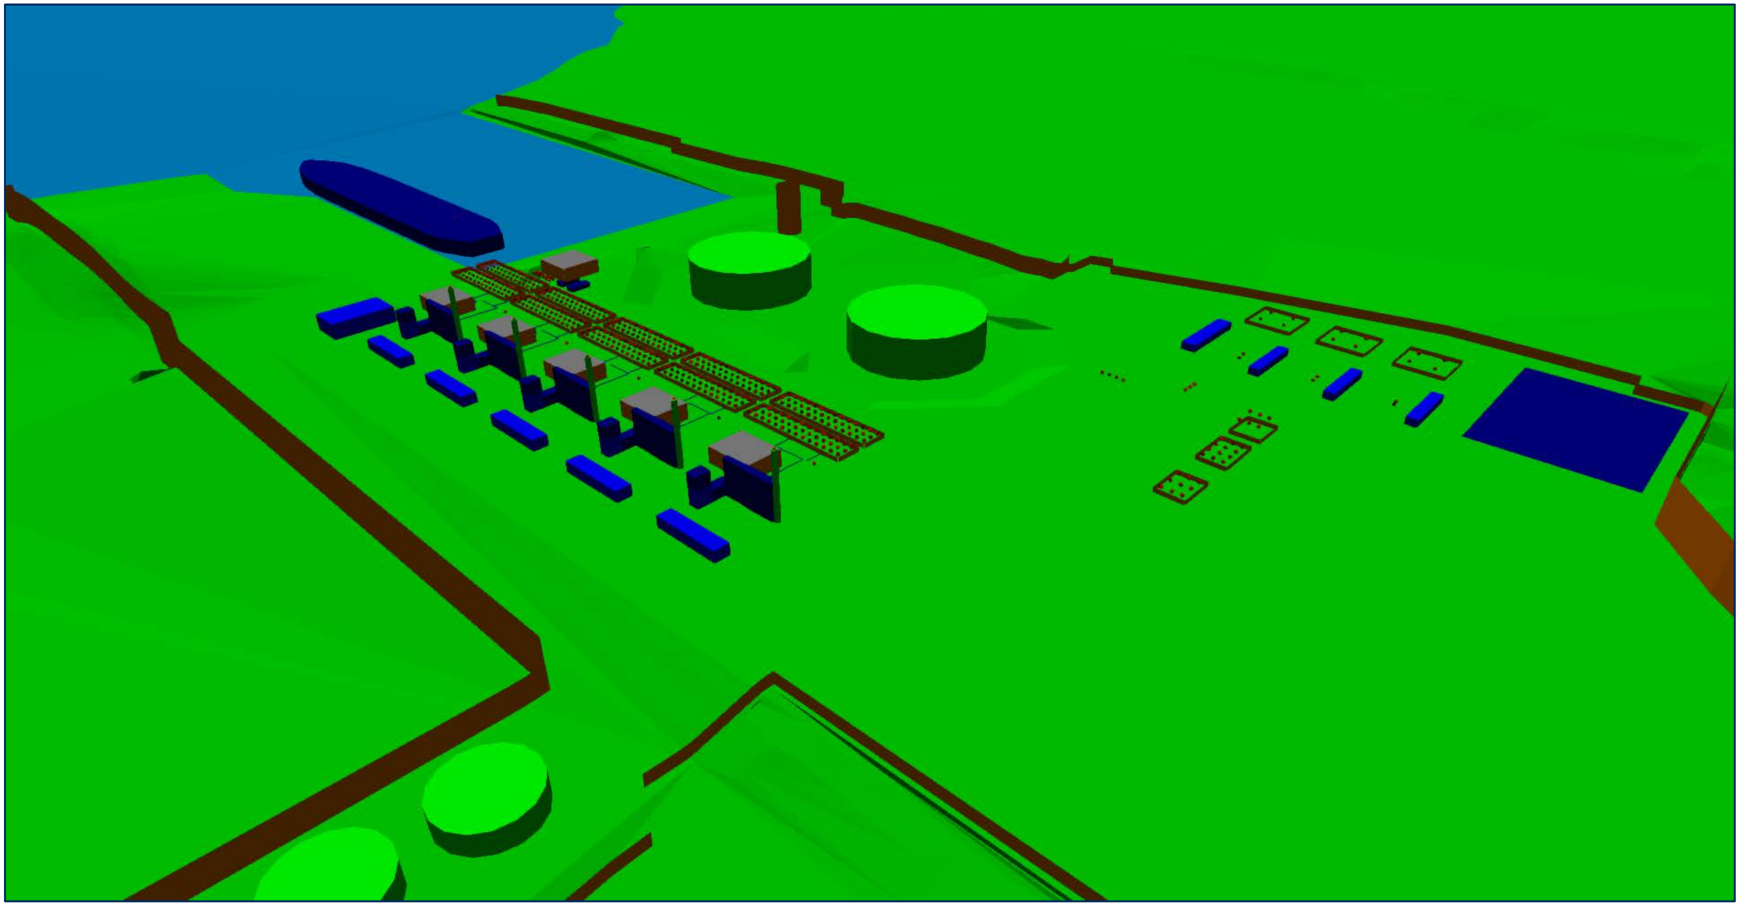

Figure 5-1 3D view of JCLNG acoustical model (from north).

6 Model Output (Results)

The results of the acoustical model were evaluated at three "noise-sensitive areas" (NSAs) that have been identified. Information regarding the location and predicted project sound levels at the NSAs is provided in Table 6-1. Figure 6-1 provides a sound level contour plot for the project and vicinity. Note that the sound levels include only project noise sources and do not include of any other sound sources, such as background noise.

Table 6-1 JCLNG Acoustical Modeling Results at NSAs

Location & Description	UTM Zone 10 Easting	UTM Zone 10 Northing	Elevation (AMSL)	Project L_{dn}	Project L_{eq}
NSA 1 – Residential	398481 m	4807460 m	29 m	51 dBA	45 dBA
NSA 2 – Residential	401292 m	4809791 m	34 m	43 dBA	37 dBA
NSA 3 – Horsfall Campground	399204 m	4810573 m	19 m	49 dBA	43 dBA

Note: L_{dn} = day-night average sound level (24-hour average sound level that includes a 10 dBA penalty for nighttime sound levels between 10 p.m. and 7 a.m.) and L_{eq} = equivalent-continuous ("steady-state" or "average") sound pressure level.

7 Mitigation

The modeling results include the effects of any standard noise control measures provided by equipment suppliers to meet the sound level specifications. Supplemental mitigation measures such as acoustical enclosures, acoustical barrier walls, and additional silencers, are not anticipated to be required for the project to achieve the sound levels noted above in Table 6-1.

Figure 7-1 JCLNG normal operations L_{dn} sound level contour plot (aerial from Google™ Earth).

APPENDIX H.9

Marine Mammal Airborne Noise Impact Assessment

Memorandum

To: Bill Gorham, AECOM

From: Briony Croft

Date: 20 September 2017

Subject: Jordan Cove LNG – Marine Mammal Airborne Noise Impact Assessment

This technical memorandum provides information on the airborne noise impacts of construction and operation of the Jordan Cove Energy Project (JCEP) LNG Terminal on marine mammals (hauled out).

Noise predictions provided in this memo have been determined using the Project's Resource Report 9 (RR9) noise model, but with noise levels presented in an unweighted format appropriate for a review of impacts to marine mammals (noting that A-weighted levels described in RR9 are appropriate for human impact assessment purposes only).

1.0 INTRODUCTION

1.1 Project Description

The marine facilities associated with the Jordan Cove Energy Project (JCEP) LNG Terminal will be on the bay side of the North Spit of Coos Bay, Oregon. Construction of the marine facilities will include several activities with the potential to generate noise affecting marine mammals in air (hauled out):

- General construction activities
- Dredging of the marine slip, access channel and materials offloading facility (MOF);
- Piling

These activities with potential for airborne noise generation are described in detail in the documents submitted to The Federal Energy Regulatory Commission (FERC) for the purpose of review of the potential environmental impacts of a proposed project under the National Environmental Policy Act (NEPA).

The most prevalent sound source during general construction is anticipated to be the internal combustion engines used to provide mobility and operating power to construction equipment.

Dredging would occur in a staged approach, with as much material as possible removed by excavation in isolation from Coos Bay behind a temporary berm. The noise levels of this activity would be broadly similar to general construction noise. Some in water dredging would also be required.

Approximately 3600 pipe piles and over 11,800 sheet piles will be will be required for the project in total, including marine and upland piles.

During operation of the LNG facility, the primary airborne noise sources would be compressors, condensers, steam turbine generators, coolers, pumps, valves and piping. The noise impacts to marine mammals during operation would generally be less than during construction.

1.2 Marine Mammal Species Considered

This assessment considers the potential for construction noise from the JCEP LNG Terminal Project to impact on hauled out marine mammals (ie, the potential for airborne noise to affect marine mammals who are on land, above the surface of the water).

RR3 Section 3.1.3 lists non-endangered marine mammals potentially occurring in the region, and Table 3.4-1 lists threatened and endangered species. Non-endangered marine mammal species potentially occurring in haul outs in the Coos Bay estuary include the California sea lion, Steller sea lion, and harbor seal.

2.0 MARINE MAMMAL NOISE IMPACT THRESHOLDS

Guidance on in-air acoustic thresholds for marine mammal disturbance are provided by the National Oceanic and Atmospheric Administration (NOAA) and the National Marine Fisheries Service (NMFS)[1]. There are no established thresholds for injury (hearing damage) applicable to marine mammals in air. The NMFS interim in-air thresholds behavioral effects are shown in Table 1.

Table 1 Interim in-air marine mammal acoustic thresholds

Criterion Definition	Threshold
Behavioral disruption for harbor seals	90 dB_{rms}
Behavioral disruption for non harbor seal pinnipeds	100 dB_{rms}

Notes: dB referenced to 20 micro Pascal (re: 20µPa).
All thresholds are based off root mean square (rms) levels and are broadband (unweighted).

Of the construction noise sources considered in this assessment, the majority are considered approximately “continuous” for the purpose of this assessment. For continuous noise sources, the rms noise level is equivalent to L_{eq} parameter. The L_{eq} is defined as the energy equivalent sound level, or the sound energy average over a defined time period. For this assessment, the rms in-air marine mammal acoustic thresholds are directly compared with the L_{eq} noise levels from general construction, dredging and operations.

Noise from impact pile driving is impulsive, characterized by rapid noise pulses with each strike of the pile. For an impulsive noise source, the rms sound level is defined as the average sound level for a duration that contains 90 percent of the total sound energy of the impulsive event. For the purpose of this assessment, the short term maximum sound level during pile driving (L_{max}) is compared directly with the rms behavioral disruption threshold. This is a conservative assessment approach, since the rms noise level for an impulsive event will always be less than the maximum sound level.

3.0 NOISE LEVEL VERSUS DISTANCE

For the purpose of this impact assessment, the objective is to quantify the noise level for the various scenarios considered, across the areas in the vicinity of the project where marine mammals may be present in air. Examples of the extent of noise impacts are provided in the form of noise isopleths corresponding to the 90 decibel (dB) and 100 dB impact thresholds in the following figures. The noise modelling process, inputs and assumptions are as described in the documents submitted to The FERC for the purpose of review of the potential environmental impacts of the project. An example of the general construction noise impacts to marine mammals in air are shown in Figure 1. Corresponding figures for in-air noise impacts to marine mammals during dredging and piling are shown in Figure 2 and Figure 3 respectively. These figures are indicative – the location of construction noise sources will move around the site, and the noise impacts will shift accordingly.

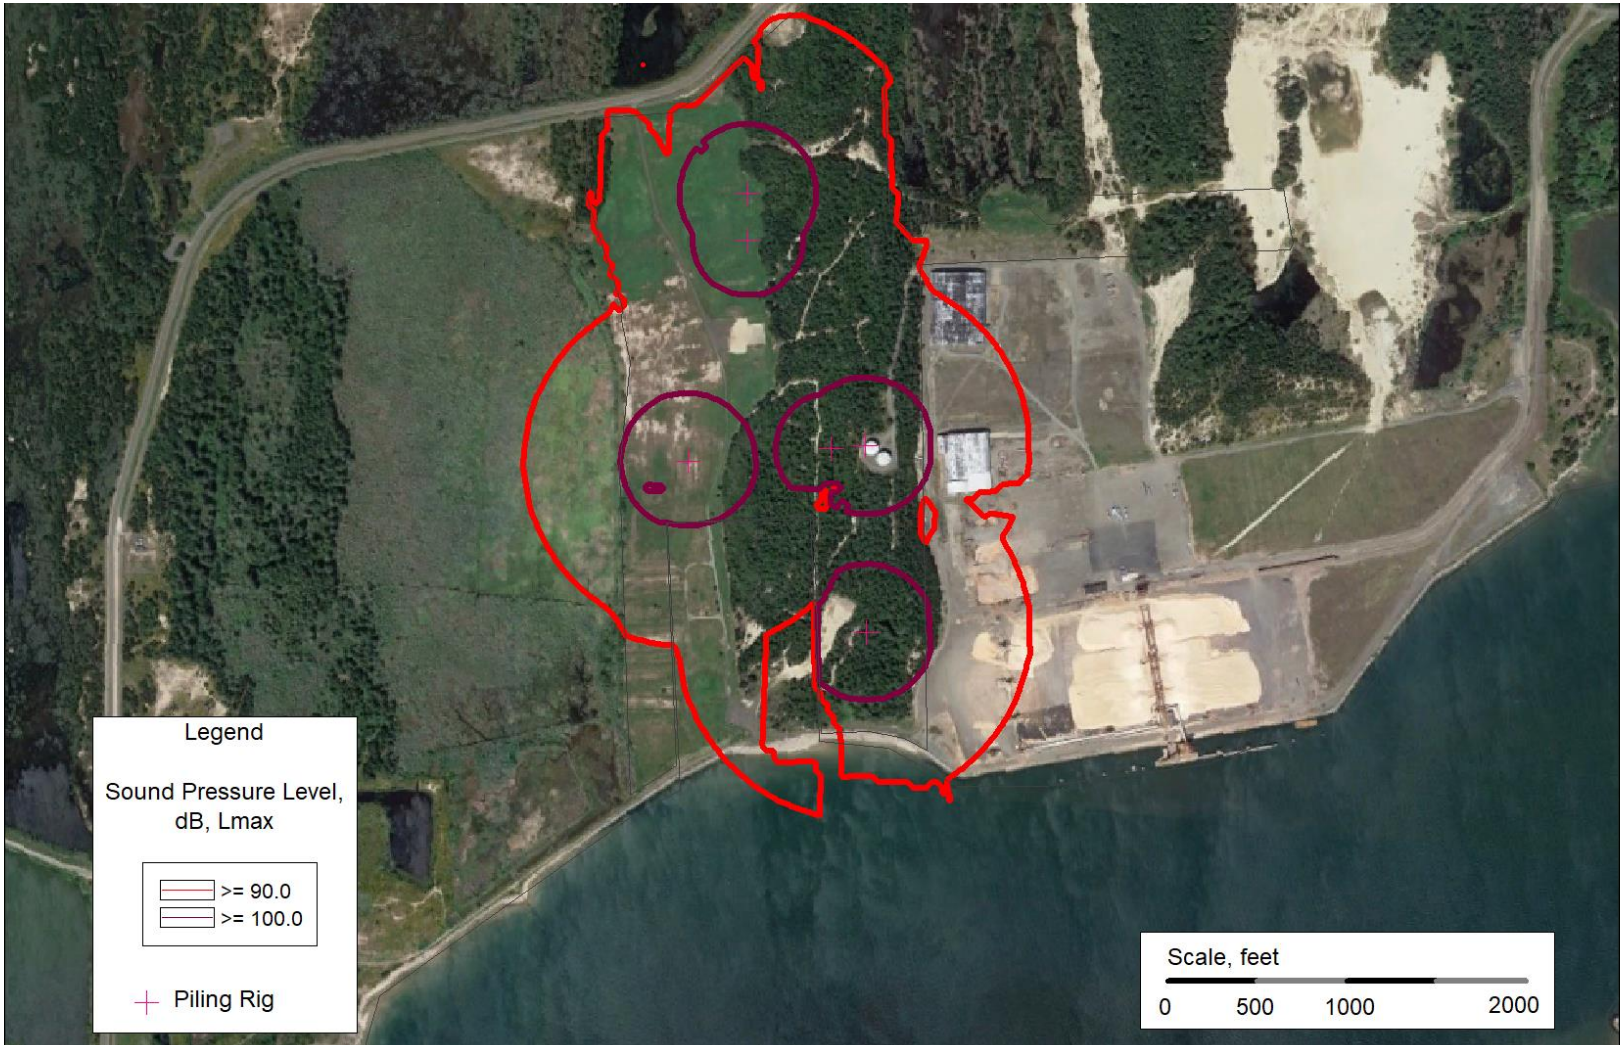
[1] http://www.westcoast.fisheries.noaa.gov/protected_species/marine_mammals/threshold_guidance.html

Figure 1 Indicative general construction in air marine mammal noise impacts

Figure 2 Indicative dredging in air marine mammal noise impacts

Note that the 100 dB threshold is not exceeded by dredging, and the 90 dB contour is exceeded only within 40 feet of the dredge.

Figure 3 Indicative pile driving in air marine mammal noise impacts



Note: the active location of piling rigs will vary from day to day, with the location of noise isopleths shifting accordingly.

4.0 SUMMARY OF IN-AIR NOISE IMPACTS TO MARINE MAMMALS

The extent of noise in-air above the NMFS interim marine mammal behavioral disturbance thresholds is limited to areas in the immediate vicinity of the noise sources. The distances to the in air thresholds for each of the various noise prediction modelling scenarios considered are summarized as follows:

- During general construction, noise levels in air would decrease to below the most stringent threshold of 90 dB rms for harbor seals at distances of the order of 275 feet from the facility boundary.
- During dredging, noise levels in air would decrease to below the most stringent threshold of 90 dB rms for harbor seals at distances of the order of 40 feet from the noise source.
- During pile driving, noise levels in air would decrease to below the most stringent threshold of 90 dB rms for harbor seals at distances of the order of 920 feet from the nearest piling rig.

The noise impacts to marine mammals during operation would generally be less than during construction.

5.0 STATEMENT OF LIMITATIONS

The services described in this work product were performed in accordance with generally accepted professional consulting principles and practices. No other representations or warranties, expressed or implied, are made. These services were performed consistent with our agreement with our client. This work product is intended solely for the use and information of our client unless otherwise noted. Any reliance on this work product by a third party is at such party's sole risk.

Opinions and recommendations contained in this work product are based on conditions that existed at the time the services were performed and are intended only for the client, purposes, positions, time frames, and project parameters indicated. The data reported and the findings, observations, and conclusions expressed are limited by the scope of work. We are not responsible for the impacts of any changes in environmental standards, practices, or regulations subsequent to performance of services. We do not warrant the accuracy of information supplied by others, or the use of segregated portions of this work product.

This work product presents professional opinions and findings of a scientific and technical nature. The work product shall not be construed to offer legal opinion or representations as to the requirements of, nor the compliance with, environmental laws rules, regulations, or policies of federal, state or local governmental agencies.

APPENDIX I.9

Underwater Noise Impact Assessment

Memorandum

To: Drew Jackson

From: Briony Croft

Date: 15 September 2017

Subject: Jordan Cove LNG - Underwater Noise Impact Assessment

This technical memorandum provides a response to Items 8 and 11 from the FERC Environmental Information Request to the Jordan Cove and Pacific Connector Project (Docket No. PF17-4-000). These items request additional information to supplement the RR9 assessment of underwater noise impacts as follows:

8. *Include an evaluation and quantification of noise impacts from sound pressure waves generated within the water due to pile driving and dredging operations, as well as noise due to the operation of the tugs and LNG vessels. Quantify sound pressure levels in the aquatic environment (in dB re: 1µPa) to a distance of 1 mile and discuss impacts to all threatened and endangered aquatic species, marine mammals, and commercial and recreational fish species.*

11. *Estimate potential in-air and underwater noise impacts associated with the construction activities and equipment needed to widen and/or modify the Coos Bay Channel as part of the proposed Pilots Project.*

In addition to this memorandum, supporting documents are attached as follows:

Appendix A – NMFS spreadsheet calculations of potential for permanent threshold shift due to dredging and vessel operations.

Appendix B – JASCO Applied Sciences technical memorandum on vibratory pile driving

Appendix C - JASCO Applied Sciences technical memorandum on impact pile driving

1.0 INTRODUCTION

1.1 Project Description

The marine facilities associated with the Jordan Cove Energy Project (JCEP) LNG Terminal will be on the bay side of the North Spit of Coos Bay, Oregon. Construction of the marine facilities will include several activities with the potential to generate underwater noise:

- Dredging of the marine slip, access channel and materials offloading facility (MOF);
- Dredging in areas along the Coos Bay navigation channel as part of the proposed Pilots project;
- Placement of a sheet pile bulkhead; and
- Construction of platforms, fenders and mooring structures.

The construction activities with the most potential for underwater noise generation are dredging and pile driving. Dredging would occur in a staged approach, with as much material as possible removed through excavation in isolation from Coos Bay behind a temporary berm. In-water work including dredging and removal the temporary berm would be undertaken with a cutter suction dredge and a clamshell dredge. The equipment to dredge the Coos Bay navigation channel is yet to be confirmed, but on the basis of comparable projects use of a cutter suction dredge is likely and represents a reasonable worst case for indicative noise impact assessment.

Approximately 3600 pipe piles and over 11,800 sheet piles will be will be required for the project in total, including marine and upland piles. The average length of steel pipe piles will be around 93 feet in length. The largest steel pipe piles to be installed in water are the MOF bollards at 36-inches in diameter. These piles will be installed by hydraulic pile driving (impact hammer). The sheet pile bulkhead forming the MOF and berth walls would be installed by vibratory pile driving.

During operation of the LNG facility, the primary underwater noise sources would be vessels, including LNG ships and tugs. The JCEP LNG Terminal will add approximately 110-120 additional LNG carriers on an annual basis to the existing approximately 50 deep draft vessels per year operating in the area.

1.2 Aquatic Species Considered

Fisheries resources are described in JCEP LNG Terminal Project Resource Report 3 (RR3) Section 3.1. Fish habitat near the JCEP LNG Terminal supports a mix of marine and estuarine species, and both recreational and commercial fishing. Federally listed fish species spending a portion of their life cycle within the estuarine environment of Coos Bay are coho salmon; green sturgeon and eulachon.

RR3 Section 3.1.3 lists non-endangered marine mammals potentially occurring in the region, and Table 3.4-1 lists threatened and endangered species. Non-endangered marine mammal species potentially occurring in the Coos Bay estuary include the California sea lion, Steller sea lion, harbor porpoise, harbor seal, and northern elephant seal. Listed marine mammals occurring in the marine analysis area (which includes the JCEP project area and the LNG carrier transit route) are the blue whale; fin whale; gray whale; humpback whale; sei whale; sperm whale; killer whale and North Pacific right whale. Of these listed marine mammal species, humpbacks, gray whales and killer whales may occasionally enter Coos Bay within the JCEP project area.

Listed sea turtle species in the marine analysis area are loggerhead; leatherback; green; and olive ridley. These species are not expected to occur within the JCEP project area.

This assessment considers the potential for operational noise from vessel traffic in the marine analysis area to affect threatened and endangered aquatic species (fish, marine mammals and sea turtles). Noise from Facility construction activities including piling and dredging is assessed for potential to impact on fish and marine mammals.

1.3 Underwater Noise Sources and Scenarios

The project description has been used to develop a list of equipment with the potential to generate underwater noise. Overall broadband source noise levels at a 1m (3.3 feet) reference distance have been determined for each potential noise source from literature as shown in Table 1. Two different parameters are used to describe the source levels. The peak noise level is the short term maximum sound pressure level (SPL). It is used to describe the maximum noise level from an impulsive or short term event such as a hydraulic hammer striking a pile. The Root Mean Square (RMS) noise level is a type of average noise level over a time period of interest. RMS can be used to describe noise from a continuous source or the average noise during an impulsive event over a defined time period. All peak and RMS underwater sound levels in this report are described in decibels (dB) referenced to 1 micro Pascal (1 μPa).

A third parameter is used in this assessment as a descriptor of potential impacts, the Cumulative Sound Exposure Level (SEL_{cum}). This parameter describes the cumulative noise exposure from repeated or extended duration events such as piling hammer strikes or long term exposure to continuous noise. SEL_{cum} has units of dB re 1 $\mu Pa^2 s$.

Source levels for a range of sizes of support vessels have been estimated by scaling from frequency dependent reference vessel noise measurements, using the formulation described in Ross (1976) to adjust source levels on the basis of ship length, power and speed, as applied by Wales and Heitmeyer (2002).

Noise from large vessels (adjusted to a 1m reference distance) can range up to 188 dB re 1μPa (McKenna et al. 2012). In practice, noise from vessels will vary depending on vessel size and power, propulsion system loading and vessel speed. A typical transit speed for vessels within the Coos Bay navigation channel of 7 knots has been assumed for this assessment. At these speeds, transiting vessel noise emissions are reduced relative to noise at higher speeds. JASCO (2006) state that broadband noise from LNG vessels at half speed is expected to be around 175 dB re 1μPa at the 1m reference distance.

Noise from tugs under load is less speed dependent. Tugs under load can be noisier than larger vessels.

Noise from cutter suction dredges varies with the capacity of the dredger and the type of material being dredged. Reine et al (2014) measured source levels for a cutter suction dredger removing rock in New York Harbor of up to 175 dB re 1µPa at 1m. A smaller dredger with overall length approximately 100 ft., a total power of 1000 hp operating the main pumps, and with dredged material moving through a 16-in. pipeline undertaking maintenance dredging in a deep water shipping channel has been recorded with source levels up to 157 dB re 1µPa at 1m (Reine and Dickerson, 2014). Use of a similar dredge is anticipated for JCEP dredging. For this assessment, a dredging source noise level of 157 dB re 1µPa at 1m is assumed. The potential noise impacts of a larger dredger are also considered in this assessment as a worst case to assess the potential impact of dredging work in the Coos Bay navigation channel.

Underwater noise from piling is described in Caltrans (2015). This reference includes specific source levels for driving steel sheet piles and 36 inch diameter steel pipe piles.

Table 1 Broadband Source Noise Levels

Noise Source	Description	Peak dB re. 1µPa @ 1 m	RMS dB re. 1µPa @ 1 m	Reference
LNG vessel	Transiting 7 knots / half speed	n/a	175	McKenna et al 2012; JASCO, 2006.
Tugs and smaller support vessels	120' and up to 5400 HP	n/a	170	Warner et al, 2014
	150' and up to 6600 HP	n/a	175	Li et al, 2011
	220' and up to 10560 HP (LNG escort tug)	n/a	185	Jasco, 2006
Cutter Suction Dredging	Marine slip, access channel and MOF	n/a	157	Reine & Dickerson, 2014
	Coos Bay navigation channel	n/a	175	Reine et al, 2014
Sheet pile driving	Vibratory pile driving	195	180	Caltrans, 2015
	Impact hammer driving	225	210	Caltrans, 2015
36 inch steel pipe pile driving	Vibratory pile driving	200	190	Caltrans, 2015
	Impact hammer driving	230	213	Caltrans, 2015

Note 1: Source levels may vary over time with variations in propulsion system loading and vessel speed.

2.0 FISH AND SEA TURTLE NOISE IMPACT THRESHOLDS

Threshold levels for underwater noise impacts on fish and sea turtles have been the subject of research over many years. The majority of research has focused on the potential for physiological effects (injury or mortality) rather than on quantifying noise levels with behavioral effects. A review of the literature and guidance on appropriate thresholds for assessment of underwater noise impacts are provided in the 2014 Acoustical Society of America (ASA) Technical Report *Sound Exposure Guidelines for Fishes and Sea Turtles* (ASA, 2014).

The ASA Technical Report includes thresholds for mortality (or potentially mortal injury) as well as degrees of impairment such as temporary or permanent threshold shifts (TTS or PTS, indicators of hearing damage). Thresholds are defined for peak noise and cumulative impacts (due to continuous or repeated noise events) and for different noise sources (eg pile driving, and continuous noise from vessels or dredging). For continuous noise from vessels or dredging, there is a low risk of mortality or injury for any fish types or sea turtles. Piling noise results in higher noise levels and hence an increased potential for injury. The ASA guideline injury thresholds for piling noise for fish and sea turtles are summarized in Table 2.

Table 2 Underwater acoustic thresholds for fish and sea turtles during piling

Type of Animal	Mortality	Recoverable Injury	TTS
Fish: no swim bladder	> 219 dB SEL_{cum}; or > 213 dB Peak	>216 dB SEL_{cum}; or > 213 dB Peak	>> 186 dB SEL_{cum}
Fish: swim bladder not involved in hearing	210 dB SEL_{cum}; or > 207 dB Peak	203 dB SEL_{cum}; or > 207 dB Peak	> 186 dB SEL_{cum}
Fish: swim bladder involved in hearing	207 dB SEL_{cum}; or > 207 dB Peak	203 dB SEL_{cum}; or > 207 dB Peak	186 dB SEL_{cum}
Sea turtles	210 dB SEL_{cum}; or > 207 dB Peak	High risk near the source only (within tens of meters)	

Notes: Peak sound pressure has a reference value of 1 μPa and is “flat” or unweighted.
Cumulative sound exposure level (SEL_{cum}) has a reference value of $1 \mu Pa^2 s$.

Since soft start methods will be used as a mitigation measure for piling, and animals in the vicinity of noise sources will be free to move away, this assessment of impacts to fish focusses on the potential for peak noise levels during piling to cause mortality or injury. These effects are not anticipated at noise levels below about 207 dB re 1μPa, or at higher levels for species without swim bladders.

3.0 MARINE MAMMAL NOISE IMPACT THRESHOLDS

Guidance on acoustic thresholds for injury (hearing damage) in the form of permanent threshold shift (PTS) and disturbance are provided by the National Oceanic and Atmospheric Administration's (NOAA's) National Marine Fisheries Service (NMFS).

3.1 Acoustic Thresholds for Disturbance

The NMFS interim underwater thresholds for behavioral effects are shown in Table 3 (NMFS, 2012). Of the sources considered, the majority are "continuous" for the purpose of this assessment, with only the noise from impact pile driving treated as impulsive.

Table 3 Interim underwater acoustic thresholds for behavioral disruption

Criterion Definition	Threshold
Behavioral disruption for impulsive noise (e.g., impact pile driving)	160 dB_{rms}
Behavioral disruption for non-impulsive noise (e.g., vibratory pile driving, vessels)	120 dB_{rms}

Notes: dB referenced to 1 micro Pascal (re: 1μPa).
All thresholds are based off root mean square (rms) levels and are broadband (unweighted).
The 120 dB threshold may be slightly adjusted if background noise levels are at or above this level.

3.2 Acoustic Thresholds for Injury (Permanent Hearing Damage, PTS)

Acoustic thresholds related to PTS are provided by Technical Memorandum NMFS-OPR-55 *Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing Underwater Acoustic Thresholds for Onset of Permanent and Temporary Threshold Shifts* (NMFS, 2016).

A dual metric approach is used for impulsive sounds, considering both cumulative sound exposure level and peak sound level. Different thresholds and auditory weighting functions are provided for different marine mammal hearing groups, which are defined in the Technical Guidance (NMFS, 2016). The generalized hearing range of each hearing group is reproduced in Table 4. The PTS thresholds are shown in Table 5. The non-endangered marine mammal species potentially occurring in the Coos Bay estuary include otariid pinnipeds (California sea lion, Steller sea lion), phocid pinnipeds (harbor seal, northern elephant seal) and the high frequency cetacean harbor porpoise. The listed marine mammal species which may occasionally enter Coos Bay within the JCEP project area are humpbacks and gray whales (low frequency cetaceans) and killer whales (mid frequency cetaceans).

Table 4 Cetacean hearing groups (from NMFS, 2016)

Hearing Group	Generalized Hearing Range
Low-frequency cetaceans	7 Hz to 35 kHz
Mid-frequency cetaceans	150 Hz to 160 kHz
High-frequency cetaceans	275 Hz to 160 kHz
Phocid pinnipeds	50 Hz to 86 kHz
Otariid pinnipeds	60 Hz to 39 kHz

Table 5 Underwater acoustic thresholds for PTS onset

Hearing Group	PTS Onset Acoustic Thresholds (Received Level)		
	Impulsive (Peak, L_{pk}, flat)	Impulsive (SEL_{cum}, weighted, 24h)	Non-impulsive (SEL_{cum}, weighted, 24h)
Low-frequency cetaceans	219 dB	183 dB	199 dB
Mid-frequency cetaceans	230 dB	185 dB	198 dB
High-frequency cetaceans	202 dB	155 dB	173 dB
Phocid pinnipeds	218 dB	185 dB	201 dB
Otariid pinnipeds	232 dB	203 dB	219 dB

Notes: Peak sound pressure (L_{pk}) has a reference value of 1 μPa and is "flat" or unweighted.
Cumulative sound exposure level (SEL_{cum}) has a reference value of 1μPa^{2}s.
SEL_{cum} received levels should be appropriately weighted for the hearing group for assessment.

4.0 NOISE LEVEL VS DISTANCE

For the purpose of this impact assessment, the objective is to quantify the noise level due to various sources at a range of distances out to 1 mile. These noise levels will then be discussed in relation to their potential to cause injury or disturbance to the species of interest, with reference to the identified thresholds.

4.1 Noise Level vs Distance

The magnitude of the noise level at a particular location depends strongly on the distance from the noise source. Underwater noise propagation models predict the sound transmission loss between the noise source and the receiver. When the source level (SL) of the noise source is known, the predicted transmission loss (TL) is then used to predict the received level (RL) at the receiver location as:

$$\mathrm{RL} = \mathrm{SL} - \mathrm{TL}$$

The transmission loss between two distances D1 and D2 may be described by a logarithmic relationship with an attenuation factor F:

$$\mathrm{TL} = \mathrm{F} \cdot \log(\mathrm{D}_1/\mathrm{D}_2)$$

If all losses due to factors other than geometric spreading are neglected, then the transmission loss would be wholly due to spherical spreading (in deep water) or cylindrical spreading (in shallow water, bounded above and below). Spherical spreading means underwater noise would attenuate by 6 dB with each doubling of distance, or F = 20. Cylindrical spreading means an attenuation of 3 dB with each doubling of distance, or F = 10.

In shallow water, noise propagation is highly dependent on the properties of the bottom and the surface as well as the properties of the fluid. Parameters such as depth and the bottom properties can vary with distance from the source. Sound energy at low frequencies may be transferred directly into the sea floor, rather than propagating through the water. Overall, the transmission loss in shallow water is a combination of cylindrical spreading effects, bottom interaction effects (absorption) at lower frequencies and scattering losses at high frequencies.

In practical cases the attenuation factor F can range from 5 up to 30. A "practical spreading loss model" based on an attenuation factor of 15 for sound transmission is commonly assumed for projects near shore (NMFS, 2012) and has been adopted for this study.

The noise attenuation vs distance is shown in Figure 1. The noise level from the various sources at a range of distances out to 1 mile is summarized in Table 6. Note that in situations with more than one noise source or several vessels operating in an area, the loudest or closest source may be assumed to dominate at any particular receiver location.

Figure 1 Noise Attenuation vs Distance – Practical Spreading Loss Model

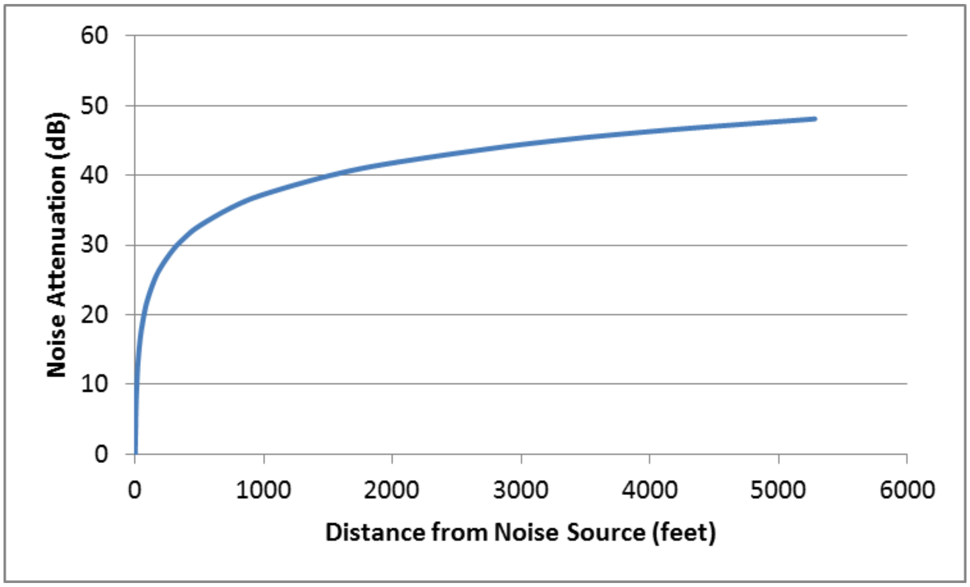


Table 6 Peak and RMS Noise Level vs Distance by Source

Parameter	Noise Source	3.3 ft	50 ft	100 ft	500 ft	1000 ft	1 mile
RMS dB re. 1µPa	LNG Vessel	175	157	153	142	138	127
	120' Support Vessel	170	152	148	137	133	122
	150' Support Vessel	175	157	153	142	138	127
	220' LNG escort tug	185	167	163	152	148	137
	CSD – marine slip, access channel, MOF	157	139	135	124	120	109
	CSD – worst case Coos Bay nav. channel	175	157	153	142	138	127
	Vibratory sheet pile driving	180	162	158	147	143	132
	Impact sheet pile driving	210	192	188	177	173	162
	Vibratory steel pipe pile driving	190	172	168	157	153	142
	Impact hammer steel pipe pile driving	213	195	191	180	176	165
Peak dB re. 1µPa	Vibratory sheet pile driving	195	177	173	162	158	147
	Impact sheet pile driving	225	207	203	192	188	177
	Vibratory steel pipe pile driving	200	182	178	167	163	152
	Impact hammer steel pipe pile driving	230	212	208	197	193	182

5.0 DISCUSSION OF POTENTIAL PROJECT UNDERWATER NOISE IMPACTS TO FISH AND SEA TURTLES

As identified in Section 2.0, mortality or injury to fish or sea turtles of any species is not anticipated at peak noise levels below about 207 dB re 1μPa, or at higher levels for species without swim bladders.

Of the various activities with the potential to generate underwater noise, only piling using an impact hammer has source levels that are high enough to potentially cause injury or mortality to fish. Impact driving of steel pipe piles is noisier than impact driving of sheet piles. For sheet piles, the potential for injury to fish is limited to within 50 feet of the noise source, in a worst case situation. For steel pipe piles, this distances increases to about 100 feet, again under worst case assumptions. Soft start methods will be used as a mitigation measure for piling, with the initial strikes applied at lower power with reduced noise levels. The areas with potential piling noise physical impacts to fish would be within the excavated and dredged area required to construct the marine facility.

Fish behavioral responses to noise from piling activity may occur over greater distances. ASA (2014) indicates a high risk of behavioral effects to fish during piling in the near to intermediate field, ie within distances of tens to hundreds of meters. The risk of behavioral effects in the far field (of the order of thousands of meters or miles) reduces to moderate. In light of the Facility location in Coos Bay, the potential for adverse behavioral impacts to fish outside of the immediate project construction vicinity (within about 1 mile) is considered to be low.

With reference to ASA (2014), the risk of adverse fish behavioral responses to noise from dredging and vessel activity is also expected to be low except in the immediate vicinity of the noise source. The noise from project dredging and vessel movements will be similar to noise from existing dredging activity and vessel movements in the Coos Bay navigation channel. Similarly the risk of adverse sea turtle behavioral responses to noise from vessel activity is low, with the noise from project activity similar to noise from existing shipping activity.

6.0 DISCUSSION OF POTENTIAL PROJECT UNDERWATER NOISE IMPACTS TO MARINE MAMMALS

6.1 Marine Mammal Impulsive Peak Noise PTS Potential

As identified in Section 3.2, permanent hearing damage to marine mammals of any species is not anticipated at impulsive peak noise levels below 202 dB re 1μPa, with the lowest threshold applicable to high frequency cetaceans which include harbor porpoises. For low and mid frequency cetaceans and pinnipeds (ie for all other species potentially affected by the project), the impulsive peak noise injury threshold is higher, above 218 dB re 1μPa.

Marine mammals inside Coos Bay in the vicinity of the Facility may be affected by noise from piling during construction. Of the various piling scenarios, only the use of an impact hammer has impulsive peak source levels that are high enough to cause PTS in any species. The greatest distance at which PTS due to impulsive peak noise may possibly occur is around 250 feet for the harbor porpoise. Soft start methods will be used as a mitigation measure for piling, with the initial impacts applied at lower power with reduced noise levels and hence reduced potential for impacts. On this basis, injury in the form of PTS to any marine mammal species is not anticipated as a result of impulsive peak noise emissions during project piling.

6.2 Marine Mammal Cumulative Noise Exposure PTS Potential

The NMFS 2016 Technical Guidance provides a calculation method for determining the potential for cumulative noise to have adverse effects to marine mammal hearing. This method includes multiple conservative assumptions and is therefore expected to result in higher estimates of hearing impairment that would be the case in a practical situation. An assessment using the NMFS spreadsheet calculator has been undertaken for each of the vessel and dredging noise sources and scenarios. Calculation sheets detailing the various assumptions and the distance to the cumulative noise PTS threshold for each noise source are attached as Appendix A. More detailed site specific investigations of the potential for cumulative piling noise impacts have been investigated by JASCO (Deveau and MacGillvray 2017, O'Neill and MacGillivray 2017) and are attached as Appendices B and C. For most species, activities and scenarios, there is very low risk of cumulative PTS in practice since individual animals would need to remain in close proximity to the noise source for an extended period of time, without moving away. The results of these various cumulative noise impact calculations are summarized as follows:

- During dredging to construct the marine facility, individual harbor porpoises would need to remain within about 500 feet of the dredge for 24 hours for there to be a potential for PTS. Other marine mammals would need to remain effectively immediately adjacent to the dredge for the same duration.
- During dredging of the navigation channel, individual harbor porpoises would need to remain within about 1.6 miles of the dredge for 24 hours for there to be a potential for PTS. Killer whales would need to remain within about 180 feet of the dredge again for 24 hours for there to be potential for PTS. Other marine mammals would need to remain effectively immediately adjacent to the dredge for the same duration.
- When tugs are operating semi-stationary under full power near the Facility, individual harbor porpoises would need to remain within about 1 mile of the tug for 1 hour for there to be a potential for PTS. Killer whales would need to remain within about 100 feet of the tug for 1 hour for there to be potential for PTS.
- During 36" steel pipe pile installation using a vibratory driver, individual harbor porpoises would need to remain within about 1.3 miles of the noise source during the driving of approximately 3 individual piles (1000 strikes) for there to be potential for PTS. Harbor seals and killer whales would need to remain within 1.1 miles of the noise source for the same duration for PTS to potentially occur.
- The noise from transiting vessels and tugs does not represent a potential risk of PTS to any of the identified marine mammal species, at any realistically occurring distance.

There is potential for cumulative noise exposure to cause PTS in harbor porpoises (high frequency cetaceans) during in water piling, particularly when a hydraulic impact hammer is used. For PTS to occur, harbor porpoises would need to remain in the vicinity during extended periods of impact piling. The potential for PTS to occur in other marine mammals is less, due to the differing hearing sensitivities of other species. The use of a combination of engineered underwater noise mitigation measures (such as pile cushions, bubble curtains) and management techniques (including soft starts, protected species observers and exclusion zones) is expected to minimize the potential for acoustic injury to marine mammals.

6.3 Marine Mammal Behavioral Disturbance Potential

Away from the JCEP project area, the potential for effects to threatened and endangered marine mammals is limited to behavioral disturbance due to noise from piling, navigation channel dredging, LNG vessels, tugs and potentially other support vessels. Vibratory sheet pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 120 dB re 1 µPa at distances of up to 1.2 miles (Deveau and MacGillvray, 2017). Impact pipe pile driving has the potential to exceed the NMFS interim behavioral disturbance threshold of 160 dB re 1 µPa at similar distances (O'Neill and MacGillvray, 2017).

The noise from project vessel movements and dredging will be similar to noise from existing vessel and dredging activity in the Coos Bay navigation channel.

7.0 SUMMARY

This assessment provides quantitative levels for underwater noise generated by the Jordan Cove LNG project and potential impacts to marine mammals, threatened and endangered aquatic species and to commercial and recreational fish species.

Of the various activities with the potential to generate underwater noise, only piling using an impact hammer has source levels that are high enough to cause potential injury or mortality to fish. In the noisiest scenario, potential physical impacts to fish would be restricted to areas within about 100 feet of the noise source, inside the excavated and dredged area required to construct the marine facility. The potential for adverse behavioral impacts to fish outside of the immediate project construction vicinity (at distances greater than about 1 mile) is considered to be low, for all construction scenarios.

The noise from project dredging and vessel movements will be similar to noise from existing dredging activity and vessel movements in the Coos Bay navigation channel, with a low risk of adverse fish behavioral responses to these noise sources.

Harbor porpoises (which are not endangered) are the only high frequency cetacean that may occur in the vicinity of the Facility. If present, this marine mammal species has the greatest potential to be affected by noise from piling or other marine facility construction noise sources. Permanent hearing impairment harbor porpoises is not anticipated as a result of impulsive peak noise emissions during project piling, provided they are not present with 250 feet of piling using an impact hammer. Individual harbor porpoises would need to remain with about 1.3 miles of the facility for the full duration of driving 3 of the largest marine pipe piles to risk permanent hearing impairment due to the cumulative noise effects of piling.

In relation to other marine mammals and the identified threatened and endangered species, there is a lower risk of permanent hearing impairment due to project noise. There is potential for behavioral disturbance due to noise from dredgers, LNG vessels, tugs and other support vessels. The noise disturbance from project vessel movements and dredges will be similar to noise from existing vessel and dredging activity in the Coos Bay navigation channel.

STEP 1: GENERAL PROJECT INFORMATION

PROJECT TITLE	JCEP LNG - Dredging
PROJECT/SOURCE INFORMATION	As per information contained in Resource Reports 1,3,9
Please include any assumptions	
PROJECT CONTACT	

STEP 2: WEIGHTING FACTOR ADJUSTMENT

Specify if relying on source-specific WFA, alternative weighting/dB adjustment, or if using default value

Weighting Factor Adjustment (kHz)¥	42	Default for high-frequency cetaceans (harbor porpoises) as a worst case

¥ Broadband: 95% frequency contour percentile (kHz) OR Narrowband: frequency (kHz); For appropriate default WFA: See INTRODUCTION tab

† If a user relies on alternative weighting/dB adjustment rather than relying upon the WFA (source-specific or default), they may override the Adjustment (dB) (row 43), and enter the new value directly. However, they must provide additional support and documentation supporting this modification.

*** BROADBAND Sources: Cannot use WFA higher than maximum applicable frequency (See GRAY tab for more information on WFA applicable frequencies)**

STEP 3: SOURCE-SPECIFIC INFORMATION

Source Level (RMS SPL)	157
Activity Duration (hours) within 24-h period	24
Activity Duration (seconds)	86400
10 Log (duration)	49.37
Propagation (xLogR)	15
Distance of source level measurement (meters)⁺	1

⁺Unless otherwise specified, source levels are referenced 1 m from the source.

Marine Mammal Hearing Group
Low-frequency (LF) cetaceans: baleen whales
Mid-frequency (MF) cetaceans: dolphins, toothed whales, beaked whales, bottlenose whales
High-frequency (HF) cetaceans: true porpoises, *Kogia*, river dolphins, cephalorhynchid, *Lagenorhynchus cruciger* & *L. australis*
Phocid pinnipeds (PW):true seals
Otariid pinnipeds (OW):sea lions and fur seals

RESULTANT ISOPLETHS

Hearing Group	Low-Frequency Cetaceans	Mid-Frequency Cetaceans	High-Frequency Cetaceans	Phocid Pinnipeds	Otariid Pinnipeds
SEL_{cum} Threshold	199	198	173	201	219
PTS Isopleth to threshold (meters)	**0.3**	**3.5**	**167.6**	**0.6**	**0.0**

1. Introduction

This technical memorandum presents results from an underwater noise modeling study undertaken by JASCO on behalf of AECOM to support a Marine Mammal Protection Act Incidental Harassment Authorization application. The planned noise-generating activity is "in the dry" vibratory sheet pile installation that will be conducted as part of the construction of a Materials Off-loading Facility (MOF) at the proposed Jordon Cove LNG Terminal at Coos Bay, Oregon. The modeling presented in this technical memorandum is based on draft engineering plans for the Jordan Cove facility and is intended to provide a screening-level assessment of potential underwater noise from sheet-pile wall construction at the MOF.

The draft construction plans call for a 30-feet wide soil berm to be installed between the water and the location of the sheet piles. The sheet piles will be installed behind the berm prior to excavation of a marine slip at the proposed facility. The purpose of the present study is to model underwater noise that would be transmitted from the sheet piles to the water, through the soils, during vibratory driving. Noise from sheet pile driving may have the potential to negatively impact nearby marine mammals in Coos Bay. The impacts of underwater noise generated by vibratory pile driving at the MOF is expected to be mainly limited to harbor seals that may be foraging near or transiting past the construction site, though other species of marine mammals may occasionally be present.

A hydrographic chart of Coos Bay is shown in Figure 1, with the location of the proposed sheet pile wall and the two transects used for underwater noise modelling in this study.

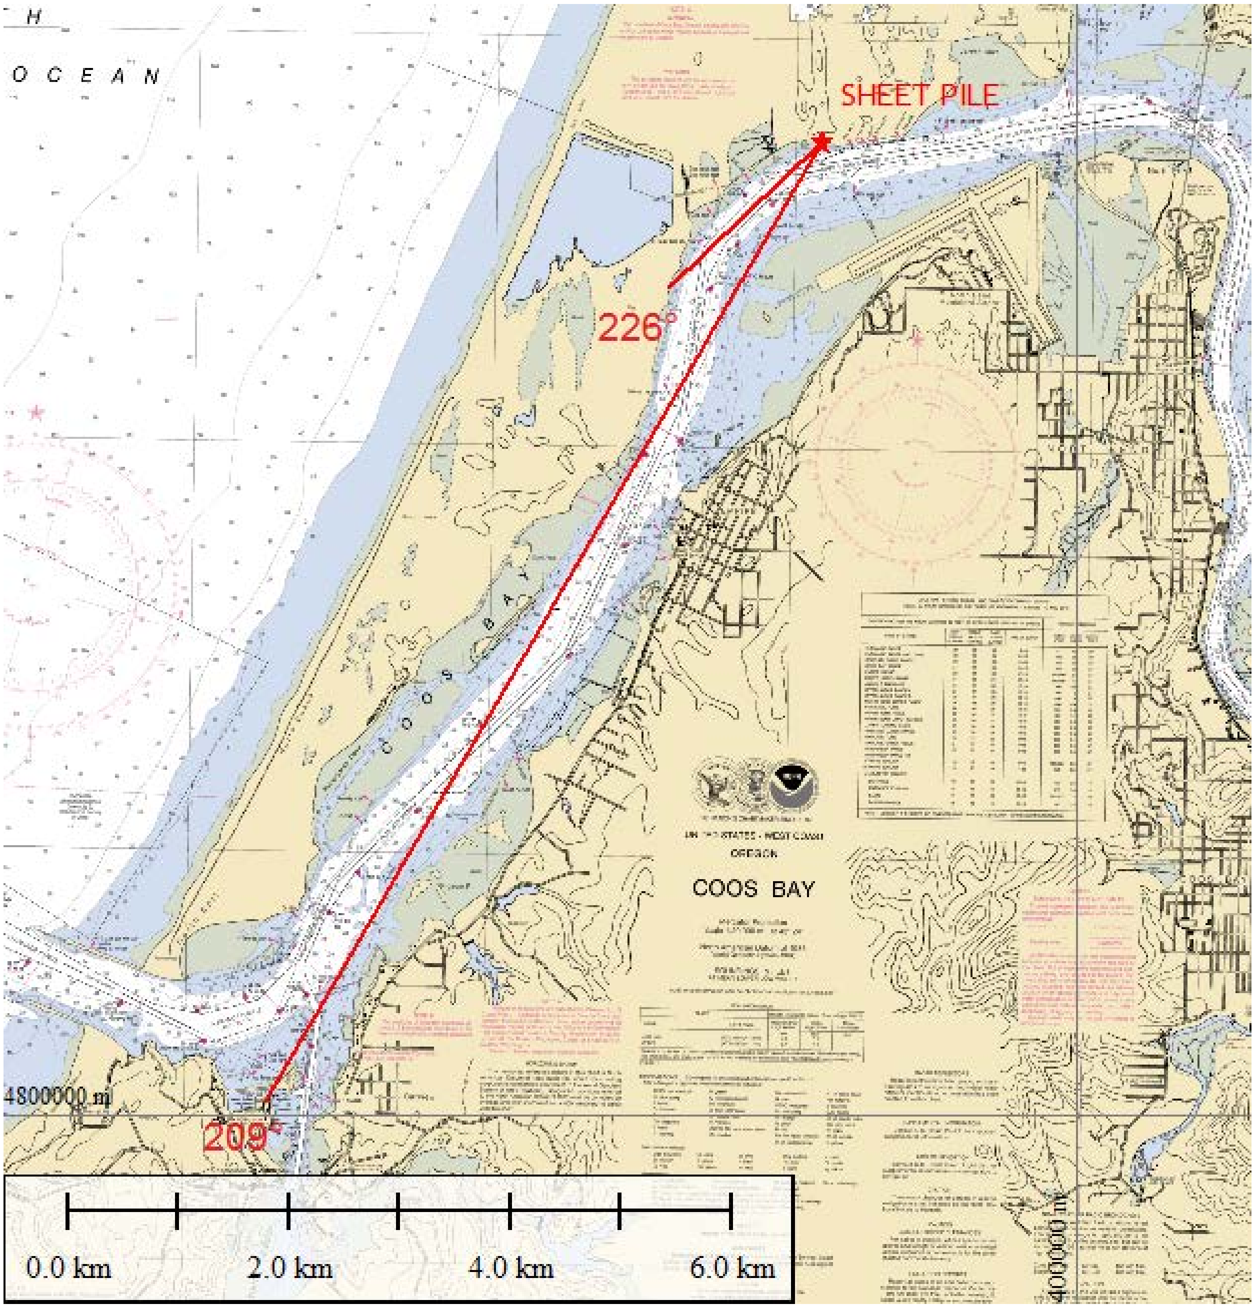

Figure 1. Annotated hydrographic chart of Coos Bay showing the location of the proposed sheet pile driving (red star) and the underwater noise modelling transects (red lines). An expanded distance scale is also provided.

2. Methods

A numerical sound propagation model was used to simulate the transmission of sheet piling noise through water-saturated soils into water. Source levels for this activity were based on published hydrophone measurements of in-water sheet pile driving. To translate the source levels from water into soil, it was assumed that the sheet piles would generate the same magnitude of vibration in soil as in water.

For modeling the sound propagation, JASCO collected environmental data describing the bathymetry, water sound speed, and seabed geoacoustics in Coos Bay. The environmental data and source levels were input to underwater noise modelling software to estimate the underwater noise received levels (RL) that would be present in the water near the pile driving.

2.1. Bathymetry

A bathymetry grid for the acoustic propagation model was constructed based on two datasets:

- U.S. Coastal Relief Model digital elevation model (DEM) with a 3-arc-second resolution (National Centers for Environmental Information, 2017)
- Coos Bay hydrographic chart, no. 18587, at 1:20,000 scale, from the Coast Survey, National Ocean Service, NOAA. (Coast Survey, 2017).

The DEM downloaded from the NCEI website provided only positive elevation values inland of the Pacific Ocean coastline. To accurately represent the bathymetry of the Coos Bay channel, 16433 spot bathymetry values were sampled from the NOAA Bathymetric Chart. These spot bathymetric readings are relative to Mean Lower Low Water (MLLW), while the DEM is relative to the mean high water (MHW) tidal level. Based on the tide information published on the Coos Bay hydrographic chart, an adjustment of 6 feet was made to the spot bathymetry samples from the chart before incorporating them into the revised DEM.

The depth/elevations from the NCEI DEM and the spot bathymetry samples from the NOAA hydrographic chart were combined into a new DEM with a 9-meter horizontal grid spacing. The underwater acoustic noise modelling has been carried-out on the basis of a tidal water level equal to the mean high water (MHW). On the basis of NOAA tidal data, this water level has been taken to be 6 feet higher than the mean lower low water (MLLW) level, which is the basis for the depth soundings and depth contours portrayed on the NOAA hydrographic charts (Coast Survey, 2017).

2.2. Sound Speed Profile

For this particular study, a uniform sound speed of 1500 m/s was assumed for the entire water column. This is a common laboratory reference value for speed of sound in sea-water. Since the water depth in this modelling area is very shallow (less than 14 m), and located in an estuary, it is reasonable to assume that that water column is well mixed and that that the speed of sound is uniform with depth.

2.3. Geoacoustics

In shallow water environments where there is increased interaction with the sea-floor, the properties of the substrate have a large influence over the sound propagation. Information on the composition of the soils at the measurement site was not available at the time of writing, therefore the geoacoustic model used in this work is based on estimated values that are thought to be typical for this environment, consisting of soft silty sand sediments of undetermined depth. The required parameters for modelling sound propagation are the density (ρ), compressional-wave speed, (c_p), shear-wave speed (c_s), compressional-wave attenuation (α_p), and shear-wave attenuation (α_s). A geoacoustic profile, Table 1, has been constructed to represent these geological conditions.

Table 1. Geoacoustic properties as a function of depth, in metres below the seafloor (mbsf). Within an indicated depth range, the parameter varies linearly within the stated range.

Depth (mbsf)	Material	Density (g/cm^3)	P-wave speed (m/s)	P-wave attenuation (dB/λ)	S-wave speed (m/s)	S-wave attenuation (dB/λ)
0–50	Silty sand	1.83	1680–1730	0.5	250	0.1
> 50			1730			

2.4. Source Level

Based on the draft engineering designs, it was assumed that individual sheet piles were 50 feet tall and 18 inches wide, embedded to a maximum penetration depth of 36 feet below MHW. For the purpose of this study, we assumed that the underwater noise of vibratory driving of the pile can be modelled as a point source located at the midpoint of the underground portion of the pile. Therefore, we used a source depth of 5.48 meters (i.e., 18 feet below MHW).

The source level (SL) spectrum of the vibratory driving of this pile for the purpose of this study was assumed to be equivalent to the SL spectrum reported for Berth 23, Port of Oakland (APE 400 3200 kN vibe hammer) vibratory pile driving (Buehler, et al., 2016). The SL, in terms of sound pressure level (SPL) at 1 meter from the source location, in 1/3-octave bands, was taken to be as shown in Table 2.

Table 2. SL of vibratory pile driving, in terms of SPL band-level at 1 meter from the source location, in 1/3-octave bands.

Frequency (Hz)	10	13	16	20	25	32	40	50	63	80	100	125	160	200
SL (dB re 1 µPa)	136.8	138.2	139.6	141.0	149.7	146.4	141.1	140.5	146.1	149.3	146.1	154.2	153.7	157.1

Frequency (Hz)	250	315	400	500	630	800	1000	1250	1600	2000	2500	3150	4000
SL (dB re 1 µPa)	158.9	156.1	158.4	160.4	165.3	171.1	174.2	170.8	172.0	170.9	166.9	163.8	162.6

2.5. Underwater Acoustic Propagation Model

The underwater acoustic propagation modeling for this study was performed using a modified version of the RAM parabolic-equation model (Collins 1993, 1996), that has been enhanced by JASCO. RAM was developed at the US Naval Research Laboratory has been extensively benchmarked and is widely used as a reference model in the underwater acoustics community.

3. Results

The modeled received level (RL) of the broadband noise in the water column generated by the vibration sheet pile driving is illustrated in Figure 2 and Figure 3, which show the sound pressure level (SPL) in dB re 1 µPa in areas of different color as a function of the horizontal distance from the source (range) and the depth of the receiver. Each of the figures is for a different azimuthal direction away from the source location (measured in degrees, clockwise from geographic true north).

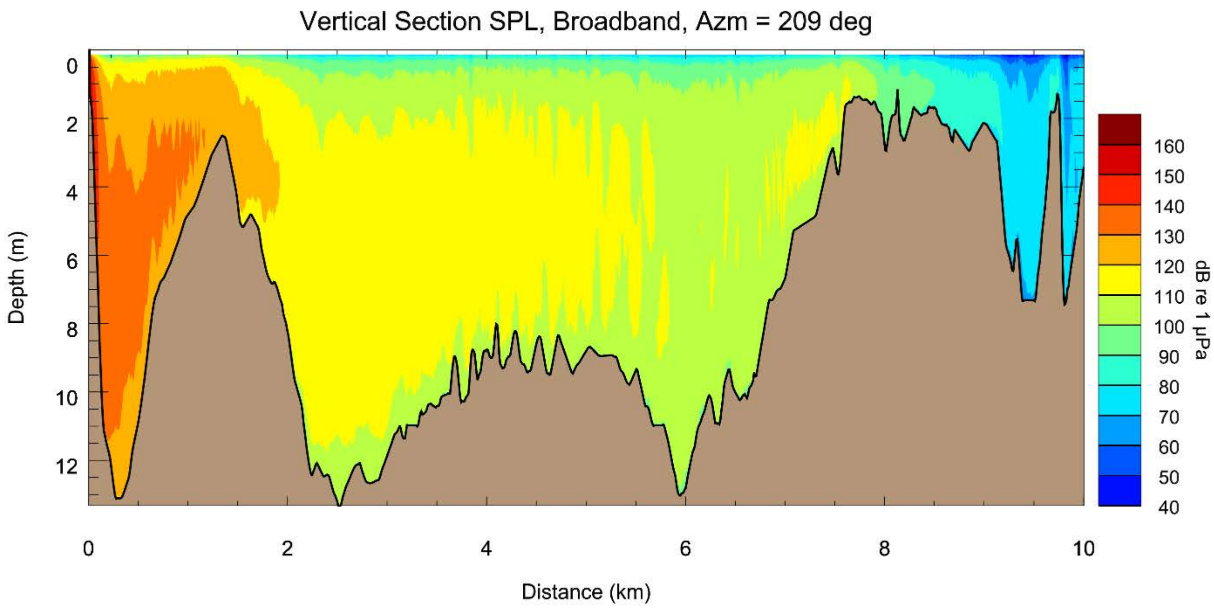

Figure 2. Broadband SPL versus horizontal range from the source and depth below the MHW tidal level for the 209° azimuth.

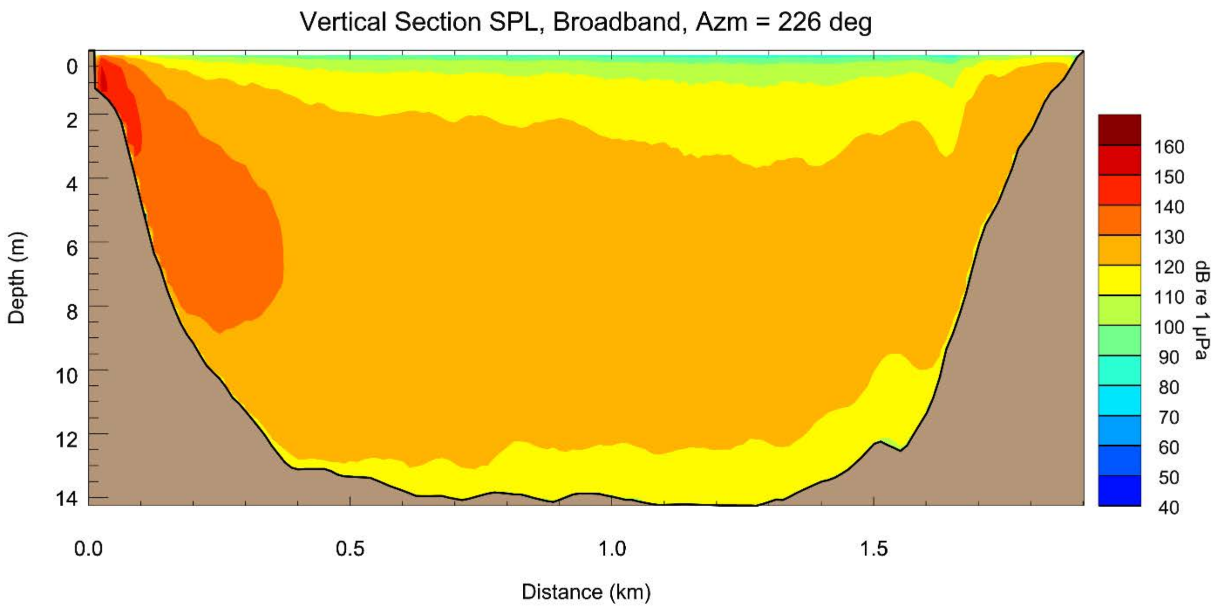

Figure 3. Broadband SPL versus horizontal range from the source and depth below the MHW tidal level for the 226° azimuth.

The 209° azimuthal direction illustrates the longest possible underwater range of noise propagation from the source location, as other directions are blocked at shorter ranges by shoals or the shoreline. The 226° azimuthal direction illustrates the highest underwater RL, at longer ranges, due to the greater water depth in that direction before shoaling is encountered.

The maximum modelled RL (over depth) as a function of range is illustrated in Figure 4 and Figure 5 for the same two azimuthal directions as the previous figures. Inspection of the 1/3-octave band RL shows that highest levels are at frequencies around 1000 Hz (Figure 6).

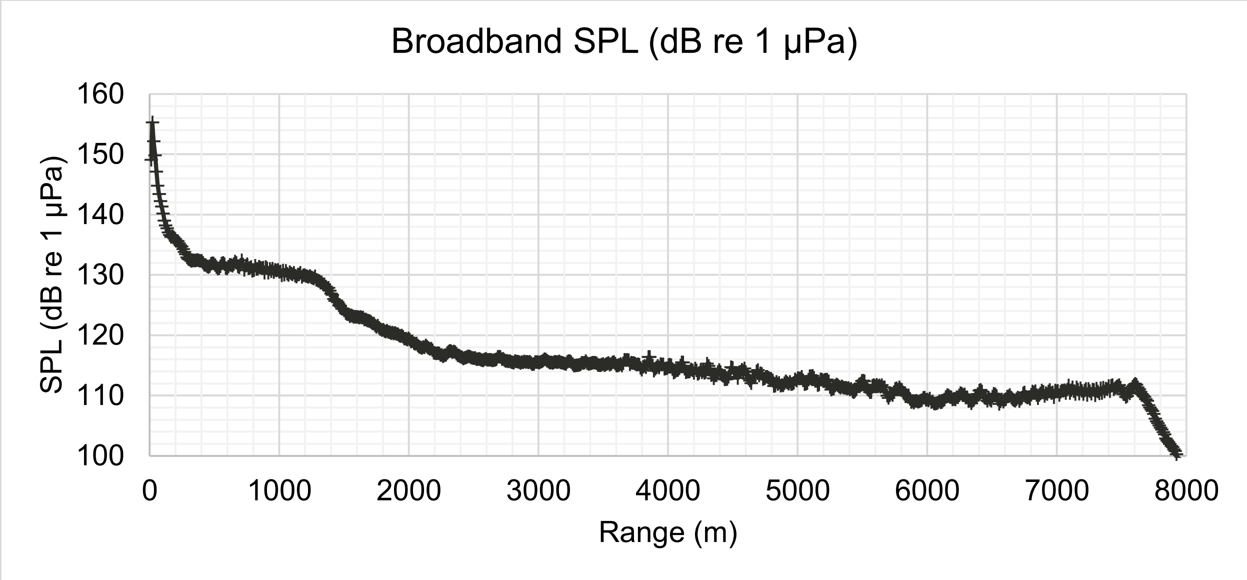

Figure 4. Maximum-over-depth broadband RL versus horizontal range from the source for the 209° azimuth.

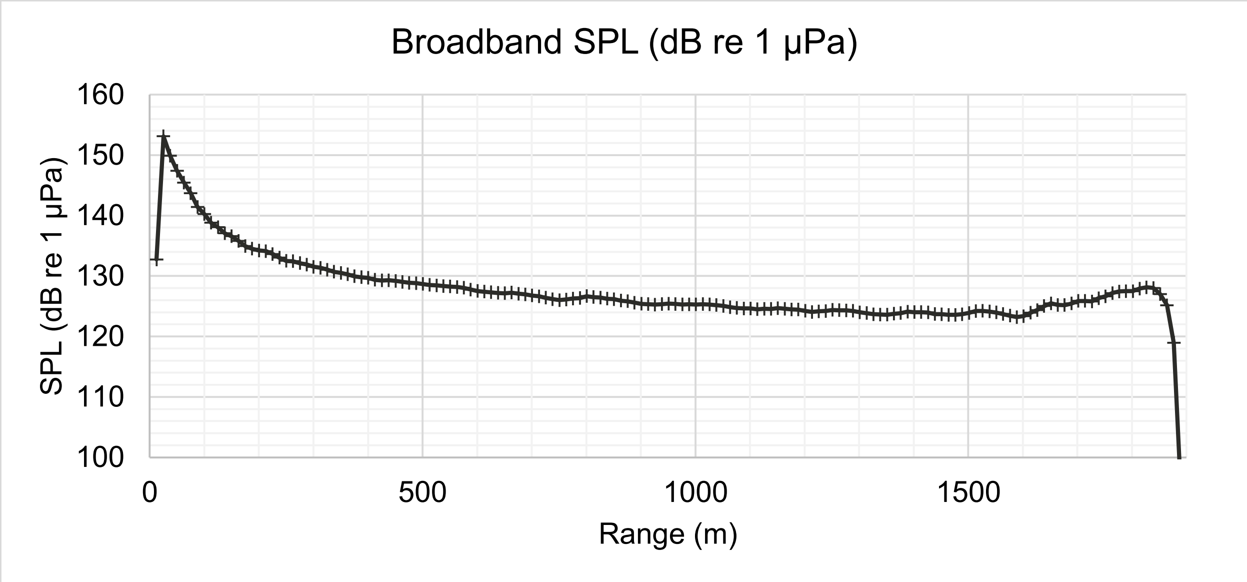

Figure 5. Maximum-over-depth broadband RL versus horizontal range from the source for the 226° azimuth.

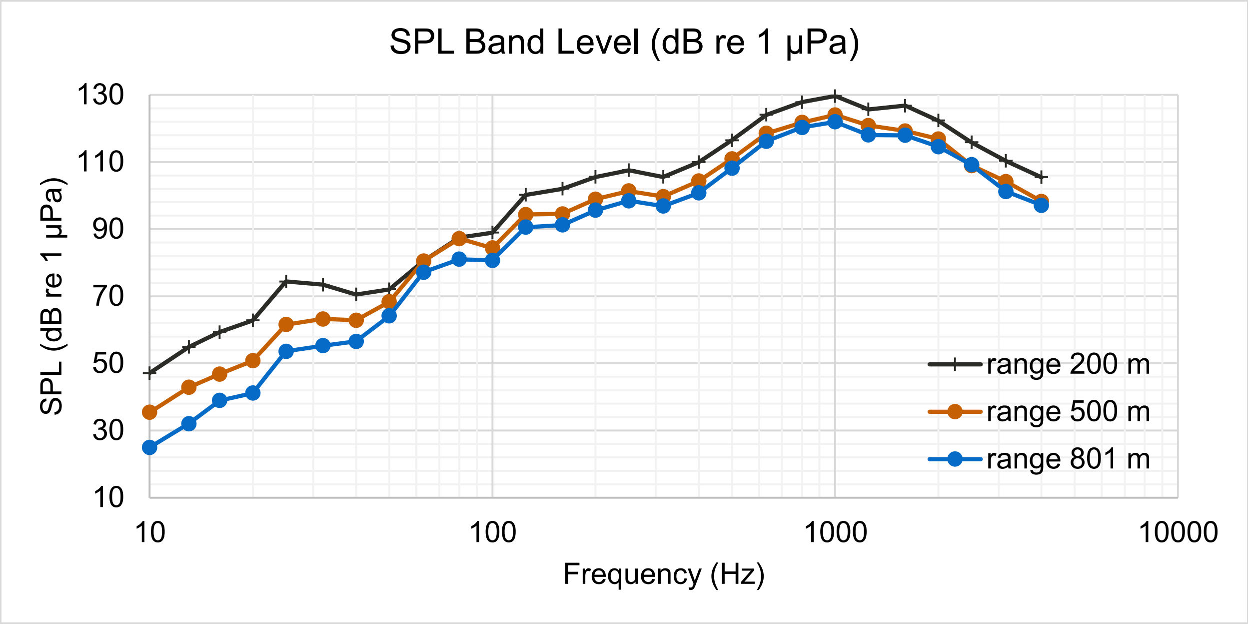

Figure 6. Maximum-over-depth SPL versus frequency in 1/3-octave bands, at three different distances, for the 226° azimuth.

4. Summary

Table 3 shows the maximum distance to the 120 dB re 1 µPa threshold along the two modelling transects considered in the current study. These results show that the highest noise levels from sheet piling at the MOF are to be found where the sound is able to propagate away from the source in deeper water for the furthest distance, before being attenuated by bottom loss in shallower water.

Table 3. Maximum modeled distance to the 120 dB re 1 µPa threshold along two azimuths.

Azimuth (° CW from North)	Maximum range to 120 dB re 1 µPa (m)
209	1914
226	1870

Glossary

1/3-octave-band
Non-overlapping passbands that are one-third of an octave wide (where an octave is a doubling of frequency). Three adjacent 1/3-octave-bands comprise one octave. One-third-octave-bands become wider with increasing frequency. Also see octave.

attenuation
The gradual loss of acoustic energy from absorption and scattering as sound propagates through a medium.

azimuth
A horizontal angle relative to a reference direction, which is often magnetic north or the direction of travel. In navigation it is also called bearing.

broadband sound level
The total sound pressure level measured over a specified frequency range. If the frequency range is unspecified, it refers to the entire measured frequency range.

compressional wave
A mechanical vibration wave in which the direction of particle motion is parallel to the direction of propagation. Also called primary wave or P-wave.

decibel (dB)
One-tenth of a bel. Unit of level when the base of the logarithm is the tenth root of ten, and the quantities concerned are proportional to power (ANSI S1.1-1994 R2004).

digital elevation model (DEM)
A sampled array of elevations (and bathymetric depths in water) for a number of geographical positions at regularly spaced horizontal intervals (i.e., on a horizontal grid).

frequency
The rate of oscillation of a periodic function measured in cycles-per-unit-time. The reciprocal of the period. Unit: hertz (Hz). Symbol: *f*. 1 Hz is equal to 1 cycle per second.

geoacoustic
Relating to the acoustic properties of the seabed.

hertz (Hz)
A unit of frequency defined as one cycle per second.

mbsf
Meters below sea floor

mean high water (MHW)
The arithmetic mean of all the high water heights observed over a period of several years. In the United States this period spans 19 years and is referred to as the National Tidal Datum Epoch.

mean lower low water (MLLW)
The arithmetic mean of the lower of the two low water heights of each tidal day, observed over a period of several years. In the United States this period spans 19 years and is referred to as the National Tidal Datum Epoch.

NCEI
National Centers for Environmental Information (formerly the National Geophysical Data Center).

NGDC
National Geophysical Data Center.

NOAA
National Oceanic and Atmospheric Administration.

octave
The interval between a sound and another sound with double or half the frequency. For example, one octave above 200 Hz is 400 Hz, and one octave below 200 Hz is 100 Hz.

parabolic equation method
A computationally-efficient solution to the acoustic wave equation that is used to model transmission loss. The parabolic equation approximation omits effects of back-scattered sound, simplifying the computation of transmission loss. The effect of back-scattered sound is negligible for most ocean-acoustic propagation problems.

point source
A source that radiates sound as if from a single point (ANSI S1.1-1994 R2004).

pressure, acoustic
The deviation from the ambient hydrostatic pressure caused by a sound wave. Also called overpressure. Unit: pascal (Pa). Symbol: *p*.

received level
The sound level measured at a receiver.

rms
root-mean-square.

shear wave
A mechanical vibration wave in which the direction of particle motion is perpendicular to the direction of propagation. Also called secondary wave or S-wave. Shear waves propagate only in solid media, such as sediments or rock. Shear waves in the seabed can be converted to compressional waves in water at the water-seabed interface.

sound
A time-varying pressure disturbance generated by mechanical vibration waves travelling through a fluid medium such as air or water.

sound pressure level (SPL)
The decibel ratio of the time-mean-square sound pressure, in a stated frequency band, to the square of the reference sound pressure (ANSI S1.1-1994 R2004).

For sound in water, the reference sound pressure is one micropascal (p_0 = 1 μPa) and the unit for SPL is dB re 1 μPa:

$$\mathrm{SPL} = 10\log_{10}\left(p^2/p_0^2\right) = 20\log_{10}\left(p/p_0\right)$$

Unless otherwise stated, SPL refers to the root-mean-square sound pressure level. See also 90% sound pressure level and fast-average sound pressure level. Non-rectangular time window functions may be applied during calculation of the rms value, in which case the SPL unit should identify the window type.

sound speed profile
The speed of sound in the water column as a function of depth below the water surface.

source level (SL)
The sound level measured in the far-field and scaled back to a standard reference distance of 1 meter from the acoustic center of the source. Unit: dB re 1 μPa @ 1 m (sound pressure level) or dB re 1 $\mu Pa^2 \cdot s$ (sound exposure level).

1. Introduction

This technical memorandum presents results from an underwater noise modeling study undertaken by JASCO on behalf of AECOM to support a Marine Mammal Protection Act Incidental Harassment Authorization application. The planned noise-generating activity is impact hammer pile driving that will be conducted as part of the construction of a Materials Off-loading Facility (MOF) at the proposed Jordon Cove LNG Terminal at Coos Bay, Oregon. The modeling presented in this technical memorandum is based on draft engineering plans for the Jordan Cove facility and is intended to provide a screening-level assessment of potential underwater noise from the construction of 36-inch diameter bollard pipes at the MOF.

The construction plans call for the bollard pipes to be installed in the dry, at a setback distance of 12 feet (ft) (3.65 meters (m)) from the sheet pile wall of the MOF. The purpose of the present study is to model underwater noise that would be transmitted from the pipe piles, through the sediment and sheet pile wall, and into the water, during impact pile driving. Noise from impact pile driving may have the potential to negatively impact nearby marine mammals in Coos Bay. The impacts of underwater noise generated by impact pile driving at the MOF is expected to be mainly limited to seals, eared seals (sea lions), and harbor porpoises that may be foraging near or transiting past the construction site, though other species of marine mammals may occasionally be present.

A hydrographic chart of Coos Bay is shown in Figure 1, with the location of the proposed pipe piles and the two transects used for underwater noise modeling in this study.

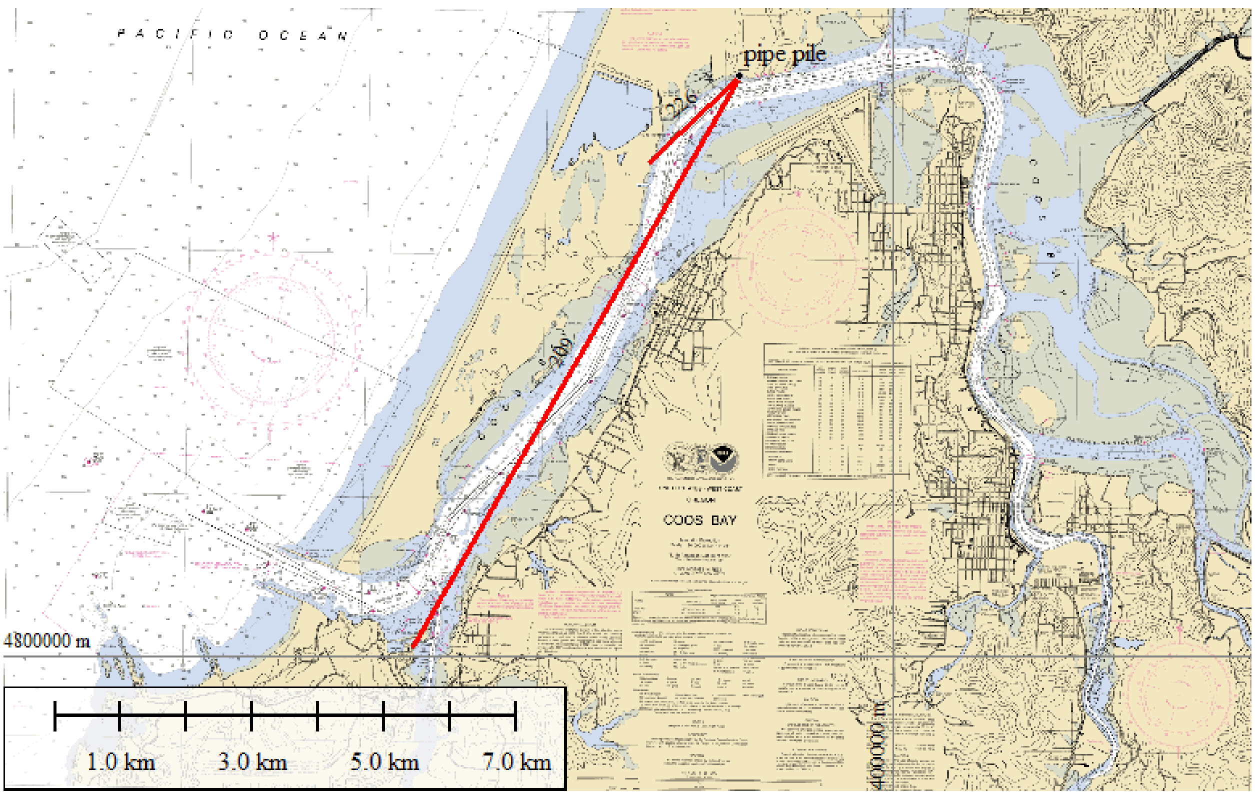

Figure 1. Annotated hydrographic chart of Coos Bay showing the location of the proposed pipe pile driving (black dot) and the underwater noise modeling transects (red lines). An expanded distance scale is also provided.

2. Methods

A full-wave numerical sound propagation model was used to simulate the transmission of impact pile driving noise through water-saturated soils into water. Source levels for impact pile driving were calculated using a thin-shell structural vibration model for cylindrical piles. For modeling the sound propagation, JASCO collected environmental data describing the bathymetry, water sound speed, and seabed geoacoustics in Coos Bay. The environmental data and source levels were input to underwater noise modelling software to estimate the underwater noise received levels (RL) that would be present in the water near the pile driving.

M-weighting was applied for multiple hearing groups, including low-frequency cetaceans, mid-frequency cetaceans, high-frequency cetaceans, phocid pinnipeds in water, and otariid pinnipeds in water, to weight the importance of received sound levels according to marine mammal hearing sensitivity, in accordance with the 2016 NOAA Technical Guidance (NMFS 2016).

2.1. Bathymetry

A bathymetry grid for the acoustic propagation model was constructed based on two datasets:

- U.S. Coastal Relief Model digital elevation model (DEM) with a 3-arc-second resolution ([NGDC] National Geophysical Data Center 2017)
- Coos Bay hydrographic chart, no. 18587, at 1:20,000 scale, from the National Oceanic and Atmospheric Administration (NOAA) Coast Survey, National Ocean Service. (Coast Survey 2017).

The DEM downloaded from the NOAA National Centers for Environmental Information (NCEI) website provided only positive elevation values inland of the Pacific Ocean coastline. To accurately represent the bathymetry of the Coos Bay channel, 16433 spot bathymetry values were sampled from the NOAA Bathymetric Chart. These spot bathymetric readings are relative to Mean Lower Low Water (MLLW), while the DEM is relative to the mean high water (MHW) tidal level. Based on the tide information published on the Coos Bay hydrographic chart, an adjustment of 6 ft was made to the spot bathymetry samples from the chart before incorporating them into the revised DEM with a 9-meter horizontal grid spacing. The underwater acoustic noise modeling was carried-out on the basis of a tidal water level equal to the MHW.

Bathymetry was manually edited to have 12 ft (3.7 m) of land before water starts. For the scenario with dredged bathymetry, water depths were uniformly 45 ft (13.7 m) from the toe of the sheet pile out to the shipping channel.

2.2. Sound Speed Profile

A uniform sound speed of 1500 meters per second (m/s) was assumed for the entire water column. This is a common laboratory reference value for speed of sound in sea-water. Since the water depth in this modeling area is very shallow (less than 46 ft (14 m)), and located in an estuary, it is reasonable to assume that this water column is well mixed and the speed of sound is uniform with depth.

2.3. Geoacoustics

In shallow water environments where there is increased interaction with the sea-floor, the properties of the substrate have a large influence over the sound propagation. Information on the composition of the soils at the measurement site was not available at the time of writing, therefore the geoacoustic model used in this work is based on estimated values that are thought to be typical for this environment, consisting of soft silty sand sediments of undetermined depth. The required parameters for modeling sound propagation are the density (ρ), compressional-wave speed, (c_p), shear-wave speed (c_s), compressional-wave attenuation (α_p), and shear-wave attenuation (α_s). A geoacoustic profile, Table 1, has been constructed to represent these geological conditions.

Table 1. Geoacoustic properties as a function of depth, in meters below the seafloor (mbsf). Within an indicated depth range, the parameter varies linearly within the stated range.

Depth (mbsf)	Material	Density (g/cm^3)	P-wave speed (m/s)	P-wave attenuation **(dB/λ)**	S-wave speed (m/s)	S-wave attenuation **(dB/λ)**
0–50	Silty sand	1.83	1680–1730	0.5	250	0.1
> 50			1730			

2.4. Source Level

Draft engineering designs describe the individual pipe piles for bollard construction: 60 ft long, 36 in diameter, and embedded to a maximum penetration depth of 55 ft. The construction plan calls for the piles to be driven using a Demag D80-23 diesel impact hammer. A forcing function for the hammer was modelled using GRLWEAP 2010 (GRLWEAP, Pile Dynamics 2010) assuming that driving was carried out using the maximum recommended hammer energy (Figure 2). The forcing function was computed assuming direct contact between the hammer and the piles (i.e. no cushion material).

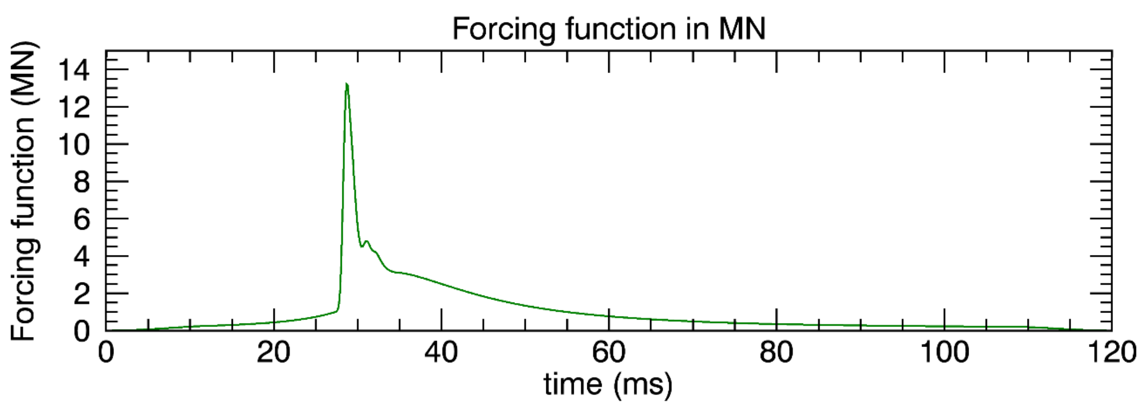

Figure 2. Force (meganewtons (MN)) at the pile tip generated by a Demag D80-23 diesel impact hammer as predicted by GRLWEAP 2010.

A structural acoustic model of pile vibration and near-field sound radiation (MacGillivray 2014) was used to predict the vibration of the struck pile (Figure 3). The sound radiating from the pile itself was simulated using a vertical array of discrete point sources to accurately characterise vertical directivity effects in the near-field zone. An extrapolation method (Zykov et al. 2016) was used to extend the modelled source levels up to 4 kHz, by applying a −2 dB per 1/3-octave-band roll-off coefficient to the source levels starting at 800 Hz.

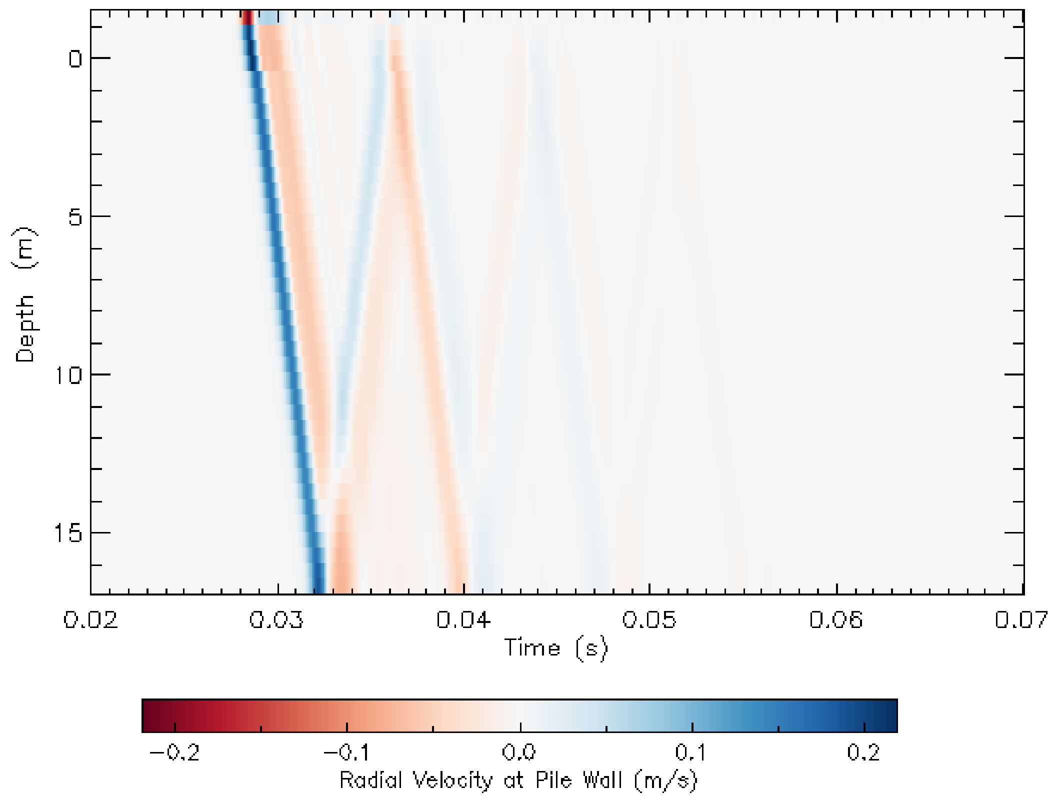

Figure 3. Radial vibration of the pile wall as predicted by the structural acoustic model.

2.5. Underwater Sound Propagation Model

For impulsive sounds from impact pile driving, time-domain representations of the pressure waves generated in the water are required to calculate sound pressure level (SPL), sound exposure level (SEL), and peak pressure level. For this study, synthetic pressure waveforms were computed using FWRAM, which is a time-domain acoustic propagation model. FWRAM computes synthetic pressure waveforms versus range and depth for range-varying marine acoustic environments, accounting for bathymetry, water sound speed profile, and seabed geoacoustics. FWRAM computes pressure waveforms via Fourier synthesis of the modelled acoustic transfer function in closely spaced frequency bands. FWRAM employs the array starter method to accurately model sound propagation from a spatially distributed source (MacGillivray and Chapman 2012).

2.6. Transmission Loss Through Sheet Pile Wall

Frequency-dependent attenuation through the sheet pile wall at the MOF was calculated according a plane wave transmission model (Jensen et al. 2011) from soil through a 0.5 inch steel layer. The frequency-dependent transmission loss (Figure 4) was applied to calculated source pressures of the pipe pile to simulate the attenuation of the pile driving noise due to the sheet pile wall.

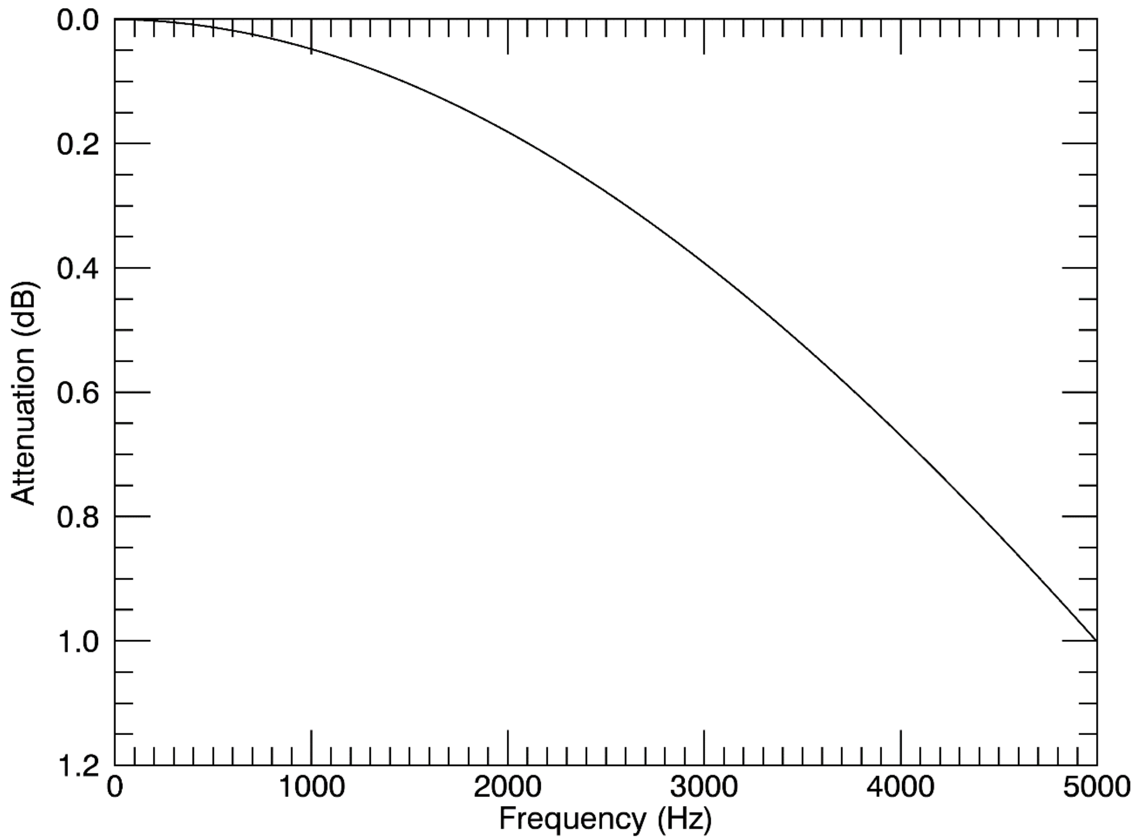

Figure 4. Calculated sound attenuation of the sheet pile wall versus frequency.

2.7. Marine Mammal Frequency Weighting Functions

In 2015, a U.S. Navy technical report recommended new auditory weighting functions for marine mammals (Finneran 2016). The overall shape of the auditory weighting functions is similar to human A-weighting functions, which follows the sensitivity of the human ear at low sound levels. The report proposed five functional hearing groups for marine mammals in water: low-, mid-, and high-frequency cetaceans, phocid pinnipeds, and otariid pinnipeds. The parameters for these frequency-weighting functions were further modified the following year and were adopted in NOAA's technical guidance that assesses noise impacts on marine mammals (NMFS 2016). Figure 5 shows the recommended frequency-weighting curves.

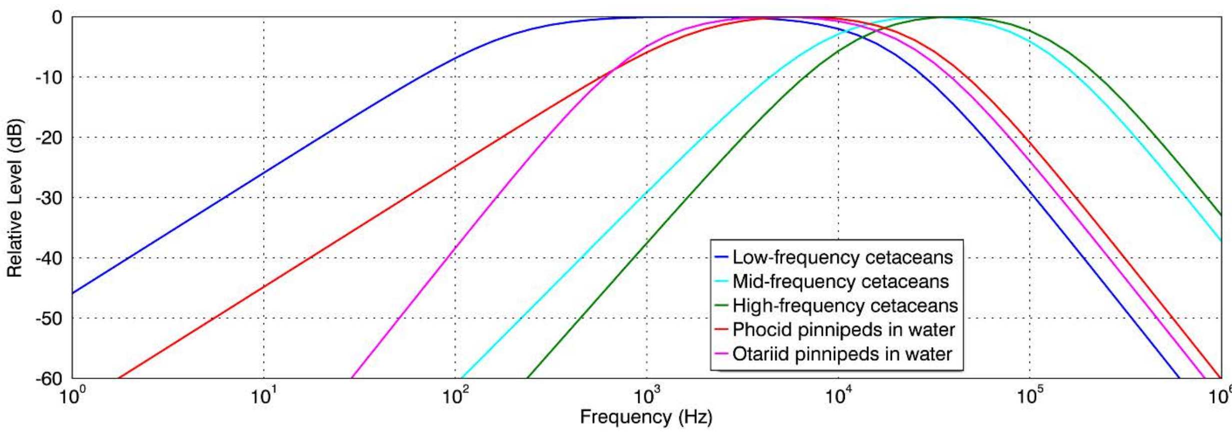

Figure 5. Auditory weighting functions for functional marine mammal hearing groups as recommended by NOAA (2016).

3. Results

The modeled received levels (RL) of the broadband noise in the water column generated by the impact pipe pile driving are illustrated in Figure 7 and Figure 7, which show unweighted, per-pulse SEL (dB re 1 µPa²s) as a function of the horizontal distance from the source and the depth of the receiver. Each of the figures is for a different azimuthal direction away from the source location (measured in degrees, clockwise from geographic true north).

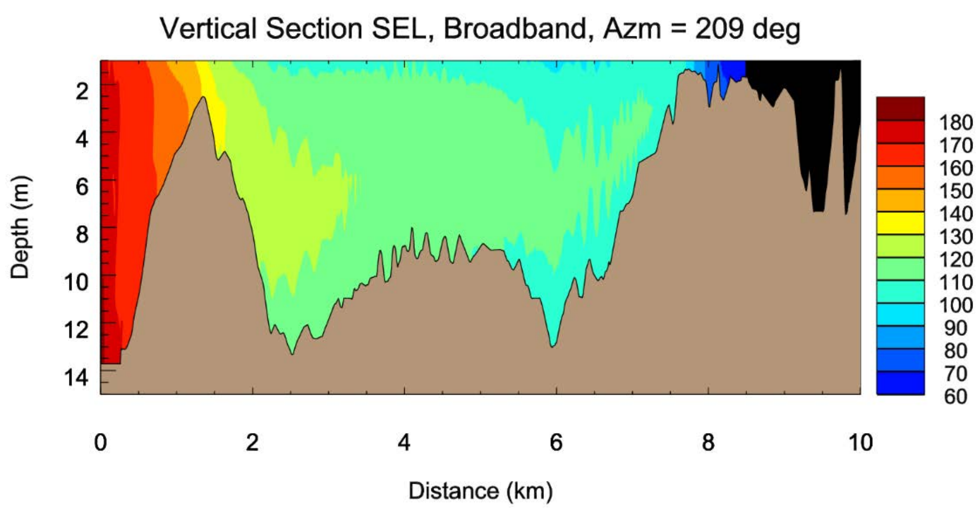

Figure 6. Per-pulse SEL (unweighted) versus horizontal range from the source and depth below the MHW tidal level for the 209° azimuth.

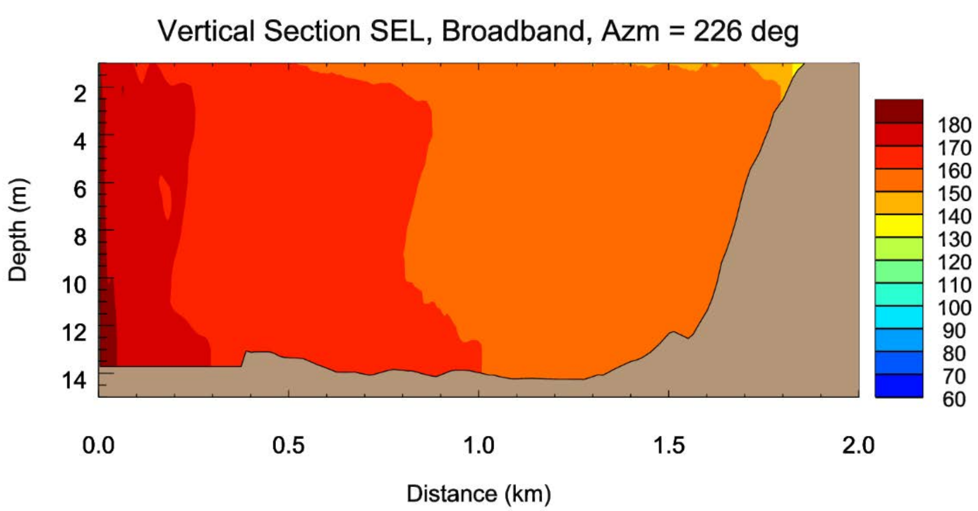

Figure 7. Per-pulse SEL (unweighted) versus horizontal range from the source and depth below the MHW tidal level for the 226° azimuth.

The 209° azimuthal direction illustrates the longest possible underwater range of noise propagation from the source, as other directions are blocked at shorter ranges by shoals or the shoreline. The 226° azimuthal direction illustrates the highest underwater RL, at longer ranges, due to the greater water depth in that direction before shoaling is encountered.

The maximum modelled RL (over depth) as a function of range is illustrated in Figure 8 and Figure 9 for the same two azimuthal directions as the previous figures. Inspection of the 1/3-octave band RL shows that highest levels are at frequencies around 300 to 500 Hz (Figure 10). These frequencies are within the hearing ranges of all marine mammal hearing groups, although killer whales (mid-frequency cetaceans) and harbor porpoises (high-frequency cetaceans) would not hear these frequencies as well as seals (phocid pinnipeds) and sea lions (otariid pinnipeds) (NMFS 2016).

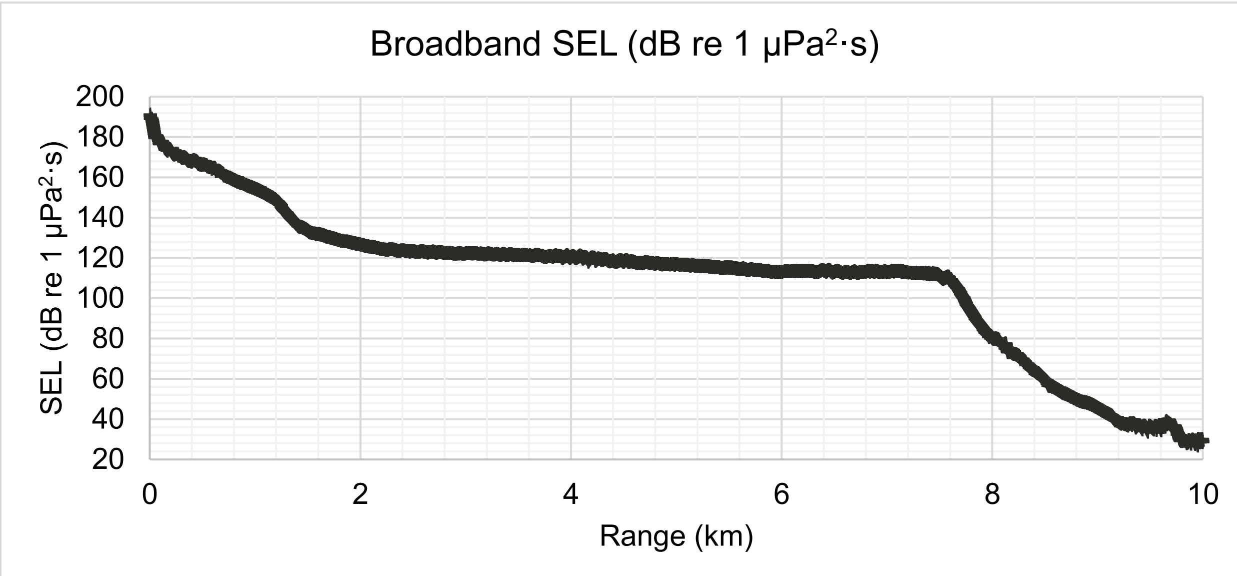

Figure 8. Maximum-over-depth per-pulse SEL (unweighted) versus horizontal range from the source for the 209° azimuth.

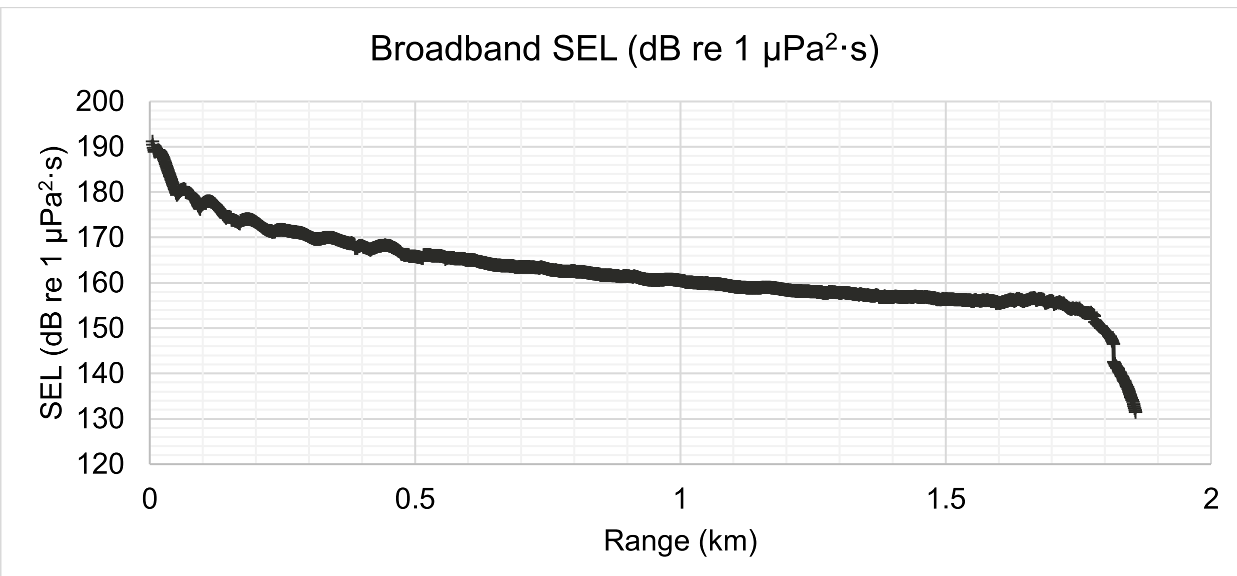

Figure 9. Maximum-over-depth per-pulse SEL (unweighted) versus horizontal range from the source for the 226° azimuth.

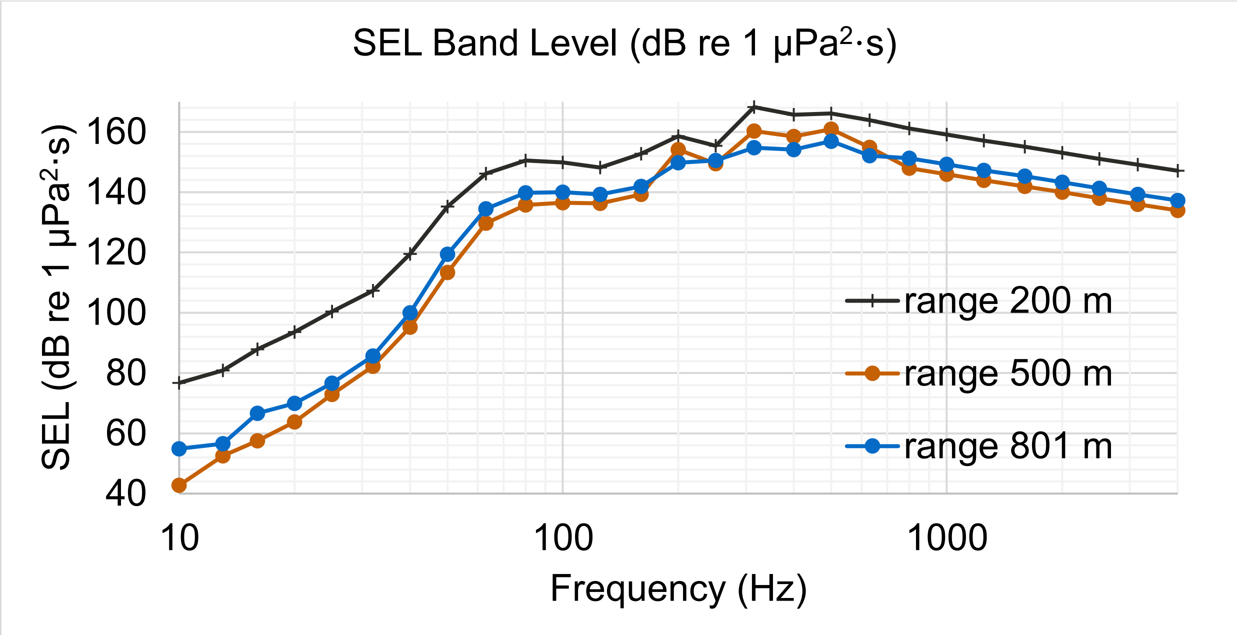

Figure 10. Maximum-over-depth per-pulse SEL versus frequency in 1/3-octave bands, at three different ranges, for the 226° azimuth.

4. Summary

NMFS criteria (NMFS 2016) define a 160 dB re 1 µPa SPL (rms) behavioral threshold for marine mammals for impulsive sound sources. Table 2 shows the maximum distance to 160 dB re 1 µPa SPL along the two modelled transects considered in the current study. The results show that bathymetry plays a strong role in sound propagation conditions in Coos Bay. Received sound levels along the 209° azimuth decrease at a greater rate within 1.8 km of the source than the received levels along the 226° azimuth. Table 3 and Table 4 show the maximum ranges to the Permanent Threshold Shift (PTS) and Temporary Threshold Shift (TTS) criteria along the two modeling transects. Because cumulative SEL depends on the total number of hammer strikes over a 24-hour period, distances were calculated for three different possible conditions: 100 strikes, 1000 strikes, and 10000 strikes. Assuming a blow rate of 40 strikes/second, these correspond to 2.5 minutes, 25 minutes, and 250 minutes of continuous pile driving during a 24-hour period.

Table 2. Maximum modeled distance to 160 dB re 1 µPa threshold along two azimuths.

Azimuth (° from North)	Maximum range to 160 dB re 1 µPa (m)
209	1299
226	1817

Table 3 Maximum range from the pipe pile to modelled peak pressure level TTS and PTS thresholds based on the NOAA Technical Guidance (NMFS 2016) A dash indicates that the threshold was not reached.

Hearing group	Peak SPL (dB re 1 µPa)			
	PTS Threshold	Range (m)	TTS Threshold	Range (m)
Low-frequency cetaceans	219	20	213	35
Mid-frequency cetaceans	230	-	224	-
High-frequency cetaceans	202	199	196	337
Phocid pinnipeds in water	218	21	212	43
Otariid pinnipeds in water	232	-	226	-

Table 4. Maximum range from the pipe pile to modelled 24h SEL thresholds based on the NOAA Technical Guidance (NMFS 2016).

Hearing Group	Weighted SEL_{24h} (dB re 1 µPa²·s)			
	PTS Threshold	Range (m)	TTS Threshold	Range (m)
100 strikes (2.5 minutes)				
Low-frequency cetaceans	183	669	168	1806
Mid-frequency cetaceans	185	613	170	1796
High-frequency cetaceans	155	1849	140	4223
Phocid pinnipeds in water	185	605	170	1795
Otariid pinnipeds in water	203	40	188	455
1000 strikes (25 minutes)				
Low-frequency cetaceans	183	1758	168	1835
Mid-frequency cetaceans	185	1726	170	1830
High-frequency cetaceans	155	2160	140	7592
Phocid pinnipeds in water	185	1726	170	1829
Otariid pinnipeds in water	203	204	188	1253
10000 strikes (250 minutes)				
Low-frequency cetaceans	183	1817	168	1860
Mid-frequency cetaceans	185	1817	170	1860
High-frequency cetaceans	155	5549	140	7732
Phocid pinnipeds in water	185	1817	170	1860
Otariid pinnipeds in water	203	750	188	1811

Glossary

1/3-octave-band
Non-overlapping passbands that are one-third of an octave wide (where an octave is a doubling of frequency). Three adjacent 1/3-octave-bands comprise one octave. One-third-octave-bands become wider with increasing frequency. Also see octave.

attenuation
The gradual loss of acoustic energy from absorption and scattering as sound propagates through a medium.

azimuth
A horizontal angle relative to a reference direction, which is often magnetic north or the direction of travel. In navigation it is also called bearing.

broadband sound level
The total sound pressure level measured over a specified frequency range. If the frequency range is unspecified, it refers to the entire measured frequency range.

compressional wave
A mechanical vibration wave in which the direction of particle motion is parallel to the direction of propagation. Also called primary wave or P-wave.

decibel (dB)
One-tenth of a bel. Unit of level when the base of the logarithm is the tenth root of ten, and the quantities concerned are proportional to power (ANSI S1.1-1994 R2004).

digital elevation model (DEM)
A sampled array of elevations (and bathymetric depths in water) for a number of geographical positions at regularly spaced horizontal intervals (i.e., on a horizontal grid).

frequency
The rate of oscillation of a periodic function measured in cycles-per-unit-time. The reciprocal of the period. Unit: hertz (Hz). Symbol: *f*. 1 Hz is equal to 1 cycle per second.

geoacoustic
Relating to the acoustic properties of the seabed.

hertz (Hz)
A unit of frequency defined as one cycle per second.

mbsf
Meters below sea floor

mean high water (MHW)
The arithmetic mean of all the high water heights observed over a period of several years. In the United States this period spans 19 years and is referred to as the National Tidal Datum Epoch.

mean lower low water (MLLW)
The arithmetic mean of the lower of the two low water heights of each tidal day, observed over a period of several years. In the United States this period spans 19 years and is referred to as the National Tidal Datum Epoch.

NCEI
National Centers for Environmental Information (formerly the National Geophysical Data Center).

NGDC
National Geophysical Data Center.

NOAA
National Oceanic and Atmospheric Administration.

octave
The interval between a sound and another sound with double or half the frequency. For example, one octave above 200 Hz is 400 Hz, and one octave below 200 Hz is 100 Hz.

parabolic equation method
A computationally-efficient solution to the acoustic wave equation that is used to model transmission loss. The parabolic equation approximation omits effects of back-scattered sound, simplifying the computation of transmission loss. The effect of back-scattered sound is negligible for most ocean-acoustic propagation problems.

point source
A source that radiates sound as if from a single point (ANSI S1.1-1994 R2004).

pressure, acoustic
The deviation from the ambient hydrostatic pressure caused by a sound wave. Also called overpressure. Unit: pascal (Pa). Symbol: *p*.

received level
The sound level measured at a receiver.

rms
root-mean-square.

shear wave
A mechanical vibration wave in which the direction of particle motion is perpendicular to the direction of propagation. Also called secondary wave or S-wave. Shear waves propagate only in solid media, such as sediments or rock. Shear waves in the seabed can be converted to compressional waves in water at the water-seabed interface.

sound
A time-varying pressure disturbance generated by mechanical vibration waves travelling through a fluid medium such as air or water.

sound pressure level (SPL)
The decibel ratio of the time-mean-square sound pressure, in a stated frequency band, to the square of the reference sound pressure (ANSI S1.1-1994 R2004).

For sound in water, the reference sound pressure is one micropascal (p_0 = 1 μPa) and the unit for SPL is dB re 1 μPa:

$$\mathrm{SPL} = 10\log_{10}\left(p^2 / p_0^2\right) = 20\log_{10}\left(p / p_0\right)$$

Unless otherwise stated, SPL refers to the root-mean-square sound pressure level. See also 90% sound pressure level and fast-average sound pressure level. Non-rectangular time window functions may be applied during calculation of the rms value, in which case the SPL unit should identify the window type.

sound speed profile
The speed of sound in the water column as a function of depth below the water surface.

source level (SL)
The sound level measured in the far-field and scaled back to a standard reference distance of 1 meter from the acoustic center of the source. Unit: dB re 1 µPa @ 1 m (sound pressure level) or dB re 1 $\mu Pa^2 \cdot s$ (sound exposure level).

Attention: Mr. Chris Haddon
Project Director

Subject: Concrete Batch Plant

References:

1. Boxcar Hill Concrete Batch Plant; JC-150-CIV-MAP-KBJ-02804-01, Rev A.
2. Example Concrete Batch Plant; J1-000CNS-SKT-03000-00, Rev A.
3. Fugitive Dust Control Plan; J1-000-CNS-PLN-KBJ-50003-00, Rev 0.

Dear Mr. Haddon,

KBJ has reviewed the findings of the Coos County Planning Department's September 23, 2019 Staff Report for the request for concurrent Land Use Application by Jordan Cove Energy Project L.P. for the Liquefied Natural Gas Terminal. To address the Coos County standards for compatibility of the temporary concrete batch plant, KBJ has reviewed the definition and has developed the following general description of the proposed support facility.

KBJ intends to construct a concrete batch plant to supply concrete for the Jordan Cove Energy Project. The plant will provide concrete supply for the construction of LNG Terminal and related facilities. The concrete needed is approximately 130,000 cubic yards. Local aggregate sources have been investigated and have been found to have deficiencies that preclude their use for concrete. Regional sourcing for the availability of on-spec aggregate has been confirmed. This plant will only be utilized to supply concrete to the JCEP and not offer concrete to the general public. The plant will be capable of producing approximately 200 cubic yards of concrete per hour, which is appropriate for the planned concrete needs for the project. KBJ has based these plans on the capabilities of current local red-i-mix concrete vendors as well as the impact on the local community concrete truck traffic on area roads if one of the local vendors was used to supply all of the concrete for the project.

The current plan for the batch plant is to be located on an approximately 5-acre parcel of land at Boxcar Hill. This will include the batch plant, aggregate storage, plant support equipment parking, and an office facility for batch plant operations. The plant layout has not been finalized, but early conceptual layouts have shown that the batch plant will use approximately 80,000 sq. feet of the approximately 5-acre (217,800 SF) area. The final layout will consider the safe traffic flow of concrete trucks and batch plant equipment, as well as proximity to property lines to keep batch plant operations away from neighboring properties. The batch plant will be located inside the property line and further set back behind a construction security fence. Attachment 1 contains an illustration of the proposed batch plant's location at Boxcar Hill.

It is expected that the batch plant will be in operation for 30-36 months. Typical batch plant operations will be from 6:00 AM – 6:00 PM Monday through Friday. There may be some extended work hours for batch plant operations to support large concrete pours on the project. During plant operations the area will be well lit to provide a safe work environment for plant personnel. This lighting will be reduced when the plant is not in operations to levels that are appropriate for security purposes. Upon completion of the construction project, the temporary concrete batch plant will be decommissioned and removed from Boxcar Hill.

The concrete batch plant will be comprised of several pieces of equipment that are used in the batching process. The major pieces of equipment will include a batching hopper, material conveyors to transport aggregate materials into the hopper and cement silos along with their associated dust control equipment. This equipment will generally be less than 16' tall with the tallest element being the cement silos which could be as tall as approximately 60 feet. An example picture of this equipment has been included as Figure 1. Figure 2 illustrates a conceptual batch plant layout. It is anticipated that power to operate the batch plant will come from a permanent electrical connection to eliminate the need for portable generators to power the facility. Auxiliary equipment will include air compressors and mobile equipment such as front-end loaders, dump trucks, and fork lifts.

KBJ or their subcontractors will be responsible for attaining all required permits to erect and operate the concrete batch plant. It is anticipated that the plant will acquire an applicable air permit, a 1200-A permit, and develop a stormwater management plan, and a site-specific fugitive dust plan (reference for terminal site has been included). The batch plant will also have a water treatment system to address any waste water generated by plant operations. A separate wash out area will be managed to be used by concrete trucks washing up to contain all concrete wastes. Concrete batch plants do not typically generate significant plumes of steam or smoke as part of their standard operations and thus, impacts to local visibility are not expected. Additionally, Oregon exempts construction noise which would include noise generated from the proposed concrete batch plant.

Figure 1 - Example of a typical concrete batch plant

Revised September 2018

EXECUTIVE SUMMARY

This applicant-prepared Draft Biological Assessment (APDBA) and Essential Fish Habitat (EFH) Assessment has been prepared for submission to the Federal Energy Regulatory Commission (FERC or Commission) to assist FERC in meeting its obligations under Section 7 of the Endangered Species Act of 1973 (ESA) and the Magnuson-Stevens Fishery Conservation and Management Act (MSA) by Jordan Cove Energy Project, LP (JCEP) and Pacific Connector Pipeline, LP (PCGP) (JCEP and PCGP are together referred to as "Applicants").

In September 2017, JCEP filed an application with the FERC under Section 3 of the Natural Gas Act, 15 U.S.C. §717b(a) (NGA), in Docket No. CP17-495-000, seeking to site, construct and operate a LNG export terminal on the North Spit of Coos Bay, in Coos County, Oregon (LNG Terminal). Under Section 7 of the NGA, PCGP also filed an application with the FERC in September 2017, in Docket No. CP17-494-000, seeking a Certificate of Public Convenience and Necessity (Certificate) to construct and operate a 229-mile-long, 36-inch-diameter, pipeline from interconnections with the existing Ruby pipeline and Gas Transmission Northwest pipeline near Malin, Oregon (Pipeline) to supply the LNG Terminal with natural gas. The proposed Pipeline would cross through portions of Klamath, Jackson, Douglas, and Coos Counties, Oregon. The LNG Terminal and the Pipeline are collectively referred to as the "Project."

Section 7 of the ESA, 16 U.S.C. §§1531 et. seq. requires federal agencies to consult with the United States Fish and Wildlife Service (FWS) or the National Marine Fisheries Service (NMFS), as applicable, to assure that any project authorized, funded, or conducted by a federal agency does not "jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species which is determined...to be critical." If, upon review of existing data, or data provided by the applicant, one (or both) of the Services find that any federally listed species or critical habitats may be affected by a proposed project, the lead federal agency is required to prepare a biological assessment (BA) to identify the nature and extent of the effects on these species and their habitats, and to recommend measures that would avoid, reduce, or mitigate impacts on habitats and/or species. FERC is the lead federal agency for this Project.

The Magnuson-Stevens Fishery Conservation and Management Act, as amended, 16 U.S.C. §§1361 et.seq. (MSA) established procedures designed to identify, conserve, and enhance essential fish habitat (EFH) for those species regulated under a federal fisheries management plan. The MSA requires federal agencies to consult with the NMFS on all actions or proposed actions authorized, funded, or undertaken by the agency that may adversely affect EFH, 16 U.S.C. §305(b)(2); 50 C.F.R. §600.920. The applicable regulations encourage consolidation of environmental review procedures to reduce duplication and improve efficiency, 50 C.F.R. §600.920(f). For this Project, the EFH Assessment has been incorporated into the APDBA, 50 C.F.R. § 600.920(e)(3).

Under the NGA, the FERC is the federal agency responsible for authorizing the siting, construction, and operation of onshore LNG terminals, as well as allowing the interstate transportation of natural gas. The FERC is also the lead federal agency for compliance with the

NEPA, in accordance with the Energy Policy Act of 2005 and inter-agency agreements.[1] On behalf of the cooperating agencies, the FERC is also the lead federal agency responsible for complying with the ESA and the MSA for the Project. The federal agencies cooperating with the FERC in the production of this BA and EFH Assessment include the United States Department of Agriculture, Forest Service (Forest Service), the United States Department of the Interior, Bureau of Land Management (BLM) and Bureau of Reclamation (Reclamation), United States Army Corps of Engineers (COE), the United States Environmental Protection Agency (EPA), the United States Coast Guard (Coast Guard), the United States Department of Energy (DOE), and the United States Department of Transportation (DOT).

PROPOSED ACTION

The Project will be located in southern Oregon. The main components of the Project include:

- The LNG Terminal and associated facilities in Coos County, Oregon; and
- The Pipeline which will cross portions of Klamath, Jackson, Douglas, and Coos County, Oregon, and associated facilities.

The Project description is provided in section 2.0, and terminology in this document is defined as follows:

- "LNG Terminal site" refers to the terminal site footprint and "LNG Terminal project" refers to the terminal and associated components.
- "Pipeline" refers to the centerline or linear facility and "Pipeline project" refers to the construction right-of-way, temporary extra work areas (TEWAs), uncleared storage areas (UCSAs), aboveground facilities, contractor and pipe storage yards, quarries and rock source disposal sites, permanent and temporary access roads (PARs and TARs, respectively), existing access roads (EARs), communication facilities, 30-foot maintenance/operation corridor, and 50-foot permanent easement.
- "in the vicinity of the Pipeline project" or in the "Pipeline project area" describes the area where impacts to fish, wildlife, and vegetation (plants) could occur outside of the Pipeline project footprint. In many instances, these terms are used generally, since the extent (or distance from the Pipeline project) of impact beyond the Pipeline project varies by fish, wildlife, and vegetation (plant) species, Pipeline project activity, habitat and site characteristics (i.e., waterbody or vegetation). Similarly, discussion of area of surveys (i.e., distance from the Pipeline project) conducted for the Pipeline varies depending on wildlife and plant species targeted, landowner (federal or non-federal), and expected impact (i.e., proposed blasting and/or helicopter use). Specific distances for survey

[1] See the May 2002 *Interagency Agreement on Early Coordination of Required Environmental and Historic Preservation Reviews Conducted in Conjunction With the Issuance of Authorizations to Construct and Operate Interstate Natural Gas Pipelines Certificated by the Federal Energy Regulatory Commission*, signed by the FERC, Advisory Council on Historic Preservation, Council on Environmental Quality, EPA, Department of the Army, USDA, Department of Commerce, DOE, USDI, and DOT; and the February 2004 *Interagency Agreement Among the Federal Energy Regulatory Commission, United States Coast Guard, and Research and Special Programs Administration for the Safety and Security Review of Waterfront Import/Export Liquefied Natural Gas Facilities*.

efforts and construction and operation impacts are discussed specifically in the individual species' sections below. See the discussion of the Action Area for purposes of Section 7 consultation below.

The Project is a market-driven response to the burgeoning and abundant natural gas supply in the US Rocky Mountain and Western Canadian markets, and the growth of international demand, particularly in Asia. The overall Project purpose and need is to construct a natural gas liquefaction and deep-water export terminal capable of receiving and loading ocean-going LNG carriers, in order to export natural gas derived from a point near the intersections of the Gas Transmission Northwest and Ruby Pipeline systems. JCEP intends to liquefy about 7.8 million tons per annum (mtpa) of LNG, which can be loaded onto LNG carriers, using a feed of about 1.2 billion cubic feet per day (Bcf/d) of natural gas. PCGP's new pipeline is designed to transport an everage of 1,200,000 dekatherms per day (dth/d) of natural gas obtained at proposed interconnections with the existing Gas Transmission Northwest LLC and Ruby Pipeline LLC systems near Malin, Oregon to be delivered to the LNG Terminal at Coos Bay.

The LNG Terminal would turn natural gas into its liquid form via cooling to about -260 degrees Fahrenheit (^{o}F), and in doing so, it would reduce in volume to approximately 1/600th of its original volume, making it easier and more efficient to transport. The LNG Terminal, related facilities, temporary construction sites, and other sites/actions associated with LNG Terminal construction are collectively referred to as the "JCEP Project Area." The JCEP Project Area is made up of the following project components:

- LNG Carrier Transit Route – the waterway for LNG carrier marine traffic for the Project extends from the outer limits of the Outer Continental Shelf approximately 12 nautical miles (nmi) off the coast of Oregon, and 7.5 nmi up the existing Coos Bay Federal Navigation Channel (FNC) to the LNG Terminal.
- LNG Terminal Site – the site includes the Ingram Yard, Access and Utility Corridor, and South Dunes site. These components are referenced throughout the document but are not described in greater detail. See JCEP's Resource Report 1 for additional information.
- Marine Slip – a permanent facility on Ingram Yard adjacent to the access channel. LNG carriers would enter the slip via the access channel, be loaded with LNG, and leave for export. The slip would include an LNG carrier loading berth and LNG loading facilities, a tug berth, and an emergency lay berth to safely moor a temporarily disabled LNG carrier.
- Access Channel – the access channel would be dredged north of the FNC to provide LNG carriers with access from the FNC to the slip.
- Pile Dike Rock Apron – a permanent rock apron located immediately west of the access channel to protect Pile Dike 7.3
- Material Offloading Facility (MOF) – a permanent facility east of the slip where fill would be placed and approximately 450 feet of dock face would be constructed for the mooring of a variety of vessel types to offload materials for construction and maintenance of the LNG Terminal. Dredging would occur to access the MOF.
- Temporary Materials Barge Berth (TMBB) – an offloading facility that would be

constructed on an existing berm west of the MOF to facilitate early construction activities, and would be removed when the access channel is dredged and the berm related to the slip construction is removed.

- Navigation Reliability Improvements – four permanent dredge areas adjacent to the FNC that would allow for navigation efficiency and reliability for vessel transit under a broader weather window.
- Trans Pacific Parkway and U.S. Highway 101 (US-101) Intersection Widening – the asymmetrical widening of Trans Pacific Parkway to the north and US-101 to the west to provide safe ingress/egress for construction traffic, by creating a left-turn lane from Trans Pacific Parkway onto northbound US-101 and a right-turn lane from US-101 onto Trans Pacific Parkway.
- APCO Site – APCO Site 1 (east) and APCO Site 2 (west) would be used as upland dredge disposal sites for the Project.
- Kentuck Project site – approximately 100-acre proposed wetland mitigation and habitat restoration site associated with the LNG Terminal and the Pipeline.
- Eelgrass Mitigation site – approximately 9.3-acre proposed mitigation site for unavoidable eelgrass impacts associated with dredging of the access channel.
- Upland Wildlife Habitat Mitigation Sites – proposed wildlife habitat mitigation sites (Lagoon, Panhandle, and North Bank) associated with the LNG Terminal.

PCGP proposes to construct and operate a pipeline that will extend approximately 229 miles[2], starting from an interconnection with the existing interstate pipeline systems of Ruby Pipeline LLC (Ruby) and Gas Transmission Northwest LLC (GTN) near Malin in Klamath County, Oregon, and extending to the LNG Terminal in Coos County, Oregon. The Pipeline would be 36 inches in diameter and is designed to transport up to 1,200,000 dekatherms per day (Dth/d) of natural gas at a maximum allowable operating pressure of 1,600 pounds per square inch gage.

PCGP's proposed jurisdictional natural gas facilities would include the following: aboveground facilities required for the Pipeline:

- the 62,200 horsepower Klamath Compressor Station at the eastern beginning of the pipeline at milepost (MP) 228.8. Within the compressor station tract would be the Klamath-Beaver and Klamath-Eagle receipt meter stations, at the interconnections with Ruby and GTN;
- the Jordan Cove Meter Station station would be at MP 0.00 at the interconnection with the LNG Terminal;
- 17 mainline block valves (MLV) located within the pipeline right-of-way or co-located

[2] Total pipeline length is 229.09 miles. However, PCGP retained its original design mileposting and accounted for realignments using equations. Therefore, although the gas would flow east to west, the mileposting is reversed, with the Klamath Compressor Station at MP 228.8 and the Jordan Cove delivery meter station at MP 0.00.

at aboveground facilities;

- 5 pig[3] launchers and receivers co-located within aboveground facilities; and
- 15 communication towers also co-located with existing or proposed facilities.

The Pipeline would traverse agricultural lands, sage and juniper woodlands ecozone of the Klamath Basin, over the Southern Cascades conifer forest and oak woodlands and conifer forest ecozones of the Klamath Mountains, through Camas Valley and Douglas-fir forests of the Coastal Range, and terminate in the Coastal lowlands.

The standard construction right-of-way would be about 95 feet wide. When crossing wetlands and certain riparian areas, the construction right-of-way may be reduced to 75 feet wide. Approximately 2,582 acres would be required for the construction right-of-way. The permanent easement would be 50 feet wide. There would be a number of ancillary use areas associated with construction of the Pipeline. PCGP proposes to use:

- 1,603 temporary extra work spaces, totaling about 922.6 additional acres;
- 320 uncleared storage areas totaling 676 acres would be used during construction,
- 20 rock source and disposal sites, totaling about 41.2 acres (an additional 20 sites, identified for rock source/disposal, are included in the temporary extra work areas, totaling 44.8 acres).
- 36 pipe storage and contractor yards, totaling about 674.2 acres.
- 670 miles of existing roads would be used to access the pipeline right-of-way during construction. PCGP would have to make improvements to portions of 27 of those existing roads, disturbing about 22.5 acres.
- build 10 new temporary access roads, totaling 3.8 acres, and permanently maintain 15 new access roads for operation of the pipeline, covering about 2.2 acres.

This APDBA and EFH Assessment considers impacts on federally listed and proposed species from the construction and operation of the FERC jurisdictional and inter-related and interdependent, non-jurisdictional facilities.

ACTION AREA

The action area includes all areas that would be affected directly or indirectly by the proposed action and not just the immediate area involved in the action. Because the proposed action potentially can affect such a variety of species inhabiting diverse habitats within marine, estuarine, riverine, and various terrestrial locations, there are multiple components of the action area that have been defined as species' analysis areas, the areas where individual or groups of listed species could be affected by the proposed action. Species' analysis areas are described in detail in each species' environmental baselines and figures of the analysis areas are provided, where appropriate. For some species there may be more than one analysis area if the listed

[3] A pig is an internal pipeline cleaning and inspection tool.

species utilizes multiple habitats in diverse locations. Analysis areas and associated species include:

- the marine analysis area is a fan shape beginning at the entrance to Coos Bay extending approximately 12-13 nautical miles (nm) off the coast of Oregon to the edge of the Outer Continental Shelf (OCS). The northern border of the fan extends from the North Jetty to the point located at the edge of the OCS near 43°, 28' 39", -124°33'34", and the southern border extends from the South Jetty to point located at the edge of the OCS near 43°24'49", -124°35'8". The analysis area is approximately 33.1 square miles. The marine analysis area applies to all listed marine mammals, short-tailed albatross, MAMU, green sturgeon, eulachon, coho salmon (Oregon Coast Evolutionary Significant Unit (ESU) and in the Southern Oregon/Northern California Coast (SONCC) ESU), and listed sea turtles;
- the gray wolf analysis area is based on the Area of Known Wolf Activity initially designated for OR-7, and applies only to the gray wolf;
- the estuarine analysis area (see figure 3.3.3-3) which encompasses all estuarine waters (and substrates) that are within the estuary between the North Jetty and South Jetty at the Coos Head entrance to the Upper Coos Bay. The estuarine analysis area is approximately 15 square miles. The estuarine analysis area applies to MAMU, green sturgeon, eulachon, and coho salmon (Oregon Coast ESU);
- the LNG terminal analysis area extends for 1.5 miles beyond the perimeter of the LNG Terminal Site (see figure 3.3.2-2) to include project components on the North Spit and APCO Site, which historically provided western snowy plover nesting habitat;
- terrestrial nesting analysis area extends inland along the Pipeline route to include MAMU Inland Zone 1 – MPs 0.00 to 53.76 - and MAMU Inland Zone 2 – MPs 53.76 to 75.40 (see figure 3.3.3-2). and applies only to MAMU;
- provincial analysis area is located within four Physiographic Provinces: Oregon Coast Range, Oregon Klamath Mountains, West Oregon Cascades, and East Oregon Cascades (see figure 3.3.4-1), and applies only to NSO;
- the riverine analysis area encompasses 5th field (watershed-level) hydrological unit codes (HUCs) and reflects an estimate of the average downstream extent that suspended sediment from any stream crossing generated by the Pipeline could equal ambient conditions within the 5th field watershed crossed. Several riverine analysis areas that are in specific geographic locations each in the respective ranges of coho salmon in the Oregon Coast ESU and in the Southern Oregon/Northern Californis Coast (SONCC) ESU, listed suckers, and Oregon spotted frogs; and
- botanical analysis areas extend to 30 meters (98 feet) each side of the Pipeline project on lands that have potential habitat for listed plant species, except vernal pool-associated species (fairy shrimp and two listed plants) where the area extends out 250 feet.

COORDINATION AND ORGANIZATION

The Applicants conferred with various federal agencies, including the FWS, NMFS, COE, EPA, DOE, Coast Guard, Forest Service, BLM, and Reclamation, as well as state resource agencies, including the Oregon Department of Environmental Quality, Oregon Department of State Lands, Oregon Department of Fish and Wildlife, Oregon Department of Forestry, Oregon Department of

Agriculture, Oregon Department of Water Resources, and the Oregon Department of Land Conservation and Development.

The presentation of the analysis in this APDBA and EFH Assessment is organized by key activities associated with construction and operation of the Project. Structural and functional elements of the Project were grouped into three major components: 1) LNG carrier traffic within marine analysis area; 2) LNG Terminal facilities; and 3) Pipeline and associated natural gas facilities. Section 3.0 discusses the potential effects on ESA listed and proposed species and critical habitat associated with each of these major components and includes our determination of effect for each species and designated or proposed critical habitat (where present in the action area). Section 4.0 discusses potential effects on EFH under the MSA.

SUMMARY OF EFFECTS DETERMINATIONS

Endangered Species Act

The FWS and NMFS were consulted to identify the federally listed and proposed species and critical habitat with the potential to occur in the action area. A total of 31 species, Evolutionarily Significant Units, and Distinct Population Segments that are federally listed as endangered or threatened have the potential to occur in the action area. Of these, critical habitat has been designated or proposed in the action area for 13 species. The findings regarding the potential effects of the Project on listed and proposed species and habitat are based on the best scientific and commercial data available.

Based on the documentation and analytical results contained herein that the Project may affect, but is not likely to adversely affect 20 species and/or their designated critical habitat, including eight whales (designated critical habitat not affected for two whale species), one land mammal, two birds, four sea turtles, one amphibian, one fish (designated critical habitat not affected), and three plants (designated critical habitat not likely to be adversely affected for one species and not affected for another species).

The Project may affect, and is likely to adversely affect 11 species, including two birds and their designated critical habitat, five fish and designated critical habitat for three of the fish species/populations, one invertebrate (designated critical habitat not likely to be affected), and three plants (designated critical habitat not affected for one of the plant species). These determinations as well as a summary of the justification for the determinations are provided in table ES-1.

TABLE ES-1

Determinations of Effect for Federally Listed and Proposed Endangered and Threatened Species Potentially Occurring In the Project Area

Listed Species	Determination of Effect a/ Species	Determination of Effect a/ Critical Habitat	Justification
Mammals			
Blue whale *Balaenoptera musculus*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable and could exceed NMFS interim noise exposure criteria for Level B non-pulse noise, but would be temporary and not likely to cause significant injury.
Fin whale *Balaenoptera physalus*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable and could exceed NMFS interim noise exposure criteria for Level B non-pulse noise, but would be temporary and not likely to cause significant injury.
Killer whale (Eastern Northern Pacific Southern Resident Stock) *Orcinus orca*	NLAA	NE	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable and could exceed NMFS interim noise exposure criteria for Level B non-pulse noise, but would be temporary and not likely to cause significant injury.
Humpback whale *Megaptera novaeangliae*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Ship noise would be detectable and could exceed NMFS interim noise exposure criteria for Level B non-pulse noise, but would be temporary and not likely to cause significant injury.
Sei whale *Balaenoptera borealis*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Sei whales are not expected to occur in marine analysis ares andcarrier noise would be detectable but would not exceed NMFS interim noise exposure criteria.
Sperm whale *Physeter macrocephalus*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable and could exceed NMFS interim noise exposure criteria for Level B non-pulse noise, but would be temporary and not likely to cause significant injury.
North Pacific right whale *Eubalaena japonica*	NLAA	NE	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. North Pacific Right Whales are not expected to occur in marine analysis ares and carrier noise would be detectable but would not exceed NMFS interim noise exposure criteria.
Gray whale (Western North Pacific Stock) *Eschrichtius robustus*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Gray Whales are not expected to occur in marine analysis ares and carrier noise would be detectable but would not exceed NMFS interim noise exposure criteria.

TABLE ES-1

Determinations of Effect for Federally Listed and Proposed Endangered and Threatened Species Potentially Occurring In the Project Area

Listed Species	Determination of Effect a/		Justification
	Species	Critical Habitat	
Gray wolf (Western Washington, Western Oregon, Northern California) *Canis lupus*	NLAA	N/A	The Pipeline route would be in the vicinity of the Rogue pack and additional estimated wolf use near Keno. Construction noise and human presence could affect wolf movements and behavior, but noises are not likely to be substantially different from the noise produced by existing recreation, hunting, and logging land uses that wolves have been shown to tolerate and are insignificant. One known den site is > 6 miles from the Pipeline.
Birds			
Short-tailed albatross *Phoebastria albatraus*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable.
Western snowy plover (Pacific Coast Population) *Charadrius alexandrinus nivosus*	NLAA	NLAA	Active nesting areas on the North Spit used by Western snowy plover are approximately 1.0 miles from the LNG Terminal, and critical habitat is 2.6 miles from the LNG Terminal. At these distances, construction noise at nesting areas and critical habitat would not be above ambient levels and is insignificant.
Marbled murrelet *Brachyramphus marmoratus*	LAA	LAA	Construction of the Pipeline would result in modification of suitable habitat, and could adversely affect the species and critical habitat.
Northern spotted owl *Strix occidentalis caurina*	LAA	LAA	Construction of the Pipeline would result in modification of suitable habitat, and could adversely affect the species and critical habitat.
Herpetofauna			
Green turtle *Chelonia mydas*	NLAA	NE	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable but would be temporary and should not adversely impair hearing of the species and is insignificant.
Leatherback turtle *Dermochelys coriacea*	NLAA	NLAA	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable but would temporary, and should not impair hearing of the species and is insignificant.
Olive Ridley turtle *Lepidochelys olivacea*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable but would be temporary and should not impair hearing of the species.
Loggerhead turtle *Caretta caretta*	NLAA	N/A	LNG carrier marine traffic would be traveling at slow speeds (10 knots or less as detailed in the Ship Strike Avoidance Measures for Whales) making the potential for ship-strike extremely low and discountable. Carrier noise would be detectable but would be temporary and should not impair hearing of the species.

TABLE ES-1

Determinations of Effect for Federally Listed and Proposed Endangered and Threatened Species Potentially Occurring In the Project Area

Listed Species	Determination of Effect a/ Species	Determination of Effect a/ Critical Habitat	Justification
Oregon spotted frog *Rana pretiosa*	NLAA	NLAA	The Pipeline construction across Spencer Creek may affect Oregon spotted frogs, because the crossing site is 6,400 feet upstream from occupied habitat. However, tffects to Oregon spotted frogs and critical habitat in Spencer Creek downstream of Buck Lake was judged to be insignificant and discountable because the right-of-way and Spencer Creek are separated by Clover Creek Road and are not hydrologically connected, and the nearest hydrostatic discharge site is approximately 2.4 miles (straight line) from occupied habitat and BMPs would prevent any potential adverse effects to designated critical habitat from sedimentation.
Fish			
Green sturgeon (Southern Distinct Population Segment) *Acipenser medirostris*	LAA	LAA	Short-term increase in noise associated with land based pile driving at the MOF and in-water pile driving at various temporary construction activities throughout the bay may create disturbance and physical injury. Exposure to suspended sediment during Pipeline construction could affect sturgeon and designated critical habitat. Slip Access Channel and Navigation Reliability Improvements dredging could reduce food supply for rearing fish in localized areas in Coos Bay Critical habitat would be adversely affected by reduction in food sources from dredging in Coos Bay for construction of the LNG Terminal.
Eulachon (Southern Distinct Population Segment) *Thaleichthys pacificus*	NLAA	NE	While some eulachon adults may be present in Coos Bay during dredging, mitigation measures would reduce turbidity from the actions so that any adverse effects from increased turbidity would be insignificant. No critical habitat coincides with the estuarine analysis area of the analysis area, so critical habitat would not be affected.
Coho salmon (Southern Oregon/Northern California Coast Evolutionarily Significant Unit) *Oncorhynchus kisutch*	LAA	LAA	Juvenile rearing stages would suffer stress and possibly mortality from elevated turbidity at Pipeline stream crossings, from fish salvage operations, and from in-stream blasting. Adult spawning success may also suffer from short-term elevated sediment from Pipeline stream crossings. Designated critical habitat would be adversely affected by reduced large woody debris (LWD) supply and riparian habitat loss and impedance of fish movement during instream construction. Critical habitat could be adversely affected by increased turbidity during construction.

TABLE ES-1

Determinations of Effect for Federally Listed and Proposed Endangered and Threatened Species Potentially Occurring In the Project Area

Listed Species	Determination of Effect a/ Species	Critical Habitat	Justification
Coho salmon (Oregon Coast Evolutionarily Significant Unit) *Oncorhynchus kisutch*	LAA	LAA	Short-term increase in noise associated with land-based pile driving at the MOF and in-water pile driving at various temporary construction activities throughout the bay may create disturbance and physical injury. Juvenile loss from entrainment during LNG carrier water intake in Coos Bay may occur. Slip, access channel and Navigational Reliability Improvements dredging could reduce food supply for fish in localized areas in Coos Bay and entrain juveniles but is not likely to contribute to significant adverse effects due to there being a small and localized area impacted. Juvenile rearing stages would suffer stress and possibly mortality from elevated turbidity at Pipeline stream crossings, from fish salvage operations, and from in-stream blasting. Adult spawning success may also suffer from short-term elevated sediment from pipeline stream crossings. Designated critical habitat could be adversely affected by reduced LWD supply and riparian habitat loss and impedance of fish movement during instream construction. Critical habitat could be adversely affectedby increased turbidity during construction.
Lost River sucker *Deltistes luxatus*	LAA	NLAA	Juvenile or adult fish may be adversely affected at Pipeline construction across several ditches/canals and the Lost River and may suffer mortality from fish salvage operations. Designated critical habitat would not be adversely affected as the use of horizontal direction drill (HDD) would avoid critical habitat in the Klamath River.
Shortnose sucker *Chasmistes brevirostris*	LAA	NLAA	Juvenile or adult fish may be adversely affected at Pipeline construction across several ditches/canals and the Lost River and may suffer mortality from fish salvage operations. Designated critical habitat would not be adversely affected as the use of HDD would avoid critical habitat in the stream.
Invertebrates			
Vernal pool fairy shrimp *Branchinecta lynchi*	LAA	NLAA	Direct or indirect impacts to vernal pool fairy shrimp may result from Pipeline construction within or adjacent to nine potentially suitable vernal pools identified between MPs 145.34 to 145.40 if species is present. Impacts to critical habitat are insignificant and discountable because an existing road separates the proposed pipeyward from critical habitat
Plants			
Applegate's milk-vetch *Astragalus applegatei*	LAA	N/A	Potential suitable habitat occurs along the Pipeline route, but comprehensive surveys have not been conducted in all potential habitat due to landowner denial. Indirect impacts to Applegate's milkvetch plants and habitat may occur if the plants or habitat are identified within 30 meters of either side of the Pipeline project. To the extent present, adverse impacts may occur as a result of land disturbing activities.
Gentner's fritillary *Fritillaria gentneri*	LAA	N/A	Not all potential suitable habitat crossed by the Pipeline was surveyed due to landowner access denial. Gentner's fritillary does not flower every year, and has been documented to not flower for several years; therefore, it is possible that this plant is present in the construction right-of-way even though it was not identified during the two years of surveys conducted for this flower. *Fritillaria sp*. leaves were documented within and adjacent to the Pipeline right-of-way and without flowers, it is nearly impossible to determine if those leaves belong to Gentner's fritillary or another *Fritillaria* species, which is not listed. To the extent present, adverse impacts may occur as a result of land-disturbing activities.

TABLE ES-1

Determinations of Effect for Federally Listed and Proposed Endangered and Threatened Species Potentially Occurring In the Project Area

Listed Species	Determination of Effect a/ Species	Critical Habitat	Justification
Large-flowered woolly meadowfoam *Limnanthes pumila ssp. grandiflora*	NLAA	NLAA	Surveys of potentially suitable habitat at proposed pipe storage yards in Jackson County and along the proposed Pipeline did not document large-flowered meadowfoam plants. Applicant would avoid using portions of proposed pipe storage yards with high-quality vernal pool habitat and/or identified plants. Effects to suitable habitat by the Pipeline would be insignificant. Construction of the Pipeline is not expected to adversely affect designated critical habitat subunit RV6C. Existing features (i.e., paved Agate Road) and proposed conservation measures would provide sufficient protection from adjacent development and weed sources such that any impacts would be insignificant and discountable.
Cook's lomatium *Lomatium cookii*	NLAA	NE	Surveyed suitable habitat at proposed pipe storage yards in Jackson County and along the proposed Pipeline did not document the presence of Cook's lomatium. Unsurveyed habitat is low quality vernal pool habitat located over 0.25 mile from known sites with no apparent hydrologic connectivity. The nearest critical habitat subunit RV6A is more than 0.5 miles from the Pipeline and therefore will not be affected by the proposed action.
Kincaid's lupine *Lupinus sulphureus var. kincaidii*	LAA	NE	Surface disturbance and excavation would occur within potentially suitable habitats, which may contain un-identified plants. Indirect impacts are expected to documented or unidentified plants outside of the construction right-of-way and along proposed access roads. All potential suitable habitat has not been surveyed due to landowner access denial. Designated Kincaid's lupine critical habitat does not occur in the action area.
Rough popcornflower *Plagiobothrys hirtus*	NLAA	N/A	Surveys for the Pipeline have not documented rough popcornflower, where survey permission has been granted. Surveys in potentially suitable habitat identified within Winchester pipe storage yard or within potential habitat identified within the botanical analysis area along the right-of-way would occur prior to ground disturbing activities; if plants are identified, conservation measures developed to avoid or minimize potential impacts to identified plants would be applied. As a result, any impacts would be insignificant and discountable.

a/ LAA –May affect, likely to adversely affect.
N/A – Not applicable (critical habitat has not been designated or proposed).
NE – No effect.
NLAA – May affect, not likely to adversely affect.

Magnuson-Stevens Fishery Conservation and Management Act (MSA)

The Pacific Fishery Management Council (PFMC) has developed four Fishery Management Plans (FMPs) that address Essential Fish Habitat (EFH) for managed species in the Project action area. The four fisheries managed by the PFMC contain highly migratory species, coastal pelagic species, groundfish, and Pacific Coast salmon.

EFH has been defined by the PFMC out to the limits of the United States Exclusive Economic Zone (EEZ). Marine traffic associated with construction and operation of the LNG Terminal may affect EFH beyond the marine analysis area (that is, beyond the limits of the OCS out to the limits of the EEZ). For example, vessel traffic would generate localized noise, and impacts on water quality may occur due to discharge of ballast water, intake and discharge of cooling water, or accidental spills of pollutants at sea. However, Coos Bay and the waters offshore out to the limits of the EEZ currently provide deepwater access for maritime commerce, and support high levels of deep draft vessel traffic. Any impacts due to the incremental increase in marine vessel traffic during construction and operation of the Project would not have a significant adverse effect on EFH outside of the marine analysis area of the Project action area. As a result, the analysis of potential adverse effects to EFH coincides with the Project action area under the ESA, and the EFH Assessment has been incorporated into the APDBA. 50 CFR § 600.920(e)(3).

The MSA defines EFH as those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity. Within the marine, estuarine and riverine analysis areas, EFH has been designated for two salmonid species, five pelagic species, 70 groundfish species, and over a dozen highly migratory species as described in Section 4.0. . According to the PFMC, all habitats accessible to these managed species, including spawning and incubation, juvenile rearing, juvenile migration corridors, and adult migration corridors, are considered EFH. Highly migratory species defined by the PFMC include tunas (three species), sharks (five species), and billfish/swordfish (one species). Based on the documentation and analytical results contained herein, the Project would have no adverse effect on EFH for highly migratory species, but may adversely affect EFH within the Project action area for coastal pelagic species, groundfish, and Pacific Coast salmon. These determinations as well as a summary of the justification for the determinations are provided in table ES-2.

TABLE ES-2

Determinations of Effect for Essential Fish Habitat

Fishery	**Analysis Area**			**Determination of Effect a/**	**Justification**
	Marine/EEZ	**Estuarine**	**Riverine**		
Highly Migratory Species	X	–	–	NAE	Discharges at sea, including any accidental spills of fuel or lubricants would not significantly diminish water quality within the marine analysis area. Vessel traffic noise would be detectable but would not exceed interim noise exposure criteria. Any impacts due to the incremental increase in marine vessel traffic would not have a significant adverse effect on EFH.
Coastal Pelagic Species	X	X	–	MAA	Loss of estuarine eelgrass habitat during dredging for LNG Terminal would adversely affect EFH for coastal pelagic species. Short-term loss of benthic food resources would also result from dredging of the slip, access channel and NRI areas; however, deep subtidal habitat is not a limited habitat type within Coos Bay and the effects would be minimal. Small juvenile and larval stages of fish could be entrained or impinged and suffer mortality from the cooling water intakes of LNG carriers while at berth; but a significant loss is unlikely.

TABLE ES-2

Determinations of Effect for Essential Fish Habitat

Fishery	Analysis Area: Marine/EEZ	Analysis Area: Estuarine	Analysis Area: Riverine	Determination of Effect a/	Justification
Groundfish	X	X	–	MAA	A localized loss of estuarine eelgrass habitat during dredging for LNG terminal access channel could adversely affect EFH for groundfish. Short-term loss of benthic food resources would also result from dredging of the slip, access channel and NRI areas. As described for coastal pelagic species EFH, these habitat types are not limited within Coos Bay and therefore the effects would be minimal. Over the long-term, eggs, larval, and small juvenile life stages of fish occupying waters near the LNG carriers at the terminal could be entrained or impinged, and suffer mortality by cooling water intakes but a substantive loss is unlikely.
Pacific Coast Salmon	X	X	X	MAA	Short-term increase in noise associated with land based pile driving at the MOF and in-water pile driving at various temporary construction activities throughout the bay may create disturbance and physical injury. Pipeline stream crossings could impact substrates and water quality over the short term, and LWD supply over the long term. Juvenile coho or Chinook salmon entrapped in isolated areas at pipeline stream crossings, as well as removal from stream crossing areas, would result in minor fish mortalities..

a/ – = Not applicable.
NAE = No adverse effect.
MAA = May adversely affect.

1.0 INTRODUCTION

1.1 PROJECT BACKGROUND

In September 2017, Jordan Cove Energy Project L.P. (JCEP) filed an application with the Federal Energy Regulatory Commission (FERC or Commission), under Section 3 of the Natural Gas Act, 15 United States Code (U.S.C.) §717b(a) (NGA), in Docket No. CP17-495-000, seeking to site, construct and operate a liquefied natural gas (LNG) export terminal on the North Spit of Coos Bay, in Coos County, Oregon (LNG Terminal). Simultaneously, under Section 7 of the NGA, Pacific Connector Gas Pipeline LP (PCGP) also filed an application with the FERC, in Docket No. CP17-494-000, seeking a Certificate of Public Convenience and Necessity (Certificate) to construct and operate a 229-mile-long, 36-inch-diameter, pipeline from interconnections with the existing Ruby pipeline and Gas Transmission Northwest pipeline near Malin, Oregon (Pipeline) to supply the LNG Terminal with natural gas. The proposed Pipeline would cross through portions of Klamath, Jackson, Douglas, and Coos Counties, Oregon. In this applicant-prepared draft biological assessment (APDBA), JCEP and PCGP are collectively referred to as “Applicants;” while the LNG Terminal and Pipeline are collectively referred to as the “Project.”

Section 7 of the Endangered Species Act (ESA), 16 U.S.C. §§1531 et. seq., requires federal agencies to consult with the United States Fish and Wildlife Service (FWS) or the National Marine Fisheries Service (NMFS), as applicable, to assure that any project authorized, funded, or conducted by a federal agency does not “jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species which is determined...to be critical.” If, upon review of existing data, or data provided by the applicant, one (or both) of the Services find that any federally listed species or critical habitats may be affected by a proposed project, the lead federal agency is required to prepare a biological assessment (BA) to identify the nature and extent of the effects on these species and habitats, and to recommend measures that would avoid, reduce, or mitigate impacts on habitats and/or species. FERC is the lead federal agency for this Project.

The Magnuson-Stevens Fishery Conservation and Management Act, as amended, 16 U.S.C. §§1361 et.seq. (MSA) established procedures designed to identify, conserve, and enhance essential fish habitat (EFH) for those species regulated under a federal fisheries management plan. The MSA requires federal agencies to consult with the NMFS on all actions or proposed actions authorized, funded, or undertaken by the agency that may adversely affect EFH, 16 U.S.C. §305(b)(2); 50 C.F.R. §600.920. The applicable regulations encourage consolidation of environmental review procedures to reduce duplication and improve efficiency, 50 C.F.R. §600.920(f). For this Project, the EFH Assessment has been incorporated into the APDBA, 50 C.F.R. §600.920(e)(3).

Under the NGA, the FERC is the federal agency responsible for authorizing the siting, construction, and operation of onshore LNG terminals, as well as allowing the interstate transportation of natural gas. The FERC is also the lead federal agency for compliance with the

NEPA, in accordance with the Energy Policy Act of 2005 and inter-agency agreements.[1] On behalf of the cooperating agencies, the FERC is also the lead federal agency responsible for complying with the ESA and the MSA for the Project. The following federal agencies have agreed to be cooperating agencies under the applicable regulations - U.S. Department of Agriculture (USDA) Forest Service (Forest Service), U.S. Department of the Army Corps of Engineers (Corps), National Oceanic and Atmospheric Administration (NOAA), U.S. Department of Energy (DOE), U.S. Environmental Protection Agency (EPA), U.S. Department of Homeland Security Coast Guard (Coast Guard), U.S. Department of the Interior Bureau of Land Management (BLM) and Bureau of Reclamation (Reclamation), and the U.S. Department of Transportation (DOT). A complete analysis of the potential impacts associated with the Project will be provided by FERC in its draft environmental impact statement (DEIS) which FERC will issue as a separate document.

In January 2018, PCGP submitted a Right-of-Way Grant application, under the Mineral Leasing Act, 30 U.S.C. §§181 et seq. to the BLM, Forest Service, and Reclamation. The Pipeline route would cross National Forest System (NFS) lands within the Umpqua, Rogue River, and Winema National Forests, and portions of the BLM's Coos Bay, Roseburg, Medford, and Lakeview Districts, and land and features within the Klamath Project managed by Reclamation.

The Applicants conferred with various federal agencies, including the FWS and NMFS, and the Corps, DOE, Coast Guard, Forest Service, BLM, and Reclamation, and state resource agencies, including the Oregon Department of Environmental Quality (ODEQ), Oregon Department of State Lands (ODSL), Oregon Department of Fish and Wildlife (ODFW), Oregon Department of Forestry (ODF), Oregon Department of Agriculture (ODA), Oregon Department of Water Resources (ODWR), and the Oregon Department of Land Conservation and Development (ODLCD). This APDBA is being provided to FERC to assist in its preparation of a BA with which to enter into formal consultations with FWS and NMFS under the applicable provisions of the ESA.

1.1 PROPOSED ACTION

The Project will be located in southern Oregon. The main components of the Project include:

- The LNG Terminal and associated facilities in Coos County, Oregon; and
- The Pipeline which will cross portions of Klamath, Jackson, Douglas, and Coos County, Oregon, and associated facilities.

The Project description is provided in section 2.0, and terminology in this document is defined as follows:

[1] See the May 2002 *Interagency Agreement on Early Coordination of Required Environmental and Historic Preservation Reviews Conducted in Conjunction With the Issuance of Authorizations to Construct and Operate Interstate Natural Gas Pipelines Certificated by the Federal Energy Regulatory Commission*, signed by the FERC, Advisory Council on Historic Preservation, Council on Environmental Quality, EPA, Department of the Army, USDA, Department of Commerce, DOE, USDI, and DOT; and the February 2004 *Interagency Agreement Among the Federal Energy Regulatory Commission, United States Coast Guard, and Research and Special Programs Administration for the Safety and Security Review of Waterfront Import/Export Liquefied Natural Gas Facilities*.

- “LNG Terminal site” refers to the terminal site footprint and “LNG Terminal project” refers to the terminal and associated components.

- “Pipeline” refers to the centerline or linear facility and “Pipeline project” refers to the construction right-of-way, temporary extra work areas (TEWAs), uncleared storage areas (UCSAs), aboveground facilities, contractor and pipe storage yards, quarries and rock source disposal sites, permanent and temporary access roads (PARs and TARs, respectively), existing access roads (EARs), communication facilities, 30-foot maintenance/operation corridor, and 50-foot permanent easement.

- “in the vicinity of the Pipeline project” or in the “Pipeline project area” describes the area where impacts to fish, wildlife, and vegetation (plants) could occur outside of the Pipeline project footprint. In many instances, these terms are used generally, since the extent (or distance from the Pipeline project) of impact beyond the Pipeline project varies by fish, wildlife, and vegetation (plant) species, Pipeline project activity, habitat and site characteristics (i.e., waterbody or vegetation). Similarly, discussion of area of surveys (i.e., distance from the Pipeline project) conducted for the Pipeline varies depending on wildlife and plant species targeted, landowner (federal or non-federal), and expected impact (i.e., proposed blasting and/or helicopter use). Specific distances for survey efforts and construction and operation impacts are discussed specifically in the indivudal species’ sections below.

1.2 ACTION AREA

The action area includes all areas that would be affected directly or indirectly by the proposed action and not just the immediate area involved in the action. Because the proposed action potentially can affect such a variety of species inhabiting diverse habitats within marine, estuarine, riverine, and various terrestrial locations, there are multiple components of the action area that have been defined as species’ analysis areas, the areas where individual or groups of listed species could be affected by the proposed action. Species’ analysis areas are described in detail in each species’ environmental baselines and figures of the analysis areas are provided, where appropriate. For some species there may be more than one analysis area if the listed species utilizes multiple habitats in diverse locations. Analysis areas and associated species include:

- the marine analysis area is a fan shape beginning at the entrance to Coos Bay extending approximately 12-13 nautical miles (nm) off the coast of Oregon to the edge of the Outer Continental Shelf (OCS). The northern border of the fan extends from the North Jetty to the point located at the edge of the OCS near 43°, 28’ 39”, -124°33’34”,and the southern border extends from the South Jetty to point located at the edge of the OCS near 43°24’49”, -124°35’8”. The analysis area is approximately 33.1 square miles. The marine analysis area applies to all listed marine mammals, short-tailed albatross, MAMU, green sturgeon, eulachon, coho salmon (Oregon Coast Evolutionary Significant Unit (ESU) and in the Southern Oregon/Northern California Coast (SONCC) ESU), and listed sea turtles;
- the gray wolf analysis area is based on the Area of Known Wolf Activity initially designated for OR-7, and applies only to the gray wolf;

- the estuarine analysis area (see figure 3.3.3-3) which encompasses all estuarine waters (and substrates) that are within the estuary between the North Jetty and South Jetty at the Coos Head entrance to the Upper Coos Bay. The estuarine analysis area is approximately 15 square miles. The estuarine analysis area applies to MAMU, green sturgeon, eulachon, and coho salmon (Oregon Coast ESU);
- the LNG terminal analysis area extends for 1.5 miles beyond the perimeter of the LNG Terminal Site (see figure 3.3.2-2) to include project components on the North Spit and Al Pierce Company (APCO) Site, which historically provided western snowy plover nesting habitat;
- terrestrial nesting analysis area extends inland along the Pipeline route to include MAMU Inland Zone 1 – MPs 0.00 to 53.76 - and MAMU Inland Zone 2 – MPs 53.76 to 75.40 (see figure 3.3.3-2). and applies only to MAMU;
- provincial analysis area is located within four Physiographic Provinces (Burns 1998): Oregon Coast Range, Oregon Klamath Mountains, West Oregon Cascades, and East Oregon Cascades (see figure 3.3.4-1), and applies only to NSO;
- the riverine analysis area encompasses 5^{th} field (watershed-level) hydrological unit codes (HUCs) (USGS 2018) and reflects an estimate of the average downstream extent that suspended sediment from any stream crossing generated by the Pipeline could equal ambient conditions within the 5^{th} field watershed crossed. Several riverine analysis areas that are in specific geographic locations each in the respective ranges of coho salmon in the Oregon Coast ESU and in the Southern Oregon/Northern Californis Coast (SONCC) ESU, listed suckers, and Oregon spotted frogs; and
- botanical analysis areas extend to 30 meters (98 feet) each side of the Pipeline project on lands that have potential habitat for listed plant species, except vernal pool-associated species (fairy shrimp and two listed plants) where the area extends out 250 feet.

1.3 ESA CONSULTATION BACKGROUND

1.3.1 Species Lists

Thirty-one federally listed and proposed endangered and threatened species may occur in the proposed project area that were identified by the FWS (2018a and b; FERC 2013) and NMFS (Wheeler 2006a and 2006b; NMFS 2009a, 2018a) and updates from agencies' websites. Table 1.4.1-1 summarizes these species, including critical habitat where designated and availability of recovery plans, and the general component of the Project where they may occur.

TABLE 1.4.1-1

Listed and Proposed Species that May Be Present within the Project Area

Listed Species	Federal Status a/	General Area of Potential Occurrence	Critical Habitat within the Project Area	Recovery Plan Drafted	Effects Determination Species b/	Effects Determination Critical Habitat b/
Mammals						
Blue whale *Balaenoptera musculus*	E	Oregon Coast	None Designated	Yes	NLAA	N/A

Rough popcornflower *Plagiobothrys hirtus*	E	Douglas County	None Designated	Yes	NLAA	N/A

a/ Status Key: E = Endangered, T = Threatened, , CH = Critical Habitat.
b/ Effects Determination: N/A – Not applicable (critical habitat has not been designated or proposed; NE = No Effect, NLAA= Not Likely to Adversely Affect, LAA = Likely to Adversely Affect

In addition, there are six listed species that occur within Oregon but for which the proposed action would have no effect. Those species include the Contiguous United States Distinct Population Segment (DPS) of Canada lynx, Coterminous United States Population of bull trout – Klamath River DPS, yellow-billed cuckoo – Western DPS, streaked horned lark, slender orcutt grass, and the western lily. In addition, the North American wolverine occurs in Oregon and has been proposed for listing as threatened under ESA. Brief synopses of the rationales to exclude these species from consideration in this APDBA are provided in section 3.1.2.

1.3.2 Information Sources

Information on listed and proposed species' distributions, habitat requirements, and potential occurrence in the Action Area as set forth in section 1.3 was gathered from many sources: 1) published scientific literature; 2) agencies' published and unpublished reports; 3) agencies' unpublished raw and/or compiled data; 4) agencies' geo-spatial databases, which document species observations; 5) on-site surveys for species and habitats (as modified during agency review); and 6) personal communications with agency personnel knowledgeable about species' ecological status in the Project area and vicinity. During the previous NEPA process, the Applicants and FERC representatives met with the Interagency Task Force, which included representatives of the FWS and NMFS, as well as Forest Service, BLM, ODLCD, Oregon Department of Energy (ODE), ODSL, Corps, ODFW, EPA, and ODEQ, to obtain specific input, guidance, and technical approach reviews. Agencies participating in the Interagency Task Force reviewed information provided by the Applicants. A subgroup of the task force, the ESA Consultation Subgroup, was established to develop habitat layers, determine extent of analyses, and provide guidance for avoidance and minimization measures for ESA species. To the extent this information remained relevant to the Project, it has been included in this APDBA. Due to changed circumstances, both regulatory and factual, certain portions of the previous information are no longer applicable to the Project and updates have been included.

Existing vegetation within the Pipeline project area was classified using several reference/data sources: 1) wetland delineation surveys conducted between 2006 and 2017; 2) county-based 2016 aerial photography; 3) BLM Forest Operations Inventory (FOI) digital geographic information system (GIS) coverage (BLM 2016c); 4) digital GIS data coverage and vegetation categories described by the Oregon Gap Analysis Project (Oregon Gap – Kagan et al. 1999); and 5) current wildlife-habitat types described and delineated by the Northwest Habitat Institute in 1999 (Kiilsgaard and Garrett 1999). Vegetation cover types within at least 100 meters of the Pipeline project were digitized with GIS from 2016 aerial photography and delineated based on the predominant vegetation physiognomy (*e.g.*, trees, shrubs, herbaceous vegetation) and the dominant species present.

Fisheries (ESA-listed species and species with EFH) information was gathered from many sources: 1) NMFS (Wheeler 2006a, 2006b, 2018b; NMFS 2017a, 2018a,b,c); 2) FWS (FWS 2017a); 3) ODFW Natural Resources Information Management Program (ODFW 2017a), which documents observations of species in the project area; 4) species' population and distribution information available online at StreamNet (StreamNet 2012); and 5) published scientific literature and agency reports. Information on other listed species was gathered from: 1) *Wildlife-Habitat Relationships in Oregon and Washington* (Johnson and O'Neil 2001), which provides relationships between specific habitats and the wildlife species that may occur in the Pipeline project area; 2) ORBIC (2017a), GeoBOB (BLM 2017), and Natural Resource

Information System (Forest Service 2017) databases; FWS GIS database and NSO demographic database; 3) National Biological Breeding Bird Survey routes and Audubon Christmas Bird Counts; 4) published scientific literature and agency reports; and 5) other state and federal databases and literature available online. Field surveys (described below) were conducted prior to formation of the Interagency Task Force, but survey results and survey protocols have been reviewed by members of a Species Survey Subgroup.

1.3.3 Species Surveys

Existing vegetation cover types within the LNG Terminal project were determined from field surveys conducted by consultants to JCEP, including wetland delineations (Stuntzner Enginering and Forestry 2005; SHN Consulting Engineers and Geologists, Inc. – SHN 2013a) that have been approved by the COE and ODSL, and botanical surveys (SHN 2006, 2013b). There is no suitable habitat for listed wildlife or plant species within the LNG Terminal project.

JCEP also had consultants conduct biological investigations for wildlife and fish at the LNG Terminal and related areas in 2005, 2006, and 2012 (LBJ Enterprises 2006; Alice Berg & Associates 2006; SHN 2013c), as well as a biological sampling program in Coos Bay in 2010 (Shanks et al. 2011). Terrestrial wildlife surveys conducted for the Project documented 11 mammal species. The most common marine mammal in the Coos Bay near the LNG Terminal project would be the harbor seal. Surveys at the LNG Terminal noted 151 avian species. Sampling by the University of Oregon Institute for Marine Biology for zooplankton in Coos Bay near the LNG Terminal access channel found sculpin, gunnels, sand lance, English sole, and surf smelt, in addition to ghost shrimp and several crab species. The results of Applicant's biological surveys relevant to federally listed or proposed species are presented in section 3.0 of this APDBA.

PCGP had Siskiyou BioSurvey, LLC (SBS) conduct botanical and biological surveys for the action area for terrestrial sensitive species between 2007 and 2017. Based on literature reviews, 108 species of mammals and 281 bird species may be present in habitats that coincide with the action area for the Pipeline. PCGP had targeted biological surveys conducted for NSO, MAMU, great gray owl, red tree vole, and northern goshawk, as well as terrestrial and aquatic mollusks. Botanical surveys were targeted for ESA-listed and State-listed vascular plant species; Survey and Manage vascular, lichen, bryophyte, and fungi species; vascular, lichen, and bryophyte species on the Oregon BLM Special Status Strategic or Sensitive Plant Lists; and vascular, lichen, and bryophyte species on Forest Service Region 6 Sensitive and Strategic Plant Lists. The results of these surveys were summarized in PCGP's Resource Report 3.

The most common native freshwater mussels present in the waterbodies crossed by the Pipeline route belong to the genus *Anadonta*. Typical warmwater fish species in waterbodies crossed by the pipeline include black and white crappie, and brown bullhead, which are not native to the region. Coolwater fish present in the project area include both non-native and native species. Some important non-native species include smallmouth bass and yellow perch. Native coolwater species include the Lost River sucker, shortnose sucker, Klamath largescale sucker, blue chub, and Umpqua chub. Resident rainbow and redband trout are the most common resident coldwater game species along the route. Eight species of anadromous fish are known in the Pipeline area: Chinook salmon, coho salmon, chum salmon, steelhead, coastal cutthroat trout, Pacific lamprey, river lamprey, and green sturgeon. Section 3 of this APDBA discusses federally listed fish, plants, and animals in more detail.

1.4 MAGNUSON-STEVENS ACT CONSULTATION

The Sustainable Fisheries Act of 1996 amended the MSA and requires federal agencies, in part, to consult with the NMFS about activities that may adversely affect EFH (NMFS 1997a). The MSA established guidelines for Regional Fishery Management Councils to identify and describe EFH in Fishery Management Plans (FMPs) to responsibly manage exploited fish and invertebrate species in federal waters. The Pacific Fishery Management Council (PFMC) has developed four FMPs that address EFH for managed species in the Project area (PFMC 1998, 1999, 2004). The four fisheries managed by the PFMC are highly migratory species, coastal pelagic species, groundfish, and Pacific Coast salmon.

This APDBA and EFH Assessment provides information to NMFS on potential effects to EFH, pursuant to Section 305(b) of the MSA. The MSA describes EFH as those waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity (NMFS 1997a). Within the Project action area, EFH has been designated for two salmonids (Chinook and coho), five pelagic species (northern anchovy, Pacific sardine, Pacific mackerel, jack mackerel, and market squid), and 70 groundfish species. All habitat accessible to these managed species, including spawning and incubation, juvenile rearing, juvenile migration corridors, and adult migration corridors, is considered EFH (PFMC 1999). Highly migratory species defined by the PFMC include tunas (five species), sharks (five species), billfish/swordfish (two species), and the dorado (also called dolphinfish or mahi-mahi).

2.0 PROPOSED ACTION

2.1 PROJECT COMPONENTS

As stated above, the Project is comprised of two parts, the LNG Terminal and the Pipeline. A more detailed description of the Project is provided in the FERC certificate applications. Below is a description of the components and construction activities which may potentially impact listed species or critical habitat associated with the LNG Terminal project (see section 2.1.1) and the Pipeline (see section 2.1.2).

2.1.1 LNG Terminal and Associated Facilities

The LNG Terminal would be located on the bay side of the North Spit of Coos Bay in southwest Oregon and would be designed to receive a maximum of 1,200,000 dekatherms per day (dth/d) of natural gas and produce a maximum of 7.8 million tons per annum (mtpa) of LNG for export. The LNG Terminal would turn natural gas into its liquid form via cooling to about -260 degrees Fahrenheit (F), and in doing so, it would reduce in volume to approximately 1/600th of its original volume, making it easier and more efficient to transport. The LNG Terminal, related facilities, temporary construction sites, and other sites/actions associated with LNG Terminal construction are collectively referred to as the "LNG Terminal project." The general location of the proposed LNG Terminal project is shown on figure 2.1.1-1. The main operational components of the LNG Terminal are shown in appendix B, figure 6.1-2. The LNG Terminal project is made up of the following components:

- LNG Carrier Transit Route – the waterway for LNG carrier marine traffic for the Project extends from the outer limits of the Outer Continental Shelf, 12 nautical miles (nmi) off the coast of Oregon, and 7.5 nmi up the existing Coos Bay Federal Navigation Channel (FNC) to the LNG Terminal.

- LNG Terminal Site – the site includes the Ingram Yard, Access and Utility Corridor, and South Dunes site. These components are referenced throughout the document but are not described in greater detail. See JCEP's Resource Report 1 for additional information.

    - Ingram Yard – the portion of the LNG Terminal site that would house permanent LNG Terminal facilities including LNG tanks and liquefaction equipment, and temporary facilities such as the Temporary Materials Barge Berth (TMBB).

    - Access and Utility Corridor – an approximately 1-mile-long corridor connecting Ingram Yard and the South Dunes site that would provide temporary construction and permanent access roads and facilities, and would include the Fire Department, underground utilities, and gas feed to the LNG Terminal.

    - South Dunes – the portion of the LNG Terminal site that would house temporary construction and permanent facilities, including a Workforce Housing Facility, metering station, administrative building, and the Southwest Oregon Regional Safety Center (SORSC), which would provide emergency response services for the facility and the southern Oregon region.

- Marine Slip – a permanent facility on Ingram Yard adjacent to the access channel. LNG carriers would enter the slip via the access channel, be loaded with LNG, and leave for export. The slip would include an LNG carrier loading berth and LNG loading facilities, a tug berth, and a lay berth to safely moor a temporarily disabled LNG carrier.

- Access Channel – the access channel would be dredged north of the FNC to provide LNG carriers with access from the FNC to the slip.

- Pile Dike Rock Apron – a permanent rock apron would be constructed west of the access channel to increase resiliency and protect the existing Pile Dike 7.3.

- Material Offloading Facility (MOF) – a permanent facility east of the slip where fill would be placed and approximately 450 feet of dock face would be constructed for the mooring of a variety of vessel types to offload materials for construction and maintenance of the LNG Terminal. Dredging would occur to access the MOF.

- Temporary Materials Barge Berth (TMBB) – An offloading facility that would be constructed on an existing berm west of the MOF to facilitate early construction activities, and would be removed when the access channel is dredged and the berm related to the slip construction is removed.

- Navigation Reliability Improvements – four permanent dredge areas adjacent to the FNC that would allow for navigation efficiency and reliability for vessel transit under a broader weather window.

- Meteorological Station – a permanent facility consisting of a tower located on the west side of the lagoon on the North Spit, used to measure wind speed, direction, and other weather data to provide weather information to the LNG Terminal and to support ship navigation.

- Industrial Wastewater Line (IWWP) and Water Line Relocation – an industrial wastewater line and water line, which would be permanently relocated in the vicinity of Trans Pacific Parkway.

- Trans Pacific Parkway and U.S. Highway 101 (US-101) Intersection Widening – the asymmetrical widening of Trans Pacific Parkway to the north and US-101 to the west to provide safe ingress/egress for construction traffic, by creating a left-turn lane from Trans Pacific Parkway onto northbound US-101 and a right-turn lane from US-101 onto Trans Pacific Parkway.

- APCO Site – APCO Site 1 (east) and APCO Site 2 (west) would be used as upland dredge disposal sites for the Project.

- Temporary Construction Sites – additional construction staging and temporary laydown of equipment would occur during LNG Terminal construction at Boxcar Hill, the Port Laydown site, and APCO Site 1. Additional construction staging, equipment laydown, and dredge materials disposal would occur at the Roseburg site, which is a portion of the adjoining Roseburg Forest Products (RFP) property leased by JCEP. Off-site park and ride lots would be developed as temporary facilities at Pony Village in North Bend and Myrtlewood Factory & RV Park north of North Bend.

- Kentuck Project site – approximately 100-acre proposed wetland mitigation and habitat restoration site associated with the LNG Terminal project and the Pipeline project.

- Eelgrass Mitigation site – approximately 9.3-acre proposed mitigation site for unavoidable eelgrass impacts associated with dredging of the access channel.
- Upland Wildlife Habitat Mitigation Sites – proposed wildlife habitat mitigation sites (Lagoon, Panhandle, and North Bank) associated with the LNG Terminal project.
- Meteorological Data Buoys – JCEP would install five meteorological ocean data collection buoys to aid navigation by measuring wind speed and direction, current speed and direction, and tide height in real time. It is anticipated that three buoys would be installed in place of currently existing buoys but may replace existing moorings and anchors using conventional construction methods. The buoys would be located in the Pacific Ocean near the bay entrance, and within Coos Bay along the LNG carrier route. Two new data collection buoys would be located near the access channel.

2.1.1.1 LNG Terminal Project Component Description

The marine facilities at the LNG Terminal would include an access channel, marine slip, LNG carrier berth, a lay berth, the MOF, and a tug berth. The LNG Terminal would include a single-use marine slip dedicated to supporting LNG exports. The east side of the slip would be utilized for the LNG carrier-loading berth and LNG loading facilities. Berths for tugboats and security vessels would be located on the north side of the slip. A lay berth would be provided on the west side of the slip to allow for berthing of a temporarily disabled LNG carrier in an emergency. This berth would have no product loading facility, but it would comply with and be designed to meet all of the safety and security standards of the Oil Companies International Marine Forum (OCIMF) and the Coast Guard. The MOF would be constructed outside of the slip to deliver construction and maintenance components of the LNG Terminal that are too large or heavy to be delivered by road or rail.

LNG Carrier Transit Route

The Coast Guard defines the waterway for LNG carrier marine traffic for this Project as extending from the outer limits of the outer continential shelf, 12 nmi off the coast of Oregon, and 7.5 nmi up the existing FNC to the LNG Terminal. For the analysis in this APDBA and EFH Assessment specific to species covered by the ESA and the MSA, impacts from LNG carrier marine traffic along the transit route includes the estuarine and marine analysis areas (see figure 2.1.1-2).

An LNG carrier traffic study conducted by Moffatt & Nichol International (Moffatt & Nichol 2008a) concluded that the additional LNG carrier traffic associated with the LNG Terminal can be accommodated in the existing Oregon International Port of Coos Bay (Port) and the FNC. The ship traffic conditions in the Port that existed when the LNG carrier traffic study was conducted have not changed. JCEP had a consultant conduct a carrier simulation study which showed that LNG carriers up to 148,000 cubic meters (m^3) in capacity could safely transit up the existing Coos Bay FNC under high tide conditions.[2] JCEP plans to excavate four submerged areas lying adjacent to the FNC (the Navigation Reliability Improvements). These minor enhancements would allow for transit of LNG carriers of similar overall dimensions to those

[2] Moffatt and Nichol, Jordan Cove LNG Terminal Coos Bay, Oregon, 148,000 m^3 Class LNG Carrier Transit and Maneuvering Simulations, March 17-20, 2008.

listed in the July 1, 2008 Coast Guard Waterway Suitability Report, but under a broader weather window. This allows for greater navigational efficiency and reliability to enable JCEP to export the full capacity of the optimized design production of 7.8 mtpa from the LNG Terminal. The proposed channel enhancements are discussed further under Navigation Reliability Improvements below.

The Coast Guard issued a new LOR and an LOR Analysis for the LNG Terminal in May 2018. The Coast Guard again limited the size of LNG carriers that could transit in the waterway to LNG carriers of approximately 950 feet length, 150 feet beam, and loaded draft of 40 feet (nominal 148,000 m^3). Depending upon the approved LNG containment system type, carriers with these approximate dimensions may range in LNG cargo capacity from 135,000 m^3 to 170,000 m^3.

The LNG Terminal could generate a maximum of 120 LNG carrier calls per year, although the average is expected to be between 110 and 120 LNG carriers per year. The actual number of LNG carriers per year would be dependent on the capacity of the LNG carriers calling on the LNG Terminal and the actual output of the LNG Terminal.

A professional Coos Bay pilot (Pilot) would board an incoming LNG carrier at about 5 nmi outside of the channel entrance.

Three 80-metric-ton bollard pull boats and two sheriff's escort boats would accompany the LNG carrier upon entering the breakwater. After passing the jetties and the southern tip of the North Spit, the LNG carrier would travel approximately 1.8 nmi and begin its turn to the north at a speed of approximately 4 to 5 knots. Transiting a distance of 1.6 nmi up the Coos Bay Range, the speed of an LNG carrier in this area would be determined by steerage and wind conditions, but would be about 4 to 5 knots. The LNG carrier would travel in a northerly direction a distance of 2.1 nmi when traversing the Empire Range and the Lower Jarvis Range. The speed of an LNG carrier in this area would be between about 4 to 5 knots.

After the Lower Jarvis Range, the LNG carrier would travel 0.8 nmi to reach the northernmost point in its transit, at the beginning of the access channel to the LNG Terminal. The vessel would be slowed and turned at the direction of the pilot. With tug assistance, the LNG carrier would back into the terminal berth.

Loaded LNG carriers, with a deeper draft, would transit through Coos Bay as close to 'slack high tide' as possible to maximize their under keel clearance at an average speed of between 4 and 6 knots. Arriving LNG carriers in ballast condition can transit at either high tide or low tide slack water conditions due to their shallower draft. Transits will be initially during daylight hours until the Pilots, Tug boat Masters and LNG Carrier Masters gain sufficient experience in navigating the channel, which is estimated to be a couple of months, after which the LNG Carrier transits will be conducted 24/7 (day or night) whenever the correct environmental conditions exist. The total average LNG carrier port time is estimated to be approximately 36 hours, assuming there are no delays caused by natural environmental conditions. This estimate includes the 1.5 hours transit time from the Pilot boarding to arrival at the LNG loading berth to the Pilot drop-off at departure, time of mooring, unmooring and cast off, the bulk LNG loading time of approximately 15 hours (using the 12,000 m^3/hr loading rate), and the 8 hours of time waiting for the next available high tide cycle needed for safe departure and transit of the FNC.

<u>Characteristics of the Waterway Within Coos Bay</u>

The following summarizes the characteristics of the portion of the waterway within Coos Bay (See JCEP Resource Report 2 - Water Use and Quality and Resource Report 3 - Fish, Wildlife, and Vegetation for a detailed description of the waterway and its associated habitats). Coos Bay is an inland estuary, meaning that it is a semi-enclosed body of water that empties into the

Pacific Ocean. As an estuary, Coos Bay is a transition zone where upland fresh water meets ocean salt water, and supports both marine adapted and riverine species. The surface area of Coos Bay covers about 12,380 acres measured at mean high water. The estuary is part of the U.S. Geological Survey (USGS)-designated watershed, Coos Bay (USGS Hydrologic Unit Code [HUC]:17100304; EPA 2012). The watershed drains an area of approximately 739 square miles of Oregon's southern coastal range, within the larger South Coast Watershed Basin (ODEQ 2012). Coos Bay is fed by about 30 tributaries, including the Coos River, Millicoma River, Catching Slough, Isthmus Slough, Pony Slough, South Slough, North Slough, Kentuck Slough, and Haynes Inlet. At its mouth, the estimated average annual discharge is 2.2 million acre-feet of water (Roye 1979).

The existing FNC in Coos Bay would be used as part of the waterway for LNG carriers transiting to the LNG Terminal. The FNC is included in the Coos Bay Estuary Management Plan (CBEMP) and is zoned Deep-Draft Navigation Channel (37-foot authorized draft). The FNC is bounded by the North Spit on the west and north, and the mainland to the south and east. Along the mainland bounding the FNC are the communities of Charleston and Barview, and the cities of Coos Bay and North Bend.

The Coos Bay FNC extends from the mouth of Coos Bay to the city of Coos Bay docks at about Channel Mile (CM) 15.1. The entrance to Coos Bay is located between two jetties that are about 2,100 feet apart and that extend about 3,000 feet from the shore. There is a bar in the Entrance Range with a depth of 37 feet, which establishes the minimum depth of the FNC. The most favorable time for crossing the bar is on the end of the flood tide. The channel width at the entrance mark is 1,500 feet, reducing to 700 feet at CM 0. From CM 1 to the LNG Terminal (at about CM 7.5) the authorized channel width is 300 feet. The FNC is maintained by the Corps.

Marine Slip

The new marine slip would be constructed by excavating an existing upland area consisting of about 16.4 acres of forest and about 20.3 acres of grasses or brush. The majority of the marine slip would be excavated from existing uplands owned by JCEP. Part of the marine slip would be constructed within state waters of Coos Bay to the Mean Lower Low Water (MLLW) line, for which the Port has obtained an easement from the ODSL.

The slip would be bounded on the east and west sides by sheetpile walls, creating a vertical face to support mooring structures. The northern side of the slip would be sloped to meet the existing bottom contours at an angle of 3 feet horizontal to one foot vertical (3:1). The inside dimensions at the toe of the slope of the slip would measure a minimum of 800 feet between the vertical sheetpile walls along the east/west axis, and approximately 1,500 feet and 1,200 feet along the western and eastern boundaries, respectively. The slip would have a minimum depth of -45 feet below MLLW (North American Vertical Datum of 1988 - NAVD88) to ensure minimum under-keel clearance is achieved for the safe maneuvering and berthing of loaded LNG carriers. Appendix B, figure 6.1-2, shows a plot plan of the marine slip. The slip is sized to provide the flexibility needed to safely maneuver an LNG carrier from the access channel into the slip when another LNG carrier is already berthed on the east or west sides, and for tugs to move a temporarily disabled LNG vessel away from the loading berth on the east side of the slip to the lay berth on the west side of the slip if necessary.

LNG Carrier Berths

The marine facilities would include two LNG carrier berths, a lay berth and a product loading berth. Each berth consists of a number of elements: the sheetpile wall, mooring structures, and breasting structures. In general, the LNG product loading berth would be about 1,280 feet long between the centers of the end mooring structures, and 312 feet long from the center of the northernmost breasting structure to the center of the southernmost breasting structure. Appendix B, figure 6.1-2, shows a plan view of the LNG carrier berth.

Sheet Pile Walls. The physical berth would be constructed of steel sheet piles to support surface structures (i.e., the loading area) or provide the foundation for the breasting and mooring structures. Under the loading facility, the wall would extend from the bottom of the slip at elevation -45.97 (minimum) to approximate elevation +34.5 NAVD88. This face would extend north and south to capture the outermost breasting structures and then turn to the east, creating a setback wall for the remainder of the slip.

Mooring Structures. Mooring structures would be provided at both the product loading berth and the lay berth for the safe breasting, berthing, and mooring of the LNG carriers docked at either berth. Six mooring structures (three on each side of the LNG berth centerline) would be used to secure the LNG carrier at both the LNG loading berth and the lay berth. The structures would be behind the sheetpile wall, set back approximately 145 feet from the face of each berth. These structures would have concrete platforms founded on steel pilings and would each have remote release mooring hooks with capstans, as well as all required equipment and instrumentation for safe mooring operations.

Breasting Structures. There would be four breasting structures located adjacent to the product loading facility (PLF); two would be located north of the PLF and two to the south. Like the mooring structures, each breasting structure would have a concrete platform founded on steel pilings and would have remote release mooring hooks with capstans, as well as all required equipment and instrumentation for safe mooring operations. Each breasting structure would also support a fender assembly sized to absorb and distribute berthing and mooring loads for the full range of LNG carriers that the LNG berth is designed for, thus preventing damage to the LNG carriers or the LNG berth. The fender system would allow the carriers to be moored a safe distance off the vertical face of the sheetpile wall. The lay berth would have four breasting structures with fenders and capstans spaced equally about the mid-ship. There would be additional breasting fender structures - two to the north and two to the south of the main breasting structures, for a total of eight. The exact number, type, and location of the breasting structures for the lay berth would be defined during detailed design to meet OCIMF requirements for non-parallel vessel approach and the full range of vessel sizes.

Product Loading Facility. The PLF would utilize a pile-supported concrete slab that provides structural support to the marine loading arms, terminal gangway, and other ancillary equipment. The PLF is designed to support a number of elements that facilitate the safe transfer of LNG product between the LNG facility and the LNG carriers.

The PLF would be constructed on top of the sheetpile wall at approximate elevation +34.5, and would be about 130 feet long and 86 feet wide. The foundation would be reinforced concrete supported by steel pilings.

The transfer equipment would consist of four marine loading arms and ancillary equipment. There would be two dedicated liquid loading arms, one hybrid arm, and one ship vapor return arm to meet the design loading rate of 12,000 cubic meters per hour (m^3/h). The hybrid arm would be designed for dual service and would be capable of transferring LNG to the LNG carriers or returning vapor from the LNG carriers to the boil-off gas (BOG) vapor management system. During normal operation, the hybrid arm would be used in liquid service along with the two liquid arms, and the vapor return arm would be used to return vapor to the BOG vapor management system.

The loading arms are designed with swivel joints to provide the required range of movement between the LNG carrier and the shore connections. Each arm would be fitted with a hydraulically interlocked double-ball valve and powered emergency release coupling to isolate the arm and the LNG carrier in the event of an emergency condition in which rapid disconnection of the connected arms is required. Each arm would be fully balanced in the empty condition by a counterweight system and maneuvered by hydraulic cylinder drives. A mezzanine-type elevated steel platform would be installed for maintenance of the triple-swivel assembly of the arms.

LNG spill containment would be accomplished by a concrete curbed and sloped area that would contain any LNG spillage, and allow the spill to safely flow away from the loading area through the LNG spill collection trench to the marine area LNG impoundment basin.

Additional structures at the LNG loading berth would include an LNG carrier gangway, area lighting facilities, aids to navigation, firewater monitors, and a dry chemical firefighting system.

Lay Berth

A lay berth on the west side of the slip would be provided with facilities to safely moor a temporarily disabled LNG carrier. Berthing facilities would be supported by the west side sheetpile wall with a top-of-wall elevation of approximately +20 feet (NAVD88). The lay berth would have pile-supported breasting structures with fenders extending above the vertical sheetpile and mooring structures on the land side of the sheet pile. A grated platform with a gangway would be placed behind the berthing breasting structures to allow for safe access and egress from the disabled LNG carrier at berth. Support infrastructure would include an access road down from the area of the tug berth building, duct bank with cabling for powering the mooring hooks and capstans, and limited lighting of the ship access area.

Along the western property line, but on the Project side of the Henderson Property buffer zone, a tsunami flow control wall would be constructed. The flow control wall would be of sufficient height and strength to prevent overtopping into the Henderson Property and would limit the drag due to the tsunami current loads on LNG carriers within the marine slip. The wall height would be approximately 34.5 feet and would be determined in accordance with the design tsunami criteria. The wall would run from the southwest side of the LNG tank impoundment area down to the entrance to the slip.

Tug Berth

The tug berth at the north side of the marine slip would accommodate four tugboats, as well as two sheriff's boats and six other visitor boats with similar characteristics as the sheriff's boats. For design purposes, the tugs are assumed to be 80-metric-ton bollard pull boats approximately

100 feet long with a beam of 40 feet. The basis for the sheriff's boat is the Willard Coast Guard Long Range Interceptor. The tug dock would generally be about 425 feet long and 18 feet wide; in addition, there would be 360 feet of 8-foot-wide floats for mooring and accessing the security vessels.

The tug dock would be composed of precast concrete box beams and a concrete topping slab supported by steel piles. The security vessel floating dock is made from 8 foot wide precast concrete sections with a polystyrene (or equal) core anchored by steel pile. The security boat dock would support two separate boat houses (canopies), roughly 35 feet by 50 feet. The canopies are composed of structural steel frame and sheet metal roof. The tug dock would be accessible from land by a pile-founded trestle, thus allowing vehicle and pedestrian access for service and support of operations. The access ramp connecting the dock to shore is roughly 110 feet to the face of sheet pile wall and is the same width and construction as the dock. An onshore tug operations building would provide storage, meeting, and sanitary facilities for the crews of the tug and security boats. Approximately 170 steel or concrete piles would be driven to support the tug boat dock complex and boat houses. No treated timber piles will be used to construct the tug dock. The pile would be installed before the removal of the berm separating the slip from the bay.

Access Channel

Access to the marine slip would be via a newly constructed access channel that would connect the slip to the FNC at approximate CM 7.3 at the beginning of the confluence between the Jarvis Turn and the Upper Jarvis Range A. The access channel and intertidal portion of the slip fall within zoning districts 5 and 6 – Development Aquatic (5-DA and 6-DA). The purpose of the 6-DA zone is to provide areas for navigation and other water-dependent uses. The access channel would flare from the narrowest portion at the mouth of the slip, with a minimum width of 800 feet, to the intersection with the FNC, with an approximate width of 2,200 feet. The proposed access channel would allow for the safe transit of vessels between the berth and the FNC, and allow the safe turning of vessels during an inbound transit so that the LNG carrier can be backed into the slip and berthed bow out, according to industry best practice requirements.

The access channel would cover approximately 22 acres below the Highest Measured Tide (HMT) elevation of 10.26 feet (NAVD 88). The walls of the access channel would be sloped to meet the existing bottom contours at an angle of approximately 3 feet horizontal to 1 foot vertical (3:1). The marine slip and access channel would have a minimum depth of -45 feet below MLLW (-45.97 feet NAVD 88) to ensure minimum underkeel clearance is achieved for the safe maneuvering and berthing of loaded LNG carriers. An allowance over and above the minimum depth would be made for advanced maintenance dredge and incidental overdredge, in accordance with industry best practices. Dredging of the access channel would affect about 15 acres of currently existing deep subtidal area below -15.3 feet below MLLW.

Pile Dike Rock Apron

During early coordination with the USACE Northwest Division, Portland District (NWP) Section 408 Project Development Team, the need was raised to protect Pile Dike 7.3 located immediately west of the access channel. A rock apron has been proposed to arrest slope migration, or equilibration, before it can progress to a condition that could potentially negatively impact Pile Dike 7.3. The preliminary design involves a 50-foot-wide by 3-foot-thick by approximately 1,100-foot long rock apron set back approximately 20 feet from the top (slope catch point) of the access channel side slope. The proposed rock size is a well graded 6-inch to 22-inch angular stone with a median size of 14-inches. This median stone size and gradation is sufficient to protect against potential stone displacement due to anticipated wave action or currents in the project area. In the area of the existing Pile Dike 7.3 rock apron, the proposed design adds additional rock to proactively maintain the current function and longevity of the pile dike. The proposed design also includes an approximately 100 foot long extension of the slip's sheetpile bulkhead at the northwest corner of the access channel to minimize slope cut-back at this location. Total required rock volume is approximately 6,500 cubic yards.

Material Off-Loading Facility (MOF)

The MOF would be constructed to deliver components of the LNG Terminal that are too large or heavy to be delivered by road or rail. The MOF would cover about 3 acres on the southeast side of the slip, adjacent to the RFP property (see appendix B, attachment D.1, Material Offloading Facility). This area includes about 1.43 acres of intertidal habitat, 0.07 acre of shallow subtidal habitat, and 1.3 acres of upland habitat, of which 0.4 acre is forested dune.

The MOF would be constructed using the same sheetpile wall system as the LNG loading berth and the lay berth. The top of the MOF would be at elevation approximately +13.0 feet (NAVD88), and the bottom of the exposed wall would be at the access channel elevation. The MOF would provide approximately 450 feet of dock face for the mooring and unloading of a variety of vessel types.

During construction of the LNG Terminal, in addition to receiving equipment and large modules (upwards of 6,000 short tons) by break-bulk cargo carriers, roll-on/roll-off cargo carriers, and barges, the MOF would allow other bulk materials to be delivered by sea to minimize impacts on the local road network. After construction, the MOF would be retained as a permanent feature of the LNG Terminal to support maintenance and replacement for large equipment components that are too large to be transported by rail and road.

Temporary Materials Barge Berth (TMBB)

The MOF construction cannot be completed during a single in-water work window and as such, to take advantage of marine deliveries as early as possible in the Project, a TMBB would be constructed on the existing shoreline within the access channel footprint (see appendix B, attachment D.2, Temporary Materials Barge Berth). The TMBB would be removed when the berm in which it sits is excavated. The TMBB would be utilized until the MOF is able to receive materials.

Construction of the TMBB would result in fewer trucks trips to the site, thus reducing Project-related road traffic. The TMBB would be an excavated slot in the shoreline that would be removed before the dredging of the slip and access channel. The TMBB would be constructed during the first available in-water work window that occurs after the initiation of overall construction activities. It would accommodate ocean-going barges that are from 100 to 250 feet in length. The barges would be berthed with one end pushed approximately 60 feet into the excavated shoreline slot. The excavated floor of the berth would be approximately 65 feet wide and extend 500 feet into the access channel footprint from the back of the berth. Use of the TMBB may be restricted during low tides if required to prevent grounding of a barge.

The construction sequence for the TMBB would be as follows: An excavator and 40-ton articulated trucks would cut soil from the shoreline area near the face of the west side of the slip. The crews would cut a notch large enough to receive and moor the end of an ocean-going barge. The excavators would cut down to an elevation of -12.97 feet NAVD88 (-12 feet MLLW) and create a channel to deeper water. The excavator would mine material as it works away from the channel, passing excavated material back to the trucks for upland disposal. A crane would be used to install six mooring piles: two in the end of the berth and two on each of the berth sides. The mooring piles would be 24 inches in diameter or less. The piles would be driven using a vibratory hammer until resistance is met, and then would be set with an impact hammer. These piles would be removed during the berm excavation.

Navigation Reliability Improvements

The Navigation Reliability Improvements would take place entirely within deep subtidal habitat at four locations adjacent to the FNC. The dredge areas are named Dredge Areas 1, 2, 3, and 4 and would be located adjacent to the FNC roughly between CM 2 to CM 7, in order from Dredge Area 1 to Dredge Area 4, as depicted in figure 2.1.1-1 and detailed in appendix B, attachment D.3, Navigation Reliability Improvements.

- Dredge Area 1 – Coos Bay Inside Range channel and right turn to Coos Bay Range: Excavation at this site would reduce the constriction to vessel passage at the inbound entrance to Coos Bay Inside Range for any ship making the 95-degree turn from the Entrance Range through the Entrance Turn and Range. JCEP proposes to widen the Coos Bay Inside Range channel from the current 300 feet to 450 feet, thereby making it easier for all vessels transiting the area to make this turn. In addition, the total corner cutoff on the Coos Bay Range side would be lengthened from the current 850 feet to about 1,400 feet from the turn's apex.

- Dredge Area 2 – Turn from Coos Bay Range to Empire Range channels: The current corner cutoff distance from the apex of this turn is about 500 feet, making it difficult for vessels to begin turning sufficiently early to be able to make the turn and be properly positioned in the center of the next channel range. JCEP proposes to widen the turn area from the Coos Bay Range to the Empire Range from the current 400 feet to 600 feet at the apex of the turn, and lengthen the total corner cutoff area from the current 1,000 feet to about 3,500 feet.

- Dredge Area 3 – Turn from the Empire Range to Lower Jarvis Range channels: JCEP proposes to add a corner cut on the west side in this area that would be about 1,150 feet, thereby providing additional room for vessels to make this turn.

- Dredge Area 4 – Turn from Lower Jarvis Range to Jarvis Turn Range channels: JCEP proposes to widen the turn area here from the current 500 feet to 600 feet at the apex of the turn, and lengthen to total corner cutoff area of the turn from the current 1,125 feet to about 1,750 feet, thereby allowing vessels to begin their turn in this area earlier.

Meteorological Station

A Meteorological Station would be located on the west side of the lagoon on the North Spit. The Meteorological Station would be a permanent facility consisting of a tower used to measure wind speed and direction, and other weather data to provide weather information to the LNG Terminal facility and to support ship navigation. The station would be mounted on an approximately 30- to 40-foot-high lattice tower, with a 30-foot-by-30-foot triangular or square footprint.

Industrial Wastewater Line (IWWP) and Water Line Relocation

Portions of the existing IWWP would be relocated or abandoned in place in order to construct the LNG Terminal. Currently, the IWWP carries water from the two existing bio-solids ponds to the existing ocean outfall via the site of the Lagoon that is southwest of the proposed LNG Terminal. Occasionally the water passing through the IWWP is supplemented by water purchased from the Coos Bay-North Bend Water Board (CBNBWB) to maintain permitted pH levels in the Lagoon system and ensure the ocean outfall remains open. The IWWP would be relocated to an easement along Trans Pacific Parkway to connect the Lagoon site to both Ingram Yard and the South Dunes site. Several connections would be made to the relocated IWWP to serve LNG Terminal construction and LNG Terminal, SORSC, and Fire Department operation.

Portions of existing CBNBWB potable water and raw water pipelines would be relocated to easements along the Trans Pacific Parkway or abandoned in place in order to construct the LNG Terminal. In addition, an interconnect to an existing CBNBWB potable water pipeline would be used for all normal operational water needs in the LNG Terminal, SORSC, and the Fire Department, as well as most construction water needs. The tie-point to the 12-inch-diameter potable water pipeline would be located near the northwest corner of the LNG Terminal, along the south side of the Trans Pacific Parkway. A connection to an existing CBNBWB 8-inch-diameter raw water pipeline would also be used for construction water, including LNG tank hydrotesting. The raw water pipeline tap, to be located near the northwest corner of the LNG Terminal on the north side of the Trans Pacific Parkway, would remain connected after construction; however, there are no normal operational uses anticipated for this raw water supply.

Trans Pacific Parkway/US-101 Intersection Widening

Traffic surveys and studies of projected construction traffic have determined that the intersection of US-101 and Trans Pacific Parkway would need to be improved. These improvements would involve widening Trans Pacific Parkway on the north side to provide a left-turn lane onto northbound US-101 to mitigate the traffic impacts that would result from construction of the LNG Terminal (see appendix B, attachment D.5, Trans Pacific Parkway/US 101 Intersection). The existing travel lanes are 11 feet wide, with less than 1 foot between the edge of the pavement and the fog line; most areas have a wide gravel shoulder. The proposed improvements would provide a wider turning radius from southbound US-101 onto Trans Pacific Parkway, two 12-foot travel lanes, a 14-foot left-turn lane, 6-foot shoulders with guardrail, and a 2-foot gravel shoulder on the north side of the guardrail. The existing gravel shoulder on the south side of the parkway would remain as currently configured. See JCEP Resource Report 5 for more information regarding the Transportation Impact Analysis.

Embankment widening on the north side of the causeway at Trans Pacific Parkway/US-101 would extend for approximately 650 feet and would be constructed on a grid of untreated timber piling driven in the soft bay mud. No treated timbers would be used. To drive the pile grid, the contractor would construct a work access bridge as pile driving is progressed parallel to Trans Pacific Parkway. The grid of piling would then be capped with riprap embankment, providing a foundation to widen the roadway to the north. Construction would be isolated from Coos Bay with a temporary sheetpile work isolation containment system and turbidity curtain. These measures to isolate the work area would minimize fill impacts.

APCO Sites

APCO Site 1 and APCO Site 2 consist of two relatively level sandy fill pads that are currently vacant, separated by a tidal mudflat, and surrounded by estuarine wetlands. APCO Sites 1 and 2 would be used as upland dredge disposal sites for the LNG Terminal Project (see appendix B, attachment D.6, APCO Dredge Disposal Site). Disposal of dredge material at APCO Sites 1 and 2 would require the "on-shoring" of the temporary dredge material pipeline discussed under the Navigation Reliability Improvements for hydraulically and mechanically dredged material, as detailed in Section 2.1.1.2 Construction Methods, in order to provide for direct pumping to the sites. If material needs to be offloaded from a barge/scow, a deck barge would also need to be moored adjacent to APCO Sites 1 and 2 using temporary piles or spuds, to provide an offloading facility for dredged materials that would be mechanically offloaded.

Hydraulically dredged (or offloaded) material would be transported via pipeline as described under the Navigation Reliability Improvements, and would be discharged directly within the containment berms at both APCO Sites 1 and 2, if deemed feasible. The pipeline would likely be placed on a cradle supported by piles or other support system where it would cross eelgrass habitat along the northern shoreline of APCO Sites 1 and 2. Decant water would be discharged to Coos Bay and/or Pony Slough via a controlled outlet.

Alternatively, dredge material could be mechanically offloaded from the barge moored adjacent to APCO Site 2. Mechanical offloading reduces the amount of water discharged onto the site, allowing direct placement of the material without an explicit need for containment berms. Details regarding the disposal, decanting, and processing of dredge materials to APCO Sites 1 and 2 are provided in the LNG Terminal Project's Dredged Material Management Plan (DMMP see Resource Report 7/Appendix N.7).

Management of dredge material at APCO Sites 1 and 2 would require the construction of a permanent bridge connecting the two sites to provide access from APCO Site 1 to APCO Site 2 for heavy earth-moving equipment. The permanent bridge would be a single-lane single-span bridge approximately 200 feet long and approximately 40.5 feet wide, and would include two concrete abutments on pile-supported footings with material-stabilized earth walls that extend landward. The bridge would completely span the intertidal wetland separating the sites, and the material-stabilized earth walls extending from the abutments would eliminate the need for fill material to extend below the HMT or wetlands.

Construction of the permanent access bridge between the two sites would begin with construction of a temporary work bridge to the north of the location of the permanent bridge that would provide access for construction of the permanent structure. The temporary work bridge would be approximately 30 feet wide and 280 feet long, and would have seven 40-foot spans. It is likely that the temporary work bridge would use three steel piles per bent, and have a steel frame and a steel or concrete bridge deck. The steel plate girders for the bridge would be assembled and installed on-site. Precast deck panels would be installed between each of the four steel girders, and a cast-in-place concrete deck would be poured over the steel girders and deck. All water that comes in contact with green concrete during pouring of the concrete bridge deck would be pumped into tanks for disposal at an approved off-site location. The work bridge pile would have temporary impacts to intertidal habitat. An impact hammer would most likely be used to construct the temporary work bridge and therefore is likely to generate acoustic impacts.

A total of 0.63 mcy of dredged material would be placed at the APCO Sites from capital dredging related to the Eelgrass Mitigation Site and the Navigation Reliability Improvement sites.

Temporary Construction Sites

Temporary facilities and construction laydown areas would be required during construction of the LNG Terminal to house construction offices, crafts lunchrooms, warehousing, equipment maintenance, and laydown of materials after delivery to the site. These facilities have been located to maximize use of land owned by JCEP within the overall site boundary and minimize the impact on wetland environments through use of brownfield land, which is suitably zoned for industrial purposes, at the Roseburg site, Boxcar Hill site, Port Laydown site, and APCO Site. A concrete batch plant would be situated on the north side of the Trans-Pacific Parkway on the Boxcar Hill site (see figure 2.1.1-1).

Kentuck Project Site

The Kentuck Project is a roughly 100-acre wetland mitigation and coho salmon habitat rehabilitation project located on the western shore of Coos Bay at the mouth of the Kentuck Slough. Construction activities at the Kentuck Project include earthwork and civil infrastructure improvements to re-establish a tidal connection to roughly 90 acres and roughly 10 acres of freshwater flooplain reconnection at this former golf course site that more closely approximates conditions at the site prior to the creation of the golf course (see appendix O – Compensatory Wetland Mitigation Plan).

Kentuck Slough has subsided approximately 2 to 3 feet from its historical profile as a result of diking and drainage; therefore, earthwork activities would include importing of dredge materials from other areas of the LNG Terminal project to raise the subgrade to a profile conducive to establishing appropriate estuarine habitat and some freshwater habitats. Historical drainage patterns would be re-established to the extent practical given the site constraints.

Infrastructure improvements would include:

- Constructing a new bridge in East Bay Drive to allow tidal exchange between Kentuck Inlet and the Kentuck Project;
- Improving the existing dike separating the site from Kentuck Slough;
- Constructing a new muted tidal regulator (i.e., a "fish-friendly" tidegate) in the upper portion of the Kentuck Project to redirect a portion of Kentuck Slough flows into the Kentuck Project site;
- Raising the profile of East Bay Drive and approximately 2,100 lineal feet of Golf Course Lane to be above the zone of tidal influence;
- Installing stormwater treatment facilities for new impervious surfaces along East Bay Drive and Golf Course Lane;

- Constructing a fish-friendly culvert or other structure within Golf Course Lane to allow passage into the drainage above the former golf course irrigation sump pond;
- Constructing a temporary unloading facility, including a hydraulic unloader on a deck barge, mooring/fleeting barges, booster pump(s), and a dredge material transport pipeline; and
- Constructing a boardwalk path upland, on the southern boundary of the site.

JCEP will continue to coordinate with ODFW and NMFS as the bridge, muted tidal regulator tidegate, and culvert designs progress to review compliance with both agencies' fish passage criteria.

Eelgrass Mitigation Site

The Eelgrass Mitigation site is approximately 9.3 acres in size and is located approximately 500 feet southeast of the offshore end of the North Bend Municipal Airport runway and about 200 feet off the opposite North Bend shoreline (see appendix O – Compensatory Wetland Mitigation Plan). The area of Coos Bay surrounding the Eelgrass Mitigation site and extending west to the FNC is composed of lower intertidal mudflat and shallow subtidal habitat(s), including eelgrass beds. Construction of the Eelgrass Mitigation site would involve lowering the bottom grade within an unvegetated sand/mudflat bordered by eelgrass. This elevated area (mound) is currently not supporting eelgrass because of its elevation. Most of this area is currently between elevations +1.0 and +2.5 MLLW (+0.00 and + 1.50 NAVD88) and would be lowered to an elevation of approximately -1.5 MLLW (-2.5 NAVD88).

Upland Wildlife Habitat Mitigation Sites

JCEP has worked closely with ODFW to identify three sites that will be used to provide upland wildlife habitat mitigation as recommended by ODFW. The Panhandle Site is approximately 133 acres located north of Trans Pacific Parkway The Lagoon Site is approximately 320 acres and is located adjacent to the Meteorological StationThe North Bank Site is approximately 156 acres located on the north bank of the Coquille River adjacent to the Bandon Marsh National Wildlife Refuge.

The proposed ecological uplift at these sites focuses on improving and preserving current habitat. For example, the proposed ecological uplift at the Lagoon Site would bury overhead powerlines that run from Trans Pacific Parkway to a small building just behind the foredune, removing potential western snowy plover predatory species perching habitat. .

Meteorological Ocean Data Collection Buoys

Meteorological ocean data collection buoys would be installed to measure wind speed and direction, current speed and direction, and tide height in real time. Three buoys would be located in the Pacific Ocean near the bay entrance, and within Coos Bay along the LNG carrier route. JCEP has identified a need to provide two new buoys within the vicinity of the access channel for the LNG carrier berth. The updated buoys would be identified in coordination with the National Oceanic and Atmospheric Administration (NOAA) and the Coast Guard, and permitted through applicable agencies. For the purposes of this APDBA, it was assumed that the buoy anchoring system would need to be replaced at existing buoy locations. Removal of the existing anchor and installation of new industry standard anchoring systems would result in temporary disturbance to the channel bed, resulting in localized turbidity. JCEP has initiated discussions with NOAA to install Physical Oceanographic Real-Time System (PORTS) sensors on three existing Coast Guard ATON buoys with the PORTS sensors being attached to the existing USCG buoys and anchor systems. The PORTS will be managed, installed, and the system will be operated by NOAA. NOAA will initiate any regulatory approvals required for the addition of PORTS sensors on the three Coast Guard ATON buoys.

2.1.1.2 Construction Methods

Timing of Construction Activities

Construction of the LNG Terminal and slip is expected to take approximately five years. To meet an in-service date of the second half of 2024, construction activities are expected to begin in the first half of 2020. The general construction schedule is described below by anticipated year an activity would occur with in-water work noted where applicable. Because the in-water work window occurs from October to February, the construction activity is shown in the year construction begins. The in-water work window a construction activity is anticipated to occur may vary as construction proceeds.

During 2020, JCEP would conduct the following activities:

- Begin final engineering design;
- Procure all major equipment;
- Mobilize to the site and set up erosion and sediment controls;
- Clear and grub the site;
- Start ground improvements;
- Start cut and fill activities;
- Construct TMBB (In-water work);
- Start MOF construction by placing clean fill in the bay (In-water work);
- Start Trans Pacific Parkway/US-101 Intersection Widening (In-water work);
- Start Eelgrass Mitigation (In-water work);
- Start Navigation Reliability Improvements (In-water work); and
- Start APCO access bridge and install work bridge (In-water work).
- Begin Kentuck Project (In-water work).

During 2021, the following activities would be conducted:

- Begin module fabrication;
- Complete ground improvements;
- Continue cut and fill activities;
- Continue MOF construction;
- Begin marine slip construction – sheet pile, pipe pile, and excavation/dredging behind the berm
- Transport excavated/ hydraulically dredged materials to Ingram Yard, the Roseburg site, the South Dunes site;
- Begin piling for process areas;
- Begin concrete work for LNG Storage Tanks;
- Begin concrete foundations for process areas;

- Begin plate work for LNG Storage Tanks;
- Begin work on site Buildings;
- Begin Workforce Housing Facility;
- Complete Trans Pacific Parkway/US-101 Intersection Widening;
- Commence excavating in front of the MOF;
- Dredge access channel (In-water work);
- Begin Pile Dike Rock Apron construction;
- Continue Navigation Reliability Improvements if not completed (In-water work);
- Complete APCO access bridge and remove work bridge (In-water work); and
- Continue Kentuck Project including installation of dredge off-loading facilities (In-water work).

During 2022, the following activities would be conducted:

- Continue Module fabrication;
- Complete and open Workforce Housing Facility;
- Complete cut and fill activities;
- Complete MOF, install fender pile (In-water work) and begin receiving major equipment;
- Complete marine slip and remove berm to connect slip to the bay (In-water work);
- Deliver dredge material to Kentuck Project (In-water work);
- Continue Navigation Reliability Improvements if not completed (In-water work)
- Begin berthing facilities;
- Complete piling for process areas;
- Complete concrete foundations for process areas;
- Continue work on site Buildings;
- Continue LNG Tank construction;
- Begin mechanical equipment installation;
- Receive and install Pipe Rack and initial Major Equipment Modules; and
- Begin BOP pipe and electrical work.

During 2023, the following activities would be conducted:

- Continue Kentuck Project;
- Complete Navigation Reliability Improvements (In-water work);
- Complete final engineering design;
- Complete Module fabrication;
- Complete berm removal and slope protection (In-water work);
- Install meteorological ocean data collection buoys (In-water work)
- Complete berthing facilities;
- Receive and install remaining Major Equipment Modules;
- Complete site Buildings and turnover essential portions;
- Continue LNG Tank construction;
- Complete mechanical equipment installation;
- Complete BOP pipe and electrical installation; and

- Begin Pre-Commissioning and Commissioning.

During 2024, the following activities would be conducted:

- Complete Kentuck Project, connect site to Coos Bay and Kentuck Creek (In-water work)
- Install final site finishes;
- Complete LNG Storage Tank construction;
- Commission and Cool Down LNG Storage Tanks;
- Complete Commissioning;
- Staged start-up and commencement of operations;
- Ship first LNG Cargo;
- Performance Testing;
- Plant Turnover; and
- Clean and demob site.

During 2025, the following activities would be conducted:

- Decommission and remove Workforce Housing Facility; and
- Clean and demob site.

Dredging and Shore Protection

For the capital dredging, about 5.7 million cubic yards (mcy) of material would be removed to create the slip basin and access channel. Of this, about 1.4 mcy would be dry excavated and about 4.3 mcy would be wet dredged. It is proposed that excavated and dredged material be distributed between Ingram Yard, the Roseburg site, the South Dunes site, and the Kentuck Project site.

During the “fresh water” construction phase of the slip about 2.2 mcy of material would be dredged in the pocket behind a temporary construction berm. During the “salt water” construction phase of the slip, about 0.7 mcy (slip and berm) of material would be dredged during removal of the temporary construction berm and finish dredging of the marine slip, of which about 0.3 mcy may be used for the Kentuck Project. It is also possible that the 0.3 mcy required to facilitate the Kentuck Project could be sourced from the salt water dredge taken from the access channel between the FNC and the proposed LNG Terminal marine slip. A total of about 1.4 mcy of material would be dredged from the bay during construction of the access channel.

The northern slip face would be armored after the slip is dredged but before the earthen barrier berm is removed. The barrier berm would remain unarmored, because it would be removed during the later stages of slip construction.

The estimated excavated and dredged material volumes and their proposed placement location are summarized in table 2.1.1-1 and further discussed in subsequent sections below.

To minimize the impacts on aquatic resources in Coos Bay, reduce the total period of estuary turbidity, and extend the time available for construction, a multi-phase approach was developed for construction of the slip and access channel. The basic concept is to maintain a natural physical barrier between the slip and Coos Bay. Therefore, construction of the slip could take place year-round without working in the waters of Coos Bay. The first phase would be the dry excavation of the upper level of the upland portion of the proposed marine berth, above the underground water table. The second phase, known as the "fresh water" phase, would be the dredging of the lower level of the upland portion of the marine slip, below the underground water table. The third phase, known as the "salt water" phase, would include the removal of the berm, and the dredging of the far southern portion of the slip and the entire access channel (including the area around the MOF) in the bay.

TABLE 2.1.1-1

Estimated Excavated and Dredged Material Volumes

Construction Phase	Volume (mcy)	Disposition Sites
Upland Excavation	1.4	Ingram Yard, Access and Utility Corridor, South Dunes
Fresh Water Dredge	2.2	Ingram Yard, Access and Utility Corridor, South Dunes, Roseburg site
Salt Water Dredge	0.2	Ingram Yard, Access and Utilitiy Corridor, South Dunes, Roseburg site
Upland Excavation	0.03	Ingram Yard, Access and Utility Corridor, South Dunes
Salt Water Dredge	0.5	Ingram Yard, Access and Utility Corridor, South Dunes, Kentuck
Upland Excavation	0.004	Ingram Yard, Access and Utility Corridor, South Dunes, Roseburg site
Salt Water Dredge	1.4	Ingram Yard, Access and Utility Corridor, South Dunes, Roseburg site
Salt Water Dredge	0.7	APCO Site 1 / APCO Site 2

Marine Construction Equipment

A variety of marine equipment would be used in the course of dredging and placing slope protection. There are two types of dredging operations that use different equipment: clamshell and cutter-suction. The following describes the equipment that would be used; exact details would be finalized during detailed design and may be impacted by market availability.

The apron excavation, berm removal, pile dike rock apron, and slope protection would be completed with a derrick barge that has an approximate capacity of 180 tons. The derrick barge would use anchors for station keeping. The barge would be supported by dredge tender for positioning and a crew boat. The crane would have both standard and flat-bottom eco-buckets for digging operations and a rock box for placing slope protection. Spoils would be placed on one of three flat deck barges with approximately 15,000 square feet of deck space. A tugboat of nominal capacity 1,500 horsepower (hp) would shuttle the spoil barges to the MOF, where the dredge spoils would be transferred to trucks for placement on the LNG Terminal site. For the material being delivered to the Kentuck Project, the same tug would deliver the deck barges for unloading and return the empties.

The dredging of the slip would be completed using a barge-mounted cutter-suction dredge of nominal capacity 3,000 hp. The dredge would be delivered by ocean-going barge to the channel, then partially disassembled and pulled over the berm into the slip area. The dredge would pump the dredge spoils to fill areas on the LNG Terminal site. The dredge would be serviced by a dredge tender and a crew boat.

Before the berm is removed, slope protection within the slip area would be installed using land-based cranes and a crawler craned mounted on a flexi float barge within the slip. A crawler crane would use a rock box to pick slope protection materials off the bank and place the material, working from the toe of slope up. This crane may also be used to service concrete work and equipment installation throughout the slip.

Other marine equipment could include boats for survey, personnel movement, and the shuttling of supplies. A variety of tugboats might also be called upon from the local area that would vary in size and role, depending on availability.

Navigation Reliability Improvement Dredging Means and Methods

Two methods of dredging could be used: mechanical dredging via clamshell or excavator, and hydraulic cutter-suction dredging. Mechanical dredging via clamshell or excavator would involve placement into a scow or hopper barge for transit to a temporary dredge offloading area and hydraulic pumping to disposal sites. Hydraulic cutter-suction dredging could involve pumping material via temporary dredge lines directly to a scow or barge for offloading at disposal sites, or pumping the material via temporary dredge lines directly to disposal sites. The total volume of capital dredged material from these excavations is approximately 590,000 cubic yards (cy). Dredged material may be distributed between APCO 1 and APCO 2 upland disposal sites, or placed entirely at APCO 2, if it is feasible.

Dredging would take place in deep subtidal habitat, which also provides habitat for benthic organisms such as worms, crustaceans, and mollusks. These activities would temporarily impact the macroinvertebrates that live within the substrate in these areas and move, rest, find shelter, and feed on the substrate and organic material. Additionally, the fish species that utilize these habitats could be temporarily affected. Dredging would result in increased turbidity within the estuarine analysis area. The restriction of construction activities to the in-water work window of October 1 through February 15, when salmonid species abundance is lower, would reduce the likelihood of impacts to these species.

Dredging would require a temporary dredge line to be placed on the bottom, running along the outer limits of the FNC, to connect the first deepening location to APCO Site 2. Navigation markers would be used where the dredge line temporarily crosses the FNC for Dredge Areas 2 and 3. There are two viable alternatives for placement of the dredge line at these two dredge locations. Option one is to use a floating line that connects the hydraulic cutter suction head dredge across the FNC and connecting to the submerged pipeline on the east side of the channel at each of these two dredge areas. The line must be floated at this location because the FNC is not deep enough to place a submerged pipeline and still maintain the required navigational underkeel clearance to the top of a submerged pipeline. The floating section of dredge line would need to be broken to allow passage of deep draft vessels restricted to the FNC. The dredge line would be flushed prior to breaking the line to minimize the release of turbid water. An alternate option is to place a submerged material pipeline along the west side of the FNC to transport the dredge material from Dedge Areas 2 and 3 and cross the FNC near Dredge Area 4 at approximately RM 6.7, where the FNC is naturally deep enough to maintain adequate clearance to a submerged pipeline. Material from Dredge Areas 1 and 4 that are located on the east side of the FNC can be managed without impact to deep draft vessels. The pipeline would also be elevated at fixed locations to feed booster pumps. The booster pumps would be located on barges, which would be moored on the eastern side of the FNC using temporary piles and/or spuds, and which would be used to move the dredge slurry toward APCO Sites 1 and 2 for disposal.

If dredged material is offloaded from a barge/scow, a temporary dredge offload facility would need to be constructed to hydraulically transfer dredge material to APCO Site 2. The hydraulic unloader would operate from a deck barge up to 40 feet by 100 feet in size. Two flat deck mooring/fleeting barges (measuring 40± feet by 160± feet) would be moored adjacent to the unloader barge. Approximately 16 temporary piles and/or spuds that would be 24 inches in diameter will be used to moor the barges, depending on actual equipment and configuration.

Indirect impacts resulting from the runoff of decant water at the APCO Site are not anticipated. The perimeter dike would be sized appropriately to allow for the settling of dredged material, and for evaporation and dewatering. During the drying phase, finer sediments would be allowed to consolidate, settle, and dewater. Water would evaporate or percolate into the ground. Weirs would also be used to enable surface water to exit the site via a culvert and would be designed with sufficient retention times to ensure that adequate sediment settling has occurred before discharge. Adequate settling before discharge would prevent turbid water from being released into the bay.

Maintenance materials would be disposed of in the upland dredge disposal sites located on the APCO Site 1 and APCO Site 2, and management of the dredge areas would be the responsibility of JCEP.

Construction of Sheetpile Wall

The sheetpile system would serve as a retaining wall for the shoreline on the east and west sides. The east side would support the LNG carrier loading facility and associated berthing and mooring facilities. The sheetpile system would be designed to support the dead loads of the soils and structures, and the live loads of the LNG carrier at berth and LNG transfer equipment, and also would be designed to meet the seismic criteria for the facility and water-imposed loads. The west side would provide a lay berth, and the sheetpile system would be designed to support the dead loads of the soils and structures and the live loads of the LNG carrier at berth.

The sheetpile wall system consists of face sheet piles for retaining the soils as well as tail-walls for anchorage of the retaining wall. All sheet piles and tail-walls would be driven from the land while the slip construction activities are isolated from Coos Bay.

Slip Construction

To minimize the impacts of construction of the marine facilities on fisheries, reduce the total period of estuary turbidity, and extend the time available for construction, a two-phase construction methodology would be used to construct the slip. The basic concept of the two-phase construction methodology is to excavate (either wet or dry) the majority of the slip area and construct the structures while maintaining a natural physical barrier between the excavated/dredged slip and the water of Coos Bay (see appendix B, attachment D.2, Temporary Materials Barge Berth). This methodology would be accomplished by retaining a natural earthen berm to provide a physical partition between the water of Coos Bay and the fresh water construction activities for the marine facilities. This construction methodology would allow year-round work on the northern portion of the slip without being in contact with or causing an impact to the waters of Coos Bay. The remaining open water work would include excavation of the access channel (including the area around the MOF), excavation/dredging of the berm area, and installation of the MOF fender piles. This work would be constructed during periods when fisheries considerations allow in-water work, which is between October 1 and February 15.

Dry Excavation

The existing natural ground surface is at an elevation of approximately +20 feet NAVD88. The water table across the slip occurs at an elevation of approximately +10 feet NAVD88. All excavated material above an elevation of approximately +10 feet NAVD88 would be removed by conventional earthmoving equipment such as excavators, scrapers, bulldozers, and front-end loaders. A berm would be maintained as a barrier to the bay during this construction phase. The permanent north slope would be of 2.5 horizontal to 1 vertical (2.5:1). The same slope would be maintained on the slip side of the temporary berm to preserve the integrity of the berm during excavation and dredging, as shown in appendix B, attachment D.2, Temporary Materials Barge Berth. Excavation during this step would remove only material that is essential for creating the slip and constructing upland structures. Contouring of the slip perimeter above +10 feet NAVD 88 would be performed during this step.

The volume of material to be excavated and dredged from the slip, including the berm, is 4.3 mcy, as shown in table 2.1.1-1. The material would be placed on the LNG Terminal site, which includes Ingram Yard, the Access and Utility Corridor, the South Dunes site, and the Roseburg site.

Excavated material would be hauled by trucks to upland areas of the LNG Terminal site. The excavated material truck haul route would go to the north of the slip through Ingram Yard and then follow the route of the Access and Utility Corridor to the South Dunes site. The route would not cross the Trans Pacific Parkway at any time, and the only potential conflict would be with chip truck traffic to the RFP wood chip facility, which would be mitigated by construction of a traffic overpass. The excavated material truck haul route would be on JCEP- or RFP-owned land.

Slip Dredging

Excavators would be used to remove material down to elevation 0.0 feet NAVD88 to build the dredge launch pad. The channel would be roughly 300 foot by 200 foot and be 10 feet deep. The launch pond preferably would be located near the slip perimeter and road access. The material would be moved to the upland disposal sites by trucks, as described in the previous section.

The dredge barge would be delivered by ocean-going barge to the channel, then pulled over the berm to facilitate hydraulic dredging of the slip. All of the material to be excavated that is located at or below the level of the water table would be removed by means of hydraulic dredging and transported to the Roseburg site. Based on scheduling efforts during detailed design, placement may be required at the South Dunes site; however, no off-site disposal is anticipated.

A hydraulic transport pipeline would connect the dredge or dredges to the disposal areas, and a decant water return pipeline would return the water to the slip area or purpose-built decant basin. The hydraulic dredges, which are capable of transporting a slurry of 30 percent solids by weight at a flow rate of 6,000 gallons per minute (gpm) or greater, would create an ever-increasing dredge prism that would, in the end, create the fully defined slip within the confines of the berm. The hydraulic dredges are capable of dredging to the final slip depth.

The slurry pipeline used for hydraulic transportation of excavated materials going to South Dunes (including the decant water return line) would follow the shoreline of the RFP property until the point where it follows the route of the future Access and Utility Corridor. Slurry lines going to the Roseburg site would be routed through Ingram Yard to the Access and Utility Corridor, and then turn south into the RFP property. The pipes would run along the ground and be braced as necessary. In the area of the RFP chip ship berth, the pipeline would be placed on the riprap along the shoreline, so that it does not affect the docking and loading of the chip ships. The pipeline would be able to span any affected wetlands or waterbodies without the need to place any structures in the wetlands or waterbodies. The pipelines are high density polyethylene) that are fusion welded together, which will greatly reduce the likehood of a rupture. Any mechanical joints would be located to avoid discharge to wetlands and waters.

The slurry pipeline and decant water return pipelines would be made of 18- to 20-inch-diameter fused polypropylene (seamless) pipe. The decant water return pipeline would be placed along, and directly adjacent to, the slurry pipeline (no spacing between the two pipelines). The decant water pipeline would be used to convey the decanted water from the settling areas back to the dredge pond. When the hydraulic transport has been completed, the pipelines would be drained, flushed with clean water, and cut apart only in those areas where any residual material in the pipeline could not potentially be released into the bay, wetlands, or other waterbodies. The pipeline would be removed by the contractor and taken off-site for reuse, recycling, or disposal in a permitted landfill. Because the pipelines would be on existing developed surfaces (grassed, paved, graveled, and riprap area of the RFP property) and areas to be developed for the LNG Terminal Project (Access and Utility Corridor), post-construction restoration would include reseeding of grassed areas that were disturbed by the location of the pipelines on the grassed area.

Access Channel Dredging

The volume of material to be dredged from the access channel is 1.4 mcy, as shown in Table 2.1.1-1. The material may be placed on Ingram Yard, the Access and Utility Corridor, the Roseburg site, and the South Dunes site. This portion of work is open to Coos Bay and therefore would be performed during the annual in-water work window, which is from October 1 to February 15.

The access channel dredging would utilize a barge-mounted crane with clamshell bucket and material barges. The channel dredging would occur during the second available in-water work window. The operation would start at the MOF in order to facilitate the relaxation of the sheets, and would continue until all material between the berm and the FNC is removed. It is expected that dredging would occur around the clock to finish in the available time frame.

Material would be loaded into material barges from the clamshell. When full, the barges would be towed to shore and the material would be transferred to trucks for placement at the available upland sites as determined by the final schedule.

Driving of Piling for Marine Structures for the LNG Terminal and Tug Dock

All of the marine piling for the tug dock would be driven concurrent with dredging of the slip and, as such, piles would be driven prior to connection of the slip to Coos Bay. Land-based mobile cranes with pile-driving equipment would be located in the slip excavation as it approaches the top of pile elevation. All piles required for the LNG loading foundation and all mooring and berthing structures for the LNG and lay berths are behind the sheetpile walls and would be driven on dry land. One hundred sixty eight 30-inch-diameter piles would be used for the mooring dolphins and one hundred sixty eight piles would be needed for the breasting dolphins. In addition, thirty-five 48-inch-diameter piles would be used to support the loading platform above the LNG carrier berth. The tugboat dock would require 109 (24-inch-diameter) pile and 62 (20-inch) fender piles.

Slope Armoring

The northern slip face would be armored from the toe to above the water line using rock, a cement based riprap, or other appropriate measures to protect the slope from scour and erosion (see JCEP Resource Report 6 – Geological Resources). The armor would be placed with a combination of land-based and barge-mounted equipment. Currently the east side (LNG Berth), west side (Emeregency Lay Berth), and MOF are proposed to be vertical steel sheetpile wall, which in part provide an active scour protection system. Scour protection will be evaluated further during final design to determine if slope armoring or pile embedment would prevent undermining of the sheetpile wall. It is anticipated that pile embedment would prevent undermining, however, additional rock, cement based riprap, or other appropriate measures may be specified to provide scour protection along the sheetpile walls. The south slip face created by the berm would also remain unarmored, because it would be removed to create the final configuration of the slip and the access channel.

The sequence for pile driving, slope dressing, and armoring could vary depending upon the means and methods chosen by the contractor performing the work.

Above the waterline, alternative scour (and wind/rain erosion) protection systems for less frequent events would be provided using any number of potential techniques, including concrete cellular mattresses, grout-injected geotextile fabric mattresses (fabriform), and/or geotextile-reinforced vegetative planting.

Connection of Slip to Coos Bay

Details of each of the steps involved during connection of the slip to the Coos Bay are outlined below.

Breaching and Removing the Berm

Once all of the fresh water construction is complete, work would begin on breaching and removing the berm (500,000 cy) and completing the remaining area of the slip. This work would be in-water work and occur during the October 1 to February 15 window. Dredging might be conducted from both the Coos Bay side and the slip side to reduce the duration of the breaching and removal activity. Material would be removed by hydraulic dredge or clam-shell dredge. A portion of the material (approximately 300,000 cy) may be transported to the Kentuck Project to be used as fill. The remainder would be placed at the South Dunes site. The temporary piles used at the TMBB would be removed at this time as well.

Final Contouring and Slope Armoring

Removing the berm would open the slip to Coos Bay. Additional dredging to contour the access channel would complete the construction dredging activities. Armoring of the remaining unarmored slip side slopes would be completed. Although not anticipated at this time, any additional in-water structures required to complete the slip and associated in-water structures then would be installed. In-water work would be performed during the allowable construction window between October 1 and February 15.

Pile Dike Rock Apron

The proposed pile dike rock apron would likely be placed within the same in-water work window as dredging/construction of the access channel side slope but may occur the following in-water work window. Construction of the rock apron following dredging of the access channel would allow for much or all the apron rock to be placed from floating equipment, such as a material barge for the rock and a barge mounted crane for placement. If the contractor's equipment could not provide the reach necessary to place all rock from a floating platform some work may occur using wide track/lower ground pressure equipment working in the intertidal zone. Land-based equipment would work in the dry or during low tide to the extent feasible. If site constraints require equipment to work in shallow water conditions, measure would be installed as needed to minimize turbidity. At the end of Pile Dike 7.3, the new rock apron will be placed directly over the visible apron rock in a careful manner so the new rock apron will not extend towards the access channel beyond the end line of the existing visible rock. Construction is anticipated to take approximately one in-water work window if all material is placed from floating equipment.

Meteorological Ocean Data Collection Buoys

Removal of the existing anchor and installation of new industry standard anchoring systems would result in temporary disturbance to the channel bed, resulting in localized turbidity of a short duration. If required, replacement of the anchoring system would occur during the in-water work window to minimize any potential impacts. Aquatic organisms in Coos Bay are adapted to and exposed to periods of high to moderate turbidity during the winter months due to existing conditions. Therefore, impacts to marine species from replacement of the anchoring systems for the three existing buoys and installation of the two new buoys are expected to be insignificant and discountable due to the limited area affected and the timing of construction that would coincide with periods of naturally higher turbidity.

Restoration

Following the excavation activities, all areas within the LNG Terminal Project footprint, including exposed slopes, would be protected from erosion and stabilized with an erosion protection system and/or an approved seed mixture specified as being capable of surviving in highly permeable, xeric regimes; binding loose sand; and withstanding burial and deflation from aeolian processes (for more information, see JCEP Resource Report 7 – Soils).

The slurry and decant water return pipelines would be removed as described above. Any areas that are disturbed by the haul truck or pipeline routes that do not become part of the Access and Utility Corridor would be restored to pre-construction conditions.

The route of the slurry/decant water return pipelines on the developed RFP property would not require restoration, because the pipelines would be placed on areas that are surfaced with gravel, concrete, or riprap. If there are any areas of the route where ground disturbance occurs, these areas would be returned to pre-construction conditions.

LNG Carrier Loading Facilities

The LNG carrier loading facilities would be constructed once the installation of the eastern sheetpile wall system is complete. All of the loading facilities would be on the shore side of the slip, with no facilities located in the water of the slip. The platform with the loading arms (inclusive of the loading and vapor return arms) would be installed on a concrete pad located at the edge of the slip. The foundation of the pad would contain a number of piles to provide a stable foundation for the loading arm platform. Separate piles, typically steel pipe piles, would be driven for the breasting and mooring structure platforms. The loading arm platform would be constructed on columns raised from the concrete pad and accessed through stairways. The LNG transfer piping would be located over LNG troughs that would contain any spills and divert the LNG to a containment basin.

The LNG carrier loading facilities would be constructed using land-based equipment to install the required structural elements for the loading platform and mooring structures. Installation of berth piping and equipment, and hookup and commissioning of the loading system and utilities would follow.

Driving of In-water Piles for Marine and Temporary Facilities

The exception to the installation of all piles "in the dry" is associated with the installation of the TMBB berthing and mooring piles, MOF fenders, the Temporary Dredge Line and Temporary Dredge Transfer Line support cradle pile, the temporary work bridge piles for the APCO Site access bridge and Trans Pacific Parkway/ US 101 Intersection Widening, and the temporary piles for the Temporary Dredge Off-loading Area at the Kentuck Project and APCO Site 2, and the Temporary Dredge Loading Area at the Eelgrass Mitigation site, which could require steel piles to be installed in open water of the bay. Untreated timber piles would be installed within a sheetpile cofferdam at the Trans Pacific Parkway/US-101 Intersection Widening to provide subgrade stabilization. All piles installed in open water of the bay would be 24 inches in diameter or smaller to minimize acoustic impacts. A vibratory hammer would likely be used to install the steel piles for these actions; however, an impact hammer might be needed if the piles cannot be installed to design depth with vibration alone. Construction activities would occur during the in-water work window (approved by ODFW), when sensitive life stages of listed fish are less abundant in the bay, which would further minimize the potential for adverse impacts.

Construction of Upland Facilities at the LNG Terminal

All facilities would be constructed in accordance with applicable regulations, including 33 C.F.R. Part 127, 49 C.F.R. Part 193, National Fire Protection Association (NFPA) Standard 59A, and 49 C.F.R Part 192. JCEP would construct its LNG Terminal facilities in accordance with its project-specific *Upland Erosion Control, Revegetation, and Maintenance Plan* (JCEP's "Plan) and *Wetland and Waterbody Construction and Mitigation Procedures* (JCEP's Procedures). JCEP has adopted the FERC's Plan and Procedures (May 2013 versions), as modified for the LNG Terminal Project, into JCEP's Plan and Procedures; therefore, there are no differences between JCEP's and FERC's Plan and Procedures. In addition, JCEP prepared Construction-phase and Operation-phase Spill Prevention, Control, and Countermeasure Plans (SPCCPs), which are included as Appendices F.2 and G. 2 in JCEP Resource Report 2 – Water Use and Quality. JCEP Resource Report 2 – Water Use and Quality also contains further information regarding the Erosion and Sediment Control Plan (ESCP) and SPCCP.

Preliminary Activities

During construction, equipment and material would be brought to the LNG Terminal site by road, rail, and marine transport. The kinds of materials and the mode of delivery to the site would depend on the origin, size, and weight of the material. It is anticipated that the larger and heavier pieces of equipment would arrive by barge or ship. Heavy equipment haul roads would be constructed from the MOF to the LNG Terminal process or laydown areas. The existing rail line to the North Spit has been acquired by the Port and is now called the Coos Bay Rail Link. Upon assumption of ownership of the line in 2010, the Port undertook an extensive repair program that placed portions of the line back in service in stages. The entire 134-mile-long line was declared fully operational in April 2013. Therefore, the railroad is available to transport equipment and materials to the LNG Terminal site.

JCEP estimated there would be an average of about 140 heavy vehicle trips to and from the LNG Terminal site per day. It is assumed that the use of an on-site concrete batch plant would reduce the potential number of delivery trips to the terminal.

JCEP further envisions that some bulk materials, such as insulation, could be shipped in standardized containers. Fabrication shops would be used to fabricate pipe spool pieces and other prefabricated units of equipment and skid-mounted process equipment modules, and would be delivered to the site in accordance with the construction schedule. Where practical, skid-mounted equipment would be used to minimize the pieces that must be delivered and installed at the site.

Construction of Terminal Facilities

Construction site preparation would require clearing, filling, and grading of the LNG Terminal site to an approximate elevation of +27 feet for the base of the LNG storage tank area and approximately +46 feet for the liquefaction process areas. The water-dependent facilities would typically be at an elevation of 34.5 feet.

Approximately 5.7 mcy of material would be removed to create the slip basin and access channel. Of this, about 1.4 mcy would be dry excavation and about 4.3 mcy would be wet dredged. The material is planned to be distributed between Ingram Yard, the Roseburg site, and the South Dunes site. Approximately 0.3 mcy may be used for the Kentuck Project. The material would be used to raise the elevation of the South Dunes site and the Access and Utility Corridor to approximately +46 feet to +70 feet. The dry-excavated material would be transported by truck to the designated location. The excavated material truck haul route would go north of the slip through the LNG Terminal site, and then follow the route of the Access and Utility Corridor to the South Dunes site. The excavated material truck haul route would be on

JCEP–owned land and would not cross the Trans Pacific Parkway. A temporary traffic overpass would be constructed to segregate traffic travelling to and from the RFP property from the LNG Terminal site construction equipment.

The wet dredged material would be conveyed by slurry pipelines laid on the surface across the RFP property, as described in section 2.1.1.2 above under "Slip Dredging." Dredge spoils would be contained within berms constructed of dry material in the spoil areas. The containment areas and berms would be sized to accommodate the dredged material delivery method and the project schedule. For dredged material delivered by truck, the wet material would be allowed to dry the disposal area. Dredged material from the cutter-suction dredge would be suspended in water and pumped to the containment area. At a low point within the containment area, a vertical riser would be installed that would allow decant water to escape the spoil area via a pipe, to be collected and pumped back to the slip via a decant return line. The dredge discharge pipe would be relocated frequently to allow for the even distribution of dredge spoils and the collection and removal of decant water.

Temporary erosion control devices, such as ditches, sediment fences, and silt traps, would be installed as necessary, in accordance with JCEP's Erosion and Sediment Control Plan (ESCP). The subsurface conditions at the site require soil improvement before any structures can be built for the LNG Terminal facilities. These conditions include the presence of peat, clay, buried driftwood, and liquefiable soil, which could cause excessive settlement and stability concerns or issues associated with liquefiable soils should a seismic event occur. Potential soil improvement methods include: soil densification using vibro-compaction or sand compaction piles, and excavation or soil mixing where organic materials are located (see JCEP Resource Report 6 – Geological Resources for more detailed information). Individual excavations would then be made for equipment foundations. Following completion of foundations, the site would be brought up to final grade. Final grading and surfacing would consist of gravel-surfaced areas, asphalt-surfaced areas, concrete-paved surfaces, anchored reinforced vegetation system, and vegetated areas utilizing salvaged topsoil and mulch.

The foundations for all equipment and structures, including the LNG storage tanks, process equipment, and pipe racks, would use either a shallow or a deep foundation system. Typically, shallow isolated or raft foundations would be used unless the design requires the use of deep foundations. A number of piling solutions would be utilized on the LNG Terminal Project, and would include driven pile and drilled pier systems. Typically, conventional pipe pile, sheet pile, or drilled piles would be used where required for earth retaining structures and deep foundations. It is anticipated that soil improvements would be sufficient to provide the bearing capacity for typical design loads.

Construction of the LNG storage tanks will be the most time-consuming element in the development of the LNG Terminal. General steps taken during construction of each LNG storage tank would include installation of the foundation, seismic isolators, and tank bottom slab, construction of the outer concrete container wall, installation of the bottom carbon steel vapor liner and floor insulation, construction of the steel dome roof and suspended deck, installation of the 9 percent nickel steel inner tank, installation of the internal tank accessories (pump columns, instrumentation, and piping), installation of external tank accessories, installation of insulation, and installation of LNG pumps. Following a successful inner container hydrotest (see following discussion), the tank will be washed down and cleaned. After installation of the LNG pumps, the tank will be closed and purged with nitrogen to a positive gauge pressure. Final insulation will be installed in the annulus between the inner and outer tank an above the inner roof. At this point in the construction process, the tank will be ready for cooldown with LNG.

For the hydrotesting of the LNG storage tanks, water would be supplied from the existing CBNBWB raw water line. The raw water line can supply 4 million gallons per day (mgd). It would take approximately ten days to fill the first tank with the 28 million gallons required for the hydrotest. If the construction sequence allows, the two tanks would be hydrotested with the same water by transferring the water at the conclusion of the hydrotesting of one tank to the other tank. The total duration of the hydrotest of the first tank from start of filling to emptying is expected to be approximately 34 days, with the second tank taking approximately three weeks. The existing 12-inch CBNBWB water line has the necessary pressure and capacity to deliver 20 million gallons over a two-week period during the low-demand period (September through May) and a three-week period during the peak demand period (Memorial Day through Labor Day). No biocides or chemicals would be added to the hydrostatic test water.

Water used in hydrotesting would be locally discharged, following testing and ODEQ approval, to the stormwater system for infiltration or discharged to the IWWP according to the applicable the National Pollutant Discharge Elimination System (NPDES) permit requirements. The rate of discharge is expected to be approximately 2.9 mgd for the bulk pumping operation, with substantially lower rates being achieved when removing the final amounts of water from the tank bottom. The IWWP connects to a previously existing, permitted ocean discharge.

Construction of foundations for buildings and installation of major mechanical equipment would occur once LNG storage tank construction is underway. Large equipment items would be set on their foundations upon delivery. After the pipe racks are completed, work would commence on the installation of the process and utility piping. The installation of mechanical equipment would be followed by electrical and instrumentation installation. Once the piping is completed and tested, piping insulation would be installed. As the construction of the process portion of the LNG Terminal progresses, work would commence on the precommissioning activities, so that these activities can be completed concurrently with the completion of the LNG storage tanks and be ready for nitrogen purging.

Construction Workers and Vehicle Traffic

Construction of the LNG Terminal would require 4,527 full-time equivalent jobs over the 53-month construction period. Construction is expected to employ 1,996 workers in the peak month and 1,023 workers in an average month. See JCEP Resource Report 5 – Socioeconomics for more detailed information.

Construction workers commuting to the job site could have impacts on terrestrial wildlife, specifically with regards to vehicle strikes on individual animals (ranging from slow-moving reptiles such as turtles to big game such as deer). The number of vehicles used for commuting to the LNG Terminal, and measures to mitigate construction traffic, are discussed in JCEP's Transportation Impact Analysis (see supplemental information to JCEP Resource Report 5 - Socioeconomics). Off-site park and ride lots would be developed as temporary facilities at Pony Village in North Bend and Myrtlewood Factory & RV Park north of North Bend.

Trash and Predators

During construction and operation, trash and food waste could attract corvids and other predators (such as crows, rats, and raccoons) that represent a threat to other species. Covered, animal-resistant receptacles would be provided in eating and break areas, parking lots, and at appropriate locations around the LNG Terminal site. During construction, the site would be policed on a daily basis to remove any food or other debris left by construction workers. During operation, the facility and grounds would be regularly inspected to ensure that no garbage is allowed to accumulate. Structures within the LNG Terminal site would be monitored to discourage their occupation or use by avian predator species.

Removal of Vegetation

Combined, the LNG Terminal and operational facilities would cover about 200 acres. Original vegetation would be cleared by construction activities and replaced with industrial facilities. The removal of upland vegetation would affect habitat for terrestrial species. During construction, it is anticipated that most mobile wildlife would leave the LNG Terminal project and relocate to similar undisturbed adjacent habitat. Site areas that are disturbed by site preparation, clearing, and construction of the LNG Terminal and related facilities would be stabilized by applying Best Management Practices (BMPs) for temporary sediment and erosion control measures until construction is complete, unless covered by equipment, gravel, or other covering. Site areas that would be disturbed only by temporary construction activities would be restored in consultation with landowners, and to the extent possible, using non-invasive native plant species to stabilize the sites and to prevent erosion of disturbed areas. If there are any areas that are disturbed by the excavated material haul truck road, the heavy haul route, or the hydraulic slurry/decant water return pipelines that do not become part of the Access and Utility Corridor for the LNG Terminal, they would be restored to preconstruction conditions.

JCEP proposes to implement various measures to avoid, minimize, and in some instances mitigate, impacts on migratory birds that may nest within the LNG Terminal project. If the construction schedule allows, all vegetation clearing at the LNG Terminal site would be conducted before March 1 or after August 31 to ensure that most nesting birds have fledged. If construction activities must occur during the nesting season, JCEP would conduct focused preconstruction surveys to determine whether there are active migratory bird nests present. If active nests are encountered within the limits of the survey, construction activities would be halted in the immediate vicinity until a qualified biologist has determined that the individuals have fledged or that the nest has failed from natural causes. Before allowing construction to proceed, JCEP would develop a Migratory Bird Conservation Plan in consultation with the FWS.

Temporary Construction Facilities Stormwater

Construction laydown areas would be surfaced to a large extent with larger, open-graded aggregate that would allow infiltration; therefore, stormwater from these areas would be self-contained and would infiltrate without the need for outfalls. Impervious surface would not be added at the Pony Village and Myrtlewood Offsite Park & Rides for the LNG Terminal project. Stormwater treatment for temporary facilities is described further in JCEP Resource Report 2 – Water Use and Quality (Storm Water Management Plan appendix), and the ESCP in an appendix to JCEP Resource Report 7 – Soils.

2.1.1.3 Impacts on Aquatic Resources Related to Construction

This section provides a general overview of the potential construction related impacts on aquatic resources. Species specific impact analysis is included in section 3.0 Species Accounts, Critical Habitat, Project Effects and Determinations of Effect and in section 4.0 Essential Fish Habitat.

Construction of the LNG Terminal marine facilities, including the access channel, slip, and berths, can cause impacts on aquatic resources in Coos Bay, including invertebrates, fish, and marine mammals. Although it is anticipated that most mobile aquatic species, such as seals, adult crabs, shrimp, and fish, could move away from the area during construction operations, some smaller juveniles and larvae could be entrained during dredging so that direct mortality or injury could occur. Impacts may also occur to aquatic organisms as a result of the removal of substrata during creation of the access channel, and due to dredging turbidity and construction noise, particularly the driving of piles, and are briefly mentioned below. More details about LNG Terminal construction and impacts on water resources and aquatic species can be found in Resource Reports 2 and 3.

Removal of Substrata

The access channel between the existing FNC and the LNG Terminalslip would be created by the salt water dredging of about 1.4 mcy of material. Dredging of the access channel and the portion of the slip in Coos Bay would affect approximately 17.6 acres of currently existing deep subtidal habitat, about 10.1 acres of intertital habitat, 4.0 acres of shallow subtidal habitat, and 2.0 acres of eelgrass.

The dredging operation to create the access channel would change physical conditions of the bay bottom in this area, locally altering the bathymetry and potentially altering the morphology and water currents. The current deep subtidal habitat at -15 feet would be taken to about -45 feet. A JCEP consultant conducted studies of the potential impact of the creation of the access channel and slip on shoreline erosion and sediment transport. Analysis of two models for wave measurement found that creation of the access channel would not change wave heights in the bay that could cause erosion along the shoreline. Likewise, an analysis of a model for sediment transfer showed that, for all design conditions, creation of the access channel would not change existing patterns of rates of bottom erosion or deposition of sediment deposits (CHE 2011).

An additional study conducted by Moffatt & Nichol analyzing the potential impact of the access channel, slip, and Navigation Reliability Improvements on shoreline erosion and sediment transport found that dredging associated with these project components would not change wave heights in the bay that could cause erosion along the shoreline. Likewise, the Moffatt & Nichol study corroborated the results of the CHE (2011) study that indicated dredging would not dramatically change existing patterns or rates of bottom erosion or sediment deposition (Moffatt & Nichol 2017b).

A comprehensive sediment sampling and analysis plan (SAP) was completed in October 2006 in order to evaluate the grain size distribution and total volatile solids composition of sediments in the proposed dredge prism for the terminal access channel (SHN 2007). The testing that was conducted to determine whether the sediments meet Dredge Material Evaluation Framework (DMEF) guidelines, relative to Lower Columbia River Management Area, for in-water disposal. Since results of the study revealed that all samples were primarily composed of medium to fine grain sand and had a very low percentage of total volatile solids, no further chemical testing was required, and the sediments were considered suitable for in-water disposal per DMEF guidelines. Furthermore, the results indicate the sediment character should not result in significant increases in bioavailability of contaminants to fish and fish food organisms within the analysis area. Based on the results of the sediment sampling, there is little to no risk of contamination as a result of dredging the access channel.

Sediment evaluations conducted by the USACE in 2004 for the Coos Bay channel maintenance and improvement dredging along the FNC revealed only low levels of sediment contaminants, all below their respective DMEF screening levels. In 2011 and 2016, JCEP conducted geotechnical investigations at the Navigation Reliability Improvements sites to support the JCEP's DMMP. Analysis of the physical character of sediments at the Navigation Reliability Improvements sites determined that sediment composition consisted of sand, silty sand, sandstone, and siltstone. This is similar to sediments collected from the adjacent FNC and from within the footprint of the proposed LNG Terminal access channel. These sediments were generally described as coarse-grained with high sand content, which the Portland Sediment Evaluation Team (PSET) previously determined suitable for unconfined aquatic disposal. Due to their proximity to previous sampling locations in the FNC and access channel, sediments to be dredged from the Navigation Reliability Improvements sites will have a similar chemical character. Therefore, they will also have a low likelihood of potential contaminants and be suitable for unconfined aquatic disposal.

JCEP's dredging for the access channel would remove benthic organisms (e.g., worms, mollusks, echinoderms, and crustaceans) from the bay bottom. Aquatic species in Coos Bay produce pelagic larvae. Species found in waters deeper than 30 feet tend to spawn in the winter months, with larvae recruited into benthic bottom habitats in the early spring and summer. Between 2009 and 2011, JCEP had the University of Oregon Institute of Marine Biology conduct samplings in the bay near the access channel to characterize the zooplankton, larvae, and juvenile fish that occupy this area. The study noted benthic species taken in samples (Shanks et al. 2011). Juvenile *Anthopleura artemesia* (a burrowing sea anemone) were found mostly from late summer through early winter. Cumaceans (a benthic crustacean) were most abundant in samples taken in fall and winter on rising tides, and on falling tides in spring and summer. Porcelain crab larvae were present year-round, mostly found on rising tide samples. Pea crab zoea were abundant in samples taken in the fall, spring, and summer. Mytilid (mussel) juveniles were uncommon only in the early summer. *Clinocardium* spp. (cockels) were present during the entire year. Juvenile bivalves were most abundant in late winter and spring. Juvenile gastropods were least abundant in spring and early summer samples.

Creation of the access channel would be a short-term impact, lasting not more than six months, and should not have population-level effects on benthic organisms in Coos Bay. It has been reported that benthic communities on mud substrates in Coos Bay, when disturbed by dredging, recovered to pre-dredging conditions after about one month (Newell et al. 1998). Therefore, removal of benthic species from the bottom of the access channel is not anticipated to have significant adverse impacts on the aquatic environment of the bay.

In addition, because the shallow tidal habitats would be converted to deeper-water habitat than what is currently there, some long-term reduction in benthic production would occur. Some of this net loss would be offset by added annual benthic production from the newly formed 38-acre slip habitat, even though it would likely be of poor quality, because this area was originally an upland. An increase in organic matter production to the Coos Bay system is expected from JCEP's proposed eelgrass and wetland mitigation sites.

Removal of Eelgrass

About 2.0 acres of eelgrass would be removed by creation of the access channel and the portion of the slip in Coos Bay, which is less than 0.6 percent of the estimated total area where eelgrass was detected in lower Coos Bay. Submerged grass meadows provide cover and food for a large number of organisms, including burrowing, bottom-dwelling invertebrates; diatoms and algae; fish that lay eggs on their leaves; tiny crustaceans and fish that hide and feed among the blades; and larger fish, crabs, and wading birds that forage in the meadows at various tides. Eelgrass provides shelter for a variety of fish and may lower predation, allowing more opportunity for foraging. Eelgrass mapping surveys conducted between 2005 and 2014 detected more than 1,400 acres of low- and high-density eelgrass communities throughout upper and lower Coos Bay (EPA 2005; David Evans and Associates, Inc. [DEA] 2007 and 2010; Ellis Ecological Services 2007 and 2013). The largest and most contiguous beds of submerged grasses are located in both the lower and upper bay, in the North and South sloughs, and in Haynes Inlet. Habitat mapping documented intertidal and subtidal aquatic beds, including submerged aquatic vegetation composed of eelgrass, in Jordan Cove and across the bay from the site of the proposed LNG Terminal in and near the mouth of Pony Slough, and adjacent to the APCO Site. Based on aerial photo interpretation and eelgrass surveys, the distribution and spatial extent of submerged aquatic vegetation within the area to be dredged for the slip is patchy and sparse. Because of the low density and narrow extent of distribution of submerged aquatic vegetation in this area, habitat value is expected to be lower than the more extensive and contiguous submerged aquatic vegetation beds located elsewhere in Coos Bay. JCEP would mitigate for the removal of eelgrass at the access channel by planting a minimum of approximately 6.03 acres of new eelgrass beds at the Eelgrass Mitigation site located south of the Southwest Oregon Regional Airport in Coos Bay (see appendix O – Compensatory Wetland Mitigation Plan).

Temporary impacts to eelgrass could occur where the Temporary Dredge Line and Dredge Transfer Line cross eelgrass habitat adjacent to the APCO Site 2, Kentuck Project site, and Eelgrass Mitigation site. To minimize impacts, the dredge lines would be placed on pile-supported cradles at the narrowest point of the eelgrass beds. Temporary impacts would occur where the piles are driven into the seabed to support the cradle.

Turbidity Caused by Dredging

A large quantity of suspended sediment can reduce light penetration, which in turn reduces primary production of both pelagic and benthic algae and grasses. Increased sediment can affect feeding of benthic and pelagic filter feeding organisms (Brehmer 1965; Parr et al. 1998), and the settling of the suspended particles can cause local burial, affect egg attachment, and modify benthic substrate. High enough levels can have direct adverse effects to fish ranging from avoidance to direct mortality.

JCEP intends to use either a hydraulic cutterhead suction dredge or a clamshell dredge to create the access channel. A study by Moffatt & Nichol (2006) modeled total suspended sediment (TSS) and turbidity for dredging based on the United States Army Corps of Engineers (USACE) DREDGE model and the two dimensional numerical model Mike21. For hydraulic dredging at a current of 1.0 meters per second (m/s) or 1.9 knots, the TSS at the elevation of the cutterhead would be approximately 250 mg/l. This dissipated to about 14 mg/l at about 60 meters (200 feet) from the dredge location based on a current of 1.0 meter/second (3.3 feet per second [ft/sec]). For mechanical dredging using an open clamshell dredge at a current of 1.0 m/s, TSS at a line source extending between the bottom and water surface would be about 700 mg/l. This dissipated rapidly to less than 50 mg/l at distance of 200 meters (about 660 feet) from the dredge site.

Within Coos Bay, ambient turbidity levels (generated by stream flows into the estuary, waves, and ship traffic) have been assessed based on several studies. As described in a report by Moffatt & Nichol (2006), the average concentration of TSS measured near the proposed LNG terminal site was 14 mg/l with a range of 0-25 mg/l. This report also references a longer record of Coos Bay background turbidity data reported by NOAA for the period of April 2002 to December 2004 at the Charleston Bridge station located closer to the bay entrance than the LNG terminal site. Based on results from this study, the average summer and winter TSS levels at the Charleston Bridge station were 10.1 and 27.3 mg/l, respectively, which are equivalent to 5.8 and 12.2 NTUs. Substantially higher values, betweem 100 and 500 mg/l, were measured during individual sampling events.

More recently, hourly turbidity readings taken at the North Spit-BLM boat ramp gauge were compiled between August 2013 and January 2015. Preliminary data processing was first conducted to remove high turbidity measurements occurring for extended periods of time, as these typically occurred when dredging activities were ongoing. In addition, based on an empirical relationship developed for nine streams in the Pacific Northwest, turbidity values expressed in nephalometric turbidity units (NTUs) were converted to TSS in mg/L. Based on these data, the average natural turbidity level was calculated to be 40 mg/L at the North Spit-BLM boat ramp gauge (Moffatt & Nichol 2016).

Moffatt & Nichol (2017c) concluded that dredging associated with the slip, access channel, MOF, and Navigation Reliability Improvements would cause elevated turbidity levels. Increased turbidity would be short term and relatively localized; however, with turbidity plumes extending up to about 3,350 feet from the dredge footprint (based on either cutter suction or clamshell dredging) for the Navigation Reliability Improvement sites; up to between 750 and 780 feet from the dredge footprint (based on either cutter suction or clamshell dredging) for the access channel and MOF; and up to about 350 feet from the dredge footprint when using clamshell dredge equipment at the slip. Since turbidity associated with dredging at the Eelgrass Mitigation Site would be generally limited to the local area of excavation, there would be no significant dispersal of suspended sediment. The highest turbidity levels in all cases would occur at the dredge location. Dredging would be limited to the approved in-water work window. As a result, turbidity caused by dredging should not have significant adverse impacts on aquatic species in Coos Bay.

Dredging methods used by the contractor would be performance based which allows flexibility in conducting dredge operations while requiring compliance with water quality standards to control generation of turbidity and suspended sediment. A preliminary Turbidity Monitoring and Management Plan (TMMP) will be prepared during final design. The TMMP will be subsequently finalized after the selected contractor confirms the means and methods of dredge operations. The primary goal of the TMMP will be to manage proposed dredging operations for the Project consistent with DEQ water quality standards and permit requirements. Provisions of the DEQ-approved TMMP will be followed during all dredging activities. In order to minimize turbidity during dredging, environmental controls will be implemented whenever possible. Such controls may include use of a cutter suction dredge or closed clamshell bucket to minimize turbidity generation at the dredging site.

Construction Noise

Airborne and underwater noise would be generated during construction of the LNG Terminal and associated facilities.

Airborne Construction Noise

Construction noise levels for the LNG Terminal are expected to be similar to typical commercial programs, which average from 47 to 57 A-weighted decibels (dBA) at 2,000 feet (Hoover & Keith Inc. [H&K] 1994). The most noticeable construction noise at the LNG Terminal would be from driving the piles for the berthing structures and the temporary construction facilities.

Piling installation activities at the LNG Terminal would take place between July 2020 and July 2022 over two 10-hour shifts per day, six days per week (i.e., not on Sundays or major holidays). Up to 14 concurrent diesel impact pile hammers would be used during construction of the facility to drive approximately 3,600 pipe piles in the plant facility area. Up to six vibratory hammers would be in use to install roughly 11,800 sheet piles. The noise of pile driving was estimated to be 88 dBA 20 feet away, with an L_{nd} of 49.6 dBA at the nearest noise-sensitive area (NSA) in the city of North Bend, about 1.3 miles south of the LNG Terminal Based on the distance of construction from western snowy plover critical habitat (2.6 miles) and potential nesting sites (1 mile) on the North Spit, acoustic disturbances from the proposed action are not expected to affect this species.

Underwater Construction Noise

On the basis of the noise levels predicted based on studies (Deveau and MacGillivray 2017; O'Neill and MacGillivray 2017), and with reference to Popper et al. (2014), there is a high likelihood of behavioral responses for fish in the vicinity of vibratory piling. More severe impacts (mortality or injury) to fish due to underwater noise from vibratory piling behind the soil berm are not expected. When piling occurs in water using an impact hammer, there is potential for fish mortality, injury or behavioral response if fish are present during pile driving.

As discussed above, the following project components would require the installation of piles in Coos Bay: TMBB berthing and mooring piles, MOF fenders, the Temporary Dredge Line and Temporary Dredge Transfer Line support cradle pile, the temporary work bridge piles for the APCO Site access bridge and Trans Pacific Parkway/US-101 Intersection Widening, the temporary piles for the temporary dredge off-loading area at the Kentuck Project and APCO Site 2, and Temporary Dredge Loading Area at the Eelgrass Mitigation site. All piles installed in open water of the bay would be 24 inches in diameter or smaller to minimize acoustic impacts. A vibratory hammer would likely be used to install the steel piles for these actions; however, an impact hammer might be needed if the piles cannot be installed to design depth with vibration alone. An impact hammer would most likely be used to construct the temporary work bridges for the APCO Site access bridge and Trans Pacific Parkway/US-101 Intersection Widening and therefore is likely to generate acoustic impacts. If sound levels are determined to exceed NMFS

Level A regulatory thresholds for marine mammals or guidelines for listed salmonids, sound attenuation measures would be used in accordance with NMFS guidelines to minimize potential effects to fish and marine mammals from higher-intensity sound waves in the water column. Construction activities would occur during the ODFW-approved in-water work window, when sensitive life stages of listed fish are less abundant in the bay, which would further minimize the potential for adverse impacts. Approximately 1,150 untreated timber piles would be installed within a sheetpile cofferdam at the Trans Pacific Parkway/US-101 Intersection Widening to provide subgrade stabilization. The untreated wood piles are approximately 30 feet long and have a 14-inch diameter at the top. The sheetpile cofferdam would likely be installed with a vibratory hammer. If an impact hammer is used, the sheetpile cofferdam would be installed when the work area is not tidally inundated.

Underwater noise may be generated by driving piles on land (dry piles) since some noise propagates through ground and sediments (especially through harder substrates such as rock and clay) and may transfer to the water column somewhere else (known as sound flanking). The propagation of underwater construction noise from the "dry" land based impact pile driving associated with the MOF was modeled in several reports prepared by JASCO Applied Sciences (O'Neill and MacGillivray 2017; Wladichuk et al. 2017; Wladichuk et al. 2018). Wladichuk et al. (2018) modeled potential impacts of land-based pipe pile driving on fish using both current guidelines (FHWG 2008) and new proposed guidelines (Popper et al. 2014). This study found that injury to fish from peak sound pressure levels (206 dB in current guidelines) would occur up to 37 meters from the face of the MOF. Also, this study predicted that injury to both small (less than 2 grams) and large (greater than or equal to 2 grams) fish from cumulative sound exposure levels (183 and 187 dB respectively under current guidelines) would occur up to 1,723 meters from the shoreline. Section 3.5 describes the potential effects and Figure 3.5.1-2 shows the modeled extent of this potential zone of injury in the analysis area from land-based pile driving at the MOF face.

Existing information suggests that fish are unlikely to be adversely affected by airborne noise levels. It is expected that the threshold for disturbance to pinnipeds would be airborne noise greater than 100 decibels (dB) root mean squared. JCEP estimated that sound levels greater than 65 dB would extend less than 0.25 mile from pile-driving operations. Therefore, it is unlikely that sound levels of 100 dB root mean squared or greater in air would be experienced within 300 feet of the piles at the LNG Terminal site There would be underwater noise associated with dredging activities in Coos Bay, which may generate sound pressure levels that could elicit responses in aquatic organisms. However, sound pressure levels in the range of 112 to 160 dB would probably not be great enough to cause physiological damage to aquatic species (Richardson 1995; Hastings and Popper 2005; Fisheries Hydroacoustic Working Group 2008).

Construction of Kentuck Project and Eelgrass Mitigation

JCEP would undertake a number of measures designed to mitigate the potential construction and operation impacts on fisheries and aquatic resources, as described in this APDBA. In addition, restoration activities at the Kentuck Project and at the Eelgrass Mitigation site would offset the permanent loss of intertidal, subtidal, salt marsh, and eelgrass habitat resulting from construction of the slip and access channel. During operation of the LNG Terminal, mitigation measures would be incorporated at the LNG Terminal site to minimize the potential for discharge of pollutants or hazardous materials into the bay. Additional mitigation procedures would be implemented to ensure that LNG carriers do not adversely impact marine organisms either through direct mortality or through the introduction of exotic marine species.

There would be short-term localized impacts to aquatic resources to construct the Kentuck Project and Eelgrass Mitigation. Kentuck Project construction activities include transporting dredged material into the site, earthwork, and civil infrastructure improvements to re-establish a connection with Kentuck Inlet and Coos Bay. Dredged material is currently proposed to be unloaded and hydraulically transported into the site through a Temporary Dredge Transfer Line from a Temporary Dredge Off-Loading Area located as close as possible to the site in a minimum 20 feet of water depth. The off-loading area could include a hydraulic unloader on a deck barge, mooring/fleeting barges, and booster pump(s). The hydraulic unloader would operate from a deck barge up to 40 feet by 100 feet in size. Two flat deck mooring/fleeting barges (measuring 40± feet by 160± feet) would be moored adjacent to the unloader barge. Approximately 16 temporary piles and/or spuds 24 inches in diameter would be used to moor the barges, depending on actual equipment and configuration. Intake water for offloading operations may be drawn through self-cleaning fish screens sized to minimize fish entrapment. Infrastructure improvements include: constructing a new bridge in East Bay Drive to allow tidal exchange between Kentuck Inlet and the Kentuck Project; improving the existing dike separating the site from Kentuck Slough; constructing a new muted tidal regulator (i.e., a “fish-friendly” tidegate) in the upper portion of the Kentuck Project to redirect a portion of Kentuck Slough flows into the Kentuck Project; and raising the profile of East Bay Drive and approximately 1,900 lineal feet of Golf Course Lane to be above the zone of tidal influence. A fish-friendly culvert or other structure would be constructed within Golf Course Lane to allow passage into the drainage above the former golf course irrigation sump pond. The earthwork and the majority of the infrastructure construction activities would be isolated from Kentuck Slough, Kentuck Inlet, and Coos Bay. Construction of the East Bay Drive bridge and muted tidal regulator would require in-water work and isolation measures. There would be a short-term increase in turbidity into Kentuck Inlet and Coos Bay when the connection is re-established to the bay and while the site equilibrates.

As part of the Eelgrass Mitigation, a shallow-water hydraulic dredge is proposed to be used to lower areas that are currently too shallow to support eelgrass. A Temporary Dredge Line would connect the dredge and Temporary Dredge Loading Area, which would be located as close to the site as possible in a minimum 20 foot of water depth. The loading area is proposed to include deck barge, transport barges/scows, and tugboats. As noted above, the number of temporary mooring pile and/or spuds would depend on equipment and configuration. The containment system on the scows and/or barges will minimize the release of turbid decant water back into the bay. If determined feasible, silt curtains at the dredge site also could be deployed to limit the dispersion of turbid waters to the local embayment as the bathymetry is modified to make it more suitable for eelgrass transplants the following year. Construction would occur during the ODFW in-water work window. Construction of the mitigation site would likely result in direct mortality of marine organisms and would temporarily elevate turbidity levels from dredging, as discussed in JCEP Resource Report 3 – Fish, Wildlife, and Vegetation, Section 3.1.4.1, Direct Mortality of Marine Organisms, and Section 3.1.4.3, Sedimentation and Turbidity Levels. The resulting habitat increase from the Eelgrass Mitigation site would provide benefits to the fish and marine organisms that utilize this habitat overall by increasing the natural cover and forage production in Coos Bay.

2.1.1.4 Impacts on Aquatic Resources Related to Operations

This section provides a general overview of the potential operation related impacts on aquatic resources. Species specific impact analysis is included in section 3.0 Species Accounts, Critical Habitat, Project Effects and Determinations of Effect and in section 4.0 Essential Fish Habitat.

Operation of the marine facilities at the LNG Terminal could affect water quality and aquatic species in several ways. Tugboats and LNG carriers could stir up bottom sediments during docking operations in the access channel and slip. While an LNG carrier is at dock, it would release ballast water while taking on cargo that could affect the salinity and dissolved oxygen levels in the slip, or introduce invasive non-native species. In addition, the recirculation of water for engine cooling while an LNG carrier is at dock could affect the temperature of the water in the slip. Also, water intake might result in impingement or entrainment of aquatic species.

LNG Carrier Transit in the Channel – Operations

LNG carrier transits in the FNC could cause shoreline erosion that might result in adding sedimentation and increasing turbidity in the bay. Likewise, LNG carriers, tugboats, and escort boats could have propeller wash that could stir up bottom sediments. Erosion, sedimentation, and turbity could adversely effect water quality and impact aquatic species in Coos Bay. Vessel wake waves could also result in fish strandings along the shoreline. These potential impacts are discussed below. JCEP conducted studies that show that LNG carriers are not likely to cause major shoreline erosion, that propeller wash would not result in major bottom erosion and turbidity, and that vessels traveling at slow speeds would not produce waves large enough to strand fish. More details about the studies these conclusions are based on may be found in appendix I.2 of JCEP's Resource Report 2.

Shoreline Erosion

The potential for LNG carrier traffic in the waterway to cause shoreline erosion was evaluated. If there was significant shoreline erosion along the navigation channel, this could result in a rise in sedimentation and turbidity in Coos Bay, which could have an effect on aquatic resources.

The possible impacts on the shoreline along the navigation channel from the pressure fields generated by passing deep-draft cargo ships and LNG vessels were analyzed at selected areas of interest along the route, namely, Pigeon Point, Clam Island, and the airport. A complete description of the modeling was attached as appendix I.2 in Resource Report 2 of JCEP's September 2017 application to the FERC (CHE 2011). The results of the analysis indicate that hydrodynamic effects from pressure field velocities along the shoreline caused by deep-draft cargo ships currently using the Port would exceed the pressure field velocities that may be generated by future LNG vessels. In short, LNG vessels transiting the waterway to and from the LNG Terminal would not cause serious shoreline erosion.

CHE (2011) also studied the potential impacts on the shoreline caused by wakes of LNG vessels in the waterway by comparing swash sediment transport for Post-Project Conditions relative to Existing Conditions. The results show that the increase in swash sediment transport from combined inbound and outbound LNG vessel marine traffic would not exceed six percent at Pigeon Point, eight percent at Clam Island, and five percent at the airport sensitive shorelines. The estimated increase in swash sediment transport due to the LNG carrier traffic is a small fraction of the swash sediment transport due to the natural wind-wave conditions. This means that waves generated by LNG vessels transiting in the waterway to and from the LNG Terminal would not be much larger than waves caused by natural wind, and would not result in significantly more sedimentation than existing conditions.

A vessel wake impacts study by Moffatt & Nichol (2017d) modeled wake impacts from three types of vessel (tug, bulk carrier, and LNG carrier), using a range of vessel sizes and speeds, and reached generally similar conclusions to those discussed above for the CHE (2011) report. Moffatt & Nichol (2017d) concluded that the LNG Terminal project will not result in significant increases in shoreline effects due to larger vessels transiting the channel, and that wave heights at the shoreline would be lower relative to existing conditions. The Moffatt & Nichol (2017d) study also found that wakes generated by outbound tugs traveling alone at a maximum speed of 10 knots could generate shoreline waves ranging from 0.6-0.8 feet in height which would be at the low end of the locally generated wind wave heights that range from 0.5 to 3 feet. Such wave heights generated by the tugs would only expose shorelines to waves a fraction of the time and at the low end of the range of those caused by locally generated wind waves (Moffatt & Nichol 2017d).

Propeller Wash

The possible impacts on the bottom of the navigation channel from propeller wash (propwash) due to LNG vessels transiting to and from the LNG Terminal was investigated by CHE (2011) using a model called "JETWASH." The turbulent force that might be experienced at the channel bottom and suspension of bottom sediment by the LNG vessel motion and propwash would be additional to the turbulence and sediment suspension caused by the deep-draft cargo ships that currently navigate the channel. Displacement of bottom material by fluid forces without replacement by deposition is defined as bottom scour. Propwash of tugs moving with the LNG vessel was not included in this analysis because the tugboats would operate at low power, and the tugboat's propeller diameter is less than a third the diameter of the LNG vessel's propeller. Further, the vertical distance between the tugboat propeller tip and the bottom is so large (about 35 feet) that tugboat effects on the channel bottom in this operation would be unsubstantial.

Bottom sediment may be disturbed by flow created by the hull passing over the bottom. The potential exists for sediment suspended from the bottom of the navigation channel to be dispersed in the flow laterally outside the channel limits to the areas that may have habitat value. Suspended material falling back to the bottom within the navigation channel limits may be disturbed or dredged at some future time. The relative amount dispersed beyond the navigation channel limits, compared to that returning to the bottom within the channel, is a measure of the physical impact by propwash on the channel bottom.

The potential increase in bottom scour was analyzed by comparing the effects of a 148,000 m^3 capacity LNG vessel with the effects caused by a typical deep-draft cargo ship that currently transit the navigation channel. The comparison of vessel effects is based on vessel propwash bottom sediment scour, suspension, and dispersal by each of the two vessel types, along with their respective proportions of re-deposition of sediment outside the limits of the 300-foot-wide navigation channel.

Analysis of propwash modeling results showed that no bottom scour outside of the navigation channel boundaries would occur during passage of the LNG vessel. The modeling results also showed that a greater level of turbulence, and thus suspended sediment dispersion, would occur in the transit of a typical bulk carrier than with an LNG vessel. Near bottom velocity created by passage of the bulk carrier is greater than that of the LNG vessel for the design conditions of tide level and vessel speed and draft. It is expected that propwash from LNG vessels, tugboats, and escort boats in the Coos Bay navigation channel would not result in major erosion of the bottom and sides of the channel, nor cause turbulence or increased suspended sediments that could significantly affect aquatic species.

Fish Stranding

Fish stranding can occur when fish become caught in a vessel's wake and are deposited on shore by the wave generated by the vessel wake. Stranding typically results in mortality unless another wave carries the fish back into the water. A series of interlinked factors act together to produce stranding during vessel traffic and may include water surface elevations, with low tides more likely to result in strandings than high tide; beach slope, with strandings more likely on low gradients than high; wake characteristics influenced by vessel size, hull form, depth underwater (draught), and speed; and biological factors, such as numbers of small fish present near the shoreline and whether fish are strong swimmers or not.

Ship wakes produced by deep-draft vessels traveling at speeds greater than the estimates for LNG vessel speeds have been observed to cause occasional stranding of juvenile salmon (Pearson et al. 2006); however, no strandings were observed as a result of vessels traveling at speeds under nine knots (10.4 miles per hour [mph]). The hull geometry of the LNG carriers is such that bow wakes are minimized, especially at the slower speeds of four to six knots that would occur during most of the transit route through Coos Bay. Therefore, the LNG vessels would be traveling at speeds less than that observed to cause stranding. In models and research conducted by JCEP (Moffatt & Nichol 2008b), wave heights produced by LNG vessel traffic would not exceed that of normal conditions in Coos Bay and overall waves would contribute to a small portion of the total waves that occur in the bay. This conclusion is supported by the results of vessel wake impacts modeling performed by Moffatt & Nichol in 2017 (Moffatt & Nichol 2017d). In addition, LNG vessels would be arriving and leaving at slack high tide, which is a period when gently sloping beaches are mostly covered and less likely dewatered from waves. Considering that LNG vessel marine traffic would enter and leave at slack high tide, have low vessel speeds, and wave height would be in normal range, it appears unlikely that the LNG Terminal Project would contribute to fish stranding within Coos Bay.

Marine Facilities Operations

LNG vessels, tug boats, and escort boats could have propeller wash that may stir up bottom sediments. Erosion, sedimentation, and turbity could adversely effect water quality, and impact aquatic species in Coos Bay. The LNG Terminal would be visited by about 120 LNG carriers per year. JCEP conducted studies that show that LNG vessels are not likely to cause major shoreline erosion (Moffatt & Nichol 2017d), that propeller wash would not result in major bottom erosion and turbidity (Moffatt & Nichol 2017e), and that vessels traveling at slow speeds would not produce waves large enough to strand fish (Moffatt & Nichol 2017d). More details about the studies these conclusions are based on may be found in the FERC certificate application.

Propeller Wash within the Marine Slip

Tugboats docking LNG vessels at the LNG Terminal may cause erosion on the slopes and bottom of the access channel and slip, due to propeller wash (propwash). Three tugboats may apply up to 75 percent of their available power for up to 60 seconds while pushing an LNG vessel backwards into the slip. It is assumed that docking would occur at a tide elevation not lower than 4 feet above MLLW. Tugboats are assumed to have 6,500 rated hp, powered by twin azimuth drives. Using the JETWASH model, it was determined that the location of maximum near-bottom velocity of 2.0 feet per second (ft/sec) is on the slip bottom, about 30 feet from the toe of the side slope. The west slope of the slip would not be subject to propwash erosion if the size of material present on the bottom and on the side slope is larger than medium sand. In this case, propwash would have no scouring effect on the armored material placed on the side slope. Analysis indicated that bottom surface sediments may be eroded during design extreme events; however, materials larger than the 96 percent finer size would not be suspended. Using a conservative approach, maximum depth of scour was estimated to be less than 2 inches at a propwash velocity of 2.16 ft/sec. This is not expected to be a significant impact on bottom stability or water quality, as mobilized materials would not be distributed far from where the scour occurs (CHE 2011).

The propwash analysis work by CHE (2011) was based on only tugs used for the berthing and unberthing of an LNG vessel. Therefore, Moffatt & Nichol (2017e) analyzed potential impacts of propwash from vessels and tugs on shoaling and scour in the Access Channel and MOF areas. The primary exposure of the Slip, Access Channel, and MOF to propwash is during berthing and unberthing of vessels calling at the LNG Terminal. Additionally, the Access Channel, Slip, and the MOF are exposed to propwash during vessel arrivals and departures.

In order to calculate the velocity fields created by vessel and tug propellers, the guidance in the Permanent International Association of Navigation Congress (PIANC 2015) was adopted. PIANC provides several methods to estimate the velocity field associated with propeller wash. Moffatt & Nichol (2017e) chose a method that considers the effect of restricted jet propagation for lateral quay walls, which is applicable to the Slip and Access Channel in the area of the MOF. Analysis of propwash modeling based on the use of ship engines and tug assist for berthing and unberthing estimated bottom velocities that were significantly larger during unberthing when main vessel engines were in operation. The largest bottom velocities (13.6 ft/sec) were estimated to occur on the eastern side of the Access Channel and Slip near the MOF. Estimated scour depths were up to nearly 0.5 feet due to propeller wash in the Access Channel and the Slip near the eastern side of the Access Channel and the slip if no slope protection is installed. However, as discussed above in section 2.1.1.2 Slope Armoring, slope armoring or pile embedment would be designed to minimize scour. During berthing, the largest bottom velocities (5.4 ft/sec) are expected to be near the western slope (Moffatt & Nichol 2017e). Propwash erosion is not anticipated along the western sheetpile wall (Lay Berth) and no additional slope protection is planned beyond the sheetpile wall.

Ballast Water Releases

An LNG vessel at dock at the LNG Terminal would release ballast water while taking on cargo. It is estimated that a 148,000 m^3 capacity vessel would release about 9.2 million gallons of ballast water, at a rate of approximately 20,250 gpm. Ballast water would be discharged into the slip through sea chests located on the hull of the vessel about -33 feet below the water line or about 12 feet from the bottom.

LNG carriers would take on ballast water from the open ocean at least 200 miles offshore. While ballast water would have a physio-chemical composition very similar to waters in Coos Bay, a potentially notable difference between ocean water and bay water may be observed relative to salinity. Ocean seawater on average has a salinity of about 35 parts per thousand (ppt). This means that every liter of seawater has approximately 35 grams of dissolved salts. Coos Bay is an inland estuary, where salty seawater mixes with inflows of upland fresh water, with the transition zone between CM 8 and 9, near the LNG Terminal (Roye 1979). Salinity in the bay varies with tides, season, and water levels. When measured over a three year period (1960-1963) at the US-101 bridge (CM 10), salinity ranged from 4 to 35 ppt (McAlister and Blanton 1963). Using more recent measurements near the LNG Terminal (CM 7.5) between August 2009 and December 2010, Shanks et al. (2011) found salinity levels varied between 15 and 35 ppt.

Another physio-chemical water quality parameter that may be influenced by the introduction of ballast water is the dissolved oxygen level. Dissolved oxygen levels are a critical component for the respiration of aquatic marine organisms. Among many other factors, dissolved oxygen levels in water can be influenced by water temperature, water depth, phytoplankton, wind, and current. Typical water column profiles indicate a decrease in dissolved oxygen with an increase in depth. Roye (1979) indicated that below CM 13, dissolved oxygen levels in Coos Bay are rarely below the ODEQ standard of 6 mg/l.

Water within the ballast tanks of a ship could have suppressed dissolved oxygen levels. While ballast water is not expected to be anoxic (i.e., lacking all oxygen), it would be lower than levels would likely be at the surface of the slip. This is because the water is contained in the ballast of the ship without exposure to sunlight or mixing from wind, waves, and currents. In addition, ambient waters near the bottom of the slip will naturally have lower dissolved oxygen levels than waters near the surface although they will be subject to mixing caused by tidal currents, LNG carriers, and tug traffic while berthing and unberthing at the terminal.

Because the slip will be located adjacent to the Coos Bay federal navigation channel, tidal mixing will tend to affect any localized temporary changes in dissolved oxygen levels in the Slip that may result from ballast water exchanges of the LNG carriers. Also, and perhaps more significantly, propeller wash from tugs and LNG carriers traveling within the slip will generate water velocities up to 13.2 feet/sec near the bottom causing substantial mixing of local waters (Moffatt & Nichol 2017e). Therefore, potential impacts on local marine species from the exchange of open ocean ballast water with potentially suppressed dissolved oxygen levels in the slip are expected to be discountable. Discharge of ballast water at the LNG terminal also will be subject to Oregon Administrative Rule 340-041-0016 to assure compliance with dissolved oxygen standards.

Water temperatures and pH are not likely to be altered as a result of introducing ballast water. Because ballast water is stored in the ship's hull below the waterline, water temperatures are not expected to deviate much from ambient temperatures of the surrounding seawater. The pH of the ballast water (reflective of open ocean conditions) may be slightly higher as compared to that of freshwater estuaries. However, this slight variation is not expected to have any impacts on marine organisms.

The release of ballast water from an LNG vessel at dock at the LNG Terminal would probably not have significant adverse effects on aquatic species in the bay due to slight changes in salinity, dissolved oxygen, and water temperature. This is because of the larger volume of water in the slip, and tidal mixing. The slip, exclusive of the access channel, would create approximately 50 million cubic feet of additional water volume from land that is currently upland, that could contain 374 million gallons of water. Roye (1979) indicated that the average annual discharge of fresh water from Coos Bay was 2.2 million acre-feet. Shanks et al. (2011) estimated that 122.5 million m^3 of water passes by the LNG Terminal in the bay during one complete high and low tidal cycle. Tidal ranges have been measured between 3.3 and 7.9 feet, with tidal currents between 3.4 ft/sec to 8.4 ft/sec; and flushing would be greatest during the spring rainy season. The discharge of 9.2 million gallons of ballast water from a 148,000 m^3 capacity LNG vessel would represent 2.4 percent of the volume of the slip, and an infinitesimal percent in comparison to the total volume of water in Coos Bay which exceeds 1.6 million acre-feet.

An environmental concern associated with the release of ballast water by LNG vessels at the LNG Terminal is the risk of introducing exotic non-native species from foreign ocean waters into the Coos Bay estuary ecosystem. The transfer of water from port to port could result in aquatic biological invasions. While some of the larger macro-organisms that may be collected during ballast water intake will often die, some of the smaller planktonic organisms could survive. Invasive species threaten to outcompete and exclude native species, resulting in a decline in biodiversity. The ballast water discharged by LNG vessels at the LNG Terminal would be from the ocean exchange occurring at least 200 miles offshore; not from a distant foreign port. The FERC would have no authority over LNG vessels, which would be owned and operated by independent third parties. However, JCEP would have agreements with the LNG vessel operators. The LNG vessel operators would have to follow federal laws and regulations regarding the prevention of invasive species through the release of ballast water, including the National Invasive Species Act, Nonindigenous Aquatic Nuisance Prevention and Control Act, National Aquatic Invasive Species Act, National Ballast Water Management Program, Shipboard Technology Evaluation Program, and Navigation and Vessel Inspection Circular 07-04, Change 1. In 2013, EPA developed specific measures for ballast water treatment, under the Vessel General Permit requirements of the NPDES permitting program under Section 402 of the CWA, to reduce the chance of releasing invasive organisms in U.S. waters.

Engine Cooling Water Recirculation

LNG carriers would need to recirculate water while loading LNG at the berth. The amount of cooling water to be recirculated is a function of the ships' propulsion systems. A steam propulsion LNG vessel typical cooling water flow rates while at the berth are expected to be approximately 11,000 m^3/hr) (2.9 million gallons per hour or 48,430 gpm). For a 148,000 m^3 ship, cooling water flows would total approximately 69.7 million gallons during the 24-hour loading of LNG cargo. If a dual fuel diesel electric propulsion system (160,000 – 170,000 m^3 ship) were used, the typical cooling water flow rates are expected to be approximately 3,200 m^3/hr (845,376 gallons per hour or approximately 14,000 gpm) for a total amount of approximately 22 million gallons of cooling water recirculated to the slip over a 26-hour loading cycle of LNG cargo . Initial estimates are that 40% of the LNG vessels loading at the terminal would be steam propulsion and 60% would be dual fuel diesel electric propulsion. Over time, the trend is anticipated to shift to a greater number of dual fuel diesel electric propulsion LNG vessels, thereby reducing the total cooling water intake per vessel call in the future. Once the

LNG fleet has been identified, cooling water flow rates and the amount of water required can be further addressed. Generally, the total water intake would occur over a 24-hour period during each loading period, about 110 to 120 times per year.

A typical LNG vessel has an upper and a lower sea chest on each side of the hull, to allow for the intake and release of ballast and engine cooling water. The lower unit is just above the keel of the ship, approximately 15 to 20 feet above the channel bottom. A sea chest is approximately 3.5 to 4.2 square meters (37.7 to 45.2 square feet) covered by a screen with 4.5 millimeter (mm; 0.18 inch) bars, spaced every 24 mm (0.94 inch). Additional finer mesh screens are located internally on the vessels to prevent larger items from entering the system. These screens would not meet NMFS (1997a) screening criteria for juvenile salmonids. It is likely that some marine organisms that are small enough to pass through the screens covering the sea chests would be drawn in with the cooling water and would be lost from the population in the slip (see section 3.5.4.3 Entrainment of Food Organisms).

LNG vessels at berth at the LNG Terminal have the potential to both warm the temperature of the marine slip while discharging engine cooling water, and to cool the temperature of the marine slip while loading LNG cargo. Water temperatures in Coos Bay have seasonal and diurnal fluctuations influenced by fresh water inflow and tidal currents. Roye (1979) indicated that bay temperatures at CM 8 ranged between about 50 and 65 degrees Fahrenheit (°F), while Shanks at al. (2011), near the same location, recently recorded bay water temperatures varying between 6 and 17 degrees Celsius (°C; 42.8 to 62.6°F), with lows in the winter and highs in summer. Moderate to large temperature increases have the potential to reduce fish and invertebrate growth, reproductive success, and if high enough can cause mortality. Studies have shown that water temperatures over about 24°C (75.2°F) would be considered lethal in the short term (a few days) for salmonids (WDOE 2002).

When an LNG vessel at the LNG Terminal puts water back into the slip after using the water to cool its engines, that released water would be slightly warmer than the temperature of the original slip water. Modeling conducted by JCEP estimated that the discharged engine cooling water would not exceed 0.3°C (0.54°F) above the ambient water temperature in the slip at a distance of 50 feet from the sea chests. Based on the volume of the slip at 4.8 mcy (3.7 million m^3 or 977.4 million gallons), the average water increase for the total slip volume during one day when an LNG vessel is at dock would range from 0.03 to 0.06°F The results of the CHE (2011) modeling were supplemented in 2017 (Moffatt & Nichol) with additional thermal plume modeling to investigate the extent of the regulatory mixing zone (RMZ) where cooling water discharge will be greater than 0.3 °C above ambient (Moffatt & Nichol 2017g). The RMZ used in the temperature plume modeling is defined as the three-dimensional extent where water quality standards may be exceeded as long as acutely toxic conditions are prevented and fish habitat and other uses are protected. This modeling analyzed LNG carriers with capacity of 148,000 m^3 and 170,000 m^3. It also modeled cooling water discharges of 10 to nearly 21 degrees C into various ambient temperatures ranging from 8 to 18 degrees C and under constant and stratified salinity conditions.

In summary, this latest modeling showed that the largest RMZ was associated with steam-driven carriers and extended up to 79.2 feet and 22.1 feet in longitudinal and transverse directions respectively, with a vertical rise of 12.1 feet under peak summer temperature conditions. Dual fuel diesel-electric driven carriers had a substantially smaller RMZ that extended up to 36.5 feet and less than 7 feet in longitudinal and transverse directions, respectively, with a vertical rise of up to 1.3 feet. In the future, LNG vessels will trend more to Dual Fuel Diesel Electric propulsion systems thereby reducing the total cooling water intake per vessel call (Moffatt & Nichol 2017g). It is unlikely that the water temperature of the slip would be greatly increased from the release of engine cooling water, therefore, no significant adverse impacts on aquatic species in the bay are anticipated.

Upland Facilities Operations and Maintenance

There are multiple ways in which the operation of the LNG Terminal facilities could have impacts on species. The accidental leakage or spills of hazardous materials or fluids into soils or waterbodies could expose species to those hazardous materials. Stormwater runoff could cause erosion or contain hazardous fluids. Erosion might result in increased sedimentation or turbidity, and hazardous fluids running off-site into waterbodies could affect aquatic species. Terminal lighting could affect the behavior of aquatic species in the slip. However, as discussed below, JCEP would implement measures to prevent, reduce, or mitigate impacts on species from operation of the LNG Terminal.

Leaks or Spills

The most likely source of hazardous liquids that may spill or leak during operation of the LNG Terminal that would have the potential to contaminate soils or surface water, include oil, gasoline, fuel, lubricants, or coolant from equipment or facilities. Because of the design of the LNG Terminal, it is highly unlikely that there would be a spill or release of LNG. Within the LNG Terminal would be a system of curbs, drains, and basin that would collect LNG if any spilled or leaked. JCEP prepared a draft Emergency Response Plan (as discussed in JCEP Resource Report 13) for the operational phase of the LNG Terminal that is intended to minimize the potential for accidental releases of hazardous materials and to establish proper protocol concerning minimization, containment, remediation, and reporting of any releases that might occur. If LNG spilled or leaked, it would turn to vapor when exposed to the warmer atmosphere, and these vapors would rise because they are lighter than air. LNG is not soluble and would not mix with or contaminate water or soils.

To minimize or reduce the impacts of spills or leaks associated with fuel storage, equipment refueling, equipment maintenance, or facilities operations, JCEP prepared an Operation-phase SPCCP to describe the preventive measures that would be implemented to avoid spills and leaks, as well as the mitigation measures utilized to minimize potential effects should a spill or leak occur. JCEP Resource Report 2 – Water Use and Quality contains further information regarding the SPCCP.

Stormwater Runoff

LNG Terminal. A stormwater management plan has been prepared to address stormwater system design, which will require approval from ODEQ (see Storm Water Management Plan in an appendix to JCEP Resource Report 2 – Water Use and Quality). Impervious surfaces associated with the LNG Terminal site include concrete at operational laydown areas, vehicle offloading areas, secondary containment areas, and working areas for operational maintenance. General surfacing in other areas where operational maintenance access would potentially be required would be dense-graded aggregate. In the areas of the Administration building and the SORSC building, finished surfacing would be asphalt for the parking lots and concrete for the helipad. The gas metering station would be surfaced with dense-graded aggregate. Runoff would be separated into either the stormwater system or the oily waste system. Stormwater with a high potential to encounter oil and grease pollution would be contained via curbs or other means and routed to an oil/water separator prior to disposal through the IWWP according to the applicable NPDES permit requirements. For areas of the site where stormwater has a low potential to encounter oil and grease pollution, the first flush of stormwater would be treated on-site by either infiltration facilities, flow-through type cartridge filter devices, or vegetated filter strips. Infiltration facilities would provide treatment for the majority of the stormwater falling on the site and would be treated to meet applicable regulatory discharge criteria. The infiltration facilities would be designed to capture and infiltrate all stormwater for 100 percent of the 2-year, 24-hour storm. Overflows from the infiltration facilities would be routed to pipe outfalls in the slip and Coos Bay. For some locations that are not feasible to infiltrate, stormwater would be routed to cartridge filter devices, where the treated effluent would be discharged to Coos Bay. Other locations will flow through filter strips. Stormwater from access roads to the site would flow through filter strips or swales for treatment before being discharged to natural grade.

Industrial wastewater would be conveyed to the existing IWWP ocean outfall, pursuant to the NPDES permit issued by ODEQ. Stormwater collection and treatment facilities would be designed in consultation with NMFS and the ODEQ. Stormwater discharges are regulated under Section 402 of the Clean Water Act and by Oregon Administrative Rules that describe policies, criteria, and standards for the protection of water quality and designated beneficial uses including those that assure suitable habitats are maintained for aquatic and other wildlife species. Discharges to the ocean from this stormwater outfall will be monitored to assure compliance with these requirements.

Trans Pacific Parkway/US-101 Intersection Widening. Stormwater generated as a result of new impervious area at the Trans Pacific Parkway/US-101 Intersection Widening would be collected and conveyed to treatment facilities to provide treatment for 100 percent of the 2-year storm event. Drainage curbs would be installed near the edge of pavement along the northwest side of the roadway. These drainage curbs would collect and convey flow from the road crown to water quality treatment facilities consisting of cartridge filtration systems. The proposed flow through cartridge filter type devices, will be designed and installed to meet applicable regulatory criteria, for example, criteria established by the Washington Department of Ecology and Oregon Department of Transportation standards for water quality treatment. The water quality facilities would provide treatment for the design flow volume and bypass higher flows before discharging the runoff into Coos Bay.

Kentuck Project Site. Roadway improvements associated with the Kentuck Project, which include elevating and repaving of East Bay Drive and Golf Course Lane, would result in the addition of new impervious area. The stormwater facilities at the Kentuck Project site would be designed to provide treatment for 100 percent of the 2-year storm event wherever feasible.

East Bay Drive would sheet flow stormwater runoff to roadside drainage curbs. Once along the curb, water would flow toward the low point of the roadway. Water quality treatment facilities would be installed to capture and treat the runoff. The water quality facilities would treat water and bypass higher design flows before discharging the runoff onto riprap road base adjacent to the receiving waters in Kentuck Inlet.

Along most of Golf Course Lane, surface water ditches and flow-through bio-infiltration conveyance systems are proposed. In these areas, collected flow that does not fully infiltrate into the underlying well-draining soils would be conveyed to an outfall into the Kentuck Slough. At the north end of Golf Course Road, runoff would be collected in drainage curbs and conveyed to flow-through water quality treatment systems before discharging to Kentuck Slough.

Lighting

Only lighting required for operation and maintenance, safety, and security, and meeting Federal Aviation Administration requirements would be used on the LNG storage tanks. Lighting would be localized to minimize off-site effects. When an LNG carrier is not in the berth, the lighting around the slip would be reduced to that required for security. The lighting levels would be based on American Petroleum Institute (API) standards. Lighting around equipment and facilities where routine maintenance activities could occur on a 24-hour basis would range from 1 to 20 foot-candles. General process area lighting would be kept to a minimum, on the order of 2 foot-candles. The lighting along the Access and Utility Corridor would be 0.4 foot-candle. Perimeter security would be on the order of 1.3 foot-candles, using evenly spaced 400-watt floodlights. As a point of reference, 20 foot-candles is close to the indoor lighting in a typical home, 2 foot-candles is typical of that found in a store parking lot, and 0.4 foot-candle is typical of residential street lighting.

The use of low-intensity lighting would minimize adverse effects on wildlife. Before construction of the LNG Terminal, JCEP would develop its final lighting plan in consultation with appropriate resource agencies, and it would include measures that would reduce impacts on wildlife.

Localized changes in light regime have been shown to affect the behavior of fish species in a variety of ways (Simenstad et al. 1999; Valdimarsson et al. 1997; Tabor et al. 2004; Nightingale and Simenstad 2001). Disorientation may cause delays in migration, while avoidance responses may cause diversion of migratory routes into deeper, less protected waters. In some cases, increased light may attract both predators and potential prey species.

Nighttime construction is likely to occur in the estuarine analysis area for in-water work activities such as dredging or placing revetment, as well as on-water activities such as receiving deliveries at the TMBB or MOF. Construction lighting would be designed, installed, and operated at a level that allows construction work to be completed safely and effectively while minimizing glare to surrounding areas. Construction lighting would be directed only to the surface waters of Coos Bay when necessary, in order to minimize impacts to aquatic organisms. Lighting for in-water work would be limited to the area around each vessel and the area of the in-water work. For example, during dredging, the area under the crane boom for clamshell dredging or derrick arm for cutter-suction dredging would be lit. Lighting is anticipated to be a mix of fluorescent and sodium fixtures around the vessels (dredge, barges, tugs, and support vessels) with larger sodium or halogen lights shining on the work area (i.e., the water) under the crane boom or derrick of the suction dredge. Lighting for on-water work, such as barge or ship unloading, would be limited to the vessels and adjacent landing areas. Final marine construction lighting requirements would be developed in consultation with appropriate resource agencies, and it would include measures that would reduce impacts on aquatic resources.

When an LNG carrier is not at the berth, the lighting would be reduced to that required for safety and security. It would be focused upon the structures and not be in proximity to the water so that it would serve as an attractant or deterrent to fish species. When an LNG carrier is at the berth, it would physically block the lighting on the berth from the slip waters and, due to its proximity to the slip wall, would block the fish from getting too close to the lighting on the berth. Lighting used at the LNG Terminal would be similar to that already in place at other Coos Bay facilities.

Lighting on the tug dock would be low-intensity lighting for safety that would provide sufficient light for personnel movements on the trestle out to the tug berth and for movement on the berth itself. There is no intention to provide lighting near the water line or high-intensity lighting that would be associated with activities other than the simple berthing of the tugs at this location. The reduced lighting levels near the water would reduce or eliminate any behavioral effects to fish at the LNG Terminal site. The final details of the lighting arrangement would be determined in consultation with NMFS, USCG, and with other resource agencies to reduce these potential adverse effects.

Strikes on Standing Structures within the LNG Terminal

During operation, bats and birds would be at risk of colliding with LNG Terminal facilities. The top of the dome of each LNG storage tank would be about 219 feet above grade Some of the facilities would be lit at night, which could attract bats and birds. There is some evidence that high-intensity continuous anti-collision lights on structures may result in an increased number of bird strikes, especially at night or during fog and overcast conditions. The number of strikes can apparently be reduced by strobing or blinking the anti-collision lights. The LNG storage tanks would not be illuminated with high-intensity lighting. The intensity and number of lights would be limited to what is required for security and operations.

Terminal Operational Noise

The predicted operational noise from the LNG Terminal would have an equivalent sound level (L_{eq}) of 45 decibels on an A-weighted scale (dBA) and day-night sound level (L_{dn}) of 51 dBA when measured about 1.3 miles away. This compares to current ambient L_{dn} noise levels of about 47.4 to 51.6 dBA in the city of North Bend, just southwest of the airport (see JCEP Resource Report 9). Because there is existing noise generated by other industrial facilities on the North Spit, and noise from the LNG Terminal would be less than the FERC standard of 55 dBA at NSAs, the operational noise from the LNG Terminal would not significantly affect any listed species.

2.1.2 Pipeline and Associated Facilities

PCGP proposes to construct and operate a pipeline that will extend approximately 229 miles[3], starting from an interconnection with the existing interstate pipeline systems of Ruby Pipeline LLC (Ruby) and Gas Transmission Northwest LLC (GTN) near Malin in Klamath County, Oregon, and extending to the LNG Terminal in Coos County, Oregon (see figure 2.1.2-1 and appendix A). The Pipeline would be 36 inches in diameter and is designed to transport up to

[3] Total pipeline length is 229.09 miles. However, PCGP retained its original design mileposting and accounted for realignments using equations. Therefore, although the gas would flow east to west, the mileposting is reversed, with the Klamath Compressor Station at MP 228.8 and the Jordan Cove delivery meter station at MP 0.00.

General Location

Aboveground facilities required for the Pipeline would include the 62,200 horsepower Klamath Compressor Station at the eastern beginning of the pipeline at milepost (MP) 228.8. Within the compressor station tract would be the Klamath-Beaver and Klamath-Eagle receipt meter stations, at the interconnections with Ruby and GTN, and the JCEP delivery station would be at MP 0.00R at the interconnection with the LNG Terminal. In addition, there would be 17 main line block valves (MLV) located within the pipeline right-of-way or co-located at aboveground facilities; 5 pig[4] launchers and receivers co-located within aboveground facilities; and 15 communication towers also co-located with existing or proposed facilities. Further detail is provided on all of these facilities, below.

The Pipeline route would traverse across the basin and range sage and juniper woodlands ecozone of the Klamath Basin, over the Southern Cascades conifer forest and oak woodlands and conifer forest ecozones of the Klamath Mountains, through Camas Valley and Douglas-fir forests of the Coastal Range, and terminate in the Coastal lowlands.

The Pipeline would cross 46.8 miles within Coos County, between MPs 0.0 and 45.7; 64.9 miles in Douglas County between MPs 45.7 and 110.1; 56 miles within Jackson County between MPs 110.1 and 166.4; and 61.4 miles within Klamath County between MPs 166.4 and 228.8. In Coos County, the Pipeline would cross lands zoned predominantly Forest and Exclusive Farm Use, as well as some Rural Residential. In Douglas County, the Pipeline would cross lands zoned predominantly Timberland Resource, Farm Forest, and Exclusive Farm Use, and to a lesser extent Farm Forest Agriculture and Woodlot and Rural Residential. In Jackson County, the Pipeline would cross lands zoned predominantly Forest Resource and a substantial length of Exclusive Farm Use. In Klamath County, the Pipeline would cross primarily lands zoned for Forest and Exclusive Farm Use, but also some Residential and Heavy Industrial. PCGP has obtained or will obtain local permits allowing for the Pipeline, including conditional use permits and land use compatibility statements from the affected counties.

The Pipeline would cross a combined total of about 142.2 miles of forest, include deciduous forest, evergreen forest, mixed forest (containing both deciduous and evergreen trees), clearcut forest, and regenerating forest. About 26.6 miles of agricultural lands would be crossed, including cropland and pasture. The Pipeline would cross about 34.0 miles of range, including herbaceous (grassy) rangelands, shrub and brush rangelands, and mixed (both grassy and brush) rangelands.

The standard construction right-of-way would be about 95 feet wide. When crossing wetlands and certain riparian areas, the construction right-of-way may be reduced to 75 feet wide. Approximately 2,582 acres would be required for the construction right-of-way for the pipeline. The permanent easement would be 50 feet wide.

There would be a number of ancillary use areas associated with construction of the Pipeline. PCGP proposes to use 1,603 temporary extra work spaces, totaling about 922.6 additional acres. In addition, about 320 uncleared storage areas would be used during construction, totaling another 676 acres. There would be 20 rock source and disposal sites, totaling about 41.2 acres (an additional 20 sites, identified for rock source/disposal, are included in the temporary extra

[4] A pig is an internal pipeline cleaning and inspection tool.

work areas, totaling 44.8 acres). PCGP would use 36 pipe storage and contractor yards, totaling about 674.2 acres. Approximately 670 miles of existing roads would be used to access the pipeline right-of-way during construction. PCGP would have to make improvements to portions of 27 of those existing roads, disturbing about 22.5 acres. PCGP would need to build 10 new temporary access roads, totaling 3.8 acres, and permanently maintain 15 new access roads for operation of the pipeline, covering about 2.2 acres. Details about TEWAs can be found in PCGP's RR 1.

2.1.2.1 Pipeline Routing Considerations

The Pipeline route was developed with consideration of the construction requirements for a large-diameter, high-pressure natural gas transmission pipeline. The Pipeline will commence near the interconnections with Ruby and GTN within the proposed Klamath Compressor Station, and end at the LNG Terminal. Routing considerations and explorations of alternatives are set out in PCGP's RR 10. For about 97.7 miles (almost 43 percent of the route) the Pipeline would be situated adjacent to existing rights-of-way, including powerlines, other pipelines, and roads. The Pipeline was routed around major urban centers. To the extent possible, PCGP attempted keep the route on top of ridges, to reduce side-hill construction, and minimize the crossing of stream valleys. Adverse geological hazards, such as potential landslide areas were avoided, where possible. PCGP also sought to reduce potential impacts on sensitive resources, such as minimizing crossings of old-growth forest and habitat for federally listed species. For the most part, the Pipeline route avoids crossing national parks and monuments, wildlife refuges, federally designated wild and scenic rivers, and wilderness areas.

Aboveground Facilities

Proposed aboveground facilities that would be associated with the Pipeline include meter stations, mainline valves, pig launchers/receivers, and one compressor station. Aboveground facilities are listed in table 2.1.2-1 and described below. Aboveground facility locations are shown on the maps in appendix A.

<u>Jordan Cove Meter Station</u>

Natural gas would be delivered to the proposed LNG Terminal via the Jordan Cove Meter Station located at MP 0.0 (see appendix A) of the Pipeline in Coos County. The meter station would be located on JCEP property adjacent to the LNG Terminal. This industrial land was the former location of the Weyerhaeuser linerboard mill. Construction and operation of the meter station would affect 1.7 acres. There are no waterbodies or wetlands at the meter station location.

The meter station would be graveled and enclosed by a 7-foot high chain-link fence. Existing power and phone service for gas control communication equipment is available. A pig receiver and mainline block valve would be located within the meter station facility. Access to the site would be from a road provided by the LNG Terminal. A building would be installed to house the gas chromatographs, moisture analyzer, communications equipment, and flow computer. A canopy would also be installed to cover the control valves and ultrasonic meters. A communications antenna would be installed to provide a link with the gas control monitoring system, and the antenna would be installed on a new 140-foot tall steel tower. The tower would stand without support of guy wires. Lighting at the meter station would be down-shielded to keep light within the boundaries of the site, which would minimize attracting nocturnally flying bats or birds to the vicinity of the tower.

TABLE 2.1.2-1

Summary of Disturbance Associated with Aboveground Facilities

Facility [1]	**MP**	**Acres Disturbed [2]**	**Land Use**	**Land Ownership**

TABLE 2.1.2-1 Summary of Disturbance Associated with Aboveground Facilities				
Facility [1]	**MP**	**Acres Disturbed [2]**	**Land Use**	**Land Ownership**

[1] BVAs denoted as ABVA are automated valves and will include a 40-foot tall communication tower.
[2] Temporary construction disturbance associated with the aboveground facilities is included within the Pipeline construction right-of-way, and is not double counted in total Pipeline disturbance estimates.
[3] The 17 mainline block valves will be located within areas disturbed by the construction right-of way or within associated aboveground facility footprints (*i.e.*, meter stations and the compressor station); however, the permanent operation acres provided will remain as permanent disturbance associated with these graded, graveled and fenced facilities.
[4] The Jordan Cove Meter Station will be located entirely within the proposed LNG Terminal.
[5] Communication facilities are included in the disturbed areas associated with the meter station, block valves and compressor station.
[6] Communication facilities will utilize existing towers and equipment buildings, where space is available for lease, with no associated disturbance. If construction of new facilities is required, PCGP will obtain an approximate 100 x 100 foot (0.23 acre) area in the immediate area of the existing communication tower facilities.
[7] The Harness Mountain Communication Tower is an existing communication facility, where no new disturbance is required.

Klamath Compressor Station and Meter Stations

The Klamath-Eagle and Klamath-Beaver meter stations would be located within the 21-acre tract for the Klamath Compressor Station at MP 228.8 (see appendix A). The tract is used for hay and pasture, and includes sagebrush steppe vegetation. No wetlands or waterbodies are within this tract.

The compressor station is located approximately 1.75 miles northeast of Malin, Oregon. The location is accessed on the south from Malin Loop Road and on the west from Morelock Road. The site is located adjacent to the existing GTN Malin/Tuscarora Meter Station and Ruby Turquoise Flats Meter Station. The compressor station would also include a pig launcher for the pipeline.

The Klamath-Eagle Meter Station would serve as the interconnect with Ruby, and the Klamath-Beaver Meter Station would serve as the interconnect with GTN.

The Pipeline would require approximately 62,200 International Organization for Standardization (ISO) hp of new compression (with one additional standby unit of 31,100 ISO hp) provided at the new Klamath Compressor Station. The compressor station would consist of turbine-driven centrifugal compressor units.

The new compression units would be installed in a new Class 1 Division 2 rated compressor building. Other facilities would include an inlet filter/separator, lube oil cooler, inlet air silencer/cleaner, exhaust system, and gas coolers. The compressor building would include skid-mounted fuel gas conditioning, measuring, and regulation equipment. Related suction and discharge headers and piping would be installed between the pipeline and the compressor units. Other buildings inside the station would include a new control room/ancillary equipment building and unit valve skid buildings. The ancillary equipment building would include an air compressor system, hot water boiler, and back-up generator. A high-pressure vent system with a silencer would be installed to allow the station to be blown down. Near where the pipeline leaves the station boundaries, aboveground pig launcher/receiver equipment and a mainline block valve would be installed.

There would be a small office in one of the buildings with phone and computer access. The station would also be used as a maintenance base for operation of the pipeline facilities. The station would not be manned 24 hours per day, but would have emergency pipe, spare parts, portable equipment such as blow-down silencers, and small hand tools stored on site. The facility would be equipped with outside lighting to support night work activities; however, these lights would only be utilized when operations personnel are working at the station. During operations, nighttime work or maintenance activities would generally not be scheduled; therefore, these lights would only be used periodically and possibly for short periods during the winter when daylight hours are shorter.

The 21-acre site would be secured by a 7-foot-high, chain-link fence. To minimize visual intrusions, the security fence around the perimeter of the station would be installed with screening slats and landscaping along appropriate sides of the station to reduce potential visual effects to area residences. Areas inside the fenced area subject to operating or maintenance traffic would have a covering of paving, concrete, crushed rock or gravel.

The nearest existing NSA is a farm residence (NSA #6) located about 1,500 feet southeast of the proposed compressor building location (subsequent to the 2012 noise survey, PCGP acquired NSAs #1 and #2). An additional NSA (NSA #7) would potentially be located 1,230 feet north of the compressor station location. This NSA location is based on a building permit for a new residence filed with the local zoning board. Estimated noise from operation of the Klamath Compressor Station would have an L_{dn} of 50.9 dBA at NSA #6, and range between 46.7 and 50.5 dBA at the four other closest NSA, which would not exceed FERC's standard of 55 dBA. Noise below that level should have no significant adverse impacts on wildlife in the vicinity of the station.

<u>Gas Control Communications</u>

PCGP would need a total of 15 radio communication towers to link the Pipeline with the company's communication systems (see table 2.1.2-2. Two new communication towers would be erected at the Jordan Cove Meter Station and the Klamath Compressor Station. The towers would be 140 feet high.

TABLE 2.1.2-2

Location of Proposed and Existing Gas Control Communication Towers

	Location							Tower Height (feet)	Land Ownership
Site Name	Latitude			Longitude			County		
Proposed New Towers within Proposed Aboveground Facility Sites									
Jordan Cove Meter Station	43	25	58.1	124	14	27.8	Coos	140	Private

Flounce Rock[1]	42	43	40.4	122	36	33.1	Jackson	120	BLM
Robinson Butte[1]	42	21	51.4	122	22	54.1	Jackson	125	Forest Service
Stukel Mountain[1]	42	5	46.0	121	38	1.0	Klamath	100	BLM

[1] New towers and equipment buildings may be necessary at these locations if lease space is unavailable at the time of construction.

PCGP intends to lease space on an existing 150-foot-high tower at Harness Mountain in Douglas County. At the Blue Ridge and Signal Tree sites, PCGPintends to lease space on the existing American towers, which are 170 feet and 120 feet tall, respectively. PCGP would also lease space on existing towers operated by other entities at the Sheep Hill MW site (125 feet high) in Douglas County, and Starvout Creek site (115 feet high) in Jackson County. New communication towers may need to be erected near existing facilities at Flounce Rock and Robinson Butte in Jackson County, and Stukel Mountain in Klamath County. The new towers at Flounce Rock and Robinson Butte would be 120 and 125 feet high, respectively, while the new tower at Stukel Mountain would be 100 feet tall. No waterbodies or wetlands would be affected at any of the communication sites.

If leased space is not available on existing facilities and construction of new facilities is required, PCGP would seek to obtain an approximate 100-foot by 100-foot (0.23-acre) area for each of the new facility installations in the immediate vicinity of the existing communication tower facilities. The new towers and communication buildings would be enclosed within a 50-foot by 50-foot (0.06-acre) fenced footprint located within the larger 100-foot by 100-foot area. In the case of Robinson Butte, within the Rogue River National Forest, the Forest Service may require the modification of the current special use permit in order to allow the addition of new communication equipment. For use of the Robinson Butte communication site, PCGP would only require light utility four-wheel drive vehicles to travel 2.2 miles on Forest Service Road 3730 from Big Elk Road (paved) to access the tower. A cable and winch system would be used to hoist the microwave antenna communication systems from the vehicle to the tower. No maintenance and/or improvements are expected along Forest Service Road 3730 because only light utility vehicles are required to access the site. The Robinson Butte communication tower is located within NSO designated critical habitat (Unit KLE-4). Currently known NSO sites are farther than one-quarter mile from activity associated with this communication tower. Also, no suitable habitat for listed plants occurs along this road or at the communications site.

Launchers/Receivers and Mainline Block Valves

MLVs would be located along the Pipeline according to DOT's spacing requirements (C.F.R. §192.179). There would be a total of 17 MLVs along the proposed route, of which 2 would be co-located at the meter and compressor stations. Each MLV would occupy a site 50 x 75 feet (0.09 acre) and would be enclosed by a 7-foot-high chain-link fence. Each MLV would require a permanent access road, and PCGP has attempted to locate final placement of block valves adjacent to existing roads to minimize the length of new permanent access roads. PCGP would paint the aboveground piping in the block valve locations green unless otherwise dictated by permit conditions. Locations of mainline block valves are depicted on the USGS quad-based general location maps in appendix A.

Pigs, or remotely operated pipe inspection and cleaning tools, would be used to inspect and maintain the inside of the pipeline. Pig launchers/receivers would be located at each end of the pipeline (Jordan Cove Meter Station and Klamath Compressor Station). Due to battery and data storage limitations, there would also be a pig launcher and receiver co-located with MLVs #6 at MP 71.5, #11 at MP 132.5 and #14 at MP 187.4. At these locations, the block valve and pig launcher/receiver assembly sites would be 95 by 200 feet (0.44 acre); however, MLV #11 would be 0.27 acre to avoid adjacent wetlands. Pigging facilities would be located inside the fenced areas at all locations.

Launchers/receivers and mainline block valves would be located within the permanent pipeline easement or within the footprints of the aboveground facilities, which have been discussed above. Areas of existing wildlife habitats associated with each block valve are included in the discussion of the construction right-of-way.

2.1.2.2 Land Requirements – Pipeline

Construction of the Pipeline would require acquisition of temporary construction rights-of-way, TEWAs, and permanent easements which are described in this section. Table 2.1.2-3 summarizes the construction and operation land requirements. Table 2.1.2-4 lists acres of wildlife habitat affected by construction of the PCGP facilities.

TABLE 2.1.2-3

Total Pipeline Project Land Requirements for Construction and Operation

Pipeline Component	Length (miles) or Number of Sites	Land Affected During Construction (acres)	Land Affected During Operation (acres)
Pipeline Facilities	229.09*	2,582.04	1,373.66[1] / 820.60[2]
Temporary Extra Work Areas[3]	1,603	922.64	(44.80)[8]
Uncleared Storage Areas	320	676.44	0.00
Quarries & Disposal Sites	20	41.18	(41.18) [7]
Contractor and Pipe Storage Yards	36	674.17	0.00
Existing Roads Needing Improvements in Limited Locations[4]	32 Improvements (27 Roads)	22.52	(22.70)[9]
Temporary Access Roads	10	3.80	0.00
Permanent Access Roads	15	2.16[5]	2.16[5]
Aboveground Facilities	17	27.01[6]	27.01[7]
	Total	**4,951.96**	**1,402.83[7, 9]**

* Because of changes in the centerline and associated MP equations, the ending MP no longer represents the actual centerline length.
[1] New permanent easement is 50-feet on private and federal lands.
[2] Acreage affected by the 30-foot corridor where brush control would be performed during operation of the pipeline.
[3] TEWAs are shown on the Environmental Alignment Sheets
[4] Includes those existing roads requiring widening in specific locations; does not include limbing/brush clearing or blading/grading for potholes.
[5] Portions of the PARs are within the construction right-of-way and permanent easement.
[6] Construction impacts associated with the aboveground facilities are included in the construction impacts for the Pipeline facilities except the 8 potential communication tower sites and the Klamath Compressor Station, which are included here (1.61 acres and 21.4 acres, respectively).

[7] Portions of the operational impacts of the aboveground facilities are included within the permanent easement acreage.
[8] Represents TEWAs, existing quarries, and rock source and disposal sites provided in appendix G that may be used as permanent storage areas. The acreages are not included in the overall operational total because the storage areas will not be used during operation of the Pipeline.
[9] Although the improvements will not be reclaimed, these road improvements are not needed for operations, and the acres are not included in the total operational acreage.

[1] The "Late Successional and Old-Growth" category (L-O) describes those forest areas with a majority of trees over 80 years of age. Forests with stands greater than 175 years are considered to have old-growth characteristics.
[2] The "Mid-Seral" category (M-S) describes those forest areas with a majority of trees over 40 years of age but less than 80 years of age.
[3] The "Grass-shrub-sapling or Regenerating Young Forest" category (C-R) describes those forest areas that are either clear-cut (tree age 0-5 years) or regenerating (tree age 5 to 40 years). Forest areas in this category are divided into forest vegetation types based on their potential to become those types of forests.
[4] Road improvements will affect approximately 22.52 acres along the margins of existing access roads; all acres of disturbance have been included in vegetation type "roads."
[5] Construction disturbance associated with aboveground facilities (4 acres: mainline block valves and meter station) are included in construction right-of-way and/or TEWA acres of disturbance. Approximately 1.61 acres associated with communication towers are not included in this table (previously disturbed sites).

Construction Right-of-Way

Temporary Construction Right-of-Way

PCGP proposes to utilize a standard 95-foot-wide temporary construction right-of-way. The temporary construction right-of-way would accommodate clearing and grading activities, storage of spoil materials, and provide a passing lane for equipment movement. The temporary construction right-of-way would be used as the primary transportation corridor, as the spread processes in a linear fashion installing the pipeline.

The temporary construction right-of-way would encompass about 2,582 acres. After construction, workspace outside of the 30-foot-wide maintenance easement would be restored to its original condition and use (although mature forest would take many years to be re-established). The restoration and revegetation of the temporary construction right-of-way would be done in accordance with PCGP's *Erosion Control and Revegetation Plan* (ECRP).[5] At wetland crossings and stream crossings, where feasible, the construction right-of-way would be reduced to 75 feet in width, to minimize impacts to these resources and be consistent with the FERC's *Procedures* (Section VI.A.3). On NFS and BLM lands where Riparian Reserves would be affected, up to a 100-foot riparian strip or to the edge of the existing riparian vegetation would be replanted adjacent to stream crossings.

Temporary Extra Work Areas

In addition to the 95-foot-wide construction right-of-way, TEWAs would also be required at numerous locations to provide additional work space during construction. The TEWAs are listed in appendix G. Generally, these TEWAs are required for (but not limited to) the following:

- steep slopes and side sloping areas to accommodate cuts and spoil storage requirements;
- bore pits and spoil storage at road and railroad crossings;
- spoil storage, staging, and construction of drag sections such as at wetland crossings, residential/industrial areas, and road crossings, etc.;
- waterbody and wetland crossings;
- pipe and equipment staging;
- additional spoil storage areas where the topography requires cut and fills or where side slopes are traversed;
- areas where tie-ins or factory bends require additional trench widths to allow workers to enter the trench and perform welds and to ensure Occupational Safety and Health Administration (OSHA) trench safety requirements;
- sharp angles or points of inflection (PIs) where additional area is required to account for the wide turning radius of stringing trucks (which would be greater than 100 feet in length);
- topsoil segregation areas to ensure topsoil and subsoils are not mixed;
- off right-of-way dewatering areas; and
- timber staging/decking.

[5] The ECRP was attached as appendix B.1 in Resource Report 1 of PCGP's September 2017 application to the FERC, and included as appendix I to PCGP's POD.

A total of about 923 acres of TEWAs would be disturbed during construction of the pipeline. All of these areas are considered temporary disturbance and would be restored upon completion of construction (see appendix F). All TEWAs that were forested prior to construction would be replanted with trees. TEWAs would be located more than 50 feet away from the edge of waterbodies and wetlands where possible, and PCGP has identified locations where site-specific conditions or other constraints prevent a 50-foot setback.

Uncleared Storage Areas

To minimize disturbance associated with the Pipeline, PCGP has specifically designated some temporary work areas as UCSAs rather than TEWAs (see appendix G). Unlike the TEWAs, the UCSAs would not be cleared of trees. These areas would be used to store forest slash, stumps, and dead and downed log materials removed from the construction right-of-way prior to construction; these materials would be scattered back across the right-of-way after construction. The amount of this type of material is expected to be large enough to hinder construction activities if it were stored within the construction right-of-way. The use of UCSAs rather than TEWAs would minimize forested habitat removal while still providing important work areas to facilitate construction.

In some locations, the UCSAs may be used to store spoil or to temporarily park equipment between the mature trees; however, storage and temporary parking of equipment/vehicles would not occur immediately adjacent to the tree so as to minimize impacts (soil compaction or tree damage). PCGP has prepared the *Leave Tree Protection Plan* (see appendix P to the Plan of Development [POD]) detailing how live trees would be protected within the UCSAs. In extremely steep and side sloping topography, the UCSAs may be required as a contingency location to contain rock that rolls beyond the construction limits. Along extremely steep and narrow ridgeline areas, logs, slash, and dead and downed material may be used as cribbing to contain excavated materials during construction (right-of-way grading and trenching activities). During restoration, some of the materials that are pulled out of the cribbing may roll beyond the construction limits. Where feasible, PCGP would retrieve materials that have rolled downhill using cables and chokers attached to standard on-site restoration equipment (i.e., bulldozers and trackhoes) to winch the material back to the right-of-way. There may be some cases where retrieval of the lost cribbing material may cause more harm to resources than allowing it to remain where it settled to naturally decompose. In these areas, it would be infeasible and impractical to retrieve all of the overcast materials because additional tree clearing and grading would be required to reach the materials.

PCGP has identified about 676 acres of UCSAs that would be used during construction. There are 115 UCSAs within riparian zones that are within 1 site potential tree height of 94 waterbodies. The UCSAs are considered temporary disturbance because they would not be cleared and the materials (i.e., slash, stumps and downed and dead material, etc.) stored within them would be removed during restoration activities, with the exception of unrecoverable materials on steep slopes as described above.

In many cases, the use of UCSAs would have impacts on the forest understory, but temporary reduction of understory shrub cover does not produce the effects of an "edge." After removal of the materials stored in the UCSAs, the understory would recover.

Contractor and Pipe Storage Yards

PCGP has identified 36 temporary pipe storage and contractor yards and rail ports (see table 2.1.2-5 and appendix A) that may be used during construction to offload and store pipe and stage contractor equipment. These sites are generally not along or immediately adjacent to the proposed Pipeline. The yards would also be used to stage equipment and store materials used during construction. Stored materials may include: construction mats, fencing materials, fuel and lubricants, stormwater control materials (straw bales, erosion control fabric, silt fence materials, etc.) and other materials. The yards would also be used for contractor office trailers and employee parking facilities. The yards that are available for use would be secured during the easement acquisition phase, which is anticipated to begin prior to construction. Figures of the proposed yards are provided in appendix I. The yards total about 674 acres.

In general, PCGP selected yard locations because they are existing industrial sites that have been previously graded and graveled, are proximate to the Pipeline project area, and can be accessed by railroad or roads. All of the currently identified sites are privately owned.

Of the 36 yards, 26 were surveyed for wetlands and access was denied to 10. No wetland features are present on 15 of the surveyed yards. Eleven yards contain wetland features or drainage ditches, which would be protected during construction. Because most of the yards are existing industrial facilities, they do not contain high quality wildlife habitat.

Rock Source and Disposal Sites

Permanent disposal sites may be required to handle excess rock, spoil, or drilling mud that are generated during construction. Prime disposal sites for these materials include existing rock/gravel quarries and pits near the pipeline route. Where existing quarries or pits are not available, PCGP has identified stable sites along the right-of-way as permanent disposal sites. PCGP has identified 20 rock source/disposal sites which total about 86 acres (see appendix G). Of these 20 rock source/disposal sites, 15 sites are existing quarries/gravel pits or abandoned quarries/gravel pits. It is not PCGP's intent to expand these sites beyond the existing or previously disturbed footprints.

Construction Access Roads

About 724 existing roads, totaling 670 miles, would be used for access to the Pipeline right-of-way during construction. Existing egress and ingress points to and from the construction right-of-way have been identified in the table in appendix J as well as on the USGS quad-based maps in appendix A. These points have been identified to allow for safe, efficient construction and movement of equipment and materials.

In some areas, it would be necessary to grade or widen existing roads (to allow large equipment a turning radius) to access the construction right-of-way. Minor improvements (i.e., filling potholes, grading to remove ruts, and/or limbing to remove overgrowth) may be needed in some areas to accommodate oversized and heavy construction equipment (see footnotes in appendix J). In general, roadway improvements would require a minimal amount of site disturbance and earthwork necessary to make the roads useable for access to the construction right-of-way. Widening access roads in the identified constricted locations is necessary to accommodate the potential for the stringing trucks to "walk" outside of the existing road footprint. In some circumstances, it may also be necessary for oncoming traffic to "pull out" of the existing road footprint for passing purposes.

TABLE 2.1.2-5

Contractor and Pipe Storage Yards that may be used during Construction of the Pipeline Project

Name	County	Size (acres)	Description
North Spit Dock Yard	Coos	4.79	Industrial dock with gravel/native surface lot
Menasha	Coos	36.93	Export log yard and dock with rail sidings
K-2	Coos	25.56	Export log yard and dock with rail sidings
Brunell	Coos	12.88	Vacant industrial lot and dock with rail siding
Millington 1	Coos	28.4	Log yard
Millington 2	Coos	5.66	Vacant industrial lot, connected to railroad
Coquille Yard	Coos	20.37	Old industrial mill site, vacant lot
Coquille Park	Coos	3.28	Sturdivant Park, adjacent to rail siding
Coquille Mill	Coos	4.37	Mill log, lumber, storage yard and parking lot, adjacent to rail siding
Coquille Sawmill Yard	Coos	7.46	Industrial lot/previous sawmill that was utilized as a contractor's yard
Winchester	Douglas	101.94	Undeveloped lots connected to rail yard, adjacent to interstate interchange
Green #1 Yard	Douglas	9.37	Vacant industrial lot, adjacent to rail siding
Green District Yard	Douglas	7.06	Vacant industrial lot/ log yard, gravel surface/ parking lot adjacent to railroad
Hult Chip Yard 2 (Pipe)	Douglas	13.30	Vacant industrial site; paved/gravel surface
Hult Chip Yard (Parking)	Douglas	2.66	Vacant industrial site; gravel surface
Hult Chip Yard 1 (Roll)	Douglas	8.91	Vacant industrial site; paved lot with rail siding
Roth	Douglas	3.79	Pasture, adjacent to rail siding, connects to project right-of-way
Weaver Highway 99	Douglas	6.37	Vacant undeveloped lot adjacent to Interstate interchange and close to railroad and sidings
Weaver Road Yard	Douglas	7.77	Vacant industrial log storage yard, adjacent to railroad
Riddle Main Street	Douglas	8.78	Vacant industrial lots including railroad siding
Riddle Pasture	Douglas	7.31	Vacant field adjacent to industrial sites and rail siding
Milo Yard 1	Douglas	5.27	Reclaimed quarry
Milo Yard 2	Douglas	10.32	Reclaimed quarry
Burrill Lumber	Jackson	61.44	Vacant lumber mill/log yard
Avenue F and 11th Street	Jackson	26.15	Industrial business and vacant graveled lot, adjacent to rail sidings
WC Short	Jackson	8.36	Rail siding and industrial yard
Rogue Aggregates	Jackson	38.90	Pasture/undeveloped land within active aggregate quarry and processing facility and undeveloped land includes rail siding
Collins Pacific Yard 1	Klamath	9.47	Active wood products plant – vacant gravel lot
Collins Pacific Yard 2	Klamath	5.41	Active wood products plant – vacant gravel lot
Klamath Falls Amuchastegui Building	Klamath	25.46	Existing commercial site and undeveloped industrial lots adjacent to rail siding
Klamath Falls Industrial Oil	Klamath	39.48	Undeveloped industrial lots adjacent highway, rail and rail sidings.
Klamath Falls Memorial Drive 2 / Bair	Klamath	65.53	Undeveloped industrial lots adjacent to rail siding
Klamath Falls Memorial Drive 1 Pipe Yard	Klamath	24.72	Vacant industrial mill site / lot, adjacent to railroad and sidings
Klamath Falls Cross Road East	Klamath	6.99	Farmland, adjacent to rail siding
Klamath Falls Cross Road West (Stukel) Rail siding	Klamath	9.93	Railroad siding
Merrill Oregon RR Siding	Klamath	9.78	Pasture adjacent to rail siding
	Total	**674.17**	

PCGP has estimated that 27 existing roads (32 locations) would need to be modified to handle construction traffic. These roads have been identified with footnotes in appendix J. PCGP has estimated that modifications of existing access roads may be required outside of the existing road bed, resulting in about 22.5 acres of disturbance.

During use of existing roads for construction, paved surfaces would be kept clear of large accumulations of mud and other debris. Dirt roads may be maintained by grading, or covered by gravel. Appropriate sediment and erosion control devices would be installed along dirt roads used during wet weather or the rainy season to contain potential impacts to the road surface.

Table 2 in appendix J lists access roads needing improvement that are within 100 feet of waterbodies. With implementation of the procedures in the ECRP (see appendix F), PCGP does not anticipate that improvement of these existing roads would have any significant impacts on nearby waterbodies, as erosion and sedimentation would be controlled and minimized. Therefore, there would be no adverse impacts from road improvements on federally listed aquatic species in those waterbodies.

New Temporary Access Roads

PCGP has identified 10 locations where it would be necessary to construct new TARs (see appendix A). Construction of the TARs would temporarily impact four acres. After installation of the pipeline, the TARs would be restored to their previous condition and land use. Table 2.1.2-6 lists all temporary and permanent access roads that are required for the Pipeline.

The potential increase in surface runoff from the Pipeline project's temporary or permanent access roads is expected to be insignificant. Most of the TARs would require minor grading to access the right-of-way from existing roads because they are located in pastures, along gentle terrain, or along existing two-track roads.

Only one of the TARs would be located within 100 feet of a wetland or waterbody (see table 2 in appendix J). Of the TARs to be constructed, three are within riparian zones of fish-bearing waterbodies and one of the three is on BLM lands within a designated Riparian Reserve (TAR-27.06 at Middle Creek). Appropriate BMPs outlined in PCGP's ECRP (see appendix F) would be utilized to ensure that potential surface runoff and potential sedimentation impacts on waterbodies and wetlands from use of these roads would be avoided or minimized.

Permanent Access Roads

PCGP would need to construct 15 new PARs for access to the right-of-way and aboveground facilities (see appendix A). These roads would provide access during operations and maintenance activities while the pipeline is in service. Most of the PARs would be located within PCGP's permanent easement. Construction of the PARs would permanently impact about 2.2 acres.

Most of the disturbance associated with these PARs would occur within disturbed areas associated with the pipeline's construction right-of-way or along existing two-track roads. Three of the permanent access roads would be located within riparian zones of three waterbodies, two of which are non-fish bearing. PCGP would ensure that the roads are appropriately stabilized using gravel and appropriate BMPs, as outlined in the ECRP (see appendix F), to minimize potential surface water runoff and to avoid potential sedimentation impacts. No waterbodies or Riparian Reserves on federal lands would be affected by PARs.

TABLE 2.1.2-6 Temporary and Permanent Access Roads for the Pipeline Project				
Access Road (TAR/PAR-MP)	**Dimension (feet)**	**Impact (acres)** [1]	**Jurisdiction**	**Purpose**

[1] All or portions of the PARs are located within the permanent Pipeline easement.
* Existing roads not included in area of impact (acreage represented in parentheses and not included in total).

2.1.2.3 Construction Methods and Potential Impacts – Pipeline

All pipeline facilities would be designed, constructed, tested, operated, and maintained to conform with DOT requirements found in 49 C.F.R. Part 192; FERC regulations at 18 C.F.R. §380.15; and other applicable federal and state regulations. PCGP would follow its ECRP while constructing the Pipeline and associated facilities. This plan was modeled on the FERC's *Plan* and *Procedures* (appendix C), with project-specific modifications, and other changes based on reviews by the BLM and Forest Service. During activities associated with constructing the Pipeline and associated facilities (survey, timber clearing, construction, and revegetation), PCGP would ensure that construction contracts include stipulations to ensure that all trash, food waste, debris, and other items attractive to corvids and other potential predators are picked up and removed from the project area on a daily basis. PCGP's environmental inspectors (EIs) and FERC's third-party Environmental Monitors would be responsible for overseeing that the construction contractor is adequately following these stipulations.

The Pipeline would be divided into seven or more construction spreads to allow for mainline construction in two construction seasons. Average numbers of personnel for the seven spreads would range between 137 and 610. It is estimated that there would be approximately 10 to 25 surveyors and 25 to 150 construction and EIs along the pipeline route during mainline construction. Construction of the Klamath Compressor Station would require between 25 and 100 workers, and the three proposed meter stations would require between 15 and 75 construction personnel.

Construction Spreads and Sequence

Standard pipeline construction proceeds in the manner of an outdoor assembly line composed of specific activities that make up the linear construction sequence. These operations collectively include survey and staking of the right-of-way, clearing and grading, trenching, pipe stringing and bending, welding and coating, lowering-in and backfilling, hydrostatic testing, right-of-way cleanup, and restoration. PCGP has determined that to efficiently construct the pipeline, construction would be divided into seven or more separate construction spreads. The construction spreads would include all construction/restoration activities within a specific milepost range along the pipeline.

Preliminary locations of construction spreads identified by PCGP include the following:

- Early Works – 0.0–7.34R
- Spread One – MPs 7.34R–29.54;
- Spread Two – MPs 29.54–51.58;
- Spread Three – MPs 51.58–71.37;
- Spread Four – MPs 71.37–94.75;
- Spread Five – MPs 94.75–132.52;
- Spread Six – MPs 132.52–162.40; and
- Spread Seven – MPs 162.40–228.81.

Surveying and Staking

Prior to the start of construction, the exterior right-of-way limits and the boundaries of TEWAs shown on the Environmental Alignment Sheets would be civil surveyed and clearly staked. Any pre-existing property line or survey monuments that occur within the construction right-of-way would be protected where possible, and if damage occurs during construction, these monuments would be replaced according to state and federal standards. Civil surveys on federal lands would be conducted in accordance with PCGP's *Right-of-Way Marking Plan* (included as appendix T to the POD). Civil survey is generally performed on foot or using all-terrain vehicles (ATVs) or off-highway vehicles (OHVs) from existing access points to the pipeline right-of-way. An EI would verify the limits of the staked right-of-way and TEWAs and these survey stakes would be maintained throughout construction. Approved access roads would be signed. Also signed would be sensitive environmental areas that would be off-limits to construction crews.

Clearing and Grading

During tree and brush clearing, all operations and tree falling would occur within the certificated construction limits. On lands supporting taller shrub-type vegetation cover (sagebrush communities), PCGP would clear the right-of-way by mowing or scalping off the tops of the shrubs with a motor-grader or a bulldozer. Hayfields and vegetation cover types such as grass, low shrubs, or other low-growth vegetation would not be cleared except in areas directly over the trench or where grading would be required. The cleared vegetation material would be stored on the edge of the right-of-way and spread back over disturbed areas during final restoration. PCGP has produced a *Right-of-Way Clearing Plan for Federal Lands* as appendix U to the POD. The general clearing procedures outlined in that plan would also apply to non-federal lands.

During clearing operations, existing fences crossed by the pipeline route would be cut and braced, and temporary gates installed to control livestock and limit public access to the right-of-way. Temporary erosion control devices would be installed at the end of clearing activities. Details about erosion control devices can be found in PCGP's project-specific ECRP, in the FERC's *Plan*, and the POD. Clearing in wetlands would be done in accordance with the FERC's *Procedures*.

Following clearing, the right-of-way would be graded where necessary to create a reasonably level working surface to allow safe passage of construction equipment and materials. During grading activities, topsoils would be separated from subsoils, and each would be stored in segregated piles within the construction right-of-way and TEWAs. The FERC's *Plan* requires topsoil segregation in residential areas, crop lands, pastures and hayfields, and in other areas as required by the landowner. The topsoil should be stripped either across the entire construction right-of-way, or over the trench line and soil storage areas. In wetlands, the FERC's *Procedures* require that the top foot of soil over the trench line be salvaged, except in areas of standing water or saturated soils. Where topsoil would be segregated on non-federal lands, PCGP has requested 10 additional feet of TEWA in addition to the 95-foot-wide construction right-of-way in uplands.

Timber Removal

Timber cruises would be conducted prior to vegetation clearing to determine timber volumes, values, and species composition within forested lands. PCGP would be required to retain qualified foresters and logging engineers to develop site-specific logging plans for each area to be logged. Merchantable timber would be removed and sold according to landowner stipulations. PCGP's ECRP (see appendix F to the POD) describes the BMPs that would be applied during timber clearing.

Clearing of forest is a two-step process: tree felling, followed by yarding. PCGP's *Clearing Plan* outlined 15 different scenarios that may be used to cut and remove timber from the right-of-way along the pipeline route, based on slope, stand density, and tree types.

The specific logging methods would not be determined until after a contractor has been selected through the bidding process for each construction spread. PCGP expects that the use of all logging methods may be necessary during clearing to efficiently remove timber from the right-of-way, depending on the site-specific geographic conditions. Timber cutting can be done by mechanical means (using tracked feller-buncher, saw, or shear) or by hand methods with a chainsaw. Alternative harvest equipment could include tracked crawler stroke-delimber and tracked crawler-chipper. Yarding can be done by cable or helicopter. Ground-based skidding and cable yarding would likely be the standard methods. Ground-based skidding would use tracked grapple and rubber-tired grapple equipment. Ground-based yarding could use shovel logging methods (with tracked feller-buncher, hydraulic grapple heel boom, or dangle-head processer).

In some isolated rugged topographic areas with poor access, helicopter logging may be utilized. Cable and helicopter logging methods would minimize the potential for soil compaction. Helicopter yarding is currently proposed for the following locations but would not be finalized until a contractor is selected for project construction:

Begin MP	End MP	Helicopter Staging
		TEWAs 6.49-W, 7.21-N, 7.44-W, 10.22-W, 13.79-W, 14.62-W, 15.75-W, 16.71-W, 18.05, 21.12-W, 23.99-N, 21.87-N
37.10	38.42	TEWAs 36.63-W, 36.97-W, 37.15-N, 38.32-W, 38.32-N, 38.90-W, 39.18-N
46.70R	47.20R	TEWAs 46.75-N, 47.53-N, 47.52-W
60.50	61.50	TEWAs 60.52-N, 60.54-W, 60.59-N, 60.87-W, 60.88-N, 61.43-N
77.80	79.90	TEWAs 77.72-N, 77.95-W, 78.99-W, 79.85-N
92.46	94.50	TEWAs 92.62, 92.62-N, 92.63-W, 93.01, 93.01-N, 94.56-W
95.10	97.05	TEWAs 95.39, 96.22-N, 96.23-W 97.02-N, 97.04-W
97.70	98.00	TEWAs 97.63, 97.79-N, 97.91-W
101.30	102.30	TEWAs 101.62-N, 101.75-N, 102.19-N
108.50	110.40	TEWAs 109.10-W, 110.34-W, 110.73 (Helicopter landing Peavine Quarry)
116.30	117.85	TEWAs 116.59-W, 117.67-N
123.30	125.15	TEWAs 123.53-W, 123.71-N, 124.30-N, 124.54-W, 124.71-W, 124.96-N

Prior to clearing operations, PCGP would flag existing snags in forested areas on the edges of the construction right-of-way or TEWAs, to protect those snags from removal during timber cutting, where feasible. These snags would be saved to benefit primary and secondary cavity-nesting birds, mammals, reptiles, and amphibians. During this process, other large-diameter trees on the edges of the construction right-of-way and TEWAs would also be flagged and saved as green recruitment or habitat trees, where possible. Some of these trees would be girdled to create snags to benefit wildlife. Snags and habitat trees would be retained if they do not pose a safety hazard to construction activities, as per the regulations outlined by OSHA.

Trees would be felled or sheared in a manner that would not impact adjacent forest or structures outside of the right-of-way. Trees would also be felled away from wetlands, waterbodies, and riparian reserves. PCGP would not remove stumps or root systems from wetlands, except along the trench line, unless necessary for safety reasons during construction. In upland forest, PCGP would also limit stump removal to the trench line and areas where grading would be necessary to create a level working surface. Any debris as a result of tree cutting that falls into a waterbody would be removed, if practical. Logs and slash would not be yarded across perennial streams unless fully suspended. Existing logs firmly embedded into the bed or banks of streams would not be disturbed, unless their removal is necessary for clearing the right-of-way, trenching, or fluming or other waterbody crossing methods. Any existing logs removed from waterbodies during installation of the pipeline would be returned during restoration (if occurring on federally-managed lands, approval would be obtained from the land-managing agency). Landings for clearing operations would not be located in wetlands or riparian reserves. Where feasible, logs yarded out of wetlands or riparian zones would be skidded with at least one end suspended from the ground so as to minimize soil disturbance. Any cut timber designated for in-stream or upland wildlife habitat enhancements would be stored at the edge of the right-of-way or in TEWAs for later use during restoration activities. Where large woody debris (LWD) is acquired for project in-stream habitat use, this material would only be obtained from the certified construction limits and would be collected outside riparian zones to maintain root structure within the riparian zone. An exception to this is where the LWD can be obtained from the trenchline or right-of-way cut areas where root systems would be removed during trench excavation or grading operations.

Trees to be cleared in forested areas along the pipeline route are typically considered too large to be taken whole for yarding. Therefore, trees would be cut, topped, limbed, and bucked on site where they have fallen. Generally, only the logs would be yarded to a landing for decking, loadout, and transport. The remainder of the wood debris from clearing (i.e., tree tops and limbs) would remain on the ground within the construction right-of-way where the trees were cut. During logging, tree tops and limbs would be broken or crushed creating a volume of small slash that would be impractical to remove from the right-of-way. Some of the slash on the ground would act as erosion control between the time the right-of-way is cleared and the pipeline is installed.

Danger trees are those trees at risk of falling on workers or vehicles and thus would need to be removed for safety reasons. A tree may be at risk of falling for a number of reasons including the tree's location and the presence of defects, insects, disease, work activities, and weather conditions. Such trees would be felled in advance of logging, pipeline construction, road construction/reconstruction, and road maintenance. Additionally, danger trees could be created from trees felled for the pipeline. This would occur if trees outside of approved construction areas are damage during felling of harvested timber. While this could result in growth loss, for which PCGP would compensate the land-management agency (or landowner on private lands) for any trees removed and any loss in timber productivity, the FERC requires that all operations be contained within the certificated work areas. Danger trees would be designated by qualified PCGP representatives, in accordance with OSHA standards and the Forest Service/BLM–published *Field Guide for Danger Tree Identification and Response* (Forest Service and BLM 2008). Danger trees would be directionally felled, when consistent with OSHA guidelines, away from the construction right-of-way if trees are to be left on the right-of-way, and towards the construction right-of-way if trees are to be removed. FERC compliance monitors in the field would review and approve as appropriate requests to remove danger trees outside the approved construction area.

Treatment of Forest Slash

Slash from timber clearing would be salvaged on or at the edge of the right-of-way and redistributed across the right-of-way during final cleanup and reclamation. Scattering the slash across the right-of-way would hinder OHV traffic on the right-of-way and would act as a natural mulch to minimize erosion (see appendix F).

Because more than one ton per acre of woody material (logs, slash, and chips) may be scattered across the right-of-way during final cleanup in many areas, PCGP requested a modification from Section IV.F.4.e. of the FERC's *Plan*. PCGP would utilize the fuel loading standards of the BLM and the Forest Service as the limit for the quantity of woody debris that would be distributed across the right-of-way to minimize fire hazard risks for this variance request. PCGP requested this modification because it would be impractical and infeasible to remove this material from the right-of-way and it is a typical silvicultural practice in the Pipeline project area (i.e., forest slash left in logged areas). Furthermore, it is expected that the woody slash material would not deplete soil nitrogen in the short term, during revegetation establishment, because the size of the woody material that would be scattered on the right-of-way would be large and would not readily decay in the short-term.

On NFS lands, the maximum amount of slash that would be scattered across the right-of-way would be 12 tons per acre (see table 2.1.2-7), and on BLM and private lands the maximum would be 15 tons per acre (table 2.1.2-8). In areas where the fuel loading exceeds these standards, PCGP would machine or hand pile and burn the excess material, depending on the site location, according to the requirement of the landowner. Burning would occur during the appropriate burning season and according to the conditions permitted by the BLM, the Forest Service, and the ODF. PCGP developed a Prescribed Burning Plan (see appendix R to the POD).

TABLE 2.1.2-7

Fuel Loading Specification by Size Class on NFS Lands

Size Class (diameter)	tons/acre
0 to 1/4 inch	< 1
1/4 to 3 inches	4 to 8
3 to 8 inches	7 to 12
Maximum Total Loading	12

0 to 1/4 inch	< 1 a/
1/4 to 8 inches	5 to 8 a/
>8 inches	10 to 15

a/ Adapted from Forest Service Fuel Loading Standards

Weeds and Forest Pathogens

Noxious weeds which are target species are listed as "Class T" by the ODA. Of the weeds documented within the pipeline area during botanical surveys conducted by PCGP, only spotted knapweed, rush skeletonweed, Dalmatian toadflax, tansy ragwort, and gorse were Class T weeds.

Invasive or noxious plants can negatively affect habitat by competing for resources such as water and light, changing the community composition, eliminating or reducing native plants, or changing the vegetation structure. The changes in community composition or vegetation structure can reduce native plant populations and can also negatively affect habitat for wildlife.

Pipeline construction can cause the spread or establishment of noxious weeds. Soil disturbance and/or removal of existing vegetation for pipeline or road construction can provide openings for invasive or noxious plants to establish or spread. Movement of equipment can also provide opportunities for seed transport into new areas. In general, habitats with more bare ground, such as grasslands, riparian areas, and relatively dry or open forests, are more susceptible to invasion than are dense, moist forests, high montane areas, and serpentine areas that have relatively closed canopy cover or have extreme climate or soils that are tolerated by fewer invasive plant species.

PCGP's ECRP includes measures to control noxious weeds, soil pests, and forest pathogens. In addition, PCGP developed an *Integrated Pest Management Plan,*[6] in consultation with the ODA (Butler 2006), BLM, and the Forest Service, to minimize the potential spread and infestation of weeds along the construction right-of-way. This plan includes surveys prior to construction to

[6] See appendix N to the POD.

determine the presence of noxious weeds; cleaning of construction equipment (in areas where weeds have been identified or when leaving these areas) to prevent the import and spread of weeds; and vegetation clearing and grading requirements in areas of noxious weeds. Additionally, disturbed areas would be replanted with appropriate seed mixes to prevent noxious weed germination. After construction, the right-of-way would be monitored and any noxious weed infestations would be controlled.

PCGP's *Integrated Pest Management Plan* also identifies BMPs and conservation measures that would be implemented to minimize the spread of forest pathogens and insects along the pipeline route. PCGP would identify/verify areas infested with forest pathogens during timber cruises prior to construction and implement minimization measures, including but not limited to cleaning equipment and vehicles upon entering/departing infested areas, applying sporax/borax on freshly cut stumps and wounds to reduce spread of root rot, and utilizing standard logging practices that minimize or prevent damage to standing trees adjacent to the Pipeline.

Forest Fragmentation and Edge Effects

The Pipeline route would cross about 142 miles of forest and 34 miles of shrubs and grasslands. Of the forested land crossed, about 39.3 miles would be late successional old growth, and 43.6 miles would be mid-seral. PCGP estimated that during clearing of the construction right-of-way, it would harvest about 1,189 acres of large mature trees over 40 years in age and approximately 911 acres of younger small to medium sized trees. During operation of the Pipeline, a 30-foot-wide corridor would be maintained in an herbaceous state, resulting in the permanent removal of about 517 acres of forest.

Fragmentation, or breaking up of contiguous areas of vegetation into smaller patches that become progressively smaller and isolated over time, has occurred and continues to occur within the areas crossed by the pipeline route. Because the Pipeline is linear, the created patch associated with the new edge would be narrow. Creation of edges by the Pipeline would affect seral stands differently. Forest edges play a crucial role in ecosystem interactions and landscape function, including the distribution of plants and animals, fire spread, vegetation structure, and wildlife habitat. Creation of forest edge adjacent to dense canopy would impact microclimate factors such as wind, humidity, and light, and can lead to a change in species composition within the adjacent forest or increase invasion by invasive species. Compared to the forest interior, areas near edges receive more direct solar radiation during the day, lose more long-wave radiation at night, have lower humidity, and receive less short-wave radiation. Increased solar radiation and wind can desiccate vegetation by increasing evapotranspiration, can affect which species survive along the edge (typically favoring shade intolerant species), and can impact soil characteristics.

Different species composition and abundance occurs in edge habitats (Forman and Gordon 1986) than within patch interiors, depending on species' tolerances for the variation in microclimatic parameters. Often present along the edge are higher levels of flower and fruit production, pollinator, and frugivore densities and seed dispersal. Some terrestrial amphibians have narrow temperature and moisture tolerances (Spotila 1972; Feder 1983). Loss of canopy cover and coarse woody debris can affect microclimatic conditions found advantageous by some amphibians. Some wildlife species use right-of-way corridors created by linear utilities. The herbaceous pipeline right-of-way would provide browse for ungulates, such as deer and elk.

Increased herbivore density provides a food source for predators (Forman 1995), so predator density can be increased along the edge.

Edge habitat created by the pipeline right-of-way is expected to have positive and negative impact on bird species. Expected positive effects are increased diversity and density of bird species, increased access to a variety of food resources, and increased ground cover favoring ground-nesting species (Rosenberg and Raphael 1986). Potential negative impacts include increased brood parasitism, increased nest depredation in grasslands, forests and edge habitats, and lower nesting success (Thomas and Toweill 1982; Burger et al. 1994; Vickery et al. 1994; Marini et al. 1995; Danielson et al. 1997; Brand and George 2000).

To minimize the effects of the Pipeline project on fragmentation and edge effects, PCGP would replant native shrubs and trees within the temporary construction right-of-way outside of the 30-foot-wide operational pipeline maintenance corridor right-of-way, per the requirements found in its ECRP (e.g., by revegetating the area, the hard edge along the fragment would be reduced, thereby minimizing the effects of fragmentation and edge effects).

Douglas-fir and western hemlock planted adjacent to edges of clearcut and/or early regenerating stands (assuming conifers from 1 to 10 feet tall at the time of construction) would modify edges with the seral stands from hard to soft to no edge as they grow. In 50 years, which is the operational life of the Pipeline, trees replanted in temporary workspaces outside of the 30-foot maintenance corridor would similarly modify edges of regenerating and mid-seral stands adjacent to the right-of-way, from hard to soft edge characteristics as tree heights increase. As the replanted trees grow, edge contrasts would decrease as would effects on forest interiors, because taller trees would reduce direct solar radiation and increase soil moisture and humidity along the edges of stand interiors (Chen et al. 1995; Heithecker and Halpern 2007).

During right-of-way restoration, PCGP would create habitat diversity features within the permanent right-of-way, such as rock and brush piles, that would provide habitat for a variety of wildlife species including mollusks, amphibians, and small mammals. Such features reduce fragmentation effects of abrupt edge characteristics by creating local irregularities. LWD placed within and/or across the right-of-way may eventually contribute to microsite diversification and provide corridors for some wildlife (e.g., terrestrial mollusks) to travel across an otherwise potential barrier. Such movements would be essential to avoid potential genetic isolation of relatively non-mobile species.

Trenching and Backfilling

A rotary trenching machine, rock trencher, track-mounted backhoe, or similar equipment would be used to excavate a trench for the pipeline. Spoil excavated during trenching would be temporarily stockpiled to one side of the right-of-way adjacent to the trench.

PCGP intends to exceed DOT requirements where possible, and bury its pipeline up to 36 inches deep in Class 1 areas with normal soils and 24 inches deep in Class 1 areas with consolidated rock. The trench may be deeper at stream crossings with scour concerns, or areas with geological hazards. PCGP committed to burying the pipeline below the estimated 100-year scour depth or into competent bedrock, whichever is shallower.

During trenching activities, in areas where shallow bedrock is encountered, PCGP would first attempt to utilize specialized excavation methods to reach the required pipeline design burial depth. These excavation methods may include ripping using hydraulic hammers or rock saws. However, if these methods prove to be ineffective or inefficient, blasting may be necessary to achieve the required trench depth.

After trenching is complete, the pipe sections would be strung along the trench, bent to fit the contour of the trench bottom, aligned, welded together, and placed on temporary supports along the edge of the trench. All welds would be visually and radiographically inspected and repaired, if necessary. Line pipe, normally mill-coated prior to stringing, would require field applied coating at the welded joints prior to final inspection. The entire pipeline coating would be inspected and tested to locate and repair any faults or voids. The pipe assembly would then be lowered into the trench by side-boom tractors, and the trench would be backfilled using a backfilling machine or bladed equipment. No foreign substance, including skids, welding rods, containers, brush, trees, or refuse of any kind, would be permitted in the backfill.

PCGP would install trench plugs (see Drawing 3430.34-X-0011 in the ERCP in appendix F) consistent with the requirements of the FERC's *Plan* (see Section V.B.1). Trench plugs would be installed at the base of slopes adjacent to wetlands and waterbodies and where needed to avoid draining of wetlands (springs). Trench plugs may be constructed from sandbags, foam, or bentonite. Topsoil would not be used to fill the bags. Trench plugs would be installed on slopes to minimize water flow down the trenchline to prevent potential subsurface erosion and to maximize stability.

<u>Blasting</u>

If blasting is required, all applicable federal, state, and local regulations would be observed and all necessary permits would be obtained. All blasting activities would be conducted by licensed blasting contractors in accordance with all applicable regulatory requirements. Table 2.1.2-9 lists areas with bedrock that may require blasting.

TABLE 2.1.2-9

Areas with Bedrock that May Require Blasting along the Pipeline Route

Blasting in uplands during construction is not expected to generate noise levels in excess of 92 dBA, with appropriate mitigation measures applied. Under worst-case conditions, the distance for noise from blasting to attenuate to 92 dBA is 175 to 200 feet away from the pipeline trench (see PCGP's *Blasting and Helicopter Noise Analysis & Mitigation Plan*, appendix P to the POD).

Where blasting is required in streambeds, PCGP proposes to utilize the dam-and-pump crossing method so that blasting activities can be completed in the dry to avoid potential impacts to aquatic species during in-water blasting. If a dam-and-pump crossing method cannot be used and in-water blasting is required, PCGP would implement other techniques such as scare charges to temporarily clear aquatic organisms from the area. It is anticipated that the preparation of the rock for blasting (drilling shot holes) would cause enough disturbance to displace most aquatic organisms from the immediate vicinity of the blast. Immediately following blasting, equipment would remove any shot rock that could impede stream flow.

Construction Noise

The typical ambient sound level for forest habitats ranges from 25 dB to 44 dB. Sound levels from construction of the Pipelne are predicted to be 93 dBA L_{eq} at 50 feet, and would attenuate to 85 dBA L_{eq} and 72 dBA at 100 feet and 300 feet, respectively. Noise would diminish rapidly as the distance from the noise source increases. Distances at which noise would attenuate to ambient levels would depend on local conditions such as tree cover and density, topography, weather (humidity), and wind, all of which can alter background noise conditions. Consequently, short-term impacts on wildlife by construction noise would vary along the length of the pipeline route.

Double rotor helicopters may be used for timber clearing along a portion (15.4 miles) of the Pipeline route. This type of helicopter generates noise of about 92 dBA within 700 feet of its area of use. Mitigation to reduce helicopter noise would include operational restrictions such as maintaining a high altitude and keeping away from noise sensitive areas whenever possible.

Noise could potentially impact wildlife for a short duration during construction activities, including clearing and grading the right-of-way, and horizontal direction drill (HDD) operations. The average time a given point along the pipeline would be disturbed by construction noise is approximately 8 weeks. This would vary, as the speed at which crew would be able to work would be affected by terrain, construction methods, weather, and environmental windows. Noise would most likely displace wildlife some distance away from noise sources especially if wildlife species are nearby. Noise would move along the construction right-of-way in a linear fashion. Therefore, impacts to wildlife because of noise would be of short duration and spatially localized.

Raptors and other forest-dwelling bird species have demonstrated more adverse impacts to project-generated sound during nesting and breeding when levels substantially exceed ambient conditions existing prior to a project (i.e., by 20 to 25 dB experienced by the animal) and when the total sound level is very high and exceeds 90 dB. Such impact could potentially result in egg failure or reduced juvenile survival, malnutrition or starvation of the young, or reducing the growth or likelihood of survival of young. However, these effects may be minimal; Awbrey and Bowles (1990) found that raptors flushed from their nests while incubating did not leave the eggs exposed for more than 10 minutes and concluded that multiple, closely spaced disturbances would be required to cause lethal egg exposure. Some raptors, for example osprey, refuse to be flushed from their nest despite closely approaching helicopters (Poole 1989).

Hydrostatic Testing

After backfilling, the Pipeline would be hydrostatically tested in accordance with DOT regulations to ensure that the system is capable of operating at the maximum operating pressure. If a leak is identified during hydrostatic testing, the line would be repaired and retested until the specifications are achieved.

PCGP's *Hydrostatic Testing Plan* (see appendix U) includes measures to prevent the transfer of aquatic invasive species and disease. Water for hydrostatic testing would be obtained from commercial or municipal sources, private supply wells, or surface water right owners (see table 2.1.2-10). PCGP would negotiate water appropriations with private owners in the year prior to construction. If water for hydrostatic testing is acquired from surface water sources, PCGP would obtain all necessary appropriations and withdrawal permits, including permits through the ODWR. As required by ODFW, pumps used to withdraw surface water would be screened according to NMFS standards to prevent entrainment of aquatic species. With the possible exception of chlorine, used to kill aquatic diseases, PCGP does not intend to add chemicals to the hydrostatic test water.

The Pipeline would be tested in approximately 32 sections; each with varying lengths and water volume requirements (see table 2.1.2-11). During the test, it may be necessary to discharge water at each of the section breaks; however, PCGP would conserve water as much as practical and minimize discharge where feasible by cascading, or transferring, water between test sections.

			Total	**N/A [2]**			

[1] The volumes in the table represent the estimated withdrawal volume from a potential hydrostatic test source, and, in some cases, alternate sources are identified for the same test segment(s) because water withdrawals would be based on conditions at the time of construction.

[2] Totaling the potential withdrawal volumes is not applicable because, as stated in footnote #1, multiple (alternate) sources have been identified for the same test segments. Without cascading (not proposed), the physical volume for all individual test segments would be approximately 64.3 million gallons, or about 40.2 acre feet. With the use of cascading, which is proposed, the minimum test water volume to be withdrawn would be approximately 25,832,000 gallons or 79.28 acre feet across all sources, an approximate 43 percent reduction in water use. The actual volume will be within this range and is expected to be at the lower end of the range.

						Total [6]	**64,275,000 (197.25)**					

[1] Mileposts were not calculated from engineering stationing. " R" and "BR" represent a revised milepost location based on the incorporation of reroutes into the Proposed Route.
[2] Section length is calculated directly from engineering footage.
[3] Section volumes were calculated using section length directly from engineering footage.
[4] Water will be cascaded between test sections, where practical, to minimize test water volume requirements, withdrawals, and potential water hauling. It is expected that the largest volume of water to be released would be associated with the longest test segment within a basin.
[5] Waterbodies were determined from USGS National Hydrography Dataset water course data(http://nhd.usgs.gov/). Distances are between the test break/header location (at MPs provided in this column) to the closest water course regardless of flow characteristics (*i.e.*, perennial, intermittent, or ephemeral); dewatering structures for the test break/header locations will be located a minimum of 150 feet from waterbodies/wetlands.
[6] Without cascading (not proposed), the maximum test volume for all individual test segments would be 64,275,000 gallons. With the use of cascading, which is proposed, the minimum test water volume to be withdrawn would be 25,832,000 gallons. The actual volume will be within this range and is expected to be at the lower end of the range.

After the test is complete, hydrostatic test water would be discharged to an upland area through a filter bag or straw bale structure to remove particulates. Hydrostatic test water would be discharged into vegetated upland areas at a rate to prevent scour, erosion, and sediment migration. Discharge rates would range from several hundred gallons per minute to several thousand gallons per minute, depending on the length of the test section, profile, topography, vegetation cover, and soil type, and as reviewed by the contractor and the EI.

Dust and Fire Control Water

During Pipeline construction, PCGP would need to obtain water for dust and fire control purposes. PCGP estimates that there would be approximately five 3,000-gallon water trucks per construction spread on a given day. Thus, the total the Pipeline would use about 75,000 gallons of water per day for dust suppression and fire control, contained in 25 water trucks over the five spreads combined. Watering trucks would spray only enough water to control the dust or to reach the optimum soil moisture content to create a surface crust. Runoff should not be generated during this operation. Water may be obtained through municipal sources or withdrawn from surface water or groundwater sources. All appropriate permits/approvals would be obtained prior to withdrawal. Table 2.1.2-12 lists potential dust control water sources that have been identified by PCGP.

TABLE 2.1.2-12

Potential Dust Control Water Sources for the Pipeline

County	Approximate MP	Source
Coos	16.5	Aqueduct Lake
Coos	37.0	Brewster Lake (WI-602)
Douglas	50.2	Lang Creek Reservoir
Douglas	79.0	Big Lick Reservoir
Jackson	128.5	Indian Lake Reservoir
Jackson	133.4	Eagle Point Irrigation Canal Crossing (Medford Aqueduct)
Jackson	141.0	Star Ranch Lake
Jackson	144.0	Unnamed Reservoir
Jackson	145.0	Gardener Reservoir
Klamath	228.5	High Line Canal
Klamath	228.7	Capek Reservoir
Klamath	229.4	Low Line Canal

Additionally, PCGP has indicated it may utilize a synthetic product such as Dustlock®, in addition to water, for dust control. Dustlock is a naturally occurring by-product of the vegetable oil refining process. Dustlock penetrates into the bed of the material and bonds to make a barrier that is naturally biodegradable, ensuring that the surrounding ground and water are not contaminated, and minimizing any potential effects to fish and wildlife. While there are no known health risks by the use of Dustlock to fish and wildlife resources, PCGP would not use Dustlock within riparian areas.

Cleanup and Restoration

Cleanup

PCGP has indicated it would make every effort to complete final cleanup of an area within 20 days after backfilling the trench. Final cleanup would include final grading and installation of permanent erosion control structures. During final cleanup, PCGP would remove all construction debris. Fences, gates, drainage ditches, culverts, and other structures that may have been temporarily removed or damaged during construction would be permanently repaired, returned to their preconstruction condition, or replaced. All drain tiles crossed by the pipeline would be checked, and if damaged, they would be repaired. PCGP would install erosion control fabric (such as jute or excelsior) to stabilize streambanks during restoration. In residential and cropland areas, additional cleanup activities prior to the preparation of a proper seedbed may include rock removal. The right-of-way would be restored as close to its original topographic contours as practicable. However, if it appears that construction may continue into the winter because of unforeseen delays and cleanup and reseeding is delayed until the spring, PCGP would implement the winterization plan (see attachment E to the ECRP in appendix F). This plan describes the procedures that would be implemented to minimize potential impacts associated with delayed cleanup (i.e., temporary erosion controls procedures, topsoil stabilization, reseeding, etc.).

Permanent Erosion Control Devices

PCGP would install permanent erosion control devices or BMPs consistent with the requirements of Section V.B. of the FERC's *Plan*, and as described in the Pipeline project-specific ECRP provided in appendix F. This would include permanent waterbars on steep slopes, spaced as specified in the PCGP's ECRP. Table 2.1.2-13 lists specifics from PCGP's ECRP for the installation of slope breakers.

TABLE 2.1.2-13

Permanent Slope Breaker Spacing From PCGP's ECRP a/

Slope	Highly Erosive Granitic Soils b/	Soils With Moderate or Low Potential for Erosion
0 to 5 percent	None required	None required
5 to 15 percent	100 feet	200 to 300 feet
15 to 30 percent	50 to 75 feet	75 to 100 feet
Greater than 30 percent	50 feet	50 feet

a/ Actual spacing would be determined at the time of installation based on site-specific topographic conditions on the right-of-way to ensure proper slope breaker construction and proper drainage to stable off-site areas. On the Umpqua National Forest between about MPs 109 and 110, where the alignment would cross the historic Thomason cinnabar claim group, waterbars would be installed at 50-foot intervals as recommended by the Forest Service.
b/ Granitic formations would be crossed by the pipeline between: MPs 79.1 to 80.5; MPs 81.6 to 82.2; MPs 87 to 88.8; MPs 97 to 101.2; MPs 103 to 105.4; and MPs 114.8 to 115.

Revegetation

All areas disturbed by construction, including the construction right-of-way, TEWAs, UCSAs, and contractor yards as necessary, would be restored and revegetated in accordance with PCGP's ECRP. Prior to seeding, the disturbed areas would be prepared as a seedbed approximately 3 to 4 inches deep using appropriate equipment, as necessary in certain areas, as determined by the EI. This could include chisel plowing or disking. In most areas, typical regrading and contouring during restoration would create a suitable rough, yet firm, seedbed, conducive to capturing seeds and retaining soil moisture. Usually, in agricultural areas, the landowner determines whether or not PCGP would be responsible for seeding. In some situations, the owner of agricultural land may do the final restoration and seeding and PCGP would compensate the landowner for those efforts.

In residential areas, PCGP would restore disturbed lawns, ornamental shrubs, gardens, and other landscape features in accordance with their agreement with the landowner. The restoration work in residential areas would be done by a contractor familiar with local horticultural or landscape practices, or PCGP may choose to compensate a landowner to restore their property.

Based on Oregon State University Extension Service recommendations for fertilization rates for nitrogen fertilizer on new pasture seedlings, PCGP intends to use a standard fertilization rate of 200 pounds per acre bulk triple-16 fertilizer on disturbed areas to be seeded. The NRCS did not recommend the addition of lime or other soil pH modifiers. Fertilizer would not be used in wetlands, unless required by the land-managing agencies, and would not be applied within 100 feet of streams. The fertilizer would be stored outside of riparian reserves and away from streams, and would not be applied during heavy rains or high wind conditions. It could be either broadcast, or incorporated in the slurry for hydroseeding.

The seed mixtures were determined in consultations with the land-managing agencies and the NRCS. The seed mixture seeding rates are based on Pure Live Seed. The seed mixture should be free of noxious weeds. Tables 10.9-1, 10.9-2 and 10.9-3 of the ECRP list species required in specific ecozones.

Of the approximate 2,100 acres of forested areas affected by the construction right-of-way and temporary extra work areas, 1,583 acres will be replanted with tree species, leaving 517 acres cleared for the 30-foot operational corridor. PCGP would plant native trees/shrubs extending 100 feet from streambanks on federal lands. Prior to construction, PCGP would submit a Request for Service to vendors and growers to provide the necessary quantity of native seed that would be required for restoration and revegetation.

It is expected that seeding would be timed to begin in August and could extend into the winter months at lower elevations. Seeding may be done by broadcast methods, drilling, or hydroseeding. Broadcast seeding, using a mechanical broadcaster seeder, is the preferred method of seeding on steep slopes. After broadcast, the seedbed would be dragged by chains or other appropriate harrows to cover the seeds thinly with soil. Hydroseeding would be done in accessible upland areas. Hydroseeding equipment would include tanks, pumps, nozzles, and other devices for mixing the seed hydraulically with wood fiber mulch and tackifier. A built-in agitator would keep the seed, mulch, tackifier, and water mixed together homogeneously until pumped from the tank. A drill seeder pulled by a tractor may be used in gently sloping areas.

Mulch would be applied on slopes were necessary to stabilize the right-of-way after seeding. Mulch would consist of native wood chips, wood fiber mulch mixed with the hydroseed, bonded fiber matrix to be used on slopes steeper than 40 percent grade (greater than 2.5 to 1), and certified weed-free straw.

Waterbody Crossings

The Pipeline would affect 346 waterbodies (63 are not crossed by the centerline): 66 are perennial, 168 are intermittent, 98 are ditches, 10 are lakes or stock ponds, and 4 are estuarine (Coos Bay/2 crossings and one HDD pullback and the Coos River). The table in appendix M lists the waterbodies affected by the Pipeline and provides the proposed crossing method for each, the rationale for the proposed method, whether federally listed species are present, the ODFW-recommended in-water work window, and whether a crossing bridge is required. All waterbodies would be crossed during the ODFW recommended in-water work windows; except the rivers crossed using HDDs or Direct Pipe (DP) technology, because no in-water work is expected at those crossings. PCGP would cross waterbodies in accordance with FERC's *Procedures*, and the *Stream Crossing Risk Analysis* (GeoEngineers, Inc. 2017d and 2017e),[7] which identified design guidance, contingency measures, and monitoring protocol specific to each crossing.

Installation of Temporary Equipment Bridges over Waterbodies

PCGP would install temporary equipment bridges over flowing waterbodies before those streams are crossed by equipment. The temporary equipment bridges would be constructed to maintain unrestricted flow and to prevent soil from entering the waterbody. Soil would not be used to stabilize equipment bridges. The bridges would span the entire ordinary high water mark (OHWM) of the waterbody. If it is not possible to span the OHWM with the bridges, a temporary culvert or pier may be required. The temporary crossings may be constructed of:

- equipment mats and culvert(s);
- equipment mats or railroad car bridges without culverts;
- clean rock fill and culverts; or
- flexi-float or portable bridges.

For any temporary equipment crossings on any stream channel (whether intermittent or perennial, wet or dry) on NFS lands, the Forest Service has stated that it is the their policy that equipment crossings must be accomplished using (1) a bridge, (2) a temporary culvert with temporary road fill to be removed after work is completed, or (3) a low water ford with a rock mat. While FERC's *Procedures* (at section V.B.5.a.) allow clearing equipment to cross waterbodies prior to bridge installation, PCGP would only cross waterbodies with its equipment after bridge placement. Where feasible, PCGP would attempt to lift, span, and set the bridges from the streambanks.

To allow for the delivery of materials and equipment up and down the construction right-of-way, it may be necessary to install some bridges outside the ODFW recommended in-water construction windows. Temporary bridges would be set during clearing operations in the first year of construction as well as during mainline construction the following year. The temporary bridges set during clearing operations would be temporarily removed after clearing is complete and would not be left in place across a waterbody over the winter. During mainline construction in the second year of construction, the temporary bridges would be reset and would be removed as soon as possible after permanent seeding. Equipment bridges would be removed as soon as possible after final cleanup.

Minor or Intermediate Waterbody Crossings

FERC defines minor crossings as waterbodies less than 10 feet across, while intermittent streams are between 10 and 100 feet wide. PCGP plans to cross intermittent flowing streams, and irrigation canals and ditches when they are dry, using standard upland, cross-country pipeline construction methods. If water is flowing at the time of the crossing, a dry crossing method would be used (i.e., flume or dam-and-pump, see below). The standard depth of cover would be 5 feet below intermittent flowing streams and ditches. Virtually all minor or intermittent

[7] Appendix O.2 to Resource Report 2 in PCGP's September 2017 application to the FERC.

waterbodies would be crossed using dry open-cut methods as discussed below. The Pipeline would cross numerous irrigation canals and ditches in agricultural fields in Klamath County. Some of the irrigation canals and ditches in this area are part of Reclamation's Klamath Project. PCGP would conventionally bore Reclamation's facilities, which would comply with Reclamation's requirement that the pipeline be installed at least 3 feet below the bed of facilities over which it has jurisdiction. Reclamation would also require that irrigation canals and ditches under its jurisdiction be crossed between October 15 and March 15, outside of the irrigation season. PCGP developed the *Klamath Project Facilities Crossing Plan* (see appendix O to the POD) to identify and protect Reclamation's facilities during construction,.

Dry Open-Cut Crossing Methods

Flume. The flume method typically is used to cross small to intermediate flowing waterbodies that are either fish-bearing or non-fish-bearing streams. The flume technique involves diversion of stream flow into a carefully positioned steel pipe of suitable diameter to convey the maximum flow of the stream across the work area, and ensures that stream flow rate is not interrupted.

Dam-and-Pump. With the dam-and-pump method, stream flow is diverted around the work area by pumping water through hoses over or around the construction work area. The goal of this technique is to create a relatively "dry" work area to avoid or minimize the transportation of heavy sediment loads and turbidity downstream of the crossing. This crossing method may be used on all waterbodies where stream flow can be diverted by pumping around the work area.

Erosion, Turbidity, and Suspended Sediments Related to Dry Stream Crossings

Some turbidity would result during instream activities and when the water is diverted to the backfilled areas; when upstream and downstream dams used to isolate the construction area are installed or removed; when water leaks through the upstream dam; when in-stream rocks or boulders have to be removed; and when streamflow is returned to the construction work area after the crossing is complete and the dams and flume are removed. GeoEngineers, Inc. (2017f) evaluated the potential risk of turbidity during construction across waterbodies and the results are detailed in the appropriate species' sections.

Reid et al. (2004) measured suspended sediment downstream from 12 flumed pipeline crossings and 23 dam-and-pump crossings. The study estimated that suspended sediment concentrations averaged 99 mg/l for flumed crossings and 23 mg/l at the dam-and-pump crossings. Reid et al. (2002) found that below four separate dam-and-pump crossings, mean suspended sediment was less than 20 mg/l within 30 meters (100 feet) downstream. PCGP estimated that suspended sediment concentrations produced during construction during summer low-flow conditions may be highest for the 10 waterbodies crossed by fluming within the Coos Bay-Frontal Pacific Ocean fifth-field watershed and 11 waterbodies crossed by fluming in the Myrtle Creek fifth-field watershed (see table 3.2-16 in PCGP's Resource Report 3). However, even for these streams, nearly all dry crossing estimates of TSS would be less than 100 mg/l within 50 meters downstream of the crossing site (see table 3.2-21 in PCGP's Resource Report 3). For the other fifth-field watershed crossings where estimates could be made, the average suspended sediment concentrations produced during fluming and dam-and pump construction would be near background suspended sediment levels (about 2 mg/l). Nearly all estimates were less than 10 mg/l between 50 and 150 meters downstream from construction sites.

PCGP would implement the BMPs in its ECRP, including sediment fences, which would reduce bank erosion into streams. Turbidity and sedimentation impacts associated with dry open-cut methods are generally minor and temporary. Pipeline construction across intermediate sized streams using dry crossing techniques is not expected to cause major erosion, turbidity, or sedimentation that could significantly affect water quality or impact aquatic species.

<u>*Removal of Substrata*</u>

The FERC *Procedures* require that the upper one foot of the trench to be backfilled with clean gravel or native cobbles in all waterbodies that contain cold water fisheries. PCGP has requested a modification to backfill the trench with existing materials removed from the stream, where the substrate is not gravel or cobbles, and site access is limited and would require unreasonable efforts to transport clean gravel to the waterbody. The Forest Service would require site-specific approval of the modifications on NFS lands.

Water Temperatures

In forested areas, shade would be reduced at waterbody crossings where trees are removed. Studies have been conducted to determine if the clearing of riparian forest would adversely affect stream water temperatures. PCGP has proposed supplemental riparian plantings as outlined in the ECRP (see appendix F) to help ensure that the core coldwater habitat temperature criteria are not exceeded at the maximum point of impact. These measures are designed to speed up the rate of riparian area recovery and provide more effective shade immediately following construction. Much of the riparian area would be allowed to regrow from plantings with herbaceous plants (only 10 feet wide would be maintained without some growth) and conifer and other trees (all but 30-foot width). On small streams and to a lesser extent on larger streams, even 10- to 15-foot-high trees would supply shade, reducing solar heating effects on streams. Thus plantings and vegetation regrowth in riparian areas would help moderate potential temperature increases in the short-term (a few years). Also, PCGP has developed a Large Woody Debris (LWD) Plan to offset impact from removal of riparian trees (reducing LWD recruitment potential) and to provide an overall benefit by enhancing stream habitat with no potential for LWD recruitment, PCGP proposes to place LWD at the waterbody flow types identified by watershed. Placement of LWD in streams adds structural complexity to aquatic systems, traps fine sediments, and can contribute to reductions in stream temperatures over time. One study (GeoEngineers, Inc. 2017c) examined 15 stream crossings, varying in width from 2 feet to 85 feet. Assuming a 75-foot-wide construction right-of-way at each crossing, and conditions typical of August, the model predicted water temperature increases averaging 0.03°F, with the maximum temperature increase at the narrowest stream crossing being 0.3°F. Modeling results indicate that within a short distance downstream from all crossings, instream water temperatures would return to ambient conditions.

Any temperature changes that may occur would gradually be reduced or eliminated over time as plantings and natural vegetation growth increases stream shading. Pipeline rights-of-way are narrow, and water would flow quickly past the crossing locations, with greater volumes in larger streams. In addition, stream temperatures are influenced by the infusion of fresh water from springs, seeps, and other groundwater sources, in addition to surface tributary runoffs, both upstream and downstream of pipeline crossings. Construction of the pipeline across streams and the removal of riparian vegetation is not expected to raise water temperatures enough to have significant impacts on aquatic species.

Major Waterbodies

Major waterbodies as defined by FERC's *Procedures* are those greater than 100 feet wide (section I.B). These waterbodies include, from west to east along the pipeline route, Coos Bay, Coos River, South Umpqua River, Rogue River, and Klamath River. The methods for crossing these major waterbodies are discussed below. Coos Bay and the Coos River, Rogue River, and Klamath River would be crossed using an HDD. The South Umpqua River would be crossed using DP technology for the western crossing, and a diverted open-cut for the eastern crossing. HDDs and DPs would not cause erosion, sedimentation, or suspended sediments in the river, except in the unlikely case of a failure, or "inadvertent return" as discussed below. Conventional bores are also likely to avoid impacting waterbodies.

Coos Bay, Coos River, Rogue River, and Klamath River

PCGP is proposing to use the HDD method for two crossings of Coos Bay and the crossings of the Coos River (MP 11.1R), the Rogue River (MP 122.7), and the Klamath River (MP 199.4). Appendix E provides HDD crossing plans for Coos Bay and for each river as well as a *Drilling Fluid Contingency Plan* and a *Failure Mode Plan*.

The HDD method involves boring under a feature and pulling the pipeline into place through the borehole that has been reamed to accommodate the diameter of the pipeline. This procedure involves three main phases, pilot hole drilling, subsequent reaming passes, and pipe pullback. HDD typically is used for the crossing of major waterbodies (i.e., those greater than 100 feet wide).

<u>Pilot Hole</u>

The pilot hole establishes the ultimate position of the installed pipeline. For this operation, an initial hole is drilled from the entry point to the exit point on the opposite side of the crossing. The head of the pilot drill string contains a pivot joint to provide directional control of the drill string. By altering or steering the drill head, the operator can control the direction as the drill progresses. Thus, the pilot hole can be directed downward at an angle until the proper depth is achieved, then turned and directed horizontally for the required distance, and finally angled upward to the surface. Tracking and steering of the HDD drill head is generally guided using a two-wire system. The system consists of two insulated wires (approximately 0.25 inch in diameter) that are laid on the ground and are charged with an electrical current. A magnetometer accelerometer probe located behind the drill bit detects the electric current to triangulate the drill bit for steering.

As the pilot drill string is advanced, additional sections of drill pipe are added at the drill rig located at the entry point. High-pressure jetting of drilling fluid at the drill head and, in harder soil formations, rotation of the drill bit, facilitates advancement of the drill string. The drilling fluid (mud) is typically a non-toxic bentonite clay mixed with freshwater to make a slurry. Once the pilot hole exits in an acceptable location, the reaming operation is initiated.

<u>Reaming</u>

During the reaming phase, a reaming head is attached to the drill pipe and pulled back through the pilot hole to enlarge it. Several reaming passes may be made with incrementally larger reaming heads to enlarge the hole to approximately 1.5 times the diameter of the pipeline. Various reaming heads can be utilized, depending on the substrate encountered. High-pressure drilling fluid is jetted through the reaming head to float out drill cuttings and debris, to cool the drilling head, and to provide a cake wall to stabilize the hole. Once the drill hole is enlarged to the proper diameter, the pipe is pulled back through the reamed hole.

Pullback

The last step to complete a successful installation is the pullback of the pre-fabricated product pipe into the enlarged hole. The pullback process is the most critical step of the HDD process. A reinforced pullhead is welded to the leading end of the product pipe and to a swivel connected to the end of the drill pipe. The swivel is placed between the drill rig and the product pipe to reduce torsion and prevent rotation from being passed to the product pipe.

During pullback, the pull section is supported with a combination of roller stands and/or product pipe handling equipment to direct the product pipe into the hole at the correct angle, reduce tension during pullback, and prevent the product pipe from being damaged. After the product pipe is in place, the installed crossing is hydrostatically tested, pigged (optional), and tie-in welds on each side of the crossing are completed.

Failures or Inadvertent Returns Related to HDDs and DPs

The HDD method has the potential for inadvertent releases of drilling mud into the waterbody. If a fault or crack in the overburden is encountered, the drilling mud can escape to the surface. This is referred to as an "inadvertent return." Drilling mud typically comprises bentonite clay and water, and can include additional additives specific to each drilling operation and would therefore be considered a pollutant. PCGP would approve any additive compounds prior to use by the drilling contractor to ensure compliance with all applicable environmental and safety regulations. Toxic additives would not be used in the bentonite drilling mud for the HDDs.

If an inadvertent return occurs, the HDD operation would be stopped temporarily to determine an appropriate response plan. PCGP would work to determine the cause of the hydraulic fracture and inadvertent return and would implement procedures to correct or mitigate the situation. Those procedures may include:

- increasing the drill fluid viscosity;
- introduction of lost circulation materials back into the hole;
- installation of steel casings; or
- use of a grout mixture.

Any inadvertent release of drilling mud into a waterbody would be monitored, and the appropriate agencies would be contacted, and approved corrective measures would be implemented. Impacts would be localized and short term, limited to species in the immediate vicinity of the inaedvertent return, and ameliorated by river volume.

While the HDDs are expected to be successful, PCGP considered procedures to be implemented in the event of a failure. If the pilot hole collapsed, material falls into the hole, pipe becomes lodged in the hole, or there is a mechanical breakdown of the rig, the contractor would remove the pipe, and the HDD would be reattempted at the same location, or slightly offset after obtaining any necessary review and approval from applicable state agencies. If the hole has to be abandoned, the contractor would grout the top five vertical feet of the hole on both the entry and exit side of the crossing with a cement type grout and the top 12 inches of the hole would be filled with native material or in accordance with the permit requirements.

Noise Generated by HDDs and DP Crossings

Some portions of HDD operations would occur as 12-hour work shifts, while other activities would normally occur as 24-hour-per-day operations. The overall duration of HDD operations should last from 2 to 4 weeks at each site.

PCGP estimated that at the various NSAs, HDD, or DP operations would generate estimated L_{dn} levels of: 1) 53.2 to 65.1 dBA/Coos Bay West; 2) 43.8 to 61.8 dBA/Coos Bay East; 3) 59.6 to 72.7 dBA/Coos River; 4). 35.3 to 64.2 dBA/South Umpqua River; 5) 67.6 to 78.5 dBA/Rogue River east entry; 6) 62.6 to 70.8 dBA/Rogue River west entry; 7) 68.3 to 79 dBA/Klamath River east entry; and 8) 57 to 58.4 dBA/Klamath River west entry.

Construction noise levels from HDD and DP activities would exceed the FERC limit of 55 dBA Ldn. PCGP has proposed mitigation measures that would be used during construction, which if implemented would result in predicted noise levels below acceptable limits.

South Umpqua River – MP 71.3

PCGP would use DP technology to cross the South Umpqua River at MP 71.3. DP is a trenchless construction method to install pipelines beneath rivers, highways, railroads, levees, wetlands and other features that require special attention to environmental and logistical concerns. DP is, in its simplest definition, a combination of the traditional microtunneling process and HDD. DPs are completed using an articulated, steerable microtunnel boring machine (MTBM) mounted on the leading end of the product pipe or casing which is jacked into position using a pipe thrusting machine mounted at or near the ground surface (see appendix E).

Internal instrumentation is typically used to survey the progress of the MTBM so that its location can be compared to the design requirements. A gyroscope mounted within the MTBM locates the orientation and a precision manometer is used to locate the elevation of the MTBM.

The MTBM exerts continuous and controllable pressure at the excavation face and is capable of excavating a wide variety of soils under significant groundwater pressures. Soil and rock are excavated by the cutting head and removed through pressurized slurry pipes to the launching pit at a rate that is balanced with the advance rate of the machine, as the MTBM and pipe are jacked through the formation. A pipe thrusting machine located in or near the launching pit provides the necessary force to advance the product pipe and provide the face pressure required for excavation. The product pipe is typically prefabricated in a continuous section or in smaller sections, typically 300 to 500 feet. The smaller sections are welded to the back of subsequent sections after each section is advanced.

Friction between the pipe and surrounding soil can create significant resistance during DP installation. To reduce the frictional resistance, over cutting is employed to create a small annular space between the pipe and external soil. The over cut is typically on the order of 1 to 2 inches. The use of bentonite slurry helps reduce the frictional resistance between the pipe and soil as well as reducing the risk of collapse of the annulus around the pipe. Bentonite lubrication is typically added from the launch seal and from a specialized lubrication ring located behind the MTBM and in front of the jacking pipe.

Following completion of the tunneling process, the MTBM is retrieved from the receiving pit. If the DP-installed pipe is to be used as casing, after completion of the grouting the product pipe may be installed within the casing using centralizers or resting on the bottom of the casing if the product pipe is concrete coated. After the product pipe is installed and tested, the interior annular space between the casing and product pipes may be filled with cement grout.

South Umpqua River – MP 94.7

The second crossing of the South Umpqua River at MP 94.7 would be done as a dry diverted open-cut, planned for the ODFW recommended in-water work window between July 1 and August 31 during the first year of construction. The South Umpqua River channel at MP 94.73 is sufficiently flat, wide, and shallow to divert all of the river flow to one side or bank of the river while work is proceeding in the dry on the opposite bank. Typically in August water levels at the crossing have been sufficiently low that a diverted open-cut crossing method could easily have been utilized at this crossing location.

This crossing method would require TEWAs to be located in the river and would require equipment to work in the river to place the diversion structures or dams to divert the river flow from one side of the river and then to the other. The diversion could be constructed using imported riprap, concrete jersey barriers, water bladder portadams, and/or sand bags to divert the river's flow temporarily away from the work area in order to minimize contact between stream flow and the excavation and backfill activities. This would require PCGP to place equipment within the stream to install, maintain, and ultimately remove the diversion structures. The crossing would take a minimum of 14 days to complete including 3 to 4 days of in-stream work to install, rearrange, and remove the diversion structures. Some turbidity would result during in-stream activities and when the water is diverted to the backfilled areas.

The diverted open-cut crossing method at this location would require an in-stream tie-in, but it would be made in the dry behind the diversion structure. During the crossing, initial trenching would first occur on the dry side of the river; however, depending on the water levels during the season, it may be necessary to install a diversion to push or divert the flow to at least the middle of the river. Once the construction right-of-way has been isolated by the diversions and/or sediment control devices, trenching would proceed to approximately the middle of the river. Trench spoil would be stored within the stream channel behind the diversion or sediment control structures to ensure that sedimentation from saturated materials does not flow back into the river. After the trench has been completed, a section of pipe would be placed in the trench. Trench boxes or another marker form would be placed at the end of the pipe section in the middle of the riverbed for the tie-in. The trench would be backfilled and the streambed restored to the original contour configuration, except for the immediate area around the tie-in.

The diversion structure would then be removed and rearranged to divert the flow temporarily to the other side or dry side of the river in order to minimize contact between stream flow and the excavation and backfill activities. This would again require PCGP to place equipment within the stream in order to rearrange the diversion structures. Once the diversion structures have been properly reconfigured and extended beyond the tie-in location and the river flow diverted to the opposite side of the river, excavation for the other section of pipe would begin. Trenching would proceed across the river bed to the tie-in point in the middle of the river where it would be uncovered. Once the excavation is complete, the second pipe section would be carried in and tied-into the first section. After the tie-in has been made, the streambed would be restored to its original contours and configuration and the diversions structures would be removed. Streambanks would be reestablished and stabilized.

During the diverted open cut, multiple discharge pumps would be required to keep the tie-in area dry while the welds are being made and to control any flow seepage in the work areas. The discharge from this activity would occur to a straw bale discharge structure located in an upland area as far away from the river as possible to prevent any silt-laden water from flowing into the river.

Medford Aqueduct (MP 133.4)

Conventional bores of waterbodies are proposed at the Medford Aqueduct (MP 133.4) and Reclamation's facilities. The specific type of bore (i.e., jack and bore, slick bore, hammer, etc.) that would be utilized would be determined during the design phase of the Pipeline and depends on construction characteristics, the type of soils present, and the contractor's familiarity with the method. The hammer is typically utilized in difficult soils containing consolidated rock, and the slick bore is used in soils with fewer frictional characteristics. Although each type of bore is somewhat different, the requirements and risks associated with each are similar. In all cases, the bore must be completed along a straight pathway requiring excavation of a bore pit on either side of the crossing (called launching and receiving pits). The depth of the bore pits must be several feet deeper than the bottom of the pipeline and can be quite deep when accounting for the depth of the feature to be crossed and the depth of cover between the bottom of the feature (e.g. stream bed) and the top of the pipeline. Welders and other laborers must work within the confined space of the bore pit; and the presence of water can be problematic.

During a standard boring operation, the spoil material is passed into the bore pit. Trackhoes then remove this spoil from the bore pit. Pipe is welded up and eventually pulled through the bore hole. Each section of the pipe is joined using full-penetration welding procedures and 100 percent of the welds are inspected using non-destructive testing procedures (x-ray) to form a continuous pipeline segment. This is a difficult operation, requiring the welders to work in the confined space of the bore pit. Because conventional boring does not limit water migrating into the bore, an important factor in the design of launching and receiving pits is groundwater control. Dewatering systems using deep wells or well points are frequently used. Trench boxes or sheet piling are often used to support the pit walls and to cut off groundwater inflows.

Timing of Construction

PCGP anticipates starting construction in the first half 2020, when Early Works (MPs 0 – 7.34R, including the two HDDs across Coos Bay) will be initiated. PCGP plans to conduct civil survey and road improvements and to clear the majority of the right-of-way in 2021 (clearing would continue into 2022). Horizontal directional drills of five waterbodies (Coos Bay Estuary/2 crossings; Coos River; Rogue River; and Klamath River) and DP installation technology for a sixth waterbody (South Umpqua River) are scheduled for 2020 and 2022. A sixth HDD to avoid severe steep side-slope on a narrow ridgeline parallel to an existing powerline easement containing two large power transmission lines and the Coos County gas transmission pipeline between them is proposed at MP 25. Figure 2.1.2-2 provides a general schedule for the Pipeline.

Mainline and facility construction is planned to begin second quarter 2022 with the in-service date scheduled for third quarter 2023. Restoration of construction disturbance in each given area is expected to begin once construction is completed in that area; restoration would be completed by the end of the winter season when forest, wetland, and riparian plantings would be installed. Depending on site-specific conditions, it may be necessary to continue restoration through the spring. Timber clearing in areas of NSO and MAMU would be conducted outside the critical breeding seasons (see table 2.1.2-14). Construction activities are scheduled to take advantage of the drier periods of the year to minimize winter construction, to reduce potential environmental impacts and construction safety risks.

PCGP plans to conduct forest clearing starting third quarter 2021 prior to mainline construction, to minimize overall work space and TEWA requirements. TEWA requirements have been minimized by proposing a two-year construction window because the same work areas used to stage right-of-way logging timber clearing activities and provide log storage and decking space would then be utilized for construction activities. Logging concurrently with pipeline construction would require additional space to work safely and efficiently. Scheduling clearing and mainline construction activities over a two-year period will minimize winter construction requirements resulting from seasonal and biological construction windows. The detailed schedule for clearing activities will include areas of known seasonal restrictions along the route. Temporary erosion control and stabilization measures will be installed where necessary in areas of disturbance. These measures will be maintained throughout construction until the Pipeline is in-service and disturbed areas are stable.

A schedule has been developed taking into consideration seasonal construction constraints (timing windows) stipulated to protect biological resources (NSO, MAMU, in-stream construction/fisheries, and big game wintering habitats) (see table 2.1.2-14). The schedule allows for reasonable time requirements to remove timber and construct the Pipeline to reduce potential environmental impacts and construction safety risks associated with winter construction. If stipulated timing windows for two or more resources conflict with each other or cannot be considered for environmental and safety reasons, efforts have been taken to reduce the seasonal constraints near the ends of recommended in-stream construction windows (ODFW 2000) and/or NSO and MAMU breeding seasons. Construction across waterbodies would occur within the ODFW-recommended in-stream construction timing windows, although the majority of bridges, where required, would be installed prior to and removed after the in-stream timing window. General timing of activities is shown schematically in figure 2.1.2-2.

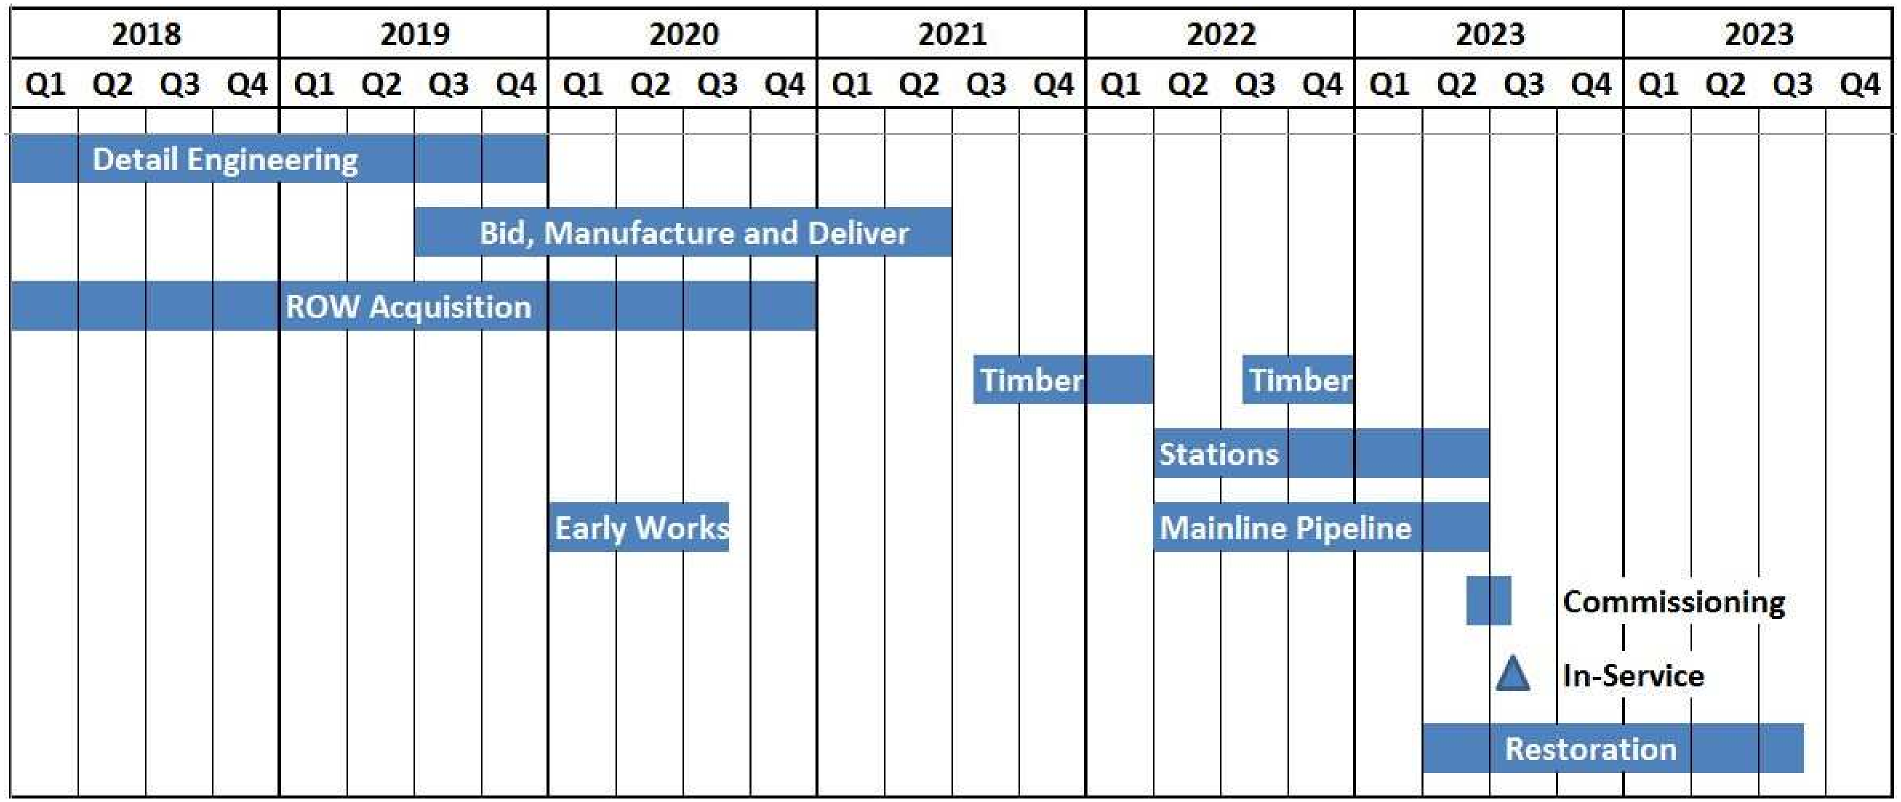

Figure 2.1.2-2 General Construction Schedule for the Pipeline

TABLE 2.1.2-14
Summary of Seasonal Timing Restrictions for Migratory Birds, Endangered Species and Raptors Based on Pipeline Activities

Pipeline Activity	Seasonal Timing Restrictions for Timber Felling, Logging, Clearing and Construction Activities						
	Migratory Birds (wooded habitat)[1]	Northern Spotted Owl[2]	Marbled Murrelet[2]	Great Grey Owl[2]	Bald Eagle[3]	Golden Eagle[3]	Peregrine Falcon[4]
Felling and Brush Mowing [5]	NO WORK Apr 1 - Jul 15	NO WORK Mar 1 - Sept 30	NO WORK Apr 1 - Sep 15 within 300-ft buffer from stand	NO WORK Mar 1 - Jul 31	NO WORK Jan 1 - Aug 31	NO WORK Jan 1 - Aug 31	NO WORK Jan 1 - Jul 31
Logging, Skidding and Processing	NO RESTRICTION [6]	NO WORK [6] Mar 1 - Jul 15	DTR [6, 7] Apr 1 - Aug 5; Apr 1 - Sep 15 w/ helicopters [8]	NO WORK Mar 1 - Jul 31	NO WORK Jan 1 - Aug 31	NO WORK Jan 1 - Aug 31	NO WORK Jan 1 - Jul 31

[1] Only considers migratory bird “wooded” habitat (meaning all forest regenerating areas [not including recent clear-cuts], deciduous tree groves, shrub/brush thickets, etc.) Note: understory and residual slash in felled timbered areas would not be considered migratory bird habitat.
[2] Applies to areas within 0.25 mile of nest site (northern spotted owl, great gray owl) or marbled murrelet stand (presumed occupied, occupied), unless otherwise noted.
[3] Applies to areas within 0.5 mile of nest site (bald eagle, golden eagle).
[4] Applies to areas within 1.5 miles of peregrine falcon eyrie as delineated by Umpqua National Forest.
[5] Includes all forested areas (not including recent clear-cuts), deciduous tree groves, shrub/brush thickets (i.e., oak).
[6] Applies if trees and brush are previously felled. Otherwise, see restriction for “felling and brush mowing.”
[7] DTRs (Daily Timing Restrictions) stipulate no work until two hours after sunrise and work must stop two hours before sunset.
[8] Where large transport helicopter use is necessary to remove logs or supply pipe.

2.1.2.4 Operations, Maintenance, and Monitoring –Pipeline

PCGP would test, operate, and maintain the proposed pipeline facilities in accordance with DOT regulations provided in 49 CFR Part 192, Transportation of Natural and Other Gas by Pipeline: Minimum Federal Safety Standards, FERC's guidance at 18 C.F.R. §380.15, and maintenance provisions of the FERC's *Plan* and *Procedures*. The Pipeline right-of-way would be clearly marked where it crosses public roads, waterbodies, fenced property lines, and other locations as necessary. Table 2.1.2-15 lists the habitat types affected by operations of the Pipeline facilities.

The Pipeline would be inspected regularly by aerial patrols or on-the-ground personnel to observe general right-of-way conditions and to identify any indications of soil erosion that may expose the pipe, stressed vegetation that may indicate a leak in the line, damage to erosion control structures, unauthorized encroachment onto the right-of-way, and other conditions that could present a safety hazard or require preventive maintenance or repairs. All inspections would be in accordance with DOT standards. Areas susceptible to damage from large storm events would be inspected and repaired as appropriate depending on the nature of damage. Permanent erosion control devices would be maintained.

In accordance with the FERC's *Plan*, a corridor centered on the Pipeline not more than 10 feet wide could be maintained in an herbaceous state annually. However, mowing would not be conducted between April 15 and August 1, to reduce impacts on nesting birds. Not more than every three years, a 30-foot-wide corridor centered on the Pipeline could be maintained. Trees within 15 feet of the pipeline could be cut. During maintenance, vegetation may be cut/trimmed in 4- to 6-foot lengths and scattered across the permanent easement to naturally decompose, discourage OHV traffic, and benefit wildlife habitat. Occasionally where site conditions allow, chipping of this material may also occur. PCGP believes that the slash materials generated and scattered across the permanent easement during maintenance activities would not exceed the fuel loading specifications discussed above. No herbicides would be used to control vegetation on the permanent easement unless approved or required by the landowner.

In forested and shrub wetland areas, vegetation maintenance would be as described above except trees and shrubs would be selectively removed as necessary to minimize equipment operating within the wetland. Where the Pipeline crosses a waterbody, vegetation maintenance would be limited to allow a riparian strip, measured from the waterbody's OHWM, to permanently revegetate with native species, with the exception of maintenance required to remove trees within 15 feet of the centerline of the pipe. On federal lands where riparian reserves are affected, a 100-foot riparian strip (or less if the pre-construction riparian vegetation did not extend to 100 feet) would be planted perpendicular to the waterbody on both sides of the waterbody (subject to the restrictions of trees within 15 feet of the centerline).

Permanent Easement

A permanent easement is needed for long-term operation and maintenance of the Pipeline. The permanent easement would be 50 feet wide, centered over the pipe. The permanent easement for the Pipeline would consist of approximately 1,374 acres. Within the permanent easement, long-term effects to wildlife habitats are based on the 30-foot maintenance corridor (821 acres) that is kept clear of large trees. The 30-foot strip centered on the pipeline would be maintained in herbaceous cover, with trees being removed due to operational considerations, such as pipeline surveys.

Cathodic Protection System

The Pipeline would be protected from external corrosion using a low voltage impressed current electrical system, referred to as a cathodic protection (CP) system, which would be installed about one year following construction, to allow for collection of post-construction data of electroconductivity soil potentials, which is required before the CP system can be designed and installed. This system would input a low-voltage electrical charge into the pipeline underground. Permitting for the CP system is not applied for in the FERC Certificate application because the system design would be conducted after the pipeline is installed. The CP system cannot be designed properly until the ground is settled and there is good soil contact with the new pipe following construction. PCGP would consult with federal, state, and local agencies regarding permitting of the CP system following Pipeline construction. The grounding bed spacing would likely be in the 30 to 40 mile range; however, soil conditions might dictate a closer spacing in some areas depending on site-specific conditions, such as rock and climate. The Pipeline is expected to need approximately 7 to 9 ground beds and rectifiers which are expected to be installed on land used within the construction footprint. The ground beds are typically parallel and adjacent to the pipeline and can normally be in the pipeline easement or what was used as temporary workspace during construction. Rectifiers are typically sited at a mainline valve site whenever possible. Should a deep well ground bed and rectifier unit need to be sited separately (200 feet x 5 feet for the ground bed and 10 feet x 10 feet for the rectifier unit), they could still be sited in the construction right of way and most likely within the permanent easement.

If a vertical deep well anode bed were to be installed, it would require a trunk-mounted drill rig to drill a 10-inch-diameter well 300 feet deep. A horizontal anode bed would require the use of a standard backhoe for installation within an area approximately 300 feet long, 2 feet wide, and 5 feet deep. Approximately 2 acres of ground surface would be disturbed during the installation of the CP system.

PCGP intends to install the CP system in full compliance with any seasonal restriction or daily timing restriction for any federally listed avian species should any of the CP sites be located within an area (e.g., MAMU stand or NSO Core area). To the extent that the CP system design allows flexibility of placement of sites, all specified avoidance and minimization efforts would be followed to locate CP sites outside of such areas. CP sites are typically installed in the operational right-of-way or immediately adjacent in the construction right-of-way, so it is not expected that additional timber removal would be required. Systems are usually designed to utilize existing permanent access roads, so crossing of streams or waterbodies by temporary bridging is not anticipated. CP sites would not be installed in riparian zones.

TABLE 2.1.2-15

Summary of Operation-Related Disturbance to Habitat by the Proposed Pipeline (acres)

[1] The "Late Successional and Old-Growth" category (L-O) describes those forest areas with a majority of trees over 80 years of age. Forests with stands greater than 175 years are considered to have old-growth characteristics.
[2] The "Mid-Seral" category (M-S) describes those forest areas with a majority of trees over 40 years of age but less than 80 years of age.
[3] The "Grass-shrub-sapling or Regenerating Young Forest" category (C-R) describes those forest areas that are either clear-cut (tree age 0-5 years) or regenerating (tree age 5 to 40 years).
[4] Total by Habitat Type includes the 30-foot maintenance corridor, permanent access roads, and aboveground facilities; 1.61 acres associated with communication towers are not included in this table (previously disturbed sites).
-Columns and rows do not necessarily sum correctly due to rounding.

3.0 SPECIES ACCOUNTS, CRITICAL HABITAT, PROJECT EFFECTS, AND DETERMINATIONS OF EFFECT

This section describes the current status of the species and critical habitat (if applicable) analyzed in this APDBA. Information provided includes descriptions of species' range and/or critical habitat that may be affected by construction, operation, and maintenance activities of the LNG terminal and Pipeline and any information relevant to a species' current status.

As applicable, the *Endangered Species Consultation Handbook* (FWS and NMFS 1998) was used for guidance to analyze the potential Project effects to plant and animal species listed under the ESA, their proposed or designated critical habitats, and their recovery. Information on listed species' distributions, habitat requirements, and potential occurrence in the project area and vicinity was gathered from many sources including 1) published scientific literature; 2) agencies' published and unpublished reports including proposed and final actions published by FWS and NMFS in the Federal Register; 3) agencies' unpublished raw and/or compiled data; 4) agencies' geo-spatial databases, which document species observations; 5) on-site surveys for species and habitats; and 6) personal communications with agency personnel knowledgeable about species ecological status in the project area and vicinity.

3.1 INTRODUCTION

The following subsections describe how the species accounts, critical habitat, Project effects, and determinations of effect were developed or determined for the species addressed in this section. Also included are rationales used to exclude seven species that are listed or proposed for listing under the ESA from consideration in this APDBA, , based on determinations of no effect.

3.1.1 Determination of Effects

Biological Assessments (BA) may serve multiple purposes, but the primary role is to document an agency's conclusions and the rationale to support those conclusions regarding the effects of their proposed actions on protected resources. Generally, one of the following three determinations will apply:

- "No effect" (NE) means there will be no impacts, positive or negative, to listed or proposed resources. Generally, this means no listed or proposed resources will be exposed to action and its environmental consequences. Concurrence from the relevant Service is not required for a NE determination.
- "May affect, but not likely to adversely affect" (NLAA) means that all effects are beneficial, insignificant, or discountable. Beneficial effects have contemporaneous positive effects without any adverse effects to the species or habitat. Insignificant effects relate to the size of the impact, and should never reach the scale where take occurs. Discountable effects are those extremely unlikely to occur. Based on best judgment, a person would not: (1) be able to meaningfully measure, detect, or evaluate insignificant effects; or (2) expect discountable effects to occur. NLAA determinations require written concurrence from the relevant Service.

  "May affect, and is likely to adversely affect" (LAA) means any adverse effect to listed species that may occur as a direct or indirect result of the proposed action or its interrelated or interdependent actions, and the effect is not beneficial, insignificant, or discountable. LAA determinations require formal consultation with the relevant Service.

3.1.2 Determinations of No Effect

There are six listed species, and one species proposed for listing as threatened that occur or could occur within Oregon but would not be affected by the proposed action. The six listed species include the Contiguous United States DPS of Canada lynx (*Lynx Canadensis*), Coterminous United States Population of bull trout – Klamath River DPS (*Salvelinus confluentus*), yellow-billed cuckoo – Western DPS (*Charadrius nivosus nivosus*), streaked horned lark (*Eremophila aphestris strigata*), the western lily (*Lilium occidentale*), and slender orcutt grass (*Orcuttia tenuis*). In addition, the North American wolverine (*Gulo gulo luscus*), occurs in Oregon and has been proposed for listing as threatened under ESA. Brief synopses of the rationales to exclude these species from consideration in this APDBA are provided below.

Canada lynx. When FWS (2000a) listed Canada lynx as threatened in a final rule, Oregon was included in the species' range based on 12 verified lynx records (see McKelvey et al. 1999) in the state during the previous 100 years. The records (in museum collections) were from the 1800s and early 1900s including one in the U.S. National Museum from the east side of the Cascade Range at Fort Klamath (pre-1900) in Klamath County (Verts and Carraway 1998). Recent lynx documented in the state were from Wallowa County (1964), Benton County (1974), and Harney County (1993), all in atypical habitats suggesting animals were dispersing from Canadian population centers (Verts and Carraway 1998; McKelvey et al. 1999). Currently, northeast Oregon/southeast Washington is recognized as a peripheral area in the lynx recovery plan (FWS 2005a) and could sustain short-term survival during lynx dispersal. Currently, there is no evidence of Canada lynx being present in the action area. There appears to be an extremely remote chance of a lynx dispersing into southwest Oregon but that is not foreseeable during the construction of the Project and as a result Canada lynx are not considered in this APDBA.

Bull trout. Bull trout in the Klamath River DPS inhabit seven isolated stream areas in the Klamath River Basin (FWS 1998b). Critical habitat for bull trout in the coterminous United States includes CHU 9, Klamath River Basin. Unit 9 includes three subunits: Upper Klamath Lake, Sycan River, and upper Sprague River subunit (FWS 2010a). The Upper Klamath Lake subunit is within the Long Lake Valley-Upper Klamath Lake fifth-field watershed, which is not crossed by the Pipeline project. Agency Lake is the only waterbody in Unit 9 with hydrologic connectivity to the Klamath River (within the Lake Ewauna-Klamath River fifth-field watershed); connectivity is through Agency Straits, Upper Klamath Lake, and Link River. As of 2010, Agency Lake was not occupied by bull trout (FWS 2010b) and no bull trout are present in the action area. Neither the species nor potentially occupied habitat would be affected by the proposed action.

Yellow-billed cuckoo. FWS listed the yellow-billed cuckoo - western DPS that nests west of the Continental Divide as threatened under the ESA on October 3, 2014 (79 Federal Register 59991). In Oregon, the western DPS included birds that nest along the Willamette River and Columbia River although the last confirmed nesting records are from the 1940s and the birds disappeared in Oregon by 1945 (Wiggins 2005). Although ORBIC (2017b) includes Klamath County within the range of yellow-billed cuckoo, surveys conducted during 1988 in Klamath County did not find any cuckoos (FWS 2013a). There are recent records (1990 to 2009) from Deschutes, Malheur, and Harney counties (FWS 2013a). Yellow-billed cuckoos are considered a riparian-obligate species and are usually found in large tracts of cottonwood/willow habitats with dense sub-canopies, but may also be found in urban areas with tall trees (FWS 2007b). No suitable habitats are present within the action area, and the species will not be affected by the proposed action.

Streaked horned lark. The streaked horned lark was listed as threatened in Washington and Oregon (Benton, Clackamas, Clatsop, Columbia, Lane, Linn, Marion, Multnomah, Polk, Washington, and Yamhill Counties) in October 2013 (FWS 2013b) with critical habitat designated in Washington and Oregon (Clatsop, Columbia, Lane, Linn, Marion, Multnomah, Polk, and Yamhill Counties (FWS 2013b). None of the counties affected by the Pipeline or the LNG Terminal are included in the streaked horned lark species range or include critical habitat. FWS (2013b, citing Gabrielson and Jewett 1940) has noted that there are historical records prior to 1940 of nonbreeding horned larks in Clatsop, Tillamook, Coos, and Curry counties. Based on communication with FWS (2017b), streaked horned larks are not present in Coos Bay and have not been documented on the Oregon Coast for more than 20 years. Streaked horned larks overwinter in areas near their nesting grounds, and therefore, would not be expected in the Coos Bay area in the wintertime (FWS 2017b). The species occurs in bare and sparsely vegetated habitats such as coastal dunes, beaches, gravel roads, airport runways, grazed pastures, and dry mudflats; however, it does not occur on rolling or steep areas at these sites. Where deflation plains occur, streaked horned larks are often behind the foredune (Pearson 2013). No such suitable habitats are present within the analysis area and the species would not be affected by the proposed action.

Western Lily. The western lily was listed as endangered on August 17, 1994 (FWS 1994). Western lilies occur in early successional fens (bogs) and in coastal scrub habitat within an extremely restricted distribution along the coast of southern Oregon and northern California. The plant has been documented in seven widely separated regions, all within 4 miles of coast. Such populations are densely clumped and occur mostly in isolated wetlands that are fewer than 10 acres in size (FWS 1994, 1998c). The nearest known occupied habitat is 5.5 miles from the Project (ORBIC 2017b).

All potential habitat for western lilies within the analysis area (i.e., poorly drained bogs with acidic organic soils and within 6 miles of the coast below 300 feet elevation) was identified and surveyed for western lilies (SHN 2013a and 2013b; SBS 2008, 2012, 2013, 2014, 2017). Within the vicinity of the LNG Terminal, potential suitable lily habitat was found to be limited due to the lack of appropriate substrate as well as the soil types present and the species' moisture requirements – potential low to moderate quality habitat was limited to the freshwater wetlands. All freshwater wetlands within the the vicinity of the LNG Terminal were surveyed for western lily during floristically appropriate seasons in 2006 and again in 2013, including sites that were in disturbed habitat along existing roads and highly degraded habitat located on fill that functions as drainage for surrounding industrial sites. No western lilies were observed. Within the vicinity of the Pipeline, potentially suitable lily habitat was identified up to MP 12 (approximately 9 miles from the coast) using available aerial photography and evaluating biological features present within the Pipeline project area (i.e., soils, geology, topography, elevation, and existing plant community, and disturbance regimes). Only one area along the Pipeline route near MP 8.2 (6.7 miles from the coast) was identified as potentially suitable lily habitat. Surveys conducted in 2014 at this site identified only a narrow band of marginal habitat that had adequate moisture and seasonally boggy areas, but it had undergone much disturbance during recent agriculture development. No plants were documented. .

While the Project occurs within the range of the species (within 4 miles of the Oregon coast), there is no suitable habitat within, the analysis area, and potentially suitable habitat surveyed for the lily did not document the plant. Based on the above, the negative survey results, habitat quality and distance from the coast, there would be no effect to the western lily, and it is not discussed further.

Slender Orcutt Grass. In 1997, the FWS (1997a) listed the slender orcutt grass as threatened in California with critical habitat designated in California in 2003 (FWS 2003c) and revised in 2006 (FWS 2006e). Slender orcutt grass occurs across a wide range of elevations (90 - 5,781 feet), but is associated primarily with large, deep vernal pools that have relatively long periods of inundation on Northern Volcanic Ashflow and Northern Volcanic Mudflow substrates (FWS 2009f). The species is known from disjunct occurrences from the Modoc Plateau in northeastern California, west to Lake County, California, and south through the Central Valley to Sacramento County (FWS 2005e). The closest designated critical habitat unit (SLEND 1A) is in California more than 50 miles south of the Pipeline (FWS 2006e). The FWS (2018b) indicated that this species may be present within the action area of by the Project, and the current range map and available GIS coverage of potential species range (FWS 2018d) identifies that the species could occur near the end of the Pipeline project; however, the species has not been documented in the vicinity of the Pipeline (ORBIC 2017a) and no suitable habitat occurs in the potential range of this species near the Pipeline (FWS 2006e). Based on the above, there will be no effect to the slender orcutt grass, and it is not discussed further.

North American Wolverine. Wolverines were proposed for listing as threatened under ESA in 2013 but the proposal was withdrawn in 2014 because the threats cited were not sufficient to warrant listing under the ESA (FWS 2014a). However, the U.S. District Court for the District of Montana vacated the FWS' 2014 withdrawal of its proposed rule to list the distinct population segment of the North American wolverine as threatened under the ESA. The wolverine is currently considered a species proposed for threatened ESA status (FWS 2016a). Wolverines have been occasionally documented in Oregon, most recently in the Wallowa-Whitman National Forest in Northeast Oregon during 2011-2012 (Magoun et al. 2013), but no evidence of a reproducing, self-sustaining population has been found. . Currently, there is no evidence of wolverines being present in the action area. There appears to be an extremely remote chance of a wolverine dispersing into southwest Oregon, but that is not foreseeable during the construction of the Pipeline, and as a result, the North American wolverine is not considered further in this APDBA.

3.1.3 Format

There are 31 species listed as threatened, endangered, or proposed for listing under the ESA considered in this section. Included are nine mammals (eight marine mammals, one terrestrial mammal), four birds, five herpetofauna (four reptiles and one amphibian), six fish, one invertebrate, and six plants. This section was organized to address similar information consistently among the diversity of organisms that could be affected by the Project. The following five sections are included for each species:

1. Species Account and Critical Habitat in which the current status under the ESA is identified, past threats that led to listing and current threats to continued existence, recovery plan components if available, abbreviated species' life history, population estimates and/or trends, and critical habitat that has been designated or proposed;

2. Environmental Baseline in which the species analysis area (portions of the Project where species are affected by the proposed action) relevant to each species is described, as well as the species' presence within the action area, species' habitat within the action area, and species' critical habitat present within the action area are described and evaluated;
3. Effects by the Proposed Action in which direct and indirect effects to the species and critical habitats are evaluated in each action area component;
4. Cumulative Effects. FWS and NMFS describe cumulative effects (50 CFR 402.02) as the result of future actions by state or private entities, not involving federal actions, but reasonably certain to occur in the action area considered in this APDBA. Future federal actions that are unrelated to the proposed action are not considered because they require separate consultation pursuant to Section 7 of the ESA.
4. Conservation Measures that have been proposed by PCGP and JCEP in addition to those defined in section 1.3; and
5. Determination of Effects in which the action agency evaluates how the proposed action would affect the species and any designated critical habitat.

3.2 MAMMALS

3.2.1 Blue Whale

3.2.1.1 Species Account and Critical Habitat

Status

The blue whale was listed as endangered throughout its range under the Endangered Species Conservation Act (ESCA) on December 2, 1970 (FWS 1970) and has been listed under the ESA since its implementation in 1973. The Eastern North Pacific blue whale population is classified as depleted and strategic under the Marine Mammal Protection Act (MMPA).

Threats

Commercial whaling played a large role in the decrease of the blue whale population (Sears and Perrin 2009). At least 9,500 blue whales were taken by commercial whalers in the North Pacific Ocean from 1910-1965 (NMFS 2013a). Commercial whaling in the eastern North Pacific is no longer a threat to blue whales. Current threats to the species include vessel strike, anthropogenic noise, hybridization with other species, pollution including entanglement in fishing gear, and environmental ocean changes that may result from climate change.

Though vessel strikes are known to occur with blue whales, this threat factor is not thought to be at a level that would be currently limiting the Eastern North Pacific blue whale population (Monnahan et al. 2015). However, because some ship strikes go undetected and unreported, and some large whales struck by vessels are not identified but could be blue whales, it has been estimated that the number of blue whales struck in the California Current exceeds the determined Potential Biological Removal (PBR) for this stock (Redfern et al. 2013).

The PBR is the maximum number of animals killed, not including natural deaths that would still allow for the population to achieve its optimum sustainable population (Barlow et al. 1995). Between 2007 and 2011, there were 10 blue whales documented as killed or injured by vessel strikes along the West Coast, nine occurred off the California coast and one off the Oregon coast (Carretta et al. 2013). Five of the deaths occurred in 2007, the highest number recorded for any year. Injured whales do not always strand or if they do, they do not always have obvious signs of trauma. Consequently, additional mortality from ship strikes could be going unreported (Carretta et al. 2014a). The risk of ship strike to blue whales is discussed in more detail below (see section 3.2.1.3).

Anthropogenic noise has been identified by NMFS (1998) as a factor influencing the distribution of blue whales. Noise from ships and boats, and other anthropogenic sources may interfere and mask cetacean communication, finding prey, avoiding predators, and possibly navigation (Würsig and Richardson 2009). Underwater noise levels vary spatially and temporally throughout the blue whales habitat. This threat factor is discussed with relevance to the Oregon coast in more detail in section 3.2.1.3.

Hybridization between blue whales and fin whales has been documented, and may decrease the fitness of hybrid offspring of the blue and fin whales (Berube and Aguilar 1998). It is difficult to quantify the level to which hybridization occurs or the risk that hybridization may pose to existing blue and fin whale populations.

The effects of pollution on blue whales are also difficult to quantify. Pollutant spills that occur in areas occupied by blue whales or their prey species have possible health consequences to individuals. Entanglement with fishing gear, particularly gillnets, is a more tangible threat to blue whales (as well as to many other species of marine life) but the number of entangled blue whales, and the extent of injuries or death is not well understood and again difficult to quantify with relevance to the Eastern North Pacific population (NMFS 1998, NMFS 2015a).

The effects of climate change on blue whales is also uncertain. The impacts from climate change could have repercussions throughout the food chain of the North Pacific Ocean, and this may have consequences on the metabolic demands of blue whales in warmer oceans. Marine populations may shift their distributions towards the poles or in the ocean depths (Fogarty and Powell 2002). Distributional variations may also occur in response to changes in ocean stratification. However, quantifying the effect of climate change as a threat to blue whales is not currently possible.

Of these identified threats, vessel strike and underwater noise have relevance to the Project and are further discussed with reference to the Oregon coast in section 3.2.1.3.

Species Recovery

NMFS drafted a recovery plan in July 1998 for the blue whale. The goals of the recovery plan (NMFS 1998) are to identify actions that will result in the minimization or elimination of effects from human activities that are detrimental to the species recovery (NMFS 1998). The stepdown outline to achieve the goal includes the following:

- Determine stock structure of blue whale populations occurring in U.S. waters and elsewhere.
- Estimate the size and monitor trends in abundance of blue whale populations.
- Identify and protect habitat essential to the survival and recovery of blue whale populations.
- Reduce or eliminate human-caused injury and mortality of blue whales.
- Minimize detrimental effects of directed vessel interactions with blue whales.
- Maximize efforts to acquire scientific information from dead, stranded, and entangled blue whales.
- Coordinate state, federal, and international efforts to implement recovery actions for blue whales.
- Establish criteria for deciding whether to delist or down list blue whales (NMFS 1998).

Life History, Habitat Requirements, and Distribution

Blue whales are the largest animals on earth, and occur throughout the world’s oceans in three separate populations: Northern Atlantic, Northern Pacific, and Southern Hemisphere. This migratory species moves seasonally between high and low latitude regions. In the eastern North Pacific Ocean, blue whales generally inhabit the Gulf of California and offshore waters of Central America during late fall and winter then migrate northwards off the west coast of North America during April and May. During the spring and summer, the whales are widely dispersed, with many blue whales occurring off the California coast, some migrating to Canadian waters while others disperse north to the Gulf of Alaska or west toward the Aleutian Islands (Sears and Perrin 2009). Blue whales also exhibit some variability in the seasonal movements, habitat use, and timing patterns.

Blue whales inhabit and feed in the coastal and pelagic environments and, as a result, are found over the continental shelf and farther offshore in deep waters. They prey mainly on two krill species, *Euphausia pacifica* and *Thysanoessa spinifera* (NMFS 1998). *E. pacifica* is an offshore euphausiid that is smaller than the more neritic euphausiid *T. spinifera*. Recent studies have shown a shift in the distribution of blue whales closer to the coast of California due to a shift in feeding more on *T. spinifera* (NMFS 1998). Blue whales typically travel alone or in pairs, but can be found in larger aggregations in feeding areas. This species generally dives for between 5 to 20 minutes, and can reach depths of 150 to 200 meters (492 and 656 feet), but shallow dives are common (Shirihai and Jarrett 2006).

Blue whales are thought to reach sexual maturity between 5 and 15 years of age, with parturition occurring in the warm winter waters. The calving interval is approximately two years (NMFS 1998). The gestation period for blue whales is between 10 and 12 months, and the calves are weaned between 6 and 8 months. Little is known of the longevity and natural mortality of blue whales, but the lifespan is estimated at up to 90 years (Shirihai and Jarrett 2006). Ice entrapment is not a known factor of natural mortality for the Pacific population of blue whales, but there has been documented killer whale predation on this population (NMFS 1998). Shark predation also occurs, though this is usually limited to neonatal and juvenile animals.

Blue whales are occasionally washed ashore, but based on records spanning 72 years (1930 - 2002), blue whales are the least frequent of five balaenopterid species found stranded on Oregon and Washington coasts, with only one female reported stranded in Washington (Norman et al. 2004).

Population Status

Blue whales occurring along the Pacific Coast of the U.S. are part of the Eastern Northern Pacific population. The best estimate of the population size is 1,647 whales, based on the time period of 2008 - 2011 (Calambokidis and Barlow 2013). The minimum population size is estimated at approximately 1,551 whales (Carretta et al. 2017a). The PBR for this blue whale population is 9.3 whales per year, but because this population spends only one-quarter of its time in United States waters, the PBR is reduced to 2.3 whales per year in U.S. waters (Carretta et al. 2017a). The Eastern North Pacific blue whale population has not been observed to increase since the early 1990's, and this is thought to be due to density dependent effects rather than specific threat factors (Carretta et al. 2017a). As of 2013, this population is now thought to be at 97% carrying capacity (Monnahan et al 2015).

Critical Habitat

As of October 2017, critical habitat for this species has not been designated in U.S. waters.

3.2.1.2 Environmental Baseline

Analysis Area

The analysis area applicable to blue whales, and all the marine mammals species presented in this document, includes the fan shaped area directly off Coos Bay out to the continental shelf break as shown in figure 2.1.1-2). Following the biological oceanographic convention, the edge of the continental shelf was defined as the 200 m contour (see Lalli and Parsons 1993). At this location along the Oregon coast, the continental shelf break is approximately 12 nautical miles (nmi) from shore. This marks the division between the inshore neritic and the offshore oceanic realms (Lalli and Parsons, 1993). As the potential effects to blue whales would be associated with the LNG carriers inbound and outbound from the LNG Terminal, the marine analysis area was refined to include that portion of the ocean under the jurisdiction of the United States relevant to the Project related traffic.

Potential markets for LNG exported from the LNG Terminal are expected to be Asian countries. JCEP executed a preliminary agreement with JERA Co., Inc., and ITOCHU Corporation for a least 1.5 mtpa of LNG capacity each from the Project. Negotiations continue with other LNG buyers for the balance of the plant capacity. For reasons described below, LNG carriers transiting to and from the LNG Terminal are assumed to traverse the continental shelf on a heading of east (inbound) or west (outbound), and for the purpose of the potential effects assessment it is assumed that the path of travel is perpendicular to the coast. The analysis area described for blue whales is the same as for all whale species for determination of the potential effects related to the LNG Terminal. For brevity, this section will be referenced, for the other marine mammal species identified in this document.

Species Presence

While inter-annual variability exists, long-term acoustic data indicates that blue whales are seasonally present in the waters between Oregon and Vancouver Island, British Columbia, Canada from July to January, but that they occupy waters farther offshore than in the more southerly parts of their U.S. range (Stafford et al. 1999). However, more recent data also indicates the use of both the inshore and offshore waters off the coast of Oregon (NMFS 2015a). Acoustic data further indicates that blue whales are present in offshore Oregon waters for an average of 21 weeks with detections commencing in October, and that they occur in lower densities than in the more southern regions of the U.S. range (Burtenshaw et al. 2004). The acoustic data suggest that the fall and winter blue whales present off Oregon are less densely aggregated than in other areas of the eastern North Pacific (Burtenshaw et al. 2004).

Line-transect ship surveys have been conducted off the coasts of Oregon and Washington during the summer and fall of 1996, 2001, 2005, and 2008 (Barlow and Forney 2007; Forney 2007; Barlow 2010). The line-transects were pre-determined to survey for pelagic cetaceans within approximately 300 nmi of the U.S. west coast. The sightings data have been used to estimate population sizes (Barlow and Forney 2007; Forney 2007; Barlow 2010), as well for habitat modeling to determine important areas and habitat-based density estimates (see Becker et al. 2012 and Calambokidis et al. 2015).

Habitat

Blue whales are not evenly distributed throughout the marine habitats of the U.S. west coast, and tend to be aggregated, particularly along the continental shelf edge, with a preference for Californian waters, rather than off Oregon or Washington (Calambokidis et al. 2015). The U.S. west coast is one of the most important feeding areas during summer and fall, although increasingly blue whales have been found feeding outside of this area (Carretta et al. 2014a). Most blue whales of this stock are believed to migrate in the winter to highly productive areas off Baja California and the Gulf of California (Carretta et al. 2017b).

Though blue whales inhabit inshore and offshore regions, the habitat-based density models of Becker et al. (2012) indicate that blue whale densities increase with decreasing latitude from Washington to California, with highest densities off San Francisco and Santa Barbara. Nine

Biologically Important Areas (BIAs) have been identified in western U.S. waters, with all occurring off the coast of California (Calambokidis et al. 2015).

Predicted mean densities of blue whales using the continental shelf habitats off Oregon, are relatively lower in the northern waters than off central and southern Oregon and range from 0.0006 – 0.0058 whales/square kilometer (km^2) throughout the state (Calambokidis et al. 2015). For comparison with other coastal areas, the lowest densities are predicted for Washington waters (0.0002 – 0.0005 whales/km^2), while the highest densities occur off southern California (0.0074 – 0.0102 whales/km^2, Calambokidis et al. 2015).

Critical Habitat

Critical habitat has not been designated for this species.

3.2.1.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include the risk of ship strikes potential adverse effects from vessel underwater noise, and potential adverse effects from accidental release of fuel. Fuel spills could additionally indirectly affect blue whales by impacting forage species. These effects are addressed below.

Ship Strike

There is an ongoing threat of ship strikes to large cetaceans around the world, causing mortality or injury. Data suggest that cetaceans collide with ships relatively infrequently (Laist et al. 2001; Jensen and Silber 2003; Douglas et al. 2008; Carretta et al. 2013). Research has identified a number of factors, related to both vessels and whales, that can influence the probability of a vessel-whale strike (e.g., Richardson et al. 1995, JWGVSAI 2012, Vanderlaan and Taggart 2007, Laist et al 2001). However, it is recognized that estimates are undoubtedly negatively biased since vessel strikes can go unreported because the event is either not witnessed, the injured or deceased animal is not observed, or the stranded carcass is not discovered.

Data provided by Carretta et al. (2013) indicated one blue whale was struck in the Oregon-Washington Exclusive Economic Zone (EEZ) between 2007 and 2011, which yielded an annual rate 0.20 blue whales struck for this region. Jensen and Silber (2003) reported 0.31 blue whales struck per year between 1987 and 2002 along the entire U.S. Pacific Coast. The existing estimates of ship strike to blue whales are below the calculated PBR for this species at 2.3 whales/year within the U.S. EEZ. Most ship strikes occur where vessel densities overlap with container port ships and blue whale feeding aggregations. There is still uncertainty about the actual rate of anthropogenic mortality due to many factors including understanding of the current carrying capacity for blue whales (Monnahan et al. 2015). Redfern et al. (2013) (as cited by Carretta et al. 2017a) has stated that the number of ship strike deaths of blue whales in the California Current likely exceeds PBR, yet Monnahan et al. (2015) suggested that current ship strike levels do not pose a threat to this population of blue whales.

Feeding aggregations of blue whales are not currently documented to occur in Oregon waters. However, some level of risk of ship strike to blue whales exists because of the spatial overlap between blue whales in the marine analysis area, the transiting Project related vessels, and existing ship traffic.

Exports of LNG originating from the LNG Terminal would likely be to markets primarily in Asia. Shipping traffic between Asia and the U.S. West Coast travels the "Great Circle route," arriving and departing the West Coast perpendicularly (east-west) or diagonally (southeast-northwest) to the coast (Pacific States/British Columbia Oil Spill Task Force 2002; Berg and Lawrenson 2015). It is expected that the LNG traffic would exit Coos Bay on a westward course, and return on a parallel, but eastwards route, as the Coast Guard has indicated that this is appropriate for LNG traffic between Oregon and Asia (Berg and Lawrenson 2015).

The current large vessel traffic into and out of Coos Bay, Oregon is approximately 50 ships per year. The LNG Terminal is expected to add as many as 120 vessels per year. In terms of the number of east-west transits expected, this adds an additional 240 vessel transits through the marine analysis area, to the existing 100 vessel transits entering and exiting Coos Bay.

Ship Strike Risk Estimation

The risk of ship strikes to large cetaceans has been assumed to be the product of ship traffic and the cetacean population densities. An index of relative ship strike risk within an explicitly defined gridded study area was described by Williams and O'Hara (2009). In that assessment, the whale density estimates at each grid point were multiplied by the nearest value of shipping intensity using regular-interval ship locations from agencies' remote monitoring of shipping in Canadian waters. Similar fine-scale data are not available within the marine analysis area. However, in order to appropriately assess the potential impact from ship strikes to the different marine mammal species, a quantitative metric was employed.

A Whale Strike Risk Estimation Model (WSREM) was developed to evaluate the relative risk to the different whale species, with the addition of vessels transiting to the LNG Terminal added to the existing conditions. The WSREM metric considered the ship strike risk to be the product of the species density, the length of the whale, the proportion of the time spent at the surface, the annual number of vessels, the number of transits/vessel, and the distance travelled per transit within the marine analysis area. This value was then multiplied by the proportion of the year each species is present in the analysis area, and divided by the spatial extent of the analysis area to yield a comparable metric in whales/km^2. The final metric is expressed in whales/1000 km^2 for ease of comparison by reducing the number of decimal places for each metric. The upper and lower whale density estimates were based on the habitat specific densities for blue whales, fin whales and humpback whales (Becker et al. 2012, Calambokidis et al. 2015). Quantified comparable estimates for other species were not available, but the existing data were examined to qualitatively determine the level of risk to these species.

The WSREM metric was calculated with the following physical variables (table 3.2.1-1)

TABLE 3.2.1-1

Physical Variables Included in the WSREM for all Species

Marine Analysis Area (km^2)	85.80
Number of Vessels	
LNG carriers Only	120
Existing Traffic Conditions	50
Exiting Traffic Plus LNG carriers	170
Number of Transits per Vessel	2
Distance Travelled Per Transit, km	24.54

This WSREM was based on several assumptions including:

- the all species in analysis area had an equal probability of being struck,
- there is an equal probability of vessel strike throughout the analysis area,
- all vessels have an equal probability of striking whales, all vessels transit the maximum length within the marine analysis area,
- all vessels complete two full transits of the marine analysis area, and
- the species are evenly distributed throughout the marine analysis area.

For conservative results, the maximum length of each species was included, but since vessel strike risk is related to the length of the whale, this assumption will result in an overestimate for all but the largest members of each species. Additionally, the risk is also related to the length and draft of the vessel, but due to the variations in different vessels, the WSREM included the area of the analysis area and assumed an equal risk throughout for all vessels for conservative results. This approach did not aim to quantify the number of individuals that could be struck due to the number of uncertainties associated with the different input variables, but rather assess the relative risk with the addition of LNG Terminal related vessels for the purpose of mitigation and strike risk reduction planning. As such, the results of the WSREM do not indicate the number of whales that would be struck, but rather the risk that is associated throughout the marine analysis area. The WSREM metric does not include any behavioral responses, learned responses or previous experiences that may be associated with different age classes and different species of whale.

Nevertheless, the WSREM is used to estimate the change in relative risk from current conditions with the forecasted number of vessels transiting to the LNG Terminal, and based on this estimate, propose potential mitigation measures to avoid or minimize vessel strike risk. The WSREM does include that the actual risk to the individual whales will change over time in response to the whales' actual distributions and habitat use which can change in response to environmental variables through the inclusion of the habitat based density estimates, the time spent at the surface which will may differ by age classes, and the number of vessels transiting which can change in response to global economic forces. As these variables can be updated, the WSREM is dynamic as it is easily adjusted to compare to future conditions with regard to shipping traffic, project related traffic and updated estimates of whale species habitat specific densities.

Estimated Ship Strikes to Blue Whales.

Determination of the WSREM for blue whales (table 3.2.1-2) included the following variables:

- Blue whale length: 30.48 m (https://www.fisheries.noaa.gov/species/blue-whale)
- Time at Surface: 5% (Lagerquist et al. 2000)
- Density – Lower = 0.0036 whales/km^2 (Calambokidis et al. 2015)
- Density – Upper = 0.0058 whales/km^2 (Calambokidis et al. 2015)
- Proportion of year in marine analysis area: July to January = 0.583

TABLE 3.2.1-2

Results of WSREM for Blue Whales

Marine Traffic	Risk Lower Estimate (whales/1000 km)	Risk Upper Estimate (whales/1000 km)
LNG Carriers Only	0.22	0.35
Existing Traffic Only	0.09	0.15
Cumulative Results	0.31	0.50

Since the LNG Terminal is expected to increase the vessel traffic in Coos Bay, from an approximately 50 vessels per year, to 170 vessels per year (including the 120 vessels/year from LNG Terminal), the estimated whale strike risk increases from existing levels. The WSREM yields an increased cumulative risk to blue whales in the marine analysis area ranging from 0.31 – 0.50 whales/1000 km. This risk was limited to the time period that blue whales are known to occur off the coast of Oregon during seven months of the year (July – January). The current conditions characterizes the existing risk and the number of blue whales known to be struck is very low (see preceding section). Therefore, while the risk is increased from the existing risk levels with the addition of LNG Terminal related vessels, the overall risk is still considered to be low, which must be analyzed recognizing that the WSREM results are considered conservative.

In addition, though there is a localized increase in the risk of ship strikes to blue whales by LNG carriers from existing levels, this localized increase is not thought to be significant for the Eastern North Pacific population as the coast of Oregon does not contain identified critical habitat nor is it a recognized area for feeding aggregations, and that current documented ship strikes in this region are low.

Underwater Noise

All vessels produce noise from the machinery and equipment onboard. The propeller cavitation produces most of the broadband noise with dominant tones derived from the propeller blade rate. Propellers create more noise if damaged, operating asynchronously, or operating without nozzles. Engines and auxiliary machinery can also radiate noise during operation which is related to ship size (larger ships are generally noisier than small ones), speed (noise increases with ship speed), and mode of operation (ships underway with full loads, towing or pushing loads, are noisier than unladen ships) (Greene and Moore 1995).

When whales are exposed to low-level sounds from distant or stationary vessels, they appear to ignore the sounds. However, in general, rorquals move away, abruptly change direction, or dive to avoid close approach by vessels. Baleen whales can interrupt normal behavior and swim away from strong or rapidly changing vessel noise, especially if a vessel is headed directly toward the whale (Richardson 1995). However, radiated ship noise of oncoming ships may not be immediately detected by whales near the surface due to bow null-effect acoustic shadow zones (Allen et al. 2012). Because of these acoustic shadow zones, whales may not hear approaching ships to allow time for their avoidance response even though whale auditory ranges overlaps with peak intensities of ship noise.

Steam turbine power has been replaced by dual fuel diesel electric (DFDE) power plants adapted to utilizing LNG gas boil-off and diesel fuel to power electric drives in many recently constructed LNG carriers. The DFDE propulsion system is more fuel efficient with less engine noise and vibration (Gilmore et al. 2005). Whether or not lower noise-producing propulsion systems would cause increased ship-strikes with marine mammals is unknown.

Ambient noise in the northeast Pacific Ocean has changed throughout the 20th century. Comparisons of ambient noise from the 1990s with noise measurements taken during the 1960s indicates an increase by about 10 dB (Andrew et al. 2002). More recent long-term analyses of vessel-traffic related noise shows that along the US west coast, noise levels are either holding steady or increasing slightly off Southern California, but decreasing off Oregon and Washington (Andrew et al. 2011). In addition to the anthropogenic sources, ambient ocean noise is a product of wind, precipitation, wave noise, and sounds generated by a diversity of marine wildlife (McDonald et al. 2008). Other sources of underwater noise include occasional events such as earthquakes and meteorological events (i.e. storms including high winds, thunder), and in high latitudes ice formation and thawing. The recent long-term acoustic analyses in the eastern North Pacific Ocean indicate non-linear changes to the ambient ocean noises over time and space.

As a result of overlap in the frequency ranges emitted and used by vessels and cetaceans, anthropogenic noise, including that from vessels, may affect communication, prey detection, predator avoidance, and possibly navigation (Würsig and Richardson 2009). While anthropogenic noise and vessel disturbance may affect blue whales, there is little information available to describe or quantify the effects, and it is difficult to determine whether, or how, vessel noise affects blue whales (NMFS 2013a). For instance, a vocalizing blue whale that had been calling prior to nearby passage of a merchant ship continued to call during the passage even though the ship noise at the whale's position exceeded the ambient sound level by as much as 26 dB (McDonald et al. 1995).

However, consideration of the effects of underwater noise is important because the intensity, duration and sound energy can have short or long term effects on the hearing of marine animals. Anthropogenic noise can cause hearing loss in cetaceans which can be temporary (abbreviated TTS for Temporary Threshold Shift) or permanent (abbreviated PTS for Permanent Threshold Shift). Repeated TTS may lead to PTS in which sensory hair cells in the inner ear are destroyed with damage to the cochlea (Nordmann et al. 2000). NMFS (2016a) has developed a new comprehensive guidance on sound characteristics likely to cause injury based on known causes of PTS from impulsive and non-impulsive sound sources. The Level B acoustic thresholds were not included in the Level A refinements, and remain unchanged (table 3.2.1-3). Both sets of acoustic thresholds are applied in MMPA permits and ESA Section 7 consultations for marine mammals to evaluate the potential for sound effects.

TABLE 3.2.1-3

NOAA Current In-water Acoustic Thresholds for Level B

Criterion	Criterion Definition	Acoustic Threshold
Level B	Behavioral disruption for impulsive noise (e.g., impact pile driving)	160 dB_{rms}
Level B	Behavioral disruption for non-pulse noise (e.g., vibratory pile driving, drilling)	120 dB_{rms} b/

a/ All decibels referenced to 1 micro Pascal (re: 1µPa). Note all thresholds are based off root mean square (rms) levels.
b/ The 120 dB threshold may be slightly adjusted if background noise levels are at or above this level.
Source: NOAA 2017

Southall (2004) provided the following descriptions of impulsive noise and non-pulse noise, based on characteristics at the noise source:

- **Single Pulse:** Single sound of short duration, fast rise time generated by a single explosion, single airgun, watergun, or sparker pulse, single ping of certain sonars/depth sounders.
- **Single Non-Pulse:** Single sound of long duration, slow rise time generated by a single vessel pass, drilling event, aircraft overflight, single ping of certain sonars.
- **Multiple Pulse:** Multiple sounds each of short duration, fast rise time generated by airguns, some sonar/depth sounder systems, waterguns, sparkers, pile driving, serial explosions.
- **Multiple Non-Pulse:** Multiple sounds of long duration, slow rise time generated by multiple vessel/aircraft passes, certain sonar systems, tomography sources.

Noises generated by vessels, including LNG carriers, transiting the marine analysis area are assumed to be single non-pulse sources during each transit and could potentially cause behavioral disruption. These are often referred to as continuous noise sources, and may affect marine wildlife through masking detection of important sounds (intraspecific communication, prey and/or predator detection, imminent ship-strike), for species within distances at which vessel noise exceeds 120 dB re 1µPa rms. Occurrences of single pulse sounds by LNG carriers cannot be completely ruled out (e.g., depth or echo sounders); however, while the sound level from this source is audible to some marine mammals, it is unlikely to cause disruption (Deng et al. 2014). As such, the acoustic thresholds with regard to these impulsive sounds have not been evaluated for vessel traffic from the LNG Terminal.

A review of LNG carriers in service during 2013 (Colton 2013; MarineTraffic 2013) revealed there are 267 vessels with capacities of 148,000 m^3 or less, the current size limit for LNG carriers utilizing the LNG Terminal. Hatch et al. (2008) determined underwater noise levels from various commercial ships while transiting the Stellwagen Bank National Marine Sanctuary off the Massachusetts coast. Estimates of sound levels from the Berge Everett (also known as the BW Suez Everett), an LNG carrier built in 2003 with 138,028 m^3 capacity (93,844 gross tonnage), are used here to estimate exposure of marine mammals to project-related shipping noise. The reported noise levels from that vessel serves as the standard for the following analysis of noise effects on blue whales (as well as other whales, where applicable) within the marine analysis area.

The LNG carrier in the Hatch et al. (2008) study produced average sound levels (with one standard error) of 182 ± 2 dB re 1 µPa @1 m (Hatch et al. 2008). Using the Practical Spreading Loss Model, the sound attenuates to 120 dB at about 13.6 km. Doubling this distance to account for both sides of the vessel (27.8 km), and taking into account the lower and upper density estimates for blue whales (see Estimated Ship Strikes to Blue Whales in section 3.2.1.3), there could be an estimated 0.10 – 0.16 blue whales/km within the area of sound attenuation to 120 dB. Assuming 120 LNG carriers call at the LNG Terminal annually, with each carrier making two transits through the marine analysis area per call and a 30-year life span of the Project, it is estimated that the number of blue whales that could be present and potentially affected could range between 432 and 648 blue whales within the 120 dB attenuation area (0.06*240*30=432 or 0.09*240*30=648) over the life of the Project.

Further, since tractor tugs would travel to meet each incoming LNG carrier and return to the port after guiding each outgoing LNG carrier from the Project, blue whales could be exposed to noise levels above 120 dB in the marine analysis area. The distance that the noise from tractor tugs could attenuate to 120 dB averaged about 5 km, as compared to 120 dB attenuation of about 13.6 km for LNG carriers. Because the lateral area within the 120 dB attenuation area for tractor tugs would be roughly 37 percent of that for LNG carriers, as many as between 160 and 240 blue whales could occur within the 120 dB attenuation area for tractor tugs over the life of the Project.

Existing commercial vessels within the marine analysis area produce underwater noise levels that are comparable to or exceed noise from the LNG carrier described by Hatch et al. (2008). Noise generated by various types of commercial ships (container ships, crude oil tankers, product tankers, bulk carriers, and others) were recently evaluated by McKenna et al. (2012). Underwater noise levels varied by ship type and also by vessel length, gross tonnage, vessel speed, and to some extent, vessel age (older vessels tended to be louder than newer vessels). For example, a 54,000-Gross Ton container ship generated the highest acoustic source level of 188 dB re 1 µPa @ 1 meter while a 26,000 Gross Ton chemical tanker had the lowest at 177 dB re 1 µPa @1 meter (McKenna et al. 2012). Noise levels from the vessels examined in that study are assumed to be typical of ship noise in the marine analysis area and would produce radiated noise levels that would exceed the threshold for Level B for continuous noise at 120 dB_{rms} (see table 3.2.1-3, above).

Some blue whales may be exposed to sound levels from LNG carriers and tugs that could cause behavioral disturbance. However, the potential numbers that could be affected are a very small fraction of the estimated population size of the Eastern North Pacific blue whale population.

Sound levels to which blue whales (or other marine mammals considered in this APDBA) will be exposed will be well below the peak sound levels and exposure would be well below the cumulative exposure levels that were developed by NMFS in 2016 and those found in NMFS' 2018 Revisions to: Technical Guidance for Assessing the Effects of Anthropogenic Sound on Marine Mammal Hearing (Version 2.0): Underwater Thresholds for Onset of Permanent and Temporary Threshold Shifts. U.S. Dept. of Commer., NOAA. NOAA Technical Memorandum NMFS-OPR-59.

In particular, average sound levels of LNG carriers studied by Hatch et al was 182 dB (re 1µPA@1 meter) while the peak PTS values for low frequency and mid-frequency whales are 199 dB and 198 dB respectively. Cumulative exposure would not occur because both the noise source and the whales would be moving and would only be in proximity for a short duration

Fuel Spills

Direct effects on blue whales from spills at sea include irritation and burning from direct contact, ulcers and internal bleeding if ingested, and inhalation of toxic fumes. Inhalation of petroleum vapors can cause pneumonia in humans and animals, due to large amounts of foreign material (vapors) entering the lungs (Lipscomb et al. 1994). Indirect effects include depletion or contamination of food sources. However, effects of potential spills from LNG carriers are not comparable to spills from oil tankers because LNG carriers only carry quantities of oil used for propulsion fuel and not the quantities transported by oil tankers.

The Federal Water Pollution Control Act, as amended by the CWA (33 U.S.C. 1251–1387), prohibits the discharge of oil upon the navigable waters of the U.S., which include out 12 nmi from shore, Contiguous Zones , and, where it can be determined that the natural resources of the United

States are impacted, out to the EEZ (200 miles). In addition to U.S. Law, International Regulation under Annex I to the International Convention for the Prevention of Pollution from Ships (commonly referred to as MARPOL 73/78)[1] requires that all ships have an oily water separator, which is a piece of equipment used to pump a vessel's bilges. As the bilge water is pumped through this equipment, water is discharged overboard, while the oil is diverted to a holding tank. Ships are also required to have waste oil holding tanks of sufficient capacity to keep all waste oil aboard for later disposition either burned in an incinerator or discharged ashore in compliance with applicable regulations.

LNG carriers calling on the LNG Terminal would be required by the Coast Guard to have a vessel response plan in order to be adequately prepared for accidental spills. LNG carriers would also be required to obtain a vessel general permit from the EPA that would outline regulations for avoiding release of even small quantities of fuel or lubricants during normal operations such as washing the vessel deck. As a result, effects to blue whales from accidental spills are expected to be insignificant and discountable.

Cumulative Effects

Analysis of direct and indirect effects to blue whales focused on the risk of ship strike, underwater acoustics, and risk of fuel spills to blue whales. As included in the WSREM, the future incidence of increased risk to the whales is assumed to be related to the blue whale population density, habitat use patterns in the analysis area, and volume of vessel traffic within the marine analysis area. The Port of Coos Bay is currently utilized by about 50 deep-draft commercial cargo ships and 50 barges per year. Annual commercial ship traffic into and out of the Port has declined in recent years from a high of 310 deep-draft vessel calls at the Port in 1988 to 52 in 2016. The Port is also visited, by conservative estimates, by 50 tug/barge units per year, with 14 tug/barge units requesting pilotage during 2016 as per data from the Coos Bay Pilots Association.(Whipple 2017).

The vessels transiting to and from the LNG Terminal would contribute to the ambient noise levels in the marine analysis area. However, the contribution of additional noise will occur within a context of regional diminishing traffic-related noise (Andrew et al. 2011), so the cumulative impact should be limited. Also, the number of blue whales that are expected to be potentially exposed within the area of underwater sound attenuation to 120 dB is very low.

Unintentional spills or releases of diesel fuel and/or gasoline are possible in the foreseeable future; these events are documented annually throughout the eastern North Pacific waters from a variety of vessel types (OSTF 2017). According to the 2016 Annual Report of the Pacific States/British Columbia Oil Spill Task Force, Oregon has had one the lowest rate of calls of spills compared to other Pacific U.S. states and British Columbia to the emergency response hotline from 1999 – 2015, with the annual number of calls generally less than 25/year (Oil Spill Task Force [OSTF] 2016). The state of Oregon participates in an international program (Spills aren't Slick) coordinated through the Pacific Oil Spill Prevention Education Team (POSPET) that recognizes there are numerous avenues from fuel docks to recreational boaters, to commercial fishing and transport that may contribute to the annual rate of spills and releases. From this data source, it appears that the background rate of spills off the Oregon coast (incidence of spills in proportion to total vessel operation) by fishing vessels, recreation vessels, and other vessel types is generally

[1] The U.S. regulations implementing MARPOL Annex I are found in 33 CFR subchapter O, parts 150-160.

low and expected to continue at low frequencies in the foreseeable future as a result of the existing programs and coordinated efforts to minimize this risk to the environment.

The foreseeable cumulative effect of the additional 120 LNG carriers per year with regard to risk of vessel strike, underwater noise, or accidental release is expected to be low. Consequently, cumulative effects to blue whales would be the same as the estimate of direct effects discussed in the previous sections. Those effects were judged to be discountable.

Critical Habitat

The proposed action would not affect critical habitat because none has been designated.

3.2.1.4 Conservation Measures

Conservation measures are included in the LNG Terminal plan to reduce the impact to marine mammals, and potentially other marine wildlife such as turtles, with regard to the risk of vessel strike, acoustic disturbance, and fuel spills. The conservation measures described for blue whales, will also apply to the other marine mammal species in this document as well as non-ESA listed species, due to the broad nature of the actions related to the LNG carriers transiting to and from the LNG Terminal. All LNG vessels calling at the LNG terminal will be required to confirm that they will comply (or have been in compliance) with all NMFS recommendations to reduce the risk of whale strikes in the waters off the coast of Oregon and the U.S. West Coast. This will be confirmed during the vessel vetting and compatibility acceptance process that each vessel will undergo prior to its first call at the terminal and at intervals of six months thereafter if the same vessel will call at the terminal on a regular basis. In addition, the LNG terminal has agreed with the Coast Guard that the LNG Vessel Transit Management Plan for Coos Bay requires LNG vessels to remain more than 50 miles off the U.S. West Coast until clearance is granted by both the Coast Guard and the Terminal for the vessel to enter port and berth at the Terminal. To further reduce the risk of vessel strike to blue whales, JCEP would require all LNG carriers calling on the LNG terminal to adherence to NMFS's best practice recommendations NMFS (2017k) such as to reduce speed to 10 knots or less within 12 nmi of the entrance to Coos Bay during the blue whale migratory period and post extra lookouts either on the bow (weather permitting) or the bridge wings who have been briefed in the techniques of spotting signs of migrating whales. If whales are spotted or are known to be in a specific area through reports, LNG Carrier to avoid transiting the specific area and go around. Additionally to report any sightings or incidents to NMFS and/or the Coast Guard as required.

During the 96-hour pre-notification process, required of all LNG carriers calling on the LNG Terminal, the LNG Carriers shall consult the Local Notice to Mariners (issued by the Coast Guard) and US Coast Pilot to understand seasonal migration patterns, times and routes and obtain current information on whale sightings in the waters off Coos Bay and the latest recommendations and advisories from the NMFS and Coast Guard. The LNG Carrier Master shall take this into account and adjust the vessel speed and route accordingly. In addition, three tractor tugs would guide the LNG carrier from a point approximately five nmi offshore of the entrance to Coos Bay and on to the LNG Terminal.

The LNG carrier operators would be required to consult the current whale sightings in the continental shelf waters near Coos Bay, prior to transiting to or from the LNG Terminal. Vessel operations would be required to be aware of the blue whale distributions in the continental shelf waters near Coos Bay, and adjust operations accordingly to avoid aggregations of blue whales as navigably possible. Vessels transiting to and from the LNG Terminal would be required to post a watch for marine mammals for the duration of the vessels' transit across the continental shelf and have the information relayed directly to the vessel master.

LNG carriers would be required to reduce speed to 10 knots or less when cow-calf pairs, or large groups are observed near an underway LNG carrier, when navigably possible. LNG carriers would also be requested to route around and maintain a 100-yard distance from the whales observed and to avoid crossing in front of the whales and maintain a parallel route, when navigably possible. In addition, for safety of the vessel and crew, course adjustments would need to be made gradually away from the whales' location or direction of travel. Lastly, the LNG carrier operators would be encouraged to review and adopt when possible guidelines to reduce underwater noise from commercial ships (International Maritime Organization [IMO] 2014).

To further increase the awareness of local marine mammal species and risk factors, JCEP would provide a Ship Strike Avoidance Measures Package to shippers calling on the LNG Terminal in Coos Bay. This package would include:

- Training to LNG carrier bridge crews, including the use of a reference guide such as the *Marine Mammals of the Pacific Northwest, including Oregon, Washington, British Columbia and South Alaska* (Folkens 2001). This is a pamphlet that would be provided to LNG carriers calling on the terminal and would be included as part of the terminal use agreement to the shippers.
- A copy of an accredited mariners guide to whales. Two options are currently considered. The first is the NMFS CD-ROM–based training program entitled *A Prudent Mariner's Guide to Right Whale Protection* (NMFS 2009b). While this training program is specific to right whales, NMFS has stated that the guidance and avoidance measures are also applicable to fin, humpback, and sperm whales. The second option is focused on Pacific species but is directed to mariners in Canadian waters (Mariners guide to whales, dolphins and porpoises of western Canada, Coastal Ocean Research Institute [CORI] 2016). In the event, that a U.S. based Pacific guide is developed before operations commence, this guide would be used. The final decision would be made in consultation with a qualified marine mammal zoologist or biologist to use the most relevant and up-to-date guide available.
- Measures discussed in the 2010 workshop in California (Reducing Vessel Strikes of Large Whales In California (DeAngelis 2010) as relevant for the species expected in coastal Oregon.
- Sightings of marine mammals are to be documented and reported to a central database. This would be arranged with consultation of NMFS and the Oregon Institute of Marine Biology. This reporting would assist in understanding patterns of distribution and occupancy in the continental shelf waters of Oregon by blue whales.
- Written guidance on expectations regarding:
    - Active watch for marine mammals.
    - Sightings data documentation, and reporting procedures.
    - Vessel speeds of 10 knots or less when mother-calf pairs or groups are sighted.
    - Maintenance of a minimum distance of 100 yards from whales, when navigably possible. This is particularly relevant if advance notice of whales locations are provided by NMFS.

- Maintenance of a parallel course to the whale(s) and avoidance of excessive speed or abrupt course changes until the vessel and whale are no longer proximal.
  - When whales are sighted in a ship's path or in proximity to a moving ship, reduce speed to 10 knots or less or shift the engine to neutral until whales are clear of the area or path of the ship, as navigably possible.
- Participate in the Oregon Emergency Response system (1-800-452-0311) to report any observed spills

LNG carrier masters would also be asked to report sightings of any injured or dead whales as soon as is practicable, regardless of whether the injury or death is caused by the ship. If the injury or death is caused by collision with the ship, within U.S. the appropriate regulatory agency (NMFS) would be notified within 24 hours of the incident. Information to be provided would include the date and location (latitude/longitude) of the strike, the ship name, the species or a description of the animal, if possible.

3.2.1.5 Determination of Effects

Species

The LNG Terminal **may affect** blue whales because:

- blue whales may occur within the marine analysis area during operation of the proposed action; and
- the proposed action would increase shipping traffic (LNG carriers) from current levels within the marine analysis.

However, the Project is **not likely to adversely affect** blue whales because:

- based on existing information, ship strikes on blue whales within the marine analysis area are expected to be discountable,
- the increase in annual ship traffic due to the proposed action is expected to result in a localized increase of the risk of ship strike to blue whales, but because blue whales do not aggregate in this region the increase in risk would be discountable,
- JCEP would provide a ship strike avoidance measures package to shippers transporting LNG cargo from the LNG Terminal that would consist of multiple measures to avoid striking marine mammals;
- LNG carriers approaching Coos Bay would be traveling slowly and be escorted by tractor tugs from 5 nmi offshore to the LNG Terminal; and
- LNG carrier noise would contribute to overall noise within the marine analysis area while transiting to and from Coos Bay and effects of ship noise on blue whales could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise, but are not expected to cause injury, and the exposure is expected to be to a discountablepercentage of the population.

Critical Habitat

No critical habitat has been designated or proposed for blue whales.

3.2.2 Fin Whale

3.2.2.1 Species Account and Critical Habitat

Status

Fin whales were listed as endangered under the ESCA on June 2, 1970 (FWS 1970). Under the ESA, this status remains in effect today for the Northeast Pacific stock of fin whales (NMFS 2015a). Under the MMPA, this stock is classified as depleted and strategic (NMFS 2015a). The stock structure within the eastern North Pacific Ocean is unclear for this species, but there are three management stocks recognized in U.S. Pacific waters: 1) Alaska (Northeast Pacific), 2) California/Oregon/Washington, and 3) Hawaii (NMFS 2015a).

Threats

Commercial whaling was the primary reason for the depletion of fin whales, however this threat ceased when commercial whaling for this species in the North Pacific ended in 1976 (NMFS 2012a). Ship strikes and disturbance by vessels are modern threats to fin whales (NMFS 2010a). Between 2010 and 2014 there were at least nine fin whales documented killed or injured by vessel strikes along the Pacific west coast (Carretta et al. 2017a). It is expected that not all vessel-whale collisions are documented, therefore estimates are expected to underrepresent the actual numbers. The total documented incidental mortality and serious injury of 2.0 whales per year (0.2 whales per year due to fisheries and 1.8 whales per year due to ship strikes) is well below the calculated PBR (81) (Carretta et al. 2017a). Further, Nadeem et al. (2016) report that this population of fin whales has increased since the early 1990s.

As with blue whales, anthropogenic noise is concern identified by NMFS (2010a) as a factor influencing the distribution of fin whales. Noise from vessels and other anthropogenic sources may interfere and mask cetacean communication, predator-prey detection, and possibly navigation (Würsig and Richardson 2009). Coastal developments and its associated anthropogenic noise may compromise the migration routes and seasonal areas used by fin whales (NMFS 2010a). As discussed previously for blue whales, pollution and climate change may affect fin whales or their prey species. The potential effect of climate change on fin whales is uncertain, but there may be effects that impact habitat selection, prey availability, breeding behaviors, and migration patterns (NMFS 2010a).

Species Recovery

NMFS finalized a recovery plan in 2010 (NMFS 2010a) and the most current five-year status review was released in December 2011 (NMFS 2011a). The goal of the recovery plan is to achieve the delisting of the species. (NMFS 2010a).

The recovery plan identifies the following recovery actions:

- Coordinate state, federal, and international actions to implement recovery actions and maintain International Regulation of Whaling for fin whales;
- Determine population discreteness and stock structure;
- Develop and apply methods to estimate population size and monitor trends in abundance;
- Conduct risk analyses;

- Identify, characterize, protect and monitor habitat important to fin whale populations in U.S. waters and elsewhere;
- Identify causes and reduce the frequency and severity of human-caused injury and mortality;
- Determine and minimize any detrimental effects of anthropogenic noise in the oceans;
- Maximize efforts to acquire scientific information from dead, stranded, and entangled or entrapped fin whales; and
- Develop a post-delisting monitoring plan.

Life History, Habitat Requirements, and Distribution

Fin whales are a baleen whale and the second-longest whale species. They are widely distributed throughout the world's oceans. The gestation period is assumed to be less than a year, and fin whale calves are nursed for 6 to 7 months. Most mating and calving takes place in winter. In the North Pacific, fin whales appear to prefer a diet of euphausiids and large copepods, followed by schooling fish such as herring, walleye pollock, and capelin (NMFS 2010a).

Fin whales can be found in groups of three to seven, but group sizes have been recorded as large as 50-100 animals in rich feeding grounds. Dive times are typically 3-15 minutes, with depths from 100-230 meters (328-755 feet). A series of two to five shallow dives for between 10 and 20 seconds is common (Shirihai and Jarrett 2006).

The reproductive age of fin whales is believed to have decreased from 12 to six years for females and 11 to four for males from the 1950s to the mid-1970s as a result of the overharvesting. They are believed to reproduce every two to three years upon reaching sexual maturity. Fin whales live between 85 to 90 years (Shirihai and Jarrett 2006).

The seasonal movements, habitat use and distribution of eastern North Pacific fin whales are not well understood. However, this species is known to occur year-round off the coast of Oregon, with seasonal abundance fluctuations with numbers being lower during the winter and spring compared to the summer and fall (Carretta et al. 2017a, Green et al 1992).

Population Status

The best estimate of the California/Oregon/Washington stock of fin whales is 9,029 whales (CV=0.12), based on line transect data from 1991-2014 (NMFS 2017). There is strong evidence this population is increasing from the time of the cessation of whaling (Carretta et al. 2014a, Moore and Barlow 2011). The minimum population is estimated at approximately 8,127 whales in 2014 (Carretta et al. 2014a). The annual PBR for this fin whale stock is 81 (NMFS 2017).

Critical Habitat

As of October 2017, critical habitat for this species has not been designated in U.S. waters.

3.2.2.2 Environmental Baseline

Analysis Area

The analysis area applicable to fin whales is the marine analysis area as described for blue whales (see section 3.2.1.2).

Species Presence

The same line-transect ship surveys discussed above for blue whales (Barlow and Forney 2007; Forney 2007; Barlow 2010) were used to estimate fin whale populations off the coasts of Oregon and Washington. The mean density of fin whales in the Oregon-Washington stratum is 0.129 whales per 100 km^2 or 0.038 whales per 100 nmi^2. Based on habitat modeling, the predicted densities of fin whales in Oregon coastal waters range from 0.0013 - 0.0048 whales/km^2, with densities in the continental shelf region off Coos Bay ranging from 0.0028 – 0.0036 whales/km^2 (Calambokidis et al. 2015).

Habitat

Fin whales occur in both nearshore and pelagic waters (Calambokidis et al 2015), but based on the line transect data referred to in the previous section, fin whales are typically found in the continental slope and pelagic zones of the Oregon coast (NMFS 2014a). Observations show fin whales to be present year-round in central and Southern California; year-round in the Gulf of California; and occurring off Oregon in the summer. However, acoustic signals from fin whales have also been detected year-round off northern California, Oregon, and Washington, with a concentration of vocal activity between September and February (NMFS 2010a). Since fin whales feed on euphausiids, similar to blue whales, they may likewise follow primary production blooms of phytoplankton and associated euphausiid biomass increases off the Oregon coast as the blooms advance from south to north (Burtenshaw et al. 2004). Green et al (1992) found fin whales using continental slope waters 85-90 km west of Newport, Oregon. Though this species has been observed in continental shelf waters, a greater proportion of sightings have occurred over the continental slope (Green et al. 1992).

Critical Habitat

Critical habitat for this species has not been designated.

3.2.2.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, underwater noise, and potential adverse effects from fuel spills. Spills could additionally indirectly affect fin whales by impacting forage species. These effects are addressed below.

Ship Strikes

There is an ongoing threat of ship strikes to fin whales throughout the world's oceans. Reduction of human-caused injury and mortality to fin whales is a principal objective for the species' recovery (NMFS 2010a). From 2007 to 2011 ship strikes of fin whales averaged 0.2 death or injury per year off the Oregon-Washington coast (Carretta et al. 2013). However, of the ship strikes reported in Carretta et al. (2013) no fin whales were reported struck in Oregon waters. Jensen and Silber (2003) reported a rate of 0.5 fin whales struck per year off the coasts of California and Washington from 1991 through 2002. Likewise, Douglas et al. (2008) compiled records of ship-strikes of fin whales in Washington State from 1980 to 2006 with an average of 0.07 whales struck per year. These are likely underestimates, as ship strikes with cetaceans can go unnoticed and therefore unknown and unreported, but reports from Oregon suggest low levels of ship strike in comparison to other parts of the Pacific Ocean off the coast of the United States.

Ship-strike risk was estimated for fin whales, as described above for blue whales (see section 3.2.1.3).

Estimated Ship Strikes to Fin Whales

Determination of the WSREM for fin whales (see table 3.2.2-1) included the following variables:

- Fin whale length: 25.91 m (https://www.fisheries.noaa.gov/species/fin-whale)
- Time at Surface: 5% (Ray et al. 1978)
- Density – Lower = 0.0028 whales/km^2 (Calambokidis et al. 2015)
- Density – Upper = 0.0036 whales/km^2 (Calambokidis et al. 2015)
- Proportion of year most likely to occur in marine analysis area: June through February = 0.75

TABLE 3.2.2-1

Results of WSREM for Fin Whales

Marine Traffic	Risk Lower Estimate (whales/1000 km)	Risk Upper Estimate (whales/1000 km)
LNG carriers Only	0.19	0.24
Existing Traffic Only	0.08	0.10
Cumulative Results	0.26	0.34

As with blue whales, the estimated vessel strike risk increases from existing levels but is again limited to the time of year that fin whales are known to occur off Oregon. Therefore, while the risk is increased from the existing risk levels (which with rounding to two decimal places have the same value for the lower and upper risk estimates) with the addition of vessels transiting to the LNG Terminal, this risk is still considered to be low based on the results of the WSREM and low documented rates of actual ship strikes in Oregon waters. In addition, though there is a localized increase in the risk of ship strikes to fin whales by LNG carriers, this localized increase is not significant for the California/Oregon/Washington stock of fin whales as the coast of Oregon does not contain identified critical habitat nor is it a recognized area for feeding aggregations.

Underwater Noise

Determining and minimizing detrimental effects of anthropogenic underwater noise on fin whales is a principal objective for the species' recovery (NMFS 2010a). The potential effects of underwater noise on fin whales are as described in section 3.2.1.3 for blue whales.

Based on the same evaluation as presented in the blue whale discussion, there could be 0.06 – 0.07 fin whales/km within the area of sound attenuation to 120 dB during the time of year that fin whales are present off the coast of Oregon. Based on the above data, and since fin whales are present in densities of roughly 0.06 - 0.07 fin whales per km^2 within the area of sound attenuation to 120 dB, there could be between 432 and 504 fin whales potentially occurring within the 120 dB attenuation area over the life of the Project. Similar to the analysis for blue whales, as many as between 160 and 186 fin whales could occur within the 120 dB attenuation area for tractor tugs over the life of the Project.

Some fin whales may be exposed to sound levels produced by Project related vessels that could cause behavioral disturbance. However, the potential number of whales that could be affected are a small fraction compared to the estimated population sizes of the Northeast Pacific stock of fin whales or the California/Oregon/Washington stock.

Fuel Spills

The potential effects of fuel spills on fin whales, as well as the laws and regulationsregarding environmental protection are the same as described as for blue whales (see section 3.2.1.3). As a result, effects to fin whales from accidental spills or release of fuel or lubricants at sea are expected to be insignificant and discountable.

Cumulative Effects

The definition of cumulative effects to fin whales is as described as for blue whales (see section 3.2.1.3). The foreseeable cumulative effect of the additional 120 LNG carriers per year with regard to vessel traffic noise, risk of vessel strike or accidental release is expected to be low. Consequently, cumulative effects to fin whales would be the same as the estimate of direct effects discussed in the previous sections. Those effects were judged to be discountable.

Critical Habitat

The proposed action would not affect critical habitat because none has been designated.

3.2.2.4 Conservation Measures

The same Conservation Measures to minimize potential effects that was described in section 3.2.1.4 (blue whales) applies to fin whales.

3.2.2.5 Determination of Effects

Species

The Project **may affect** fin whales because:

- fin whales may occur within the marine analysis area during operation of the proposed action; and
- the proposed action would increase shipping traffic (LNG) within the marine analysis area.

However, the Project is **not likely to adversely affect** fin whales because:

- ship strikes to fin whales within the marine analysis area have not been documented;
- the risk of ship strike is expected to be discountabledue to the low occurrence of fin whales in the nearshore environment of the marine analysis area and this species' habitat preferences;
- JCEP would provide a ship strike avoidance measures package to shippers transporting LNG cargo from the LNG terminal that would consist of multiple measures to avoid striking marine mammals;
- LNG carriers approaching Coos Bay entrance would be traveling slowly and escorted by tractor tugs from 5 nmi offshore to the Port; and

although LNG carrier noise would contribute to overall noise within the marine analysis area while transiting to and from the LNG Terminal and effects of ship noise on fin whales could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise, these noise levels are not expected to cause injury, and the exposure is expected to be to a discountablepercentage of the population.Critical Habitat

No critical habitat has been designated or proposed for fin whales.

3.2.3 Killer Whale

3.2.3.1 Species Account and Critical Habitat

Status

Eight stocks of killer whale are recognized within Pacific United States waters, with three relevant to the Oregon coast (NMFS 2013b):

1. Eastern North Pacific Southern Resident stock – occurring from Alaska to California, with a summer preference for the inland waters of Washington and southern British Columbia (winter preferences are not defined), listed as endangered under the ESA November 18, 2005 (NMFS 2005a). The Southern Resident population is classified as depleted and strategic under the MMPA;
2. Eastern North Pacific Transient stock – occurring from Alaska to California (unlisted);
3. Eastern North Pacific Offshore stock – occurring from Southeast Alaska to California (unlisted).

A status review of Southern Resident killer whales conducted in 2002 concluded that listing as threatened or endangered was not warranted because Southern Resident killer whales were not a species or DPS for ESA application (NMFS 2005a). The status review recognized, however, that the Southern Resident killer whale was a depleted stock under the MMPA. A challenge to NMFS' decision to not the list the species ("not warranted") and subsequent judicial intervention resulted in an updated status review, which found that the Southern Resident killer whale stock is discrete and significant with respect to other resident stocks and should be considered a DPS for listing under ESA (NMFS 2005a).

NMFS (2012b) published a 90-day finding on a petition to remove (delist) the Southern Resident killer whale DPS from the ESA list. The finding determined that the petitioned action might be warranted and NMFS announced their initiation of a status review to determine if the petitioned action is warranted. In 2011, NMFS completed a five-year review of the status of Southern Residents killer whales and concluded that no change was needed in the species' ESA listing status; the Southern Resident killer whale DPS would remain listed as endangered (NMFS 2011b).

Threats

The Southern Resident killer whale DPS primarily occurs in the inland transboundary waters of British Columbia and Washington in the summer and fall and in outer coastal waters in winter and spring. The spring and winter habitat use (including Oregon waters) is not well defined, and therefore the threats associated with this time of year can only be generalized. The NMFS (2008a) identified the factors that currently pose a risk for Southern Residents, including the following:

- Reductions in quantity or quality of prey;

- High levels of organochlorine contaminants and increasing levels of many "emerging" contaminants (e.g., brominated flame retardants), putting Southern Residents at risk for serious chronic effects similar to those demonstrated for other marine mammals (e.g., immune and reproductive system dysfunction);
- Sound and disturbance from vessel traffic; and
- Oil spills.\

Reductions in prey availability, primarily that of salmon, over the past 150 years has limited the carrying capacity for the Eastern North Pacific Southern Resident stock (NMFS 2008a). Other reasons for the reduction in Southern Resident stock numbers includes the live-capture of whales for aquaria, and targeted shooting that was common before 1960 (NMFS 2013b).

Commercial and recreational vessel traffic have increased considerably during the past decades. The threats to killer whales from acoustic disturbance, and risk of ship strike are as previously discussed for blue and fin whales.

Environmental pollution is a known threat to killer whales. High levels of polychlorinated biphenyls (PCBs) have been found in the Southern Resident stock, and increasing levels of polybrominated diphenyl ethers and other contaminants are being found in ocean habitats with increasing frequency (NMFS 2008a). Ross et al. (2000) found that the Southern Resident stock was one of the most contaminated cetaceans worldwide, and noted that fish-eating marine mammals that are found in industrialized coastal waters are generally high in PCB concentration levels.

Killer whale food sources may be damaged and they may gain new stressors with certain climate changing processes such as global warming similar to those discussed above for blue whales (Fogarty and Powell 2002).

Species Recovery

NMFS published a recovery plan for the Southern Resident killer whales in 2008 (NMFS 2008a). The goal of the recovery plan is to remove the species from the ESA. The interim goal is to reclassify the Southern Resident killer whale DPS from endangered to threatened. The following is a list of recovery measures needed to achieve the goals and objectives provided in the recovery plan (NMFS 2008a):

- Protect the Southern Resident killer whale population from factors that may be contributing to its decline or reducing its ability to recover (salmon stock, pollution, vessel disturbance).
- Protect Southern Resident killer whales from additional threats that may cause disturbance, injury, or mortality, or impact habitat (oil spills, acoustic effects, disease, invasive species).
- Develop public information and education programs.
- Respond to killer whales that are stranded, sick, injured, isolated, pose a threat to the public, or exhibit nuisance behaviors.
- Encourage transboundary and interagency coordination and cooperation.
- Monitor status and trends of the Southern Resident killer whale population.
- Conduct research to facilitate and enhance recovery efforts for Southern Resident killer whales.

Life History, Habitat Requirements, and Distribution

Killer whales are found in all oceans, but the Southern Resident killer whale population occurs only in the coastal waters of the western U.S. and Canada. Southern resident killer whales live in stable matrilineal societies, with the groups consisting of family units of both sexes and a range of ages. Southern resident killer whales prey upon a number of different fish species including salmonids, lingcod (*Ophiodon elongates*), halibut (*Hippoglossus stenolepis*), rockfish (*Sebastes* spp.) and Dover sole (*Microstomus pacificus*)sh, but seasonality existing with the summer and fall months diet consisting mostly chinook and chum salmon (*Oncorhynchus tshawytscha* and *O. keta*) - (Fisheries and Oceans Canada 2011; Hanson et al. 2010). Genetic stock identification analyses are indicating that the main chinook salmon stocks that southern resident killer whales target are from the relatively large drainages of Washington and California (Hanson 2015). Less is known of the diet composition during the winter and spring months, and research into this important life history component is continuing.

Sexual maturity of female killer whales is size dependent and occurs when the whales reach lengths of approximately 15 to 18 feet. Mating appears to occur at any time, with no identified breeding season (American Cetacean Society 2004). The female Southern Resident killer whales average births every 4.9 to 7.7 years, and are polygamous. This species can live beyond the reproductive years with males living up to about 50 years and females nearing 100, however, it is possible that males may continue to be reproductively viable throughout their lives. Males tend to have death rates that increase by 18 percent each year after reaching 30 years old (American Cetacean Society 2004). Dives are relatively short, with patterns consisting of several shallow dives with breaths every 10 to 35 seconds , followed by deeper, longer dives lasting up to about 17 minutes (Shirihai and Jarrett 2006).

Population Status

In 1993 there were 96 individual killer whales in the three pods that comprise the Eastern North Pacific Southern Resident stock. The population increased to 99 whales in 1995, then declined to 79 whales in 2001, and most recent population size is 78 whales, as of December 2016 (CFWR 2017).

It is believed that the entire population is identified and accounted for each year due to extensive effort and photographic identification of individual animals. The recent analysis of long-term population growth, from 1979 to 2011, for the Southern Resident killer whale DPS indicates the maximum annual growth rate is R_{MAX} = 3.5 percent (Carretta et al. 2017a). The PBR is calculated at 0.14 whales per year and appears to be approaching a rate of zero for human-related mortality and serious injury (Carretta et al. 2017a).

Southern resident killer whales are known to use the outer coasts of British Columbia, Washington, Oregon and California, particularly during the winter and spring months (Hanson 2015). Observations of Southern Resident killer whales in Oregon are infrequent and have been restricted to offshore areas near Depoe Bay (1999 and 2000), near Yaquina Bay (2000), and near the Columbia River (2006) (NMFS 2006a). Passive acoustic and telemetry data also indicate that during the winter/spring months southern resident killer whales transit Oregon waters, through more utilized habitats appear to be in northern California and Washington (Hanson 2015). Since the Eastern North Pacific Southern Resident killer whale stock has been sighted along the Oregon coast and as far south as Monterey Bay, California (Carretta et al. 2017a), these animals may occur in the marine analysis area on an infrequent basis with likely short residency times based on the sparse sightings data.

Critical Habitat

Critical habitat for the Eastern North Pacific Southern Resident stock of killer whales was designated on November 28, 2006 (NMFS 2006a). Three specific areas were designated:

1. the Summer Core Area in Haro Strait and waters around the San Juan Islands;
2. Puget Sound; and
3. the Strait of Juan de Fuca.

None of the identified critical habitats are in Oregon waters.

NMFS (2014b) announced a 90-day Petition Finding and Request for Information for possibly revising the 2006 critical habitat designation for the Southern Resident killer whale DPS. The petition requests revision of critical habitat to include inhabited Pacific Ocean marine waters along the West Coast of the United States that constitute essential foraging and wintering areas. Additionally, the petition requests adoption of protective in-water sound levels as a primary constituent element for both currently designated critical habitat and the proposed revised critical habitat. NMFS found that the petition to revise critical habitat presented substantial scientific information indicating the petitioned action may be warranted. However, this petition did not result in any additions to the critical habitat identified for Southern Resident killer whales.

3.2.3.2 Environmental Baseline

Analysis Area

The analysis area applicable to killer whales is the marine analysis area as previously described for blue whales (see section 3.2.1.2).

Species Presence

Most sightings of the ESA-listed Southern Resident killer whales have occurred during summer and fall within inland waters of Washington and southern British Columbia. The specific areas that make up their winter range are uncertain (Carretta et al. 2014a), but acoustic detections have shown a higher than expected usage of the waters near the Columbia River (Hanson et al 2013). While southern resident killer whales are known to occur off the Oregon Coast the data indicate their presence in this part of their range is lower than the more northerly extents (Hanson et al. 2013).

While, Southern Resident killer whales may occur in or travel through the marine analysis area, this occurrence is likely on an infrequent and seasonal basis. Killer whales occasionally enter lower Coos Bay in search of prey resources (COE 1994), but these are likely to be transient killer whales (mammal eating), not Southern Resident killer whales. The available sightings data for southern resident killer whales in Oregon (see above) indicate that the habitats used are in the more northern areas of the state, and in areas with larger riverine drainages.

Habitat

Killer whales are less restrained by depth, temperature, and salinity of the water than other whales (NMFS 2008a). The Southern Resident stock tends to spend more time in deeper water or waters where there is more salmon abundance. Documented occurrences off of Oregon have led to the belief that the California Current ecosystem is used by this stock (NMFS 2008a). Green et al (1992) found that killer whales were widely distributed in Oregon waters, but that all sightings were over continental shelf waters, particularly near the shelf break. These sightings were thought be transient (mammal-eating) type killer whales, but this was not definitive (Green et al. 1992). Habitat-based density estimates were not available for Southern Resident killer whales, and are likely inappropriate due to the small population size and social dynamics.

Critical Habitat

No critical habitat for southern resident killer whales occurs in or near Oregon waters.

3.2.3.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, effects due to ship noise, potential adverse effects from a fuel spills, and potential effects on prey resources. These effects are addressed below.

<u>Ship Strikes</u>

Ship strikes are a concern for killer whales. However, of 10 whale species studied by Jensen and Silber (2003), killer whales were the least likely to be struck by ships, with one documented occurrence of a killer whale calf being struck by a ship. One killer whale from the Southern Resident stock was killed by a ship strike in 2006, but this was an unusual occurrence because that whale (L98) had become habituated to vessel interaction while it resided in Nootka Sound after being separated from its pod. In the five-year period, 2007-2011, no killer whales had been struck by vessels (Carretta et al. 2013, 2014b).

The available information indicates that killer whales are less susceptible to ship-strike than larger baleen whales, as carcasses indicating trauma and/or wounds from boat propellers have not been reported along the Oregon and Washington coasts (Norman et al. 2004). From 1995 to 2006, 10 killer whales were injured (eight) or killed (two) within the inland waterways of British Columbia (including L98, see Williams and O'Hara 2009) but none of the records were from whales struck in the open ocean.

<u>Estimated Ship Strike Risk to Southern Resident Killer Whales</u>

Due to the lack of data and habitat-based density estimates, it was not possible to quantify the risk of vessel strike to Southern Resident killer whales in the marine analysis area. However, qualitatively this risk is considered to be very low based on the apparently low use of the region by Southern Resident killer whales and the low rate at which these animals are struck in other open ocean parts of their eastern North Pacific range. It is worth noting that southern resident killer whales are known to successfully live in areas (i.e. Puget Sound) with extensive deep sea traffic. In any event, all vessel strike related conservation actions would also pertain to killer whales.

<u>Underwater Noise</u>

Determining and minimizing any detrimental effects of anthropogenic underwater noise on killer whales is a principal objective for the species' recovery (NMFS 2008a). Killer whales are highly vocal, producing a variety of clicks, whistles, and pulsed calls for echolocation and social communication (Ford 2009). As described for blue whales above, southern resident killer whales are also exposed to a variety of underwater noises. Southern Resident killer whales critical habitat was delineated in the inshore waters of Washington and British Columbia that are also used by a variety of vessel traffic, including those going to commercial ports near Seattle and Vancouver. Studies have shown that killer whales can increase their call amplitude by 1 dB for every 1 dB increase in background ambient noise levels (Holt 2008).

Due to the lack of occupancy data and habitat-based density estimates, it was not possible to quantify the potential exposure to underwater noise by Southern Resident killer whales in the marine analysis area. However, qualitatively this risk is considered to be very low based on the apparently low use of the region by Southern Resident killer whales.

While the effects by Project LNG carrier-related noise on killer whales are possible in the marine analysis area, the noise sources are not novel, and within the experience of Southern Resident killer whales given their use waters in and near shipping lanes in U.S. and Canadian critical habitats, which includes Juan de Fuca Strait with designated traffic separation schemes for deep sea vessel transit between the open Pacific waters and the Ports of Seattle and Vancouver. The exposure would be commensurate with existing noise levels and would not be expected to cause injury or disturbance.

It is unlikely that LNG carriers transiting the marine analysis area would produce noise at levels that could negatively affect Southern Resident killer whales, due to the low usage of the marine analysis area waters, the experience with commercial vessel traffic, and the absence of critical habitat in Oregon.

Prey Resources

Because the Coos Bay estuary and associated riverine extents crossed by the Pipeline are salmon habitats, and southern resident killer whales primarily target salmon stocks, the construction and operation of the Project have a potential to affect the prey resources for this marine mammal. However, as discussed below, the effects are likely to be very low because southern resident killer whales primarily target salmon stocks from other river systems and southern resident killer whales spend a low proportion of their time on the Oregon coast.

The construction of the Project has a potential to affect salmon habitat that could, in turn, affect southern resident killer whales if there were a significant reduction in their primary prey species, which are Chinook salmon. However, relatively few adult fall Chinook salmon and fewer adult spring Chinook salmon are expected to be present in Coos Bay and in known riverine habitats at the time of construction.

The distribution of spawning fall and spring Chinook (ODFW 2017d) includes streams in several of the 5th field watersheds crossed by the Pipeline project (Coos River, Coquille River, South Umpqua River, and Upper Rogue River sub-basins) although no spring Chinook apparently inhabit streams within the Coos River sub-basin. There is relatively little Chinook salmon habitat within the four sub-basins crossed by the Pipeline compared to the habitats available within Oregon (smaller yet if comparisons included occupied habitats in Washington and California), particularly for occupied and spawning habitats used by spring Chinook.

Recent research indicates that southern resident killer whales prey on adult Chinook salmon, at least on the whales' summer range in the Salish Sea, as Chinook salmon return to the Fraser River (Ford et al. 2016). During late summer and fall, the southern resident killer whale DPS feeds on

Puget Sound Chinook (as well as chum and coho). Some whales may travel as far south as Monterey Bay, California during winter. Whales prey on Chinook from Grays Harbor, the Columbia River, the Klamath and Sacramento river systems (spring-run Chinook) during winter and early spring (NOAA 2014). Abundance of Chinook salmon prey has been positively related to fecundity of the Southern Resident killer whale DPS (Ward et al. 2009).

The Project would potentially affect a very small portion of Chinook salmon habitat and consequently could potentially affect a very small portion of the prey base potentially utilized by southern resident killer whales as they occasionally travel along the coast from Washington to Monterey Bay. However, this potential effect is considered to be very low since in this area, the salmonid fishes have not been identified as primary habitats or targeted prey species of southern resident killer whales. Because the Project could potentially affect a very small portion of Chinook salmon habitat, it would not have a measureable impact to the prey base for southern resident killer whales.

Fuel Spills

The potential effects of fuel spills on killer whales, as well as the laws and regulations regarding environmental protection are the same as described as for blue whales (see section 3.2.1.3). As a result of these factors limiting the effects of spills, and low usage of the marine analysis area by killer whales, the effects of fuel spilled from LNG carriers are expected to be insignificant and discountable.

Cumulative Effects

The definition of cumulative effects to Southern Resident killer whales is as described for blue whales (see section 3.2.1.3). The foreseeable cumulative effect of the additional 120 LNG carriers per year with regard to vessel traffic noise, risk of vessel strike or accidental release is expected to be low, or effects to prey species. Consequently, cumulative effects to Southern Resident whales would be the same as the estimate of direct effects discussed in the previous sections. Those effects were judged to be discountable, particularly in light of the apparently low usage of the marine analysis area by Southern Resident killer whales.

Critical Habitat

The proposed action would not affect designated critical habitat as it is located in the inland waters of British Columbia and Washington, and does not extend into the open Pacific waters, nor is near Oregon. There is no identified critical habitat for this species in Oregon.

3.2.3.4 Conservation Measures

The same Conservation Measures to minimize potential effects to blue whales that was described in section 3.2.1.4 applies to killer whales.

3.2.3.5 Determination of Effects

Species

The Project **may affect** southern resident killer whales because:

- these whales may occur within the marine analysis area during construction and operation of the proposed action; and

- the proposed action would increase shipping traffic (LNG carriers) within the marine analysis area.

However, the Project is **not likely to adversely affect** killer whales because:

- ship strikes to killer whales within the marine analysis area are discountable;
- the risk of ship strike is expected to remain discountable due to the low usage of the area by Southern Resident killer whales, and their low rate of ship strike in other areas;
- JCEP would provide a ship strike avoidance measures package to shippers calling on the LNG terminal that consists of multiple measures to avoid striking marine mammals;
- LNG carriers approaching the Coos Bay entrance would be traveling slowly and escorted by tractor tugs from 5 nmi offshore to the LNG Terminal;
- LNG carrier noise would contribute to overall noise within the marine analysis area while transiting to and from the LNG Terminal and effects of ship noise on Southern Resident killer whales could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise, but are not expected to affect Southern Resident killer whales due to the low usage of the area;
- no expected change in the quantity or quality of prey species populations that may occur within the marine analysis area is expected as a result of the proposed action;
- an insignificant amount of habitat for prey species would be affected and would not result in measureable impacts to the killer whale's prey base;
- no expected change in the quantity or quality of prey species populations that may occur within the marine analysis area is expected as a result of the proposed action; and
- while southern resident killer whales may occasionally use Oregon coastal waters, it is not recognized as a regularly used area and the whales primarily target salmonids from other larger river systems.

Critical Habitat

The Project would have **no effect** on designated critical habitat for the Eastern North Pacific Southern Resident stock because:

- there is no critical habitat in Oregon;
- the nearest critical habitat to Coos Bay is the Strait of Juan de Fuca, Washington, more than 390 nmi north; and
- no LNG carriers associated with LNG Terminal are expected to transit designated critical habitat.

3.2.4 Humpback Whale

3.2.4.1 Species Account and Critical Habitat

Status

Humpback whales were listed as endangered under the ESCA on December 2, 1970 (FWS 1970). This status remained under the ESA implemented in 1973. As discussed in the 2016 Stock Assessment (Carretta et al. 2017), "NMFS has conducted a global Status Review of humpback whales (Bettridge et al. 2015), and recently revised the ESA listing of the species (81 FR 62259, September 8, 2016)." "The humpback whale ESA listing final rule established 14 distinct population segments (DPSs) with different listing statuses. The DPSs that occur in waters under the jurisdiction of the United States do not necessarily equate to the existing MMPA stocks. Some of the listed DPSs partially coincide with the currently defined [California/Oregon/Washington] CA/OR/WA stock. Until such time as the MMPA stock delineations are reviewed in light of the DPS designations, NMFS considers this stock to be endangered and depleted for MMPA management purposes (e.g., selection of a recovery factor, stock status). Consequently, the CA/ORWA stock is automatically considered as a "strategic" stock under the MMPA."

Threats

Commercial whaling was the primary contributor to the decline of Pacific humpback whale populations (NMFS 1991). This threat is no longer present. The main threats are entanglement in fishing gear and vessel strikes (NMFS 2013c). Anthropogenic noise is also considered a habitat concern for this species (NMFS 1991; Carretta et al. 2007). The effects of climate change on the North Pacific Ocean coastal ecosystem may also affect humpback whales, but as with the previously discussed species, it is currently not possible to quantify this potential threat factor.

Species Recovery

NMFS finalized a recovery plan in 1991 (NMFS 1991). The plan identifies three main goals: biological, numerical and political; the intent is to achieve humpback whale populations that are large enough to be resilient to episodic changes, that the population equals at least 60% of the historical environmental carrying capacity for the Atlantic and Pacific ocean basins where whales enter U.S. jurisdictional waters, and that populations are abundant enough that the species can be down listed or delisted. The plan's four major objectives are:

- Maintain and enhance habitats used by humpback whales currently or historically;
- Identify and reduce direct human-related injury and mortality;
- Measure and monitor key population parameters; and
- Improve administration and coordination or recovery program for humpback whales.

Life History, Habitat Requirements, and Distribution

The humpback whale is a large baleen whale occupying all ocean basins. Migration and reproduction is tied to seasonal progression (NMFS 1991). The Pacific humpback whales over-winter in temperate and tropical waters and migrate in summer to waters of high biological productivity in higher latitudes (NMFS 1991). Breeding and parturition take place in wintering areas, when little feeding takes place. Although along the U.S. west coast, one stock of humpback whales is recognized, there appears to be division into two separate feeding groups: 1) California and Oregon, and 2) northern Washington and British Columbia. The humpback whale diet of both groups consists of krill, along with fish including cod, pollock, anchovies, and mackerel.

Humpback whales generally travel alone or in pairs, with cow-calf pairs often very close together. Group sizes range from 12-15 animals. Dives usually last from 3 to 15 minutes, but can last up to 40 minutes – particularly in breeding habitats. Humpback whales can dive to 150 meters (492 feet). Humpback whales display cooperative hunting behaviors including a coordinated encirclement of prey in bubble nets (Shirihai and Jarrett 2006).

Sexual maturity for humpback whales is generally reached between 4 and 6 years of age. Once mature, females tend to give birth every two to three years (NMFS 1991). The gestation period is 11-12 months, with calves being weaned by 12 months of age. Calves may continue to associate with their mothers for one to two years. Information is lacking on lifespan and natural mortality but humpbacks are known to live to be at least 50 years old (Shirihai and Jarrett 2006). Predators include killer whales and sharks, though as with other large baleen whales, predators generally target neonates or juveniles.

Population Status

The best estimate of abundance for the California/Oregon/Washington stock of humpback whales is 1,918 (CV≈0.03), with a minimum population estimate of 1,876 animals (Carretta et al. 2017a). The observed annual growth rate of the California/Oregon/Washington stock is estimated between 6 and 7% (Carretta et al. 2017a).

The PBR for humpback whales is estimated at 22 animals, but since this stock spends half its year outside U.S. waters, the U.S. allocation of the PBR is reduced to 11 whales/year (Carretta et al. 2014a).

Critical Habitat

As of October 2017, critical habitat for this species has not been designated in U.S. waters.

3.2.4.2 Environmental Baseline

Analysis Area

The analysis area applicable to humpback whales is the marine analysis area as described for blue whales (see section 3.2.1.2).

Species Presence

The California/Oregon/Washington stock of humpback whales is separate from other populations that may occur in the Pacific waters west of the United States. The northern boundary of this population is the border of Washington and British Columbia, with individuals being found throughout the West Coast feeding area and concentrated primarily off of California (Carretta et al. 2007).

Systematic surveys have documented humpback whales in Oregon waters between May and November (Green et al. 1992). However, as the population size has increased since these surveys, humpback whales may now occur outside of this temporal frame, though will likely be limited by this species' annual migratory patterns. The minimum population estimate for the California/Oregon/Washington stock of humpback whales is 1,876 animals (NOAA 2014a).

Based on habitat modeling, the predicted mean densities of humpback whales off the Oregon coast range from 0.003835 – 0.008106 whales/km^2, with densities off Coos Bay higher than in some other coastal areas at 0.005330 – 0.008106 whales/km^2 (Calambokidis et al. 2015). This difference in densities could be related to the productivity and bathymetric relief of the coastal waters of south/central Oregon (see next section).

Habitat

Humpback whales are present along the west coast of the United States primarily during the spring and fall migrations. They are present off the coast of the United States in migratory routes and feeding grounds where they search alone or in groups for krill and small fish, and employ "bubble netting" to corral and trap their prey (Shirihai and Jarrett 2006). Modeled habitat use indicates that humpback whales are strongly associated with latitude and bathymetric features (including depth, slope and distance to the 100-meter isobath). Predictive habitat modeling identified seven humpback whale feeding BIAs, with one in northern Oregon at Stonewall and Heceta Bank from May – November, and one just south of the Oregon/California border at Point St. George from July to November (Calambokidis et al. 2015). Preferred habitat for this species off Oregon includes the continental shelf and slope waters (Green et al. 1992).

Critical Habitat

Critical habitat for this species has not been designated.

3.2.4.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, adverse effects from vessel underwater noise, and potential adverse effects from fuel spills at sea. Spills could indirectly affect humpback whales by impacting forage species. These effects are addressed below.

Ship Strikes

There is an ongoing threat of ship strikes to humpback whales around the world. From published accounts, humpback whales collide with ships relatively often compared to other species, with calves being particularly vulnerable (Laist et al. 2001). Jensen and Silber (2003) found that humpback whales were second most likely behind fin whales to be struck by ships. They reported two humpback whales struck between 1995 and 2000 along the U.S. Pacific Coast, whereas Douglas et al. (2008) reported only one strike off Washington between 1980 and 2006, with an average rate of 0.04.

A more recent, but temporally compressed evaluation, found that ship strikes of humpback whales averaged 0.2 deaths per year along the entire Pacific Coast between 2000 and 2004, and 0.17 deaths per year within Oregon and Washington waters, combined (Carretta et al. 2007). The average annual serious injury and mortality of humpback whales attributable to ship strikes during 2010-2014 is 1.0 whale per year (Carretta et al. 2017a). However, only one humpback whale was reported as struck in Oregon waters, and review of the case specific details yielded that the whale had breached and landed on a sail boat (Carretta et al. 2013). As with other species, these estimates are likely conservative since ship strikes may go unknown and unreported.

Estimated Ship Strike Risk

Ship-strike risk was estimated for humpback whales, as described above for blue whales (see section 3.2.1.3).

Estimated Ship Strikes to Humpback Whales

Determination of the WSREM for humpback whales (table 3.2.4-1) included the following variables:

- Humpback whale length: 18 m (NMFS 2017a) (http://www.fisheries.noaa.gov/pr/species/mammals/whales/humpback-whale.html)
- Time at Surface: 5% (NMFS 2017b)
- Density – Lower = 0.0053 whales/km^2 (Calambokidis et al. 2015)

– Density – Upper = 0.0081 whales/km^2(Calambokidis et al. 2015)
– Proportion of year in marine analysis area: spring and fall = 0.5

TABLE 3.2.4-1

Results of WSREM for Humpback Whales

Marine Traffic	Risk Lower Estimate (whales/1000 km)	Risk Upper Estimate (whales/1000 km)
LNG carriers Only	0.16	0.25
Existing Traffic Only	0.07	0.10
Cumulative Results	0.23	0.35

Since the LNG Terminal is expected to increase the vessel traffic in Coos Bay, from approximately 50 vessels per year, to 170 vessels per year (including the 120 vessels/year from the LNG Terminal), the estimated whale strike risk increases from existing levels. The WSREM yields an increased risk to humpback whales from the existing conditions at 0.07 – 0.10 whales/1000 km to 0.23 – 0.35 whales/1000 km in the marine analysis area. As with other species, the risk is limited to the time period that humpback whales are known to occur off Oregon during the spring and fall migrations.

To reference the projected risk, the current conditions characterize the existing risk and the number of humpback whales known to be struck in Oregon is very low (see Ship Strikes above). Therefore, while the risk is increased from the existing risk levels with the addition of Project related vessels, this risk is still considered to be very low based on the low documented rates of actual ship strikes in Oregon waters and WSREM results.

In addition, though there is a localized increase in the risk of ship strikes to humpback whales by Project-related LNG carriers from existing levels, this localized increase is not thought to be significant since the recognized biologically important area (Point St. George) is not within the marine analysis area.

Underwater Noise

Humpback whales are well known for their vocalizations, particularly in breeding habitats. Male humpback whales sing long, complex songs that function to attract females and may play roles in establishing dominance hierarchies or cooperative behavior among males (Clapham 2009). Studies have found that low frequency sounds, whether generated by sonar or ships, cause singing humpback whales to lengthen their singing, perhaps as compensation for the acoustic interference (Miller et al. 2000). Characteristics of humpback whale songs (duration, tempo or pace, frequency structure) indicated masking of songs by noise from large boats (Norris 1995).

Determining and minimizing any detrimental effects of anthropogenic underwater noise on humpback whales is a principal objective for the species' recovery (NMFS 1991). The potential effects of underwater noise on humpback whales are the same as described for blue whales.

Based on the same evaluation as presented in the blue whale discussion, there could be 0.07 – 0.11 humpback whales/km within the area of sound attenuation to 120 dB during the time of year that these whales are present off the coast of Oregon. Based on the above data, and since humpback whales are present in densities of between 0.07 and 0.11 humpback whales per km within the area of sound attenuation to 120 dB, there could be between 504 and 792 humpback whales potentially occurring within the 120 dB attenuation area over the life of the Project. Again, as similar to the analysis for blue whales, as many as between 186 and 293 humpback whales could occur within the 120 dB attenuation area for tractor tugs over the life of the Project.

Some humpback whales may be exposed to sound levels produced by the Project related vessels that could cause behavioral disturbance. However, the potential numbers that could be affected are a small fraction compared to the estimated population sizes of the California/Oregon/ Washington stock of humpback whales.

Fuel Spills

The potential effects of fuel spills to humpback whales, as well as the laws and regulations regarding environmental protection are the same as described as for blue whales (see section 3.2.1.3). As a result, effects to humpback whales from accidental spills or release of fuel or lubricants at sea are expected to be insignificant and discountable.

Cumulative Effects

The definition of cumulative effects to humpback whales is as described as for blue whales (see section 3.2.1.3). The foreseeable cumulative effect of the additional 120 LNG carriers per year with regard to vessel traffic noise, risk of vessel strike or accidental release is expected to be low. Consequently, cumulative effects to humpback whales would be the same as the estimate of direct effects discussed in the previous sections. Those effects were judged to be discountable.

Critical Habitat

The proposed action would not affect critical habitat because none has been designated.

3.2.4.4 Conservation Measures

The same Conservation Measures described to minimize potential effects to blue that was described in section 3.2.1.4 applies to humpback whales.

3.2.4.5 Determination of Effects

Species

The Project **may affect** humpback whales because:

- humpback whales may occur within the marine analysis area during operation of the proposed action; and
- the proposed action would increase shipping traffic (LNG carriers) within the marine analysis area.

However, the Project is **not likely to adversely affect** humpback whales because:

- existing information indicates ship strikes to humpback whales within the marine analysis area are discountable;
- the risk of ship strike due to the increase in vessel traffic is considered to be discountable due to the relatively small area used by the vessels for transit;
- the seasonal use of the area by humpback whales and that the recognized biologically important area is outside of the marine analysis area;

- JCEP would provide a ship strike avoidance measures package to shippers calling on the LNG Terminal that consists of multiple measures to avoid striking marine mammals;
- LNG carriers approaching the entrance of Coos Bay would be traveling slowly and escorted by tractor tugs from 5 nmi offshore to the LNG Terminal; and
- LNG carrier noise would contribute to overall noise within the marine analysis area while transiting to and from the LNG Terminal and effects of ship noise on humpback whales could exceed NMFS interim noise exposure criteria for Level B single non-pulse noise, but are not expected to cause injury, and the exposure is expected to be to a discountable percentage of the population.

Critical Habitat

No critical habitat has been designated or proposed for humpback whales.

3.2.5 Sei Whale

3.2.5.1 Species Account and Critical Habitat

Status

Sei whales were listed as endangered under the ESCA on December 2, 1970 (FWS 1970) and have been listed as endangered throughout its range under the ESA since its implementation in 1973. Sei whales off the U.S. West Coast are in the Eastern North Pacific stock and are classified under the MMPA as depleted and strategic.

Threats

Commercial whaling was the cause of the sei whale population decline. This cause is no longer a threat in the eastern North Pacific Ocean; however as with other whale species, vessel strike, interactions with fisheries gear, and anthropogenic noise are contemporary threats (Carretta et al. 2014b, Carretta et al. 2007, NMFS 2011c). In addition, the effect of climate change on the eastern North Pacific ecosystem may be a threat factor for sei whales, but the magnitude of the threat is currently not quantifiable.

Species Recovery

A draft plan for recovery of the sei whale (and fin whale) was issued in 1998 (NMFS 1998a) and the plan was finalized in 2011 (NMFS 2011c). The goal of the recovery plan is to promote recovery of the species in order to eventually down list and ultimately delist this species. The two main objectives for sei whales are to 1) achieve sufficient and viable populations in all ocean basins, and 2) ensure significant threats are addressed (NMFS 2011c). The recovery plan lists the following tasks as those necessary to achieve the goal:

- Coordinate state, federal, and international actions to maintain international regulation of whaling for sei whales.
- Develop and apply methods to collect sei whale data.
- Support existing studies to investigate population discreteness and population structure of sei whales using genetic analyses.
- Continue to collect data on “unknown” threats to sei whales.
- Maximize effort to acquire scientific information from dead, stranded, and entangled sei whales.

- Estimate population size and monitor trends in abundance.
- Initiate new studies to determine population discreteness and population structure of sei whales.
- Conduct risk analyses.
- Identify, characterize, protect, and monitor habitat important to sei whale populations in U.S. waters and elsewhere.
- Investigate human-caused threats, and, should they be determined to be medium or high, reduce frequency and severity.
- Develop a post-delisting monitoring plan (NMFS 2011c).

Life History, Habitat Requirements, and Distribution

The sei whale is a large baleen whale found in both the northern and southern hemispheres. They feed in temperate waters on zooplankton (especially copepods and euphausiids), small schooling fish, and squid (Shirihai and Jarrett 2006). Calving occurs in midwinter, in low latitude portions of the species' range (OBIS-SEAMAP 2007). Sei whales are generally found alone or in pairs, although sometimes they may be found in groups of up to five. They generally dive between 5 and 20 minutes relatively close to the surface (Shirihai and Jarrett 2006). They are known for moving away from boats, and being one of the fastest swimming large whales, capable of speeds up to 26 knots (Laist et al. 2001).

Females reach reproductive age when 10 years old. Once mature, females give birth every 2 to 3 years to one calf. The gestation time is between 11 and 13 months, and calves are weaned between 6 and 9 months. It is expected that sei whales live up to 70 years (Shirihai and Jarrett 2006).

Population Status

Sei whales are encountered less frequently than other baleen whales that were depleted by commercial whaling. The best estimate of abundance for California, Oregon and Washington waters combined is 519 (CV=0.40), with a minimum population estimate of 374 whales (Carretta et al. 2017a). There are no data to estimate the current population trend for sei whales (Carretta et al. 2014a). The PBR for sei whales is 0.17 (Carretta et al. 2017a).

Critical Habitat

As of October 2017, critical habitat for this species has not been designated in U.S. waters.

3.2.5.2 Environmental Baseline

Analysis Area

The analysis area applicable to sei whales is the same as described for blue whales (see section 3.2.1.2).

Species Presence

Sei whales are an offshore species and generally do not occupy coastal habitats. Nine confirmed sightings of sei whales were made in California, Oregon, and Washington waters during extensive ship and aerial surveys between 1991 and 2008 (Carretta et al. 2017a). Two of the reported sightings were off the coast of Oregon (Carretta et al. 2007), but were westward of the continental shelf break. As there were only two sightings in pelagic waters westward of the continental slope of Oregon, it is unlikely this species would be encountered.

Habitat

Sei whales tend to use temperate waters, and do not associate with specific coastal features (Carretta et al. 2007) and are uncommonly associated with waters of continental shelves (Horwood 2009). Consequently, they are seldom observed.

Critical Habitat

Critical habitat for this species has not been designated.

3.2.5.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, effects from anthropogenic underwater noise, and potential adverse effects from fuel spills at sea. Spills could indirectly affect sei whales by impacting prey species. These effects are addressed below.

<u>Ship Strikes</u>

As with all large whale species, the risk of ship strike is a risk factor for sei whales. Sei whales are struck by ships less often than most other whales (Jensen and Silber 2003). Ship strikes of sei whales averaged 0.2 deaths per year along the Pacific Coast between 2000 and 2004 (Carretta et al. 2007), which exceeded the PBR (Carretta et al. 2007), but that rate has not been documented since then. In this time, only a single sei whale was documented struck and killed off Washington in 2003 (Douglas et al. 2008). For the period of 2004 to 2008, the average observed annual mortality due to ship strike was zero (Carretta et al. 2014b). The current PBR for sei whales from California to Washington is 0.17 whales per year.

<u>Estimated Ship Strike Risk to Sei Whales</u>

Currently data on this species are insufficient to estimate a project specific ship strike risk. However, qualitatively the risk of vessel strike within the marine analysis area is considered to be extremely low as a result of the rarity of the species, the low rate of population increase, and habitat preference for waters further from shore.

<u>Underwater Noise</u>

Determining and minimizing any detrimental effects of anthropogenic underwater noise on sei whales is a principal objective for the species' recovery (NMFS 2011c). The potential effects of underwater noise on sei whales is the same as described for blue whales (see section 3.2.1.3).

Currently data on this species are insufficient to estimate a Project specific vessel noise exposure level. However, qualitatively the risk of that behavioral disturbance would occur is considered to be extremely low as a result of the rarity of the species, the low rate of population increase, and habitat preference for waters further from shore.

<u>Fuel Spills</u>

The potential effects of fuel spills on sei whales, as well as the Federal Requirements regarding environmental protection are the same as described as for blue whales (see section 3.2.1.3). As a result of the federal environmental protections, the low probability of occurrence in the marine analysis area, and the overall rarity of this species, effects to sei whales from accidental spills or release of fuel or lubricants at sea are expected to be insignificant and discountable.

Cumulative Effects

The definition of cumulative effects to sei whales is as described as for blue whales (see section 3.2.1.3). The foreseeable cumulative effect of the additional 120 LNG carriers per year with regard to vessel traffic noise, risk of vessel strike or accidental release is expected to be low. Consequently, cumulative effects to sei whales would be the same as the estimate of direct effects discussed in the previous sections. Those effects were judged to be discountable, particularly in light of the rarity of the species.

Critical Habitat

The proposed action would not affect critical habitat because none has been designated.

3.2.5.4 Conservation Measures

The same Conservation Measures described to minimize potential effects to blue whales by LNG carriers that was described in section 3.2.1.4 applies to sei whales.

3.2.5.5 Determination of Effects

Species

The Project is **not likely to adversely affect** sei whales because:

- likelihood of encountering sei whales in the marine analysis area is discountable;
- all conservation measures for other species would also apply to sei whales, if a chance encounter occurred with this species.
-

Critical Habitat

No critical habitat has been designated or proposed for sei whales.

3.2.6 Sperm Whale

3.2.6.1 Species Account and Critical Habitat

Status

Sperm whales were listed as endangered under the ESCA on December 2, 1970 (FWS 1970) and have been listed as endangered throughout their range under the ESA since its implementation in 1973. For the MMPA stock assessment reports, sperm whales within the Pacific United States are divided into three discrete, non-contiguous areas: 1) California, Oregon, and Washington waters; 2) waters around Hawaii; and 3) Alaskan waters. The latter two will not be specifically discussed. Sperm whales are classified as depleted and strategic under the MMPA.

Threats

Commercial whaling was the cause of population reduction and for the endangered status (NMFS 2012c). This threat no longer exists in the eastern North Pacific Ocean. Contemporary threats include fisheries gear entanglement, ingestion of plastic debris, collisions with vessels, contaminants and pollutants, and possibly increasing levels of anthropogenic ocean noise (NMFS

2014c, NMFS 2010b, Carretta et al. 2007). As discussed previously for other large whale species, the effect of climate change on sperm whales is uncertain, but there may be effects that impact habitat selection, prey availability, breeding behaviors, and migration patterns (NMFS 2010a, NMFS 2010b).

Most populations were depleted by modern whaling, and commercial whaling ended in 1988 with a moratorium issued by the International Whaling Commission (NMFS 2010b). However, Japan continues to take a small number of sperm whales each year (NMFS 2010b). The only commercial fishery that is considered to likely incidentally take sperm whales is the offshore drift gill-net fishery. From 2000 to 2004, the California and Oregon thresher shark and swordfish drift gill-net fishery accounted for no deaths, but an unspecified fishery was reported to have caused one death (Carretta et al. 2007). A total of 18 sperm whales were stranded in Washington and Oregon from 1930 to 2002, with seven in Oregon and 11 in Washington (Norman et al. 2004).

Species Recovery

A draft recovery plan was released in June 2006 (NMFS 2006b) and a five-year status review was initiated on January 22, 2007 (NMFS 2007a). The recovery plan was finalized in 2010 (NMFS 2010b). The goal of the recovery plan is to eventually down list and then delist the species. To that end, the final recovery plan lists the following recovery measures:

- Coordinate state, federal, and international actions to implement recovery actions and maintain international regulation of whaling for sperm whales.
- Develop and apply methods to estimate population size and monitor trends in abundance.
- Determine population discreteness and population structure of sperm whales.
- Conduct risk analyses.
- Identify and protect habitat essential to the survival and recovery of sperm whale populations in U.S. waters and elsewhere.
- Investigate causes and reduce the frequency and severity of human-caused injury and mortality.
- Determine and minimize any detrimental effects of anthropogenic noise in the oceans.
- Maximize efforts to acquire scientific information from dead, stranded, and entangled or entrapped sperm whales.
- Develop post-delisting monitoring plan.

Life History, Habitat Requirements, and Distribution

Sperm whales are the largest of the toothed whales and exhibit sexual dimorphism, with males larger than females. They are a deep water species, and prey upon deep water squid, sharks, skates, and fishes. They are deep divers, with the average dive depth greater than 400 meters (1,300 feet) that can last longer than 2 hours (NMFS 2007a). Cows, calves and juveniles can be found in groups ranging from 10 to 50 animals, with bachelor groups of males occurring separately (Shirihai and Jarrett 2006).

The breeding season can be extended - lasting from December to August, but the peak breeding season occurs from March/April to May. Length of the gestation period is not exactly known, but likely ranges from 15 to 18 months (NMFS 2010b). Most sperm whales fully sexually mature in their twenties, although females begin ovulation between the ages of seven and thirteen. Females give birth every 4 to 6 years once sexually mature, with senescence occurring sometime after the age of 40. Sperm whales have a low reproductive rate, with a maximum of no more than two percent per year. Compounding the effects of this slow rate of increase, is that larger and older mature males were targeted by commercial whalers, and this has been a primary reason for the reduction of reproductive rates, meaning that both large and older males and females are needed to increase the rate of reproduction (NMFS 2010b).

Longevity exceeds 60 years for sperm whales. Known natural reasons for mortality include predation, competition, and disease. Calves are susceptible to predation by killer whales and sharks. Diseases that are believed to have an impact on sperm whales include myocardial infarction, gastric ulceration, and a type of cumulative bone necrosis that is believed to be caused by deep dives and resulting nitrogen bubbles during ascents (NMFS 2010b).

Population Status

The best estimate of sperm whale abundance in the California Current is 2,106 animals (CV=0.58), with a minimum population estimate of 1,332 (Carretta et al. 2017a). The current population trend is not clear, but the PBR is estimated at 2.7 animals/year (Carretta et al. 2014a).

3.2.6.2 Environmental Baseline

Analysis Area

The analysis area applicable to sperm whales is as described for blue whales (see section 3.2.1.2).

Species Presence

Sperm whales are widely distributed across the entire North Pacific and into the southern Bering Sea in summer, but the majority are thought to be south of latitude 40º N in winter (Carretta et al. 2007). Sperm whales have been reported off Oregon between March and September (Mate 1981), and Green et al (1992) documented sperm whales during the summer and fall.

Habitat

Sperm whales are considered to be almost cosmopolitan, preferring areas along the continental slope where water is as deep as 1,000 to 3,000 meters (3,280 to 9,843 feet) (Shirihai and Jarrett 2006). This deep water species can utilize the entire water column, but has shown a preference for foraging on or near the bottom (NMFS 2010b).

Critical Habitat

As of October 2017, critical habitat for this species has not been designated in U.S. waters.

3.2.6.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, effects due to anthropogenic underwater noise, and potential adverse effects from fuel spills. Spills could indirectly affect sperm whales by impacting forage species. These effects are addressed below.

<u>Ship Strike</u>

Ship strikes with sperm whales are infrequent in coastal U.S. waters, compared with other large whale species. From the available literature, one sperm whale was struck by a ship off the U.S.

West Coast in 1965 (Jensen and Silber 2003) resulting in injury but not mortality, another single animal was reported injured by an apparent ship strike (propeller injury) off the Oregon coast and another was reported as a possible ship-strike in Washington State between 1980 and 2006 (Douglas et al. 2008). More recently (2007-2011), two sperm whales were reported struck, with one of these from the waters offshore of Lane County, Oregon – the other was in the offshore waters of Washington (Carretta et al. 2013). The data from Carretta et al. (2013) yield an average yearly rate of 0.40 strikes per year for the U.S. Pacific west coast, although no ship strikes were reported for the five-year period between 2008 and 2012 (Carretta et al. 2014b).

Ship Strike Risk Estimation. The ship strike risk to sperm whales could not quantitatively addressed because habitat based density estimates were not available for the marine analysis area. Qualitatively, the risk of ship strike to sperm whales in the marine analysis area is considered to be very low based on the spatial separation of the analysis area and preferred habitats of this species. Ship strike to sperm whales in the Oregon continental shelf analysis area is possible as animals do occasionally move outside of preferred habitats, but death or injury of sperm whales by ship strikes in the marine analysis area is considered unlikely.

Underwater Noise

Determining and minimizing any detrimental effects of anthropogenic underwater noise on sperm whales is a principal objective for the species' recovery (NMFS 2010b). The potential effects of underwater noise on sperm whales is the same as described for blue whales (see section 3.2.1.3).

Reduced calling or cessation of vocalizations by sperm whales have been documented in response to pingers and military sonar signals, in response to low-frequency "Acoustic Thermometry of Ocean Climate"–like sounds, and in response to seismic surveys (Weilgart 2007). However, sperm whales and other cetaceans have been documented remaining in or returning to high noise environments, probably motivated by food and/or availability of mates (Weilgart 2007). In those situations, an individual's hearing could be damaged. For example, two sperm whales killed by collision with a ferry in waters off the Canary Islands never responded behaviorally to low frequency sounds that were generated as a test to warn and repel sperm whales from the ferry routes. Histological analyses of the inner ears of both animals showed nerve degeneration and fibrous growth in response to low frequency inner ear damage, consistent with prolonged exposure to noise from heavy maritime traffic (André and Degollada 2003). It is also possible that the whales did hear the warning signal, but did not correlate the warning signal with the approach of the ferry.

The exposure to Project related sound levels that could cause disturbance to sperm whales could not quantitatively addressed because habitat based density estimates were not available for the marine analysis area. However, qualitatively effects of Project related noise on sperm whales are possible in the marine analysis area, but increased noise levels are not expected to influence or affect sperm whales due to their general absence from the nearshore waters over the continental shelf.

Fuel Spills

The potential effects of fuel spills on sperm whales, as well as the laws and regulations regarding environmental protection are the same as described as for blue whales (see section 3.2.1.3). As a result of these regulatory requirements, and the low probability of occurrence in the marine analysis area, effects to sperm whales from fuel spills are expected to be insignificant and discountable.

Cumulative Effects

The definition of cumulative effects to sperm whales is as described as for blue whales (see section 3.2.1.3). The foreseeable cumulative effect of the additional 120 LNG carriers per year with regard to vessel traffic noise, risk of vessel strike or accidental release is expected to be low. Consequently, cumulative effects to sperm whales would be the same as the estimate of direct effects discussed in the previous sections. Those effects were judged to be discountable, particularly in light of the low probability of occurrence in the marine analysis area.

Critical Habitat

The proposed action would not affect critical habitat because none has been designated.

3.2.6.4 Conservation Measures

The same Conservation Measures described to minimize potential effects to blue whales that was described in section 3.2.1.4 applies to sperm whales.

3.2.6.5 Determination of Effects

Species

The Project is **not likely to adversely affect** sperm whales because:

- sperm whales generally do not inhabit the continental shelf waters off Oregon;
- JCEP would provide a ship strike avoidance measures package to shippers calling on the LNG terminal. The package consists of multiple measures to avoid striking marine mammals;
- LNG carriers approaching the Coos Bay entrance would be traveling slowly and escorted by tractor tugs from 5 nmi offshore to the Port;
- LNG carrier noise would contribute to overall noise within the marine analysis area while transiting to and from the LNG Terminal but effects of ship noise on sperm whales are not expected due to the low probability of occurrence in the marine analysis area; and
- all conservation measures for other species would also apply to sperm whales, if a chance encounter occurred with this species.

Critical Habitat

No critical habitat has been designated or proposed for sperm whales.

3.2.7 North Pacific Right Whale

3.2.7.1 Species Account and Critical Habitat

Status

North Pacific right whales were listed as endangered under the ESCA (35 Federal Register 18319, Dec. 2, 1970) (FWS 1970) and remained classified as endangered when the ESA was passed in 1973 (NMFS 2013d). Consequently, the North Pacific right whale is listed as depleted and strategic under the MMPA. Sightings of this species are extremely rare due to commercial whaling that continued through the 1960s (NMFS 2013d).

The North Pacific population has been further divided into a western and an eastern population, with the eastern population primarily located in the U.S. EEZ (NMFS 2013d). The eastern North Pacific right whale population is the most endangered stock of large whales in the world for which abundance estimates are available (NMFS 2015b). The western population is located primarily in the EEZ of the Russian Federation, Japan and China (NMFS 2013d). This population will not be further discussed.

Threats

Commercial whaling decimated this population, which continued illegally into the 1960's. There are a variety of potential threats to eastern North Pacific right whale population, that are similar to other large baleen whales and includes vessel interactions (strikes and disturbance), anthropogenic noise, contaminants, interactions with marine debris and fishery gear entanglements (NMFS 2013d). However, the magnitude of these threats cannot be assessed due to the species rarity and scattered distribution (NMFS 2013e). Impacts from direct hunts as well as changes in prey species resulting from climate change are also unknown (NMFS 2013d). One of the greatest threats to this populations' survival is its very small population size, estimated at about 30 individuals (NMFS 2013d).

Species Recovery

A recovery plan for the North Pacific right whale was published in June 2013 (NMFS 2013d). The primary goal of this recovery plan is data collection to facilitate improved population size estimation, monitoring trends in abundance, and determining the population structure (NMFS 2013d). The goals of the recovery plan are to first down list the right whale from endangered to threatened and then eventually delist the species all together. These goals are attained through two objectives:

1. Achieve sufficient and viable populations throughout the ocean basin; and
2. Ensure threats are addressed.

The recovery plan describes the criterion for determining when the objectives are met, which includes descriptions of factors that may interfere with population growth. The outline for Recovery Action includes the following:

- Coordinate state, federal, and international actions to maintain international regulation of whaling for North Pacific right whales,
- Determine right whale occurrence, distribution, and range,
- Identify, characterize, protect, and monitor habitat important to North Pacific right whale populations;
- Estimate population size and monitor trends in abundance; and
- Investigate human-caused threats, and should they be determined to be medium or high, reduce frequency and severity.

Life History, Habitat Requirements, and Distribution

North Pacific right whales are large, black baleen whales with a stocky body, and are distinguishable by their lack of dorsal fin. Further distinguishing characteristics include a broad, deeply notched tail and callosities on the head. The few data gathered indicate that right whales generally live for about 50 years with females having their first calf at 9-10 years. Right whales feed on zooplankton; however, their feeding method differs than that of most baleen whales. This species moves through the water open-mouthed and removes prey from patches of zooplankton, a method known as skimming (NMFS 2013d).

The International Whaling Commission has identified four different habitat categories for the right whale that includes: feeding, calving, nursery, and breeding. Breeding and nursery habitats are not known, but are thought to be in shallow coastal waters. Calving occurs in the winter in lower latitudes, while foraging occurs in the spring and summer in higher latitudes (NMFS 2013d).

Historic populations of eastern North Pacific right whales occupied waters ranging from the Gulf of Alaska to Baja, Mexico. Recent sightings of eastern North Pacific right whales have occurred in Bristol Bay, the southern Bering Sea, near Hawaii and off California.

Population Status

The rarity of sightings and few individuals seen in any one year indicate the eastern North Pacific population is very small. The minimum population estimate for eastern North right whales is 26 individuals (Muto et al 2017). There are no data on population trends and calf sightings are extremely rare. The PBR for this species is 0.05 whales, or 1 whale every 20 years, however this is considered unreliable as the population is far below the historic population which exceeded 11,000 whales (NMFS 2015b).

Critical Habitat

Two areas have been designated as critical habitat for the North Pacific right whale. One area is within the Gulf of Alaska and the other area is within the Bering Sea (NMFS 2013d) - neither area is in or near the Oregon coast.

3.2.7.2 Environmental Baseline

Analysis Area

The analysis area applicable to North Pacific right whales is the continental shelf as described for blue whales (see section 3.2.1.2).

Species Presence

Since 1950, there have been at least four sightings of North Pacific right whales off Washington, but none off Oregon (NMFS 2013d). No abundance or density estimates are available for Oregon (Forney 2007).

Habitat

Based on habitat preferences during calving in the Atlantic Ocean, the Southern California Coast and Baja Peninsula were judged to provide suitable calving habitat for North Pacific right whales (Good and Johnston 2009) but no evidence of calving is present in historical records (Gendron et al. 1999).

The distribution of eastern North Pacific right whales includes the U.S. West Coast extending south to Baja California (NMFS 2013e). North Pacific right whales have been sighted off the California coast and coastal Baja California during winter (January to early April) and spring (April to June) and may indicate a seasonal pattern of migration to southwestern coast during winter (Gendron et al. 1999). There are so few North Pacific right whales left, that it is difficult to determine what constitutes their preferred habitat, but it is unlikely that the continental shelf waters of Oregon are key habitats based on the complete lack of sightings and acoustic recordings.

Critical Habitat

Two areas have been designated as critical habitat for the North Pacific right whale, one within the Gulf of Alaska, the other within the Bering Sea (NMFS 2013d). Neither are in or near the analysis area for the Project.

3.2.7.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, effects due to ship noise, and potential adverse effects from fuel spills. Spills could indirectly affect North Pacific right whale by impacting forage species. These effects are addressed below.

Ship Strike

As with all large whales, ship strike is a concern for North Pacific right whales (NMFS 2013d). However, due to the lack of habitat use data, it was not possible to quantify the Project related ship strike risk to eastern North Pacific right whales. However, qualitatively, the risk of vessel strike within the marine analysis area is considered to be extremely low due to the rarity of the species, the low rate of population increase and the lack of sightings from this part of the range.

Underwater Noise

Determining and minimizing any detrimental effects of anthropogenic underwater noise on eastern North Pacific right whales is a principal objective for the species' recovery (NMFS 2013d). Existing data indicates that this species' response to noise disturbance and vessel activities depends on their behavior at the time; feeding or courting right whales may be relatively unresponsive to loud sounds and slow to react to approaching vessels (NMFS 2013d). However, due to the extremely low population size, lack of data on use of the continental shelf of Oregon, and very low probability of occurrence, the noise associated with the LNG carriers or the assisting tug boats is unlikely to influence or affect North Pacific right whales.

Fuel Spills

The potential effects of fuel spills on North Pacific right whales, as well as the Federal Requirements regarding environmental protection are the same as described as for blue whales (see section 3.2.1.3). NMFS (2013d) lists the relative impact to recovery of North Pacific right whales from contaminants and pollution, including oil spills, as unknown due to lack of data from past spills and unknown likelihood of future spills occurring and eastern North Pacific right whales being exposed to the spilled oil. As a result of this and the extreme rarity of the species, effects to North Pacific right whales from fuel spills are expected to be insignificant and discountable.

Cumulative Effects

The definition of cumulative effects to eastern North Pacific right whales is as described as for blue whales (see section 3.2.1.3). The cumulative effects of the Project to this species is determined to be insignificant and discountable in the marine analysis area as a result of the species rarity and the extremely low probability that this species occurs in this region.

Critical Habitat

The proposed action would not affect critical habitat as none has been designated in or near Oregon.

3.2.7.4 Conservation Measures

The same Conservation Measures described to minimize potential effects to blue whales that was described in section 3.2.1.4 applies to North Pacific right whales, in the rare event that they were encountered by Project related vessels.

3.2.7.5 Determination of Effects

Species

The Project is **not likely to adversely affect** right whales because:

- there is no existing information to indicate that ship strikes to right whales occur within the marine analysis area; and

likelihood of encountering North Pacific right whales within the marine analysis area is discountable, but if they were encountered, the conservation measures would equally apply to this species.Critical Habitat

The Project would have **no effect** on critical habitat for the North Pacific right whale because:

- no critical habitat has been designated in or near Oregon.

3.2.8 Gray Whale (Western North Pacific Stock)

3.2.8.1 Species Account and Critical Habitat

Status

In 1970, the gray whale was listed as endangered under the ESCA (FWS 1970), and in 1973 was listed as endangered throughout its range under the ESA. There are two geographic distributions of a single species of gray whale in the North Pacific Ocean: 1) the eastern North Pacific population, and 2) the western North Pacific stock (Carretta et al. 2016a). The eastern population is found along the west coast of North America from Baja California, Mexico to the Bering, Beaufort, and Chukchi Seas, while the western stock is found in eastern Asia and Russia. In 1994, the eastern population was removed from the ESA list due to numerical recovery (NMFS 1994), but the western Pacific stock maintained its ESA endangered status (NMFS 1994; Carretta et al. 2016a). The western Pacific gray whale stock is classified as depleted under the MMPA (Carretta et al. 2016a). The eastern Pacific population will not be further discussed, unless relevant to the western North Pacific gray whale stock.

Threats

Commercial whaling decimated the western North Pacific gray whale stock, and it was considered extinct until small group of animals was discovered in the 1990s (Marine Mammal Commission 2017). Though commercial whaling is no longer a threat (Swartz et al. 2006), a variety of anthropogenic threats threaten this small stock including: entrapment and entanglement in fishing gear, vessel collision, local catastrophic events such as oil spills, illegal and/or resumed legal whaling, acoustic disturbance, physical disturbance and contamination of prey populations, and habitat degradation (Weller et al. 2002, Brownell et al. 2010). Activities related to oil and gas exploration, such as geophysical seismic surveying, pipe-laying and drilling operations, increased vessel traffic, and oil spills interest near the primary feeding ground near Sakahlin Island, Sea of Okhotsk, are of primary concern to the recovery of the western North Pacific stock (Reeves et al. 2005).

In addition, natural threats also exist. These include predation, disease, entrapment in ice, starvation, and the small stock size. This latter point is compounded by the low numbers of reproductively active females which could limit recovery (Reeves et al. 2005).

Species Recovery

No recovery plan exists for the western North Pacific gray whale.

Life History, Habitat Requirements, and Distribution

Gray whales are a medium size migratory baleen whale that primarily inhabits the shallow coastal waters along the margins of the North Pacific Ocean. As the name implies, these animals have a gray colouration that can be mottled with white patches, scars and external parasites. Gray whales generally feed in northern areas in the summer and early autumn, then migrate south for the winter to the breeding and calving grounds (Swartz et al. 2006).

During the summer, the western North Pacific gray whale stock occupies feeding areas in the Sea of Okhotsk, and the Bering Sea off the southeastern Kamchatka Peninsula, Russia (Carretta et al. 2016a; Weller et al. 2012; Reeves et al. 2005). The main feeding habitat is the shallow (5-15 m depth) shelf of northeastern Sakhalin Island, particularly off the southern portion of Piltun Lagoon, where the main prey species appear to be amphipods and isopods (Weller et al. 1999). Offshore feeding grounds in 30-35m depth southeast of Chayvo Bay, are also sometimes used, where benthic amphipods and cumaceans are the main prey species (Fadeev 2003). Other habitats include the waters off western Kamchatka (Reeves et al. 2005), and in Severnaya Bay on the north coast of Sakhalin (IUCN 2006).

The migration route and wintering reproductive areas are poorly known, but may include the eastern shore of Sakhalin Island, Japanese coasts, and the Chinese coast from the northern Yellow Sea to the Hainan Strait in the south (references in Weller et al. 2012). No sightings off South Korea have been reported since 1968 (Reilly et al 2008). Most recent Japanese observations are on the Pacific side, suggesting this is now the more important migration route (Reilly et al 2008). The calving grounds are unknown but may be around Hainan Island, this being the southwestern end of the known range (Brownell and Chun 1977).

Migratory gray whales travel alone or in small, unstable groups up to 16 individuals, but in northern feeding grounds gray whales are often solitary (Leatherwood et al. 1982; NOAA 2016). Recent information from telemetry studies, photo-identification, and genetic studies have documented western North Pacific gray whales occurring in the range of the eastern North Pacific gray whale population (Weller et al. 2012). It is not known if this is a distributional anomaly, a recent occurrence or has been occurring, but undocumented for longer periods of time.

Observations outside the putative usual range for the western North Pacific gray whale have occurred during the winter migratory period (Weller et al. 2012; Carretta et al. 2016a). Up to 27 individual western North Pacific gray whales have been identified in the range of the eastern North Pacific gray whale (Mate et al. 2011, Weller et al. 2012, NOAA 2015a). Western gray whales that have migrated to eastern Pacific have been observed in small groups and/or in close proximity to conspecifics (Weller et al. 2012). It is thought that perhaps not all western North Pacific gray whales share a common wintering ground (Weller et al. 2013).

Population Status

Both stocks of gray whales were greatly reduced from commercial whaling in the 18th and 19th centuries. The eastern gray whale has returned to pre-exploitation population numbers (eastern gray whale population consists of approximately 20,990 individuals; Caretta et al. 2016a; Weller 2010). Abundance of western gray whales prior to commercial hunting has been estimated to be between 1,500 and 10,000 individuals (Yablokov and Bogoslovskaya 1984 in Reeves et al. 2005), but by the 1930s the population was considered extinct or was so low in abundance that whales were not observed (Weller et al. 2002). A small number are now known to exist.

A recent population assessment of the western gray whale estimates that there are approximately 140 individuals (excluding calves), including an estimated 36 reproductive females (Caretta et al. 2016a; Cooke et al. 2013); total population estimate including calves was approximately 155 in 2012 (IUCN 2012). An increase in the western gray whale population was observed from 2002 to 2012; the estimated average annual rate of population increase during this period was 3.3 percent (Cooke et al. 2013). Although population growth has been observed for the western gray whale, the population is relatively small so that additional deaths, particularly females, could jeopardize the recovery of the population (Reeves et al. 2005). The overall potential biological removal for gray whales in the western population is 1 whale per every 17 years (Carretta et al. 2016a).

Details of the life history of the western North Pacific stock are not well known. However, calf production has been monitored annually since 1995 through photo-identification surveys off Sakhalin Island, and the numbers are very small ranging from 2 calves in 1995 to 15 calves in 2011 (Burdin et al. 2012; Mate et al. 2011).

Migratory gray whales travel alone or in small, unstable groups up to 16 individuals, but in northern feeding grounds gray whales are often solitary (Leatherwood et al. 1982; NOAA 2016). Recent information from telemetry studies, photo-identification, and genetic studies have documented western North Pacific gray whales occurring in the range of the eastern North Pacific gray whale population (Weller et al. 2012). It is not known if this is a distributional anomaly, a recent occurrence or has been occurring, but undocumented for longer periods of time.

Observations outside the putative usual range for the western North Pacific gray whale have occurred during the winter migratory period (Weller et al. 2012; Carretta et al. 2016a). Up to 27 individual western North Pacific gray whales have been identified in the range of the eastern North Pacific gray whale (Mate et al. 2011, Weller et al. 2012, NOAA 2015a). Western gray whales that have migrated to eastern Pacific have been observed in small groups and/or in close proximity to conspecifics (Weller et al. 2012). It is thought that perhaps not all western North Pacific gray whales share a common wintering ground (Weller et al. 2013).

Critical Habitat

Critical habitat for this species has not been designated.

3.2.8.2 Environmental Baseline

Analysis Area

The analysis area applicable to western gray whales is the marine analysis area as previously described for blue whales (see section 3.2.1.2).

Species Presence

The degree to which western gray whales occur in Oregon waters is uncertain, however a few records do exist from the known spatial and temporal overlap with the eastern gray whale population (Weller et al. 2012). These records include six western North Pacific gray whales off Vancouver Island, two off California, 13 whales in San Ignacio Lagoon, Mexico, and three migrating from Russia to the west coast of North America (Weller et al. 2012; Lang et al. 2011; Urban et al. 2013; Mate et al. 2015). One whale, named "Flex" was confirmed within 11 nmi (20 km) of the central Oregon coast (Mate et al. 2011).

Therefore, western North Pacific gray whales may occasionally occur in the marine analysis area, but the frequency of occurrence and duration of stay cannot be quantified. Qualitatively, if western gray whales did occur in the analysis area, it would most likely be related to the winter migration, with a very low probability of occurrence given the small size and rarity of this stock.

Habitat

Gray whales are a coastal species that occupy shallow continental shelf waters up to 152 meters (500 feet). They typically use the nearshore waters within about 20 miles of shore (Greene et al. 1995). Weller et al. (2012) also noted that western gray whales may spend an extended period of time feeding off the coast of the Pacific Northwest prior to setting out for the long-distance, open water crossing to summer feeding grounds off the coast of Russia.

Critical Habitat

Critical habitat for this species has not been designated.

3.2.8.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, effects due to ship noise, and potential adverse effects from fuel spills. Spills could indirectly affect western gray whales by impacting forage species. These effects are addressed below.

Ship Strikes

As with other baleen whales, ship strike is a concern for western North Pacific gray whales (Weller et al. 2002), and although no vessel strikes to western gray whales have been reported, Reeves et al. (2005) stated that at least one western gray whale off the northeastern coast of Sakhalin Island had scars that appeared to be caused by a vessel. However, due to the lack of habitat use data and frequency of occurrence in the marine analysis area, it was not possible to quantify the Project.

Qualitatively, the risk of vessel strike within the marine analysis area is considered to be extremely low due to the small population size, the low rate of population increase, that occurrence in Oregon waters currently appears infrequent, existing data indicate that movements to the eastern North

Pacific are temporally limited to the winter migratory period, and that this stock primarily inhabits the western North Pacific Ocean.

Underwater Noise

The effects of underwater noise on western North Pacific gray whales is difficult to characterize. Disturbance from underwater noise is a recognized potential threat in the foraging grounds of western North Pacific gray whales (Reilly et al. 2008), and it is known from eastern North Pacific gray whale research that underwater noise along the migratory corridor could result in altered routes (Brownell et al. 2010; Gailey et al. 2016). However, recent behavioral observations of western gray whales from 4-D seismic surveys off northeastern Sakhalin Island, Russia, found no significant change in whale movement in response to the loud seismic activity, but did observe variation in the orientation of gray whales in relation to vessel activity depending on whether the vessel was less than 15 km, or greater than 25 km distance away (Gailey et al. 2016). Threats from underwater noise within the migratory route of the western gray whale is considered a low conservation concern due to the many factors contributing to existing noise along the annual migratory corridor that gray whales have been subjected to including military training ranges, oil and gas exploration and development areas, and shipping lanes that converge at some of the world's busiest and largest port cities (Brownell et al. 2010).

Due to the small population size, the low rate of population increase, that occurrence in Oregon waters currently appears infrequent, existing data indicate that movements to the eastern North Pacific are temporally limited to the winter migratory period, and that this stock primarily inhabits the western North Pacific Ocean, the noise associated with LNG carriers of the assisting tug boats is unlikely to influence or affect the western North Pacific grey whales within the marine analysis area.

Fuel Spills

The potential effects of fuel spills on western North Pacific gray whales, as well as the laws and regulations regarding environmental protection are the same as described as for blue whales (see section 3.2.1.3). While chemical pollution in migratory corridors is a recognised threat (Weller et al. 2002), the marine analysis area is outside the putative migratory corridors for western North Pacific gray whales. As a result of this and the rarity of the members of this population in the eastern North Pacific, effects to the western North Pacific gray whales from fuel spills are expected to be insignificant and discountable.

Cumulative Effects

The definition of cumulative effects to western North Pacific gray whales is as described as for blue whales (see section 3.2.1.3). The cumulative effects of the Project to this stock is determined to be insignificant and discountable in the marine analysis area as a result of the rarity and the extremely low probability that individuals from the western North Pacific occur in this region.

Critical Habitat

The proposed action would not affect critical habitat because none has been designated.

3.2.8.4 Conservation Measures

The same Conservation Measures described to minimize potential effects to blue whales that was described in section 3.2.1.4 applies to western North Pacific gray whales, in the rare event that they were encountered by Project related vessels.

3.2.8.5 Determination of Effects

Species

The Project is **not likely to adversely affect** gray whales from the western population because:

- western North Pacific gray whales generally do not inhabit the continental shelf waters of Oregon;
- the western North Pacific gray whale stock is very small, with a range that is well beyond the limits of the marine analysis area; and
- likelihood of encountering western North Pacific gray whales in the marine analysis area is discountable, but if they were encountered, the conservation measures would equally apply to this species.
-

Critical Habitat

No critical habitat has been designated or proposed for the western North Pacific stock of gray whales.

3.2.9 Gray Wolf

3.2.9.1 Species Account and Critical Habitat

Status

The gray wolf was listed as endangered in 1974 (FWS 1974). FWS delisted the gray wolf within the Northern Rocky Mountain (NRM) DPS on May 5, 2011. The NRM DPS includes wolves in Montana, Idaho, Wyoming, the eastern one-third of Washington and Oregon, and a small part of north-central Utah (FWS 2011a). However, some gray wolves in the Pacific Northwest, including western Washington, western Oregon, and northern California, are not included in the NRM DPS and are still listed as endangered. FWS still regards any wolf residing in the western two-thirds of Oregon as a listed species that is therefore protected under the ESA (ODFW 2017b).

New information on gray wolf taxonomy, cited by FWS (2013c), indicates that the gray wolf subspecies in the contiguous United States does not warrant listing under the ESA, and FWS (2013c) published a proposed rule to remove the gray wolf from the list of endangered and threatened wildlife. In 2015, FWS acted on a petition to reclassify the gray wolf as threatened throughout the conterminous United States. The FWS (2015) found that the petition did not warrant initiation of a status review and the gray wolf, except for the NRM DPS and nonessential experimental populations, remains listed as endangered.

Threats

Wolves in the Pacific Northwest (Oregon and Washington) were pursued and killed by humans through the 1940s and were primarily restricted to remote mountainous areas, primarily in National Forests of the Cascades, before they were completely extirpated from the region (FWS 2012a).

Mech and Boitani (2010) summarize the following as ongoing threats to the species: 1) competition with humans for livestock, especially in developed countries; 2) exaggerated concern by the public concerning the threat and danger of wolves; and 3) fragmentation of habitat, with resulting areas becoming too small for populations with long-term viability.

Species Recovery

FWS released a recovery plan for gray wolves in the NRM DPS in 1987. The plan focused on recovery in Montana, Wyoming, and Idaho. Although eastern Oregon and eastern Washington coincided with the historical distribution of wolves in the NRM DPS, no recovery areas were designated for either state. Recovery goals of the NRM DPS of equitably distributed wolf population containing at least 300 wolves and 30 breeding pairs in three recovery areas within Montana, Idaho, and Wyoming for at least three consecutive years were reached in 2002 (FWS et al. 2016). By 2012, the entire NRM DPS was delisted, and wolves were managed under State authority in those areas (FWS et al. 2016).

No recovery plan has been developed for ESA-listed gray wolves in western Oregon. Wolves are classified as endangered under the Oregon State ESA (ORS 496.171 to 496.192 and 498.026). ODFW (2017b) has developed a draft Wolf Conservation and Management Plan (Oregon Wolf Plan) to achieve recovery of the species and manage wolves in the state once they became de-listed from the ESA.

The Oregon Wolf Plan established recovery goals to protect wolves from overutilization for commercial, recreational, scientific, and educational purposes. The plan would serve as a deterrent to illegal killing of wolves by the public in the absence of federal protections. With the de-listing of the NRM DPS in 2011, the Oregon Wolf Plan applies to wolves in the eastern one-third of the state. The boundary between east and west wolf management zones is defined by U.S. Highway 97 from the Columbia River to the junction of U.S. Highway 20, southeast on U.S. Highway 20 to the junction with U.S. Highway 395, and south on U.S. Highway 395 to the California border (ODFW 2017b). Wolves west of that boundary are still under federal protection.

Life History, Habitat Requirements, and Distribution

Gray wolves are predators of large ungulates, including elk, mule deer, white-tailed deer, and moose, where available, and occasionally of other, smaller prey such as ground squirrels, snowshoe hare, and grouse (Larsen and Ripple 2006). Wolves are habitat generalists that only require ungulate prey and human-caused mortality rates that are not excessive (FWS 2013d). Habitats supporting wolves historically varied considerably, but extant populations in the NRM DPS and British Columbia utilize forest habitats adjacent to open habitats (meadows, prairies, tundra). Prey availability and minimal human presence and/or harassment are important components of suitable habitat (WDFW 2009). Wolves appear most vulnerable to human disturbance in and around denning and rendezvous sites (Larsen and Ripple 2006). Based on these characteristics, key components of wolf habitat that appear consistent across the diversity of landscapes inhabited by wolves include the following: 1) a sufficient year-round prey base of ungulates and alternate prey, 2) suitable and somewhat secluded denning and rendezvous sites, and 3) sufficient space with minimal exposure to humans (Larsen and Ripple 2006).

Wolves are highly social and their formation of packs, centered on male-female pair bonding, is essential to successful reproduction, survival of offspring, and successful hunting (FWS 1987). Most packs produce one litter per year ranging from one to nine pups. Wolf pairs (packs) establish home ranges/territories, centered on the den location, and are defended against other wolves (ODFW 2017a). Wolf pack territory size is a function of prey density, and can range from 25 to 1,500 square miles (FWS 2013d). Bunnell and Kremsater (1990) concluded that wolves need about 7,818 mi^2 (20,250 km^2) to maintain a viable population of 50 individuals. Herman and Willard (1978) summarized that gray wolves choose home territories with a variety of topographic features. Forests, open meadows, rocky ridges, and lakes or rivers all comprise a pack's territory. Both male and female wolves disperse, sometimes more than 600 miles (FWS 2013d).

Because of the proximity of northeastern Oregon to Idaho packs, dispersing wolves initially occupied areas in northeastern Oregon. Wolf breeding pairs in these areas could be considered more secure and stable because of their proximity and connectivity to the wolves in Idaho. Wolf movement and dispersal between the two populations would allow gene flow between the populations. Oregon's close proximity to the Idaho and Greater Yellowstone populations that number more than 786 wolves provides certainty that dispersing wolves will continue to enter Oregon at an unknown rate (ODFW 2017b).

Population Status

In 2016, an estimated 112 wolves in 11 packs and 8 breeding pairs were documented in Oregon (ODFW 2017b), including wolves in the southwest. By 2015, the conservation objective of four breeding wolf pairs for three consecutive years in the East Wolf Management Zone (the boundary shown in figure 3.2-9-1) had been achieved (Management Phase I Objective), and by 2016 there were at least seven breeding pairs for three consecutive years indicating the Management Phase III Objective had been achieved. Although the population objective for the East Wolf Management Zone (WMZ) was achieved in 2015, the population in the West WMZ is low and there are fewer than seven breeding pairs present. A breeding pair of wolves is defined as an adult male and an adult female with at least two pups surviving to the end of December. Management of wolves in the West WMZ remains at Phase I.

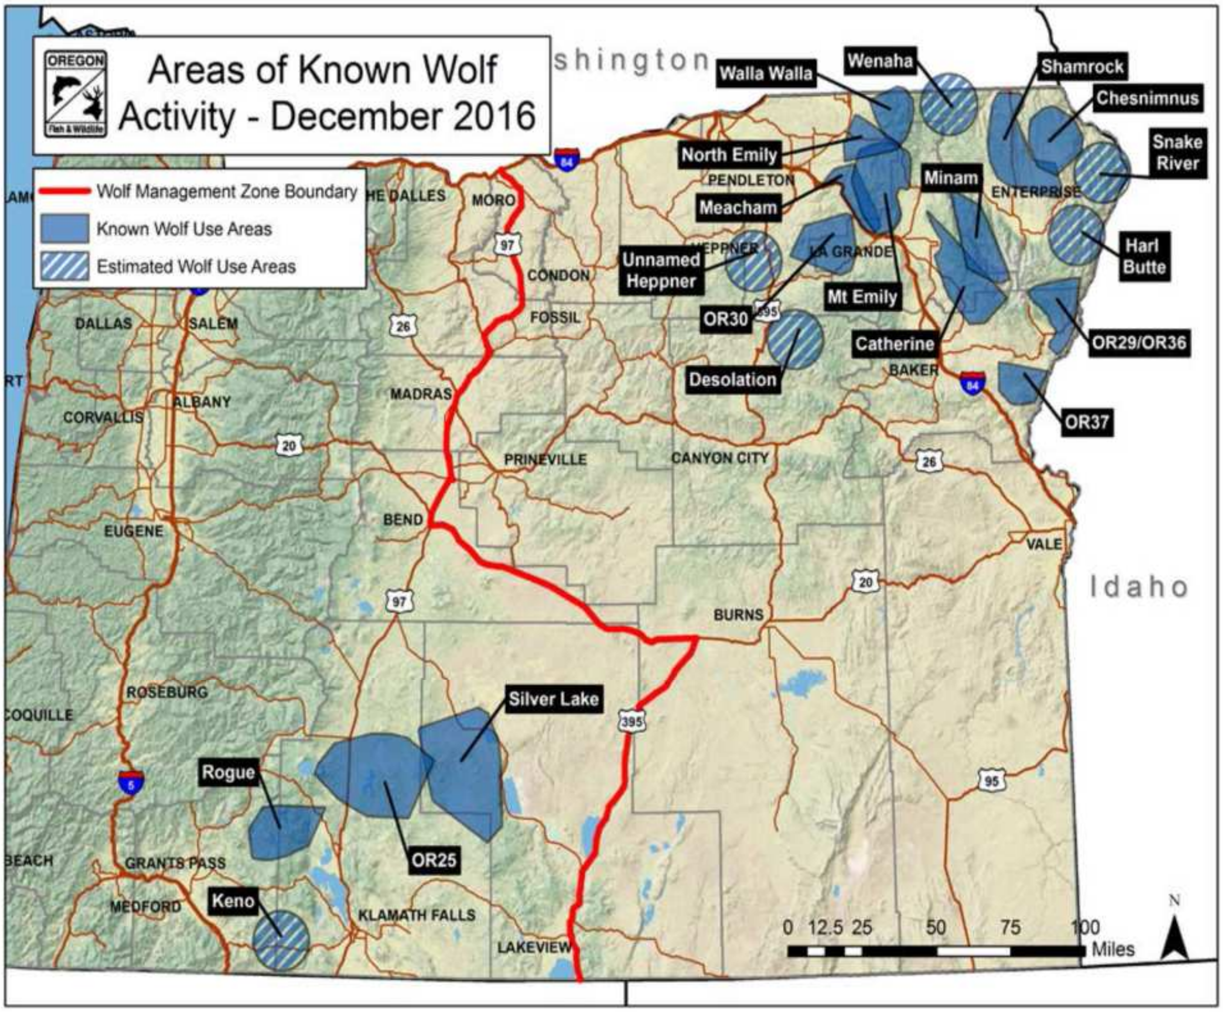

Figure 3.2.9-1 Areas of Known Wolf Activity as of December, 2016 (from ODFW 2017b)

Critical Habitat

Critical habitat for the gray wolf has not been designated in Oregon.

3.2.9.2 Environmental Baseline

Analysis Area

The action area includes all areas that would be affected directly or indirectly by the proposed action and not just the immediate area involved in the action. Because the proposed action potentially can affect such a variety of species inhabiting diverse habitats within marine, estuarine, riverine, and various terrestrial locations, there are multiple components of the action area that have been defined as species' analysis areas, the areas where individual or groups of listed species are affected by the proposed action. The gray wolf analysis area is based on the Area of Known Wolf Activity initially designated for OR-7 (now the Rogue pack) in 2014 in Jackson, Klamath, and Douglas Counties (ODFW 2014a). Although current known and estimated wolf use areas in the southern Cascades were refined in January 2017, the gray wolf analysis area is based on this larger initially identified area because it includes the extent of suitable wolf habitat in the vicinity of the Pipeline, and the areas where wolves have the potential to occur. The analysis area for gray wolves extends as far as project-related noise attenuates to ambient noise, assumed to be 40 dB on both sides of the construction right-of-way.

Species Presence

The Rogue pack currently occupies portions of southwestern Oregon, including habitats north of the Project in Jackson and Klamath Counties (ODFW 2017b). The Rogue pack was initiated by a single male wolf (OR-7) that dispersed from northeastern Oregon in 2010. Wolf OR-7 was born in northeastern Oregon in spring 2009, a member of the Imnaha pack that inhabits the Imnaha River drainage in Wallowa County, Oregon (ODFW 2017b). OR-7 dispersed from the Imnaha pack in September 2011 and was located (via radio telemetry) within Baker, Grant, Harney, Deschutes, Lake, Klamath, and Douglas counties during its migration. OR-7 traveled more than 373 miles in a straight line distance from where he was born to northern California (FWS 2013c). Since moving, the wolf had been living in the southern Cascades in Jackson, Klamath, and Douglas Counties, Oregon (ODFW 2014a) and in Siskiyou, Modoc, Shasta, Lassen, Tehama, Butte, and Plumas Counties, California (CDFW 2013).

In 2014 OR-7 was joined by a female, probably from the same area, and they produced their first litter that year. Additional pups were born in 2016 (ODFW 2017b). The Area of Known Wolf Activity (AKWA) for the Rogue Pack covered 359.3 square miles in 2015 and was about 7.1 miles northeast of MP 131.76 at its closest point (ORBIC 2017). In 2016, the AKWA shifted in size and shape but was still within 9 miles from the Pipeline project. In 2014, FWS indicated that the den was located on the west slope of the Cascades between Crater Lake and Mt. McLoughlin, in the Rogue River National Forest (Young 2014). The proposed route is greater than 6 miles from the den. The pack has spent the majority of its time in the South Cascades in the upper Rogue River watershed and the Rogue Wildlife Management Unit in eastern Jackson County.

A second AKWA (Keno) was established in southwest Oregon in 2014 with limited evidence that three wolves inhabited an area approximately 280 square miles. The Keno AKWA lies southwest of the Pipeline but overlaps the route from MP 173.93 to MP 176.41. In 2016 and 2017, three different wolves were documented in the Keno AKWA but there have been no reports of breeding. In January 2015, ODFW designated an estimated Wolf Use Area for this wolf activity (Keno, figure 3.2.9-1; ODFW 2017b). The Pipeline runs along the northeast boundary of the Keno Estimated Wolf Use Area.

Three other radio-collared wolves dispersed from northeastern Oregon to southwest Oregon. One single male wolf (OR25) dispersed in 2015 and established an AKWA spanning northern Klamath County with portions in adjacent Jackson County and Lake County. A radio-collared female wolf (OR28) dispersed in late 2015 and was joined by a collared male (OR3) to establish the Silver Lake AKWA which coincides with the Silver Lake Wildlife Management Unit in western Lake County. The pair produced one pup in 2016 but the male was killed in 2016 (ODFW 2017b). In 2016, ODFW (2017b) reported four depredation incidents on livestock (four calves dead or injured) within the Rogue AKWA. One incident was reported in the Silver Lake AKWA. Given the recent occurrence of both dispersing and resident wolves in the southwestern Cascades in the vicinity of the Pipeline, wolves are expected to occur in the wolf analysis area.

Habitat

The route crosses the gray wolf analysis area (OR-7's previous Area of Known Wolf Activity) for about 33 miles, from MP 147.7 to MP 180.7. The Pipeline would cross Very Sensitive Wildlife Areas in the Rogue Wildlife Management Area for about 8 miles from MP 147.7 to MP 155.8.

Black-tailed deer and Roosevelt elk occur within the gray wolf analysis area. Those big game species are likely to provide a prey base for wolves, especially during winter when animals are concentrated and old, sick individuals are more easily preyed on, and/or carrion is more readily available. Often, big game will remain on or near winter ranges during birthing, which also would provide wolves that are present with accessible prey (newborns). The gray wolf analysis area coincides with multiple big game winter ranges:

- elk and deer winter range in the Keno Wildlife Management Area;
- Very Sensitive Wildlife Areas (big game winter ranges) in the Rogue Wildlife Management Area;
- Very Sensitive Wildlife Areas (big game winter ranges) and Sensitive Big Game Ranges in the Dixon Wildlife Management Area; and
- Sensitive Big Game Ranges in the Indigo Wildlife Management Area.

Based on ODFW population index data, black-tailed deer in the Rogue Wildlife Management Area Unit had been significantly increasing ($P<0.01$) between 1998 and 2012. In western Oregon, black-tailed deer are found in heavy brush areas at the edges of forests and chaparral thickets, but not in dense forests. Black-tailed deer prefer early successional stages created by clear-cuts or burns, because they provide grasses, forbs, and shrubs (ODFW 2006a; Csuti et al. 2001). Most black-tailed deer that summer in the high Cascades winter at lower elevations on the west slope, although some may winter east of the Cascade crest (ODFW 2006a).

Critical Habitat

Critical habitat for the gray wolf has not been designated in Oregon.

3.2.9.3 Effects of the Proposed Action

Direct and Indirect Effects

Approximately 2.48 miles of Pipeline in Spread 4 would pass through the Keno AKWA which has most recently been occupied by three wolves. However, breeding has not been reported in the AKWA. Potential direct effects of the Pipeline include disturbance from:

- Construction-related noise,
- Increased risk of collision with construction vehicles along project area roadways;
- Wildland fire as an indirect effect associated with increased Pipeline project-induced human presence;
- Habitat alteration; and
- Locally concentrated human activities.

<u>Project-Related Noise.</u> Pipeline construction would produce noise, cause locally concentrated human activities, and remove forested habitat that might be used by some species that are preyed upon by wolves. Specific studies to measure impacts to the gray wolf from noise generated from construction of a pipeline have not been conducted; however, it is expected that construction noise

in remote areas that are relatively free from noise would have a greater potential to disturb wildlife including the gray wolf. Ambient sound levels in much of the Pipeline project area probably would be similar to the Washington Fish and Wildlife Office's determination (FWS 2003b) of 40 dB in the Olympic National Forest. Considering ambient sound as a base, noise levels associated with some common machines and activities which would be present during construction are included in table 3.2.9-1. Distances at which noise would attenuate to ambient levels would depend on local conditions such as tree cover and density, topography, weather (humidity), and wind, all of which can alter background noise conditions.

TABLE 3.2.9-1

Common Sound Levels for Equipment/Activities Potentially Associated with the Pipeline

Measured Sound Source	Range of Reported dB Values (at Distance Measured 50 ft)	Relative Sound Level a/
Chain Saw (various types/conditions)	61 – 93	Low - Very High
Pickup Truck (idle to driving)	55 – 71	Very Low - Moderate
Mowers	68 – 85	Low - High
Log Truck	77 – 97	Moderate - Very High
Dump Truck	84 – 98	High - Very High
Rock Drills	82 – 98	High - Very High
Pumps, Generators, Compressors	87	High
Drill Rig	88	High
General Construction	84 – 96	High - Very High
Track Hoe	91 – 106	Very High - Extreme
Helicopter or Airplane (various types/conditions)	96 – 112	Very High - Extreme
Rock Blast	112 b/	Extreme

Source: FWS 2006a.

a/ A general, subjective ranking of noise levels created by the sources considered when used for analysis of relative noise effects on species.

b/ Blasting required for the Pipeline project would be underground and muffled which should result in a lower dB value at 50 feet.

These project-related noises could disturb wolves potentially present if close enough to detect the noise above ambient levels, assumed to be 40 dB. If noise due to helicopter or blasting is the highest level produced during construction (112 dB), those noise levels would be expected to attenuate to ambient levels as far as 38,800 feet (7.3 miles) away (assuming no intervening topography or vegetation and a noise reduction rate of 7.5 dB for every doubling of distance from the source). On the other hand, noise from a pickup truck generating 70 dB while driving would attenuate to ambient levels about 800 feet away (with the same assumptions as above). Pipeline noise from helicopters or blasting could be detected by wolves in the Rogue pack as their Wolf Use Area is within 7.3 miles of the Pipeline. Individuals within the Keno AKWA could also detect construction noise because the AKWA borders the Pipeline. Additionally, dispersing or currently undocumented wolves in the immediate vicinity of the Pipeline would detect construction noise.

The response of wolves to project-related noise would probably be similar to their response to other anthropogenic noise including noise related to recreation, hunting, and logging that already occur within the gray wolf analysis area. There is no information specific to wolves' responses to existing anthropogenic noise. Larsen and Ripple (2006) found that road density, human density, and human presence were all lower in wolf pack areas than random polygons within their study area, although this avoidance was not attributed to noise specifically, and dispersing wolves have been shown to travel through areas of high road densities in order to find suitable habitat (Mech 1995). Thiel (1985) found that wolf breeding occurred in areas with relatively low road densities, although Mech (2006) suggested that these findings were a result of wildlands being the only place where wolves avoided human persecution historically. Additionally, wolves have been documented denning in wheat fields in Europe (Vila et al. 1993 as cited in Mech 2006), and denning and raising pups in other areas of high human disturbance (Heilhecker et al. 2008; Thiel et al. 1998 as cited in Mech 2006). There is a small chance that a gray wolf present in the Pipeline project area at the time of construction would detect project-related noise above ambient forest noise. There would be a much smaller chance that a wolf present during operation would detect project-related noise and a chance that project-related noise could interfere with wolf communication is expected to be very remote. As a result, the effects of Project noise on wolves if present, including denning wolves, are expected to be insignificant.

Vehicle-Related Mortality. A small number of wolves have been killed by vehicles. For example, 80 percent of all wolf mortalities in the Northern Rocky Mountain population are caused by humans but only 3 percent are due to accidental human interactions including vehicle collisions and capture mortality (FWS 2012a). The chance that a project-related vehicle would kill or injure a gray wolf would be remote.

Wildland Fire. Potential indirect effects from the construction and operation of the Pipeline include increased human access and presence in the area which increases the possibility of human-related wildfire. Many vegetation communities within the Pipeline project area have been directly and indirectly affected by fire over the past 100 years; highest fire risks in the Pipeline project area are the overstocked mixed conifer stands with saplings as ladder fuels. The possibility of ignition in both mixed conifer and sagebrush/grass fuel types could range from low to extreme depending on weather conditions and patterns, current fire risk rating, moisture conditions, and fuel loadings. There is some possibility of human-caused fire, whether related to Pipeline project activities or to project-induced increase of human presence in the area (see Comer 1982).

Habitat Alteration. The portion of the Pipeline that coincides with the gray wolf analysis area passes through several types of forested habitats for 33.05 miles (from MP 147.66 to MP 180.73); including Southwest Oregon Mixed Conifer-Hardwood Forest for 15.8 miles; Westside Oak and Dry Douglas-fir Forest and Woodlands for 0.5 mile; Ponderosa Pine Forest and Woodland for 5.2 miles; and Montane Mixed Conifer Forest for 6.3 miles (habitat categories follow Johnson and O'Neil 2001). Most of the Pipeline passes through forested habitats that are regenerating (11.8 miles), clearcut (0.03 mile), mid-seral (4.5 miles), late successional (6.5 miles) or old growth (5.1 miles). Within the gray wolf analysis area, the construction of the Pipeline would remove 87.0 acres of old-growth forest (more than 175 years old), 97.8 acres of late successional forest (80 to 175 years old), 77.7 acres of mid-seral forests (40 to 80 years old), 249.72 acres of regenerating forest (5 to 40 years old), and 0.7 acre of recent clear-cut forest (0 to 5 years old). The Pipeline project would create a corridor through those forest-woodland types and seral stages.

Corridors created within forested habitats are used for movement and foraging by big game species. A study conducted in Alberta by Brusnyk and Westworth (1985) focused on forage and browse production and big game use on a 17-year-old pipeline right-of-way and on a two-year-old right-of-way. Deer appeared to utilize browse in the 17-year-old corridor but returned to adjacent undisturbed forest, probably utilizing available hiding or thermal cover. Deer utilized the corridors for travel in early winter prior to when deep snow limited travel. Elk utilized forage on the two-year-old right-of-way primarily where portions were adjacent to forested habitats. The principal conclusion of this study was that pipeline corridors increased local habitat diversity and that diversity, i.e., juxtapositions of browse or forage to undisturbed forested habitat, increased use of the corridors by ungulates; however, this increase was not necessarily due to increased vegetative production, per se, within pipeline rights-of-way. Increased herbivore density provides a food source for predators (Forman 1995), so predator density can be increased along the edge created by the corridor as well.

Locally Concentrated Human Activities. Wolves potentially present could be drawn to conflict situations brought about by construction if attracted to garbage at the workplace and/or drawn to roadside carrion killed by project vehicles. Some wildlife species may be directly impacted by construction if they are killed by vehicles traveling to and from construction sites. Species most susceptible to vehicle-related mortality include those that are more active at dusk and dawn such as deer (Leedy 1975; Bennett 1991; Forman and Alexander 1998; Trombulak and Frissel 2000). However, carcasses of prey species (e.g., deer and elk) naturally occur on the landscape, usually associated with road kills or wildlife killed by natural causes (ODFW 2010). Food associated with human presence during construction activities could increase some wildlife populations within the vicinity of the Pipeline.

The response of gray wolves to human activities would likely be similar to their response to other anthropogenic disturbances including noise related to recreation, hunting, and logging that may already occur within the area. Wolves selected logged areas less during the denning period and rendezvous during summer where road density was highest; wolves selected roads most where road density was low. During fall and winter, when logging activities and traffic were low, wolves showed a strong selection for roads (Houle et al. 2010). However, wolves crossed high-use roads less than low-use trails; while neither were absolute barriers to movements, the presence of roads and trails altered wolf movement across their territories (Whittington et al. 2004). Denning wolves, when disturbed by humans, tended to move pups to an alternate site although reproductive success of wolves was not influenced by human disturbance (Frame et al. 2007). During winter, wolves subject to heavy snowmobile use were found to have higher levels of fecal glucocorticoids than wolves inhabiting areas with no snowmobile use (Creel et al. 2002), indicating a physiological stress response to snowmobile stimuli (Creel et al., 2002). Project-related stimuli could elicit a similar response in wolves within the Rogue AKWA and Keno AKWA if any was present at the time of construction.

Cumulative Effects

Cumulative effects to the gray wolf would be generated by timber harvesting and other sources of disturbance, habitat loss, and increased human presence on non-federal lands in the foreseeable future in the gray wolf analysis area. However, the majority of the gray wolf analysis area is on federal land, including the Rogue River and Winema National Forests, and Medford and Lakeview BLM Districts. No specific foreseeable state or private actions have been identified within the gray wolf analysis area.

Critical Habitat

Critical habitat for the gray wolf has not been designated in Oregon.

3.2.9.4 Conservation Measures

PCGP has stated that all trash, food waste, and other items attractive to predators and scavengers would be picked up and removed from the project area on a daily basis to minimize potential attraction of predators, including the gray wolf.

3.2.9.5 Determination of Effects

Species

The Project **may affect** the gray wolf because:

- dispersing and resident wolves have been documented recently within the gray wolf analysis area;
- the OR-7 wolf family den was located in the vicinity of the Pipeline in 2014;
- construction noise could disturb wolves if present in the vicinity of the Pipeline; and
- increased human presence associated with construction activities could impact wolf behavior and movements, including the chance of collisions with vehicles.

However, the Project is **not likely to adversely affect** the gray wolf because:

- human presence and noise generated during construction may be detected and would disturb wolves if present, but project-related noises are not likely to be substantially different from the noise produced by existing recreation, hunting, and logging land uses that wolves have been shown to tolerate;
- the one known den in southwestern Oregon is at least 6 miles from the proposed Pipeline;
- following construction, the Pipeline corridor is likely to increase local habitat diversity, forage, and be used for movements by ungulates that would be prey for gray wolves; and
- during construction, on-site trash and carrion caused by animal-vehicle collisions could attract the gray wolf to the project area and create conflict situations but trash would be removed on a daily basis and roadside carrion is expected to be present as an existing condition, and not substantially increased by the Project. Project-related effects to the gray wolf would be insignificant and discountable.

Critical Habitat

Critical habitat for the gray wolf has not been designated in Oregon.

3.3 BIRDS

3.3.1 Short-tailed Albatross

3.3.1.1 Species Account and Critical Habitat

Status

The short-tailed albatross was proposed for listing in the United States in 1980 under the ESA and was listed as endangered throughout its range in the United States on July 31, 2000 (FWS 2000b).

Threats

The primary threat leading to the species' decline and ultimate listing was over-harvest for their feathers in the early 1900s (FWS 2000b), but that threat is no longer present. Another major threat to the short-tailed albatross is their small population size and the existence of few breeding populations, one of which is threatened by volcanic activity on Torishima Island (Japan) as well as by mudslides and erosion (FWS 2005b, 2008a). Petroleum development occurs in many parts of the short-tailed albatross' marine range, and oil spills are a threat to conservation and recovery.

The possibility of volcanic eruption on Torishima remains the primary ongoing threat to short-tailed albatross because 80 to 85 percent of the breeding population nests there (FWS 2005b). Typhoons and monsoon rains generating mudslides and erosion threaten extant nesting colonies on a regular basis. Secondary threats include adverse effects related to global climate change (oceanic circulation and patterns of upwelling), incidental take by commercial fisheries (longline fisheries trawl fishing in the North Pacific), ingestion of plastic debris (especially beverage bottle caps), contamination by oil and other pollutants (metals, pesticides, PCBs), vulnerability to predation by non-native species, and other human actions including collisions with airplanes (FWS 2005b). When populations are small and confined to only a few locations such as the known breeding colonies for short-tailed albatrosses, there is a heightened risk of catastrophic loss from random or unpredictable events (environmental stochasticity).

Species Recovery

The FWS drafted a recovery plan for the short-tailed albatross in October 2005 (FWS 2005b), describing actions necessary to achieve conservation and survival of the species. Human harvest of the short-tailed albatross no longer is a threat to the species' existence, nor are human-related limitations. Therefore, focus for recovery is on protection and creation of safe breeding colonies (i.e., without potential for volcanic eruption or massive erosion) on remote islands in the Pacific Ocean (FWS 2008a). The goal of the plan is to recover the species to the point that protection under the ESA is no longer required. The plan listed the following recovery tasks:

- Support ongoing population monitoring and habitat management on Torishima.
- Monitor a second population in Japan (Senkaku population).
- Conduct telemetry studies.
- Establish one or more nesting colonies on non-volcanic islands.
- Continue research on impact from fisheries operations and mitigation measures.
- Conduct other research.
- Conduct other management-related activities.
- Conduct outreach and international negotiations as appropriate.
- Develop models and protocols for all aspects of recovery work.

Life History, Habitat Requirements, and Distribution

The short-tailed albatross nests on flat or sloped sites with sparse or full vegetation on isolated windswept offshore islands with limited human access (FWS 2000b). It requires remote islands for breeding (FWS 2005b). The only terrestrial area within U.S. jurisdiction where the short-tailed albatross is currently nesting is the Midway Atoll (FWS 2012b).

In the North Pacific, the coastal habitat for the short-tailed albatross is in high-productivity areas with expansive deep water beyond the continental shelf. Short-tailed albatrosses eat squid, fish, eggs of flying fish, shrimp, and other crustaceans (FWS 2000b). Short-tailed albatross foraging areas are closely associated with shelf-edge habitats where tidal currents and steep bottom topography generate strong vertical mixing of ocean waters. Areas are most prominent along the Aleutian Archipelago but also include several locations along the U.S. West Coast in the Santa Barbara Channel and Monterey Bay Canyon in California and the Juan de Fuca Canyon near Vancouver Island (Piatt et al. 2006).

Population Status

Prior to the publication of the final rule to list the birds, FWS (2000b) estimated a worldwide population of 600 breeding age birds and 600 immature birds (younger than 6 years old) for a total of 1,200 individuals. In 2005-06, there were an estimated 500 breeding pairs and approximately 2,000 individual short-tailed albatrosses (FWS 2005b). Population estimates in 2008-2009 indicate 418 breeding pairs (836 breeding adults) on Torishima with a total adult population of 1,045 and an estimated adult population on Minami-kojima of 200 during the 2008-2009 nesting season. The worldwide total adults of breeding age in 2008-2009 was 1,245 birds and 1,327 birds of sub-breeding age (under age 5 or 6) (FWS 2009a). The total population estimate for breeding age short-tailed albatrosses in the 2013-2014 nesting season was 1,928 individuals (FWS 2014b). Overall population size of 750 breeding pairs required for reclassification to threatened was estimated to have been met in 2013 and the delisting criteria of 1,000 breeding pairs is estimated to be met in 2017 (P. Sievert, pers. comm. 2010 as cited in FWS 2014b). More recent population data were not available.

Critical Habitat

Critical habitat has not been designated for the short-tailed albatross. Designation of critical habitat is "not prudent" given, overall, the lack of habitat-related threats to the species within the United States and its territories and absence of specific areas under U.S. jurisdiction that could serve as critical habitat (FWS 2005b).

3.3.1.2 Environmental Baseline

Analysis Area

The analysis area within which the proposed action could affect the short-tailed albatross is the edge of the marine analysis area along the continental shelf. Within the analysis area, effects to the short-tailed albatross would be associated with LNG carriers, which are assumed to transect the marine analysis area perpendicularly – east and west – as they approach and depart from Coos Bay (see the discussion above under section 3.2.1.3).

Species Presence

The short-tailed albatross has not been documented within 25 miles of the proposed JCEP LNG Terminal or Pipeline (ORBIC 2012), and the nearest known nesting population is within the Hawaiian Islands, on the Midway Atoll. Three percent of locations for sub-adult short-tailed albatrosses tagged with satellite transmitters in Alaskan waters were along the continental shelf margin, within 200 nmi, of the U.S. West Coast (Suryan et al. 2007). The data is gridded on 1° lines making it unclear if albatrosses within the study area came within the marine analysis areas. Most recent records for the species in Oregon have been at sea in the vicinity of Perpetua Bank, which is 32 miles west of Yachats, Lincoln County (Marshall et al. 2006). Short-tailed albatrosses have also been observed at Heceta Bank (Audubon Society of Portland 2013), 15 to 30 miles off the central Oregon coast, part of the same seamount ridge formation as Perpetua Bank, promoting upwelling of ocean currents interacting with seafloor topography with concomitant primary production.

Habitat

Short-tailed albatrosses spend much of their time feeding in nutrient-rich areas of ocean upwelling which often occur at continental shelf breaks (FWS 2005b). In Oregon, the continental shelf extends from 10 miles off the coast at Cape Blanco to 46 miles from the Oregon central coast (Oregon Ocean-Coastal Management Program 2008). The Perpetua Bank and Heceta Bank are within the continental shelf break zone and ocean upwelling presumably occurs in the vicinity to support foraging by short-tailed albatross. This habitat occurs on the edge of the marine analysis area, approximately 12 nmi to the outer continental shelf.

Critical Habitat

Critical habitat has not been designated for the short-tailed albatross.

3.3.1.3 Effects of the Proposed Action

Direct Effects

None of the factors that have threatened the short-tailed albatross in the past or that are ongoing threats to the species would be produced by any components of the proposed action.

Seabirds collide with fishing trawlers in the North Pacific although take of short-tailed albatross has not been reported (FWS 2009a). Collisions of seabirds with stationary objects (including off-shore wind energy turbines) are possible, either by collisions of ships with birds on the ocean surface or collisions of birds in flight with ship structures although empirical data are limited (Wilson et al. 2007). Collisions between short-tailed albatrosses and LNG carriers are possible but not likely within the marine analysis area.

Cumulative Effects

The definition of cumulative effects to short-tailed albatross is as described as for blue whales (see section 3.2.1.3). As discussed above for blue whales, ship traffic at the Port has declined in the past two decades and is not expected to change from the current level in the near future (ECONorthwest 2012), although it may increase in the distant future if proposed improvements are implemented (Port of Coos Bay 2014).

The foreseeable cumulative effect of the additional 120 LNG carriers per year with regard to risk of vessel strike, underwater noise, or accidental release is expected to be low. Consequently, cumulative effects to short-tailed albatross would likely be the same as the estimate of direct effects discussed in the previous section. Those effects were judged to be discountable.

Releases of diesel fuel and/or gasoline by commercial and recreational vessels are possible. According to annual reports published by the Pacific States/British Columbia Oil Spill Task Force (2002), ODEQ reported 34 spills from fishing vessels or other harbor craft in 2002, 38 spills in 2003, and 7 spills from fishing vessels plus spills from 27 other vessel types in 2004. Those relatively consistent incidences apparently increased in 2005 with 18 spills from fishing vessels, 20 from recreational vessels, and 27 spills by other vessel types. By contrast in 2006, there were three spills from fishing vessels, six spills from recreational vessels, and only six spills from other vessel types. Though not known, it appears that the background rate of spills off the Oregon coast (incidence of spills in proportion to total vessel operation) by fishing vessels, recreation vessels, and other vessel types is generally low. Based on existing information, future rates of offshore releases are also expected to be low and potential for short-tailed albatross to be affected by contamination by oil and other pollutants is not expected to increase above existing levels.

Critical Habitat

No critical habitat would be affected by the proposed action; none has been designated.

3.3.1.4 Conservation Measures

No measures have been included in the proposed action to specifically conserve short-tailed albatross. However, the same Ship-Strike Reduction Plan that was described in section 3.2.1.4 (Blue Whale) to minimize potential ship strikes to cetaceans by LNG carriers could benefit short-tailed albatross within the marine analysis area.

3.3.1.5 Determination of Effects

Species

The Project **may affect** short-tailed albatross because:

- short-tailed albatross may occur within the marine analysis area during operation of the proposed action; and
- the proposed action would increase shipping traffic (LNG carriers) within the marine analysis area.

However, the Project is **not likely to adversely affect** short-tailed albatross because:

- collisions of any albatross species with ships are unknown and are expected to be highly unlikely;
- the increase in annual ship traffic due to the proposed action is expected to cause an ummeasurable increase for potential ship strikes to short-tailed albatrosses; and
- LNG carriers approaching Coos Bay would be traveling slowly and escorted by tractor tugs from five nmi offshore to the LNG Terminal.

Critical Habitat

No critical habitat has been designated or proposed for the short-tailed albatross.

3.3.2 Western Snowy Plover

3.3.2.1 Species Account and Critical Habitat

Status

The Pacific Coast population of western snowy plover has been listed as a threatened species under the ESA since March 5, 1993 (FWS 1993). In March 2004, FWS issued an initial 90-day review in response to a petition to de-list the western snowy plover. However, in April 2006 after further review, the de-listing petition was found to be unwarranted (FWS 2006c). It is also listed under Oregon's ESA as threatened.

Threats

Historic records indicate that western snowy plovers nested in at least 29 locations on the Oregon coast (FWS 2009b). At the time of the species' listing, there were only six known nesting locations

(FWS 1993). The breeding population in Oregon declined from 139 adults in 1983 to 30 adults in 1992. Similar declines within wintering habitats were also reported in Southern California (FWS 1993). Active nesting areas and breeding and wintering populations declined due to habitat degradation caused by urban development (industrial, residential, recreational facilities including homes, parking lots, and commercial establishments), introduced beachgrasses used to stabilize sand dunes, expanding predator populations, particularly corvids (crows, ravens), and non-native red foxes, and human disturbance (beach walking and jogging, ORV use, horseback riding, beach raking, pet walking [FWS 2007a]). Nesting from mid-March through mid-September corresponds with the period of intensive human use of beaches during summer, which has been documented to adversely affect adult survival as well as reproduction and fledging success.

Habitat destruction and degradation continue as the primary threats to western snowy plovers along the Pacific coast (FWS 2007a). Beach stabilization efforts have continued with permanent habitat losses due to homes, resorts, parking lots, and increased human recreational use of beaches. Other human-related threats include sand mining, disposal of dredged materials that also alter beach habitat dynamics and increase recreational access to habitats, driftwood removal (for firewood, decoration), camping and campfires, reduction in sand delivery to beach by water diversions or waterbody impoundments, and maintenance of salt ponds (FWS 2007a). Non-native beachgrasses continue to degrade the landscape along the Oregon coast by changing patterns of dune stabilization, making beach habitats less suitable for nesting and brood-rearing snowy plovers (FWS 2007a).

Species Recovery

In 2007, the FWS issued a recovery plan for the western snowy plover, Pacific Coast population, with the primary objectives to increase the numbers and productivity of breeding adults throughout the Pacific Coast and to provide for long-term protection of breeding and winter plovers and their habitat. The recovery plan provides management goals for six recovery units established within the breeding range of the Pacific Coast population in Washington, Oregon, and California. Recovery Unit 1, specifically population OR-13 (Coos Bay North Spit), is near the proposed action. The management goal for recovery unit OR-13 is 54 breeding plovers (FWS 2007a). The 2007 recovery plan's primary objective is to remove the species from the List of Endangered and Threatened Wildlife and Plants by:

- increasing population numbers distributed across the range of the Pacific Coast population;
- conducting intensive ongoing management for the species and its habitat and developing management mechanisms; and
- monitoring western snowy plover populations and threats to determine success and refine management actions.

The recovery plan lists the following necessary actions:

- Monitor breeding and wintering populations and habitats of the Pacific Coast population of the western snowy plover to determine progress of recovery actions to maximize survival and productivity.
- Manage breeding and wintering habitat of the Pacific Coast population of the western snowy plover to ameliorate or eliminate threats and maximize survival and productivity.

- Develop mechanisms for long-term management and protection of western snowy plovers and their breeding and wintering habitat.
- Conduct scientific investigations that facilitate the recovery of the western snowy plover.
- Conduct public information and education programs about the western snowy plover.
- Review progress towards recovery of the western snowy plover and revise recovery efforts, as appropriate.
- Dedicate FWS staff to allow the Arcata Fish and Wildlife Office to coordinate western snowy plover recovery implementation.
- Establish an international conservation program with the government of Mexico to protect western snowy plovers and their breeding and wintering locations in Mexico.
- Coordinate with other survey, assessment, and recovery efforts for the western snowy plover throughout North America (FWS 2007b).

The BLM administers the bulk of the lands on the Coos Bay North Spit (about 1,864 acres) with other federal and state agencies having jurisdiction over various portions of the North Spit; privately owned lands are also scattered throughout the area (U.S. Army Corps of Engineers 2016a). Snowy plover habitat on the North Spit is currently owned by the BLM and COE and managed by the BLM, Forest Service, and Oregon Parks and Recreation Department (OPRD). U.S. Army Corps of Engineers (2016b) developed a Site management plan to protect habitat for western snowy plovers on lands under their jurisdiction on the Coos Bay North Spit. The plan includes habitat management and restoration, seasonal and area restrictions, access and public use, predator management, and population and productivity monitoring. Additionally, the BLM management plan (BLM 2016a) contains directives to avoid road or trail development within designated critical habitat and restricts timing and location of beach activities to avoid distrupting nesting behaviors. A Habitat Conservation Plan was prepared, as part of OPRD application for an incidental take permit, to implement OPRD management and regulatory activities along the Oregon Coast that could affect the snowy plover (ICF 2010). OPRD would implement potential recreation restrictions and beach management activities within covered lands.

Life History, Habitat Requirements, and Distribution

The Pacific Coast breeding population of the western snowy plover extends from Mexico to mid-way up the Washington coast. Coastal populations, including those in Oregon, typically consist of both resident and migratory birds. Large concentrations of migratory snowy plovers winter primarily in coastal California, Baja California, and along the coastal mainland of Mexico (FWS 1993). The Pacific Coast population of the western snowy plover includes the birds that nest adjacent to tidal waters, including all nesting birds on the mainland coast, peninsulas, offshore islands, adjacent bays, estuaries, and coastal rivers (FWS 1993). They breed on coastal beaches from southern Washington to southern Baja California, Mexico, from early March through late September (FWS 1993 and 2001). Coastal beach breeding habitat is often dynamic because of unconsolidated soils, high winds, storms, wave action, and colonization by plants. Preferred nesting sites include sand spits, dune-backed beaches, beaches at creek and river mouths, and salt pans at lagoons and estuaries (Wilson 1980; Stenzel et al. 1981). Less frequently, western snowy plovers nest on bluff-backed beaches, dredged material disposal sites, salt pond levees, dry salt ponds, and river bars (FWS 2001).

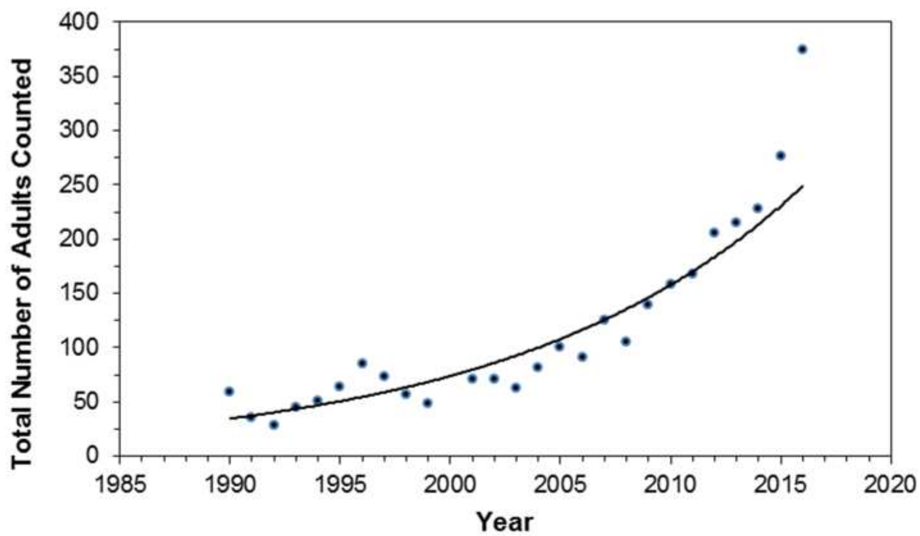
Nesting in Oregon may occur as early as mid-March but peak nest initiation occurs from mid-April through mid-July (Wilson-Jacobs and Meslow 1984). Nests typically occur in flat, open areas with sandy or saline substrates; vegetation and driftwood are usually sparse or absent (Wilson 1980). Nests consist of a shallow scrape or depression lined with beach debris (e.g., small pebbles, shell fragments, plant debris, and mud chips); nest lining progresses as incubation progresses.

Usual clutch size is three eggs but can vary from two to six. Both males and females incubate the eggs. After losing a clutch or brood (i.e., group of chicks) or successfully hatching a nest, western snowy plovers may re-nest at the same site or move substantial distances to nest at other sites (Wilson 1980; Warriner et al. 1986).

Eggs hatch within 30 days. Young are very precocial and ready to leave the nest within 1 to 3 hours of emergence at which point the attending parent would lead them to suitable feeding grounds. Broods rarely remain in the nesting area and have been observed on the North Spit as far as three miles north of the jetty at the mouth of the bay (Todd 2007). Chicks are able to fly approximately one month after hatching (FWS 2007a). Plovers feed on small invertebrates in wet sand areas of the intertidal zone, along the wrack line, in dry sandy areas above the high tide line and along surf-cast driftwood and kelp.

Population Status

Along the Oregon Coast there are nine main nesting areas, though several other areas may be utilized in some years (FWS 2007a). The lowest population estimates for nesting plovers on the Oregon Coast averaged 33 individuals annually between 1991 and 1993. From 1993 to 2016, the Oregon Coast population of adults has increased to 375 birds following an exponential trend (see figure 3.3.2-1). In 2016, nesting success for those breeding sites was the highest recorded since monitoring began in 1990, with 339 birds fledging in 2016 compared to only six birds that fledged in 1991 (Lauten et al. 2016). The plover population exceeded recovery goals exceeded in 2016 (Lauten et al. 2016).



Source: Lauten et al, 2016

Figure 3.3.2-1 Number of Adult Western Snowy Plovers Observed During the Breeding Season on the Oregon Coast, 1990 to 2016. The exponential relationship is significant (r^2 = 0.87, P<0.001)

The 2016 estimate of resident snowy plovers on the Oregon Coast was 518 individuals, the highest estimate recorded since monitoring began in 1990. This estimate was attained using the 10-day interval method by comparing minimum numbers of unbanded individuals against the number of banded individuals (Lauten et al. 2016).

Critical Habitat

Critical habitat for the western snowy plover was designated on January 6, 2000 (FWS 1999a), including 278 acres in proximity to Coos Bay, and re-designated in 2005 (FWS 2005c). The most recent revised designation of critical habitat for the western snowy plover was in June 2012 (FWS 2012c). The closest critical habitat to the Project is Unit OR-10 which occupies 273 acres on the Coos Bay North Spit, approximately 2.6 miles southwest of the proposed LNG Terminal site. A second critical habitat Unit OR-9, at the mouth of Tenmile Creek on the Siuslaw National Forest, is 7.7 miles northwest of the LNG Terminal site at its closest location to the Project. Both CHUs were occupied by western snowy plovers at the time of listing (1993) and in 2016. Approximately 55 breeding resident males with 42 fledglings occupied Unit OR-9 in 2016, while 83 breeding male snowy plovers with 43 fledglings were documented with Unit OR-10 on the North Spit in 2016 (Lauten et al. 2016).

Based on the Pacific Coast western snowy plover's requirements for reproduction, feeding, forage and shelter, the FWS (2012c) identified the following essential physical and biological features of designated critical habitat: 1) sparsely vegetated areas above daily high tides that are relatively undisturbed by the presence of humans, pets, vehicles or human-attracted predators; 2) sparsely vegetated sandy beach, mud flats, gravel bars or artificial salt ponds subject to daily tidal inundation, but not under water, that support small invertebrates; and, 3) surf or tide-cast organic debris such as seaweed or driftwood located on open substrates. Critical habitat in the vicinity of the project area (Unit 10 Coos Bay North Spit), contains expansive, sparsely vegetated interdune flats, areas of sandy beach above and below the high tide line with occasional surf-cast wrack supporting small invertebrates, and close proximity to tidally influenced estuarine areas (FWS 2012c).

Threats that may require special management in this unit are introduced European beachgrass that encroaches on the available nesting and foraging habitat; disturbance from humans, dogs and OHVs in important foraging and nesting areas; and predators such as the American crow and common raven (FWS 2005c).

3.3.2.2 Environmental Baseline

Analysis Area

The LNG Terminal analysis area extends for 1.5 miles beyond the perimeter of the LNG Terminal Site (see figure 3.3.2-2) to include project components on the North Spit and APCO Site, which historically provided western snowy plover nesting habitat. The only portion of the Pipeline that occurs within this analysis area either overlaps the LNG Terminal site, APCO site, or is submerged across Coos Bay. The LNG carrier transit route and Navigation Reliability Improvements are included in the estuarine analysis area with Dredge Area 1 located within 0.25 mile of Critical Habitat (see figure 2.1.1-2). Therefore, the only proposed Project facilities addressed within this analysis area are the LNG Terminal facilities, APCO Site, Port Laydown Site, Dredge Area 1, Meteorological Station, the PCGP Jordan Cove Meter Station, and the pipeline HDD from the APCO Site to where it exits on South Dunes after crossing beneath Coos Bay.

Species Presence

Western snowy plovers have been recorded on the National Audubon Society's Christmas Bird Counts (CBC) in the Coos Bay count circle most years since 2000, and sporadically in earlier surveys. There is no CBC data for the Coos Bay count circle for 2010 and 2014, and no plovers were counted in 2002 and 2007. For the years with data between 2000-2016, an average of 9.9 snowy plovers have been counted per year; the most reported in any annual survey were 32 counted during 130 observation hours in 2011 (Audubon Society 2016). Western snowy plovers are known to nest at the upper edge of the beach below the foredunes, on bare spits at small estuary mouths and on old dredge spoils (Marshall et al. 2006). No western snowy plovers were detected during field surveys of the LNG Terminal site (LBJ Enterprises 2006).

In the summer of 2012, 16 adults (8 males, 8 females) were documented by the Forest Service on the Tenmile Creek Unit OR-9 and 52 adults (35 males, 17 females) were documented by personnel with BLM and COE on the Coos Bay North Spit, CHU OR-10. In 2012, the nest success rate on the North Spit was 87 percent, similar to 2011, and the highest rate on the Oregon Coast since predator management was implemented in 2002 (Lauten et al. 2012). Nesting success at the Tenmile Creek unit has been very poor; only 13 percent of nests were successful in 2012, mostly due to depredations by corvids (common ravens) and great horned owls (Lauten et al. 2012). The total number of nests documented on the North Spit has increased most years between 2006 and 2016 (see figure 3.3.2-3).

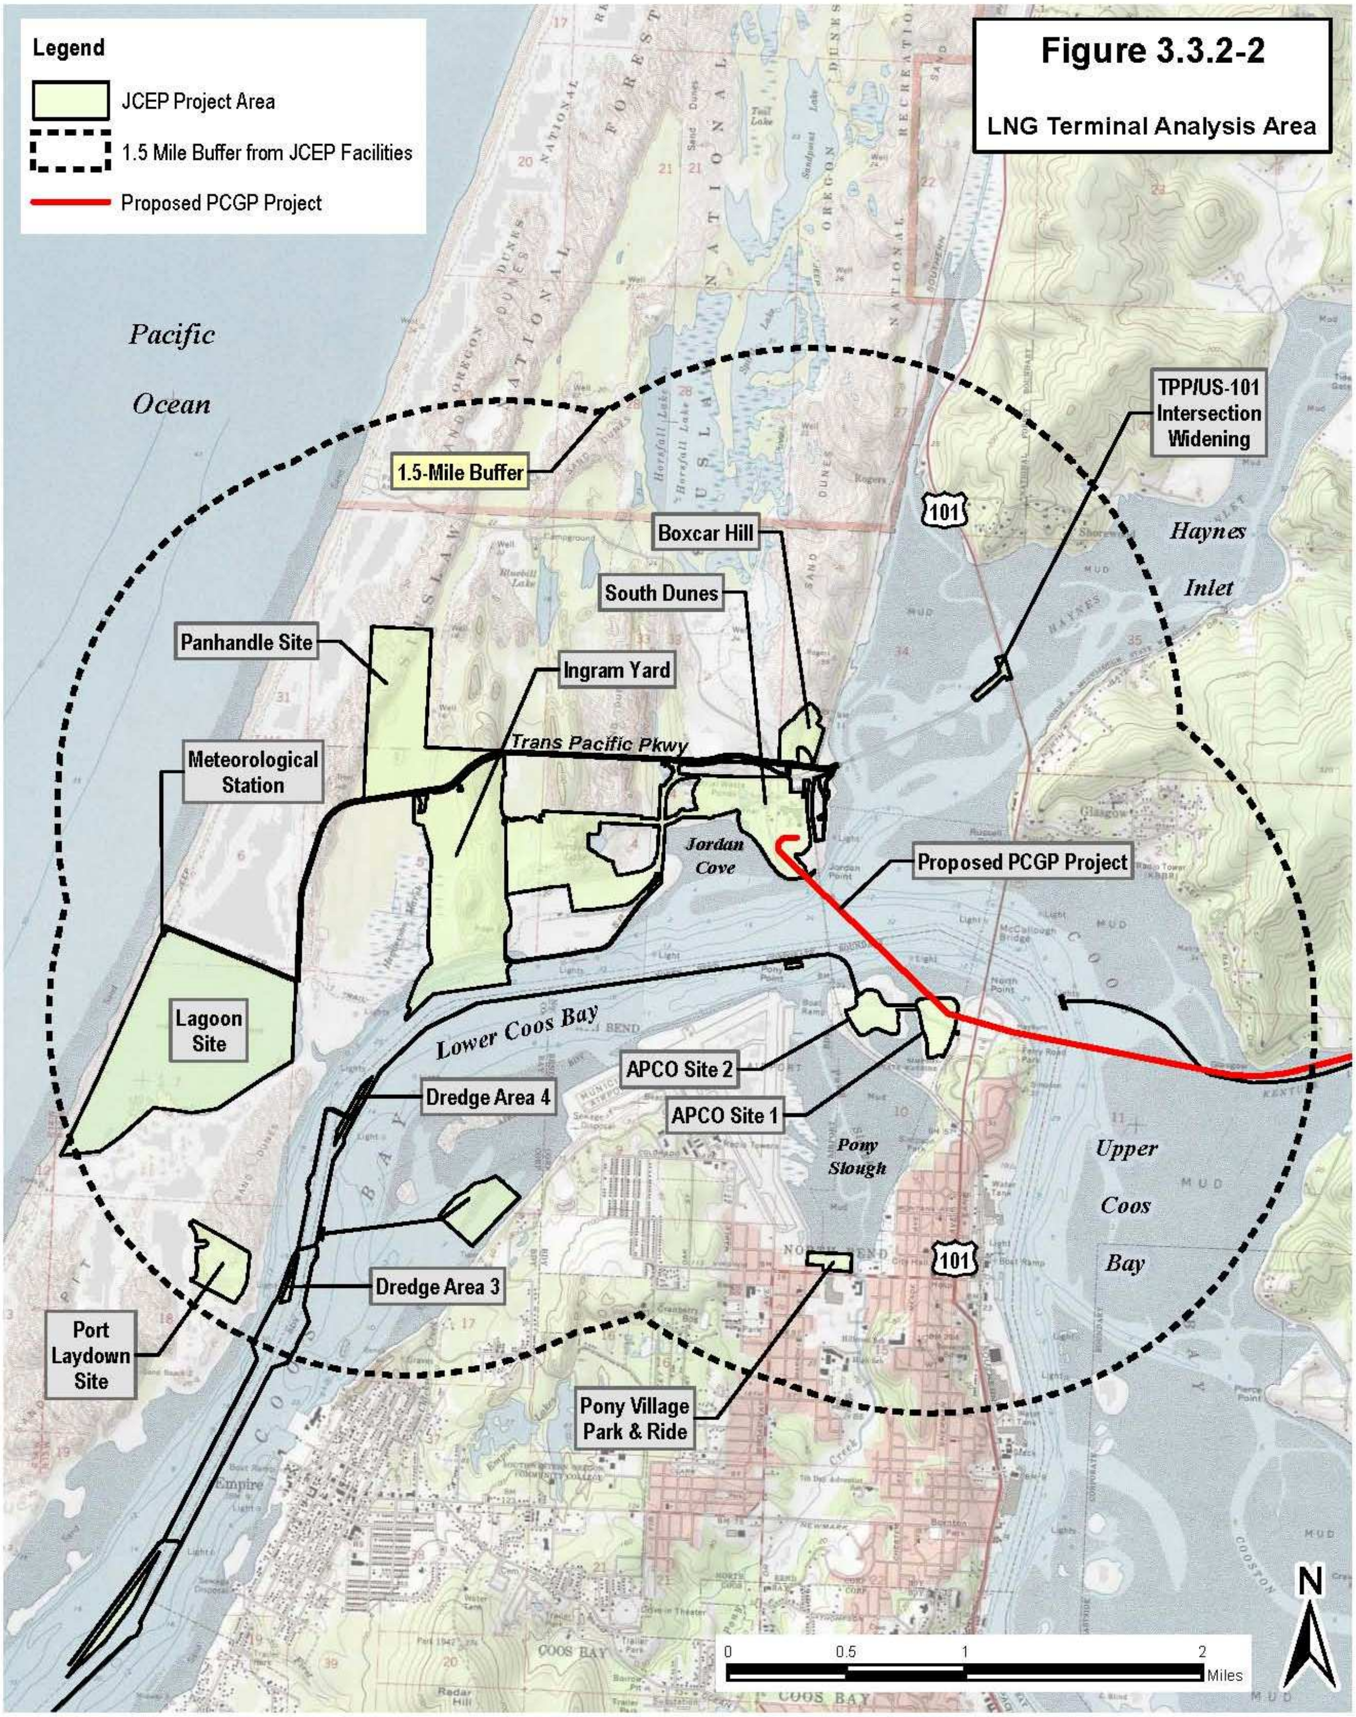


Exhibit 36
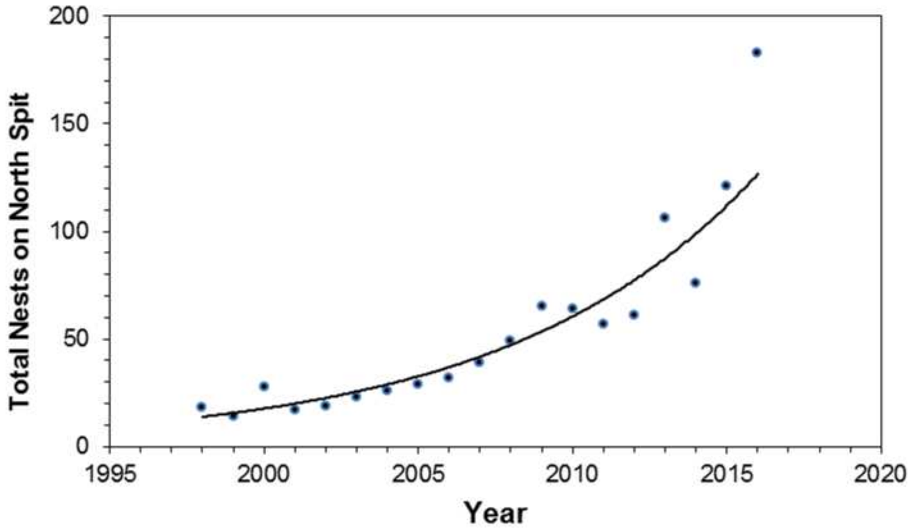
Page 214 of 1074



Source: Lauten et al. 2016

Figure 3.3.2-3 Total Number of Western Snowy Plover Nests Observed on the Coos Bay North Spit from 1998 to 2016. The increasing exponential trend is significant (r^2 = 0.92, P<0.001)

However, overall nest success at the North Spit in 2016 was the lowest since monitoring began and over 40 percentage points lower than 2015 (Lauten et al. 2015; Lauten et al. 2016). In 2016, combined nest success at the three sites measured at the North Spit was 35 out of 183, or 19%. Although 100 more eggs were laid at the North Spit in 2016 than in 2015, more than 100 fewer eggs hatched, yielding the lowest recorded hatch rate for this site (Lauten et al. 2016). The mean fledglings per male was 0.6, the lowest rate in the 13-years of study, considerably lower than the average of 1.34 +/- 0.33 over that time (Lauten et al. 2016). Lauten et al. state that "the low number of fledglings per resident male was due to many males never successfully hatching nests, and thus having no productivity in 2016." In 2016, a total of 149 adult plovers were determined to be present at the North Spit, all of which were residents. This is the largest plover population of the nine study areas (Lauten et al. 2016). Western snowy plovers may be encountered in the LNG carrier transit route from nearshore coastal waters to the LNG Terminal.

In the 2016/2017 winter window survey, 91 western snowy plovers were observed at the Coos Bay North Spit on US Army Corps of Engineer and BLM lands. No plovers were documented on the Horsfall Beach – N Jetty Coos Bay area (US Forest Service, County and Department of State Lands). There has been an increase in the number of wintering birds observed in this area beginning in 2015/2016 counts (85 birds) compared to the previous six year counts that ranged from 10 to 37 birds) (FWS 2018a).

Habitat

The northern end of critical habitat on the North Spit is approximately 2.6 miles from the LNG Terminal site. Nesting habitat, reported by ORBIC (2017a), extends north of the North Spit designated critical habitat for nearly 2 miles along the beach. The 2016 surveys on the North Spit indicated that the closest active nest to the Project was approximately 1 mile from the LNG Terminal site, which is approximately 0.5 mile south of Horsfall Beach (Lauten et al. 2016). The Meteorological Station is located approximately 100 feet east of the northern extent of known nesting sites (ORBIC 2017a). In 1990, one western snowy plover nest was documented at Menasha Spoils at the mouth and along the east side of Pony Slough at its confluence with Coos Bay (ORBIC 2017a), approximately 0.2 mile west of MP 1.08 where the HDD exits at North Point from crossing beneath Coos Bay. Since 1990, vegetation has invaded the Menasha Spoils site and the site may no longer be suitable as snowy plover nesting habitat since it is no longer an expanse of sparsely vegetated interdune flats. The nest was unsuccessful and there have been no nest sites documented within the Coos Bay estuary since 1990.

The existing land use of the LNG Terminal site is industrial. It has been disturbed by past and present activities. The site area has been filled in the past as evidenced by deposits of clamshells and wood chips and it is a licensed landfill facility. Elevation ranges from near sea level to an approximate elevation of 67 feet. Topography is variable, ranging from low lying deflation basins to semi-stable dunes. Existing vegetation comprises upland coniferous dune forests and upland herbaceous dominated areas.

There is no suitable habitat for western snowy plover within the JCEP Project Area.

Critical Habitat

No designated critical habitat for western snowy plover is present in the LNG Terminal analysis area. The northern end of critical habitat (OR-10) on the North Spit is located approximately 2.6 miles from the LNG Terminal site.

3.3.2.3 Effects of the Proposed Action

Direct Effects

Direct effects of the proposed action include increased noise associated with construction of the LNG Terminal and operation activities associated with LNG carrier traffic.

<u>Noise</u>

Noise associated with construction and operation of the facility is the only potential direct effect to plovers associated with the proposed action. The 2007 western snowy plover recovery plan states that: "sources of noise that would disturb snowy plovers should be avoided," but the levels of noise likely to disturb plovers are not provided. The recovery plan identifies noise associated with dredging as having a potentially negative effect on breeding and wintering western snowy plovers; noise associated with driftwood removal, especially if chainsaws and vehicles are used, can disrupt nesting; noise from beach cleaning machinery, from beach pyrotechnics, and from aircraft overflights (especially helicopters) can also cause adverse effects (FWS 2007a).

Ambient noise levels in the vicinity of the LNG Terminal were measured continuously for 24 hours between August 31 and September 1, 2005 at two residences (noise sensitive areas [NSA]), one of which was 1.4 miles south of the Terminal and the other 2.3 miles east. A new sound level survey was performed in May 2017. Ambient noise levels were not reported directly at the LNG Terminal site or on the Coos Bay North Spit (see JCEP's Resource Report 9). Average noise levels from these studies of 52.7 dBA at NSA 1, south of the LNG Terminal site, and 65.2 dBA at NSA 2, east of the site. At REC 1, the recreation area west and northwest of the LNG Terminal site, ocean surf sounds are a significant and continuous source of ambient sounds. Occasional aircraft could be heard at the Southwest Oregon Regional Airport just across the bay from the site. NSA 3, the Horsfall campground northeast of the LNG Terminal, and REC 1 were added to the 2017 noise study. The ambient noise results at these sites was 56.3 dBA at NSA 3 and 55.2 dBA at REC 1 (see JCEP's Resource Report 9). Local conditions such as aircraft, vehicle traffic, vegetation, topography, breaking waves, and winds characteristic of the location can alter background noise conditions. Noise levels at existing NSAs nearest the LNG Terminal site are controlled primarily by vehicular traffic. Noise levels experienced at the NSAs are similar in level to those in suburban areas where traffic is the primary source of noise (see JCEP's Resource Report 9). Sound levels (dB) at outdoor rural residential locations of about 40 dB, averaged for day and night periods (see for example, EPA 1974) have been accepted as standard. More than likely, ambient noise levels on the North Spit, near breaking waves, would be higher than 40 dB; noise generated by breaking wavecrests in the surf zone can be 15 dB higher than background levels (Dean 1999). Daytime ambient noise is typically 10 dB higher that night levels (EPA 1974).

Construction – LNG Terminal Facilities

Construction of the LNG Terminal site wouldcontribute to potential noise sources within the analysis area. Noise levels 50 feet away from typical construction equipment that might be used during LNG Terminal construction are provided in table 3.3.2-1.

TABLE 3.3.2-1

Average Maximum Noise (Lmax) at 50 feet from Construction Equipment and
Estimated Distance to Attenuate to Ambient Levels near the Surf Zone on the North Spit a/

Construction Activity	Equipment	Noise dBA (Lmax measured at 50 feet) b/	Distance (feet) to Attenuate to Assumed Ambient Noise Level of 55 dBA a/	
			Soft Site Reduction at 7.5 dBA per double of distance	Hard Site Reduction at 6 dBA per double of distance
Clearing and Grading	Grader	85	800	1,600
	Scraper	84	729	1,425
	Warning Horn	83	665	1,270
	Dozer	82	606	1,131
	Excavator	81	553	1,008
	Backhoe	78	419	713
	Pickup Truck	75	317	504
	Flatbed Truck	74	289	449
Rock Excavation	Mounted Impact Hammer	90	1,270	2,851
	Auger Drill Rig	84	729	1,425

	Air Compressor	78	419	713
	Welder Torch	74	289	449

a/ WSDOT 2011
b/ FHWA 2006

The standard for noise reduction from point sources such as construction machinery is 6 dBA per doubling of distance under hard site conditions (over calm water, or hard, smooth ground surface) and 7.5 dBA per doubling of distance under soft site conditions (because of roughened ground and/or vegetation cover; WSDOT 2011). Based on the data in table 3.3.2-1, the noise produced by construction activities would attenuate to daytime ambient noise levels (estimated at 55 dBA because of breaking wave noise) within distances of 230 feet to 2,850 feet, depending on equipment/actions and hard site or soft site reduction ground surface conditions. Obscuring vegetation (tree cover), topography (interruption of line-of-sight), and atmospheric conditions (wind, air temperature, humidity) also affect noise reduction but can be highly variable between locations and over time and are generally not taken into account in estimates of noise attenuation over short distances (see JCEP's Resource Report 9). Consequently, predictions of noise levels some distance from the noise source are likely to be higher than actual noise levels. Based on this information, general construction noise would not affect nesting or wintering western snowy plover located approximately 1 mile from the LNG Terminal.

Construction of the LNG Terminal and slip is expected to take 60 months (see JCEP's Resource Report 1). Prior to the excavation work starting for the LNG carrier slip, an open cell sheet pile bulkhead and retaining wall would be installed. Sheet piling is typically installed with a vibratory pile driver. Pile-driving activities would take place over approximately an 24-month period and are expected to occur on a schedule of two shifts, 6 days per week (see JCEP's Resource Report 9). Sheet pile driving would occur initially followed by the on-shore berthing structures as the marine foundation work begins. Sheet piling could be installed during the snowy plover breeding, nesting or rearing periods. The cumulative long term average airborne sound level created by pile driving activities for 14 impact pile driving rigs and 6 vibratory pile driving rigs in operation, simultaneously, was used to calculate the day and night sound levels (L_{nd}) (see JCEP's Resource Report 9). The same analysis model was used to calculate the pile driving daytime average (L_d or L_{eq} daytime) to determine potential impacts to nesting and wintering snowy plovers. The noise produced by sheet pile and pile installation activities would attenuate to daytime ambient noise levels (estimated at 55 dBA because of breaking wave noise) within distances of approximately 4,200 feet (SRL 2017). Based on the distance of construction from western snowy plover critical habitat (2.6 miles) and potential nesting sites (1 mile) on the North Spit, acoustic disturbances from the proposed action are not expected to affect western snowy plover wintering, breeding, nesting, or rearing activities.

A Meteorological Station would be installed on the west side of the Lagoon adjacent to the northern extent of the snowy plover nesting area (ORBIC 2017a). In reviewing the Western Snowy Plover Annual Reports from 2010 to 2017, the number of documented nests at the north end of Coos Bay North Spit is low and no nests have been documented immediately adjacent to the proposed location for the meteorological station. The annual reports documented one nest located about 1.8 miles north of the station in 2016 and 2017 and one to three nests per year located 1.3 to 3 miles south of the station during this eight-year period (FWS 2018a). Although western snowy plovers were not observed during the winter window surveys, they could occur on the beach adjacent to the station but this area is not documented as being used in the winter. Based on this information, the use of the beach by snowy plovers immediately adjacent to the meteorological station is likely low. The Meteorological Station would be constructed outside the nesting season (March 15 to September 15) to avoid disturbance to snowy plovers. The station would be mounted on an approximately 30 to 40-foot-high lattice tower. If guy wires are required during final design, bird deterrent measures would be added to the wire to reduce the likelihood of bird collisions. Deterrent measures such as cones or other anti-perching/anti-nesting devices would also be installed on any surface that could provide potential perching/nesting habitat for predatory species. Security lighting would be installed at the station and would be shielded in order to minimize glare while meeting safety requirements.

Additional construction staging and temporary laydown of equipment would occur during construction of the LNG Terminal at the Port Laydown site. This site is located on the North Spit over 3,500 feet from the northern extent of the snowy plover nesting area (ORBIC 2017a). Based on the data in table 3.3.2-1, noise produced by construction activities would attenuate to below daytime ambient noise levels in the vicinity of western snowy plover nests.

The Navigation Reliability Improvements would occur in four locations along the edge of the FNC. Access to Navigation Reliability Improvements will be by marine transport. No land-based access near primary snowy plover habitat is planned for pedestrians or vehicles. Dredge Area 1 is located approximately 0.25 mile from known nesting habitat and designated Critical Habitat OR-10. Dredging operations would take place within the ODFW in-water work window, which is outside of the nesting period for western snowy plovers but wintering birds may forage on the bay side of the North Spit. An airborne noise analysis for dredging determined that the 55 dBA contour, which is the estimated ambient noise level, would extend to the nearshore area of the bay where plovers may forage. Airborne noise from dredging within Critical Habitat was determined to be 40 to 45 dBA. Predicted dredging noise levels are shown in figure 9.4-3 in JCEP's Resource Report 9. Since these levels are below estimated ambient noise levels, dredging is not anticapted to impact wintering plovers. The remaining dredge areas are located over one mile from known nesting habitat and are not expected to impact snowy plovers during winter or nesting seasons.

While noise levels from dredging activities are anticipated to be at or below ambient noise levels, temporary mooring piles to support the dredging equipment may need to be set with an impact hammer. Impact hammers could be used between 0.25 mile and about 1 mile from known snowy plover habitat. As noted above in Table 3.3.2-1, mounted impact hammers attenuate to 55 dBA at 2,851 feet over hard site conditions and 1,270 feet over soft site conditions. The areas between the dredge areas and snowy plover habitat are a mix of hard and soft site conditions; the distance varies based on the roughness of the water and other environmental conditions on a given day. These distances are within the range of snowy plover habitat along the eastern edge of primary nesting area at 0.25 mile (1,370 feet) away from Dredge Area 1. If present, noise from an impact hammer could temporarily disturb snowy plovers wintering within this area on the North Spit.

The Navigation Reliability Improvement disposal site is located at the APCO site. Placement of dredge spoils could create nesting habitat for western snowy plover. Creation of nesting habitat for plovers is considered undesirable because it could result in dispersal of existing breeding populations on the North Spit to an area where they could be more susceptible to nest predations. Additionally, any habitat created would be temporary, as opposed to the permanent habitat available on the North Spit. To prevent plover use of the area, it is recommended to plant American dune grass (FWS 2017b).

Construction - Pipeline

Construction of the Pipeline across Coos Bay may occur between January 1 through August 31, which is within the nesting and fledgling season for the species on the Oregon coast (early April through August; FWS 2001). It is not possible to anticipate any local occurrence of western snowy plover in the project area at the time of construction, although habitat near the HDD activity does not currently provide suitable nesting habitat, even though an historic snowy plover nest was documented at Menesha Spoils in 1990, approximately 0.2 mile from HDD activity.

Construction of the Jordan Cove Meter Station and the HDD beneath Coos Bay will require surface disturbance of 13.63 acres of previously developed industrial land on the Jordan Cove side and 2.87 acres of industrial land on the North Point side 0.2 mile from Menasha Spoils at the mouth and along the east side of Pony Slough at its confluence with Coos Bay. Neither site currently provides suitable nesting habitat.

Operation

The following major noise-producing equipment would normally be in operation at the LNG Terminal:

- five (5) refrigerant compressors, combustion turbines, heat recovery steam generators (HRSGs), and associated piping;
- refrigerant compressor interstage and discharge aerial coolers;
- three (3) steam turbines and their associated air-cooled condensers;
- two (2) boil-off gas (BOG) compressors with interstage and discharge aerial coolers; and
- various other condensers, coolers, pumps and valves.

The above equipment packages have been specified to meet sound level requirements appropriate to support an overall far-field sound level that does not exceed the applicable FERC regulatory limits. As explained in section 9.3.2.1 of JCEP's Resource Report 9, a constant sound level of less than 48 dBA would ensure compliance with all applicable regulations, including the FERC requirement limiting the average day/night noise level at the nearest residential NSAs to ≤55 dBA. With that restriction, noise generated by equipment at the LNG Terminal would not exceed 55 dBA at western snowy plover breeding, nesting or rearing habitat on the North Spit. Therefore, noise from operations at the LNG Terminal would have no affect the snowy plover.

Operational activities at the Meteorological Station will be maintenance only. Planned maintenance activities that would generate noise levels above ambient conditions would be scheduled outside of nesting season to minimize potential disruption to western snowy plover. Other activities will be limited to existing pathways and inside fence lines.

During operations of the Pipeline, aerial inspections would occur over the permanent right-of-way. Nesting snowy plovers are not expected to be impacted since the closest nesting population is more than four miles from proposed aerial inspections and air traffic is a constant disturbance with the existing North Bend Municipal Airport within less than three miles of the nesting habitat on North Spit.

Indirect Effects

All indirect effects to western snowy plovers are expected to be due to an increased human population base, whether as a result of the requirements of the action itself (the workforce needed to construct or operate the Project) or as a consequence of the action (need for ancillary goods, services, opportunities resulting from the Project). Potential indirect or secondary effects by a project include increased recreation demand (including OHV use), increased habitat conversion, habitat degradation by human encroachment, and increased illegal harvest (Comer 1982).

The following indirect effects of the proposed action on western snowy plovers could occur: 1) increased human presence at the LNG Terminal site, and 2) increased predation of western snowy plovers by crows and ravens due to increased human presence. In addition, increased human presence may lead to destruction of nests and/or disturbance of plovers from the following activities: OHV usage, visitors or their dogs, predators such as crows and ravens (that are attracted to areas with humans and their garbage), beach walking or jogging, horseback riding, and beach raking.

Human Presence

The Coos Bay North Spit is currently utilized by a variety of recreational users for OHV driving, beach combing, boating, bay-shore clamming and crabbing, day hiking, picnicking, kayaking, surfing, and fishing (Natural Resource Trustees 2006). In addition, the North Spit has become one of the most popular horseback riding areas in the region (BLM 2005). Snowy plover habitat on the North Spit is currently owned by the BLM and COE and managed by the BLM, Forest Service, and OPRD. This area is known as the Coos Bay North Spit Recreation Management Area (CBNS RMA) and extends about 3.4 miles north from the southern tip of the North Spit along the ocean-side shoreline, encompassing some, but not all, of the Snowy Plover Critical Habitat on the North Spit.

According to the OPRD 2007 Plover Habitat Conservation Plan, the peak number of visitors to the 15.6 miles of beach from Tenmile Creek to Coos Bay (the beach segment including the CBNS RMA) was 3.8 people per mile (OPRD 2005 and 2007), and the distribution of these visitors was described as "dispersed." The number of visitors per mile at the eight recreational management areas currently utilized by nesting plovers ranged from 3.5 to 13.2 (OPRD 2007). The Habitat Conservation Plan for Western Snowy Plovers published by the OPRD in September 2007 states (with regard to the CBNS RMA), "This beach is open to street legal vehicle driving only, but is closed during the breeding season. There is illegal ATV [all-terrain vehicle] use on this beach. Recreation use here is low, but higher than other RMAs due to its close proximity to Coos Bay/North Bend/Charleston. The area is a popular surfing site."

The primary reasons that the public accessed the North Spit beach were to walk/run (16 percent) or to relax (21 percent). Of those surveyed, 4 percent reported bringing dogs to the beach (OPRD 2007). The percentage of people with dogs was significantly lower than the statewide average of 35 percent. All of the human-caused disturbances listed above can result in destruction of nests (by dogs or through inadvertent trampling and deliberate vandalism) and in diverse plover responses to human presence, including: flushing from and abandonment of nests, separation from broods, shifting to marginal habitat, cessation of foraging and adoption of vigilant or cryptic behaviors (FWS 2007a).

The number of people employed on the North Spit in 2007 was approximately 110 (Southport Lumber Products – 70, Roseburg Forest Products – 20, DB Western Marine Division – 20). The Project would result in a large but temporary increase in people employed on the North Spit during construction (an average of 1,023 construction workers per month over the four-year construction period) and a much smaller long-term increase of operations staff (180 employees at the LNG Terminal). Construction would take approximately 60 months, and the number of construction personnel would peak at 1,996 workers.

An increase in workers supporting the Jordan Cove Project would likely result in an increase in recreational activities in the area. Recreation on the beach has been shown to cause a reduction in plover productivity. In total, it was estimated that between 2000 and 2006, recreational activities on the Oregon Coast resulted in the loss of 30 hatchlings and 11 fledglings per year, which equated to an annual loss of 5 adult equivalents (Jones and Stokes 2007). It is difficult to predict how the increase in short-term and long-term employment due to the LNG Terminal Site on the North Spit would translate into increased recreational use of areas near snowy plover habitat. However, it is reasonable to assume that the LNG Terminal operations staff, their family and friends would be introduced to the area, and some minor increases in recreational use could occur. This increase in recreational use could result in increased plover disturbance. However, mitigation measures to educate construction and operations employees on recreational use restrictions will be employed to minimize any such effect. The measures are discussed below in Conservation Measures, section 3.3.2.4.

Predators

Predation of snowy plovers along the Oregon coast has been attributed to the low nest success in 2016. Northern harriers (*Circus cyaneus*) supplanted corvids as the most frequently identified nest predator along the Oregon coast. A minimum of 61 nests were depredated by harriers in 2016, far more than the previous high of 20. Harriers-caused nest failure was far more prevalent at the North Spit than the other eight sites, accounting for 74% of total harrier depredation along the coast (45 of 61 nests; Lauten et al. 2016). One harrier was removed from the North Spit to alleviate nest depredation, although harrier depredation continued after its removal (Bell 2017 as cited in Lauten et al. 2016). Harriers are anticipated to be an ongoing threat to nesting plovers unless removed. The study suspects that harriers were also responsible for all unknown causes of depredation after April and likely some earlier depredations as well.

Corvids caused nine nests to be lost at the North Spit in 2016, where no corvid depredations had been recorded since 2005 (Lauten et al. 2016). In study areas along the coast where harriers have been removed, ravens in particular have increased their plover depredation rates. Exclosures have been used less frequently in recent years and not at all in 2016 due to increased nest success, presence of predators that can cause adult plover mortalities at exclosed nests, workload limitations, and a plover population above recovery goals (Lauten et al. 2016).

Increased foot traffic through snowy plover nesting has been shown to increase scavenger predation (Buick and Paton 1989; Castelein 2008). Therefore increased recreational use of the North Spit ocean beaches by off duty employees could create additional predation pressure. Food enticements associated with human presence could increase predator populations on the North Spit. Corvids, coyotes, cats and skunks are all curious, adaptable animals attracted to food waste and non-food human refuse. An increase in the numbers of these predators could be detrimental to the recovery of snowy plover populations; however, mitigation measures will be employed to minimize any such effect. The measures are discussed below in Conservation Measures, section 3.3.2.4

Cumulative Effects

Additional projects within the action area (estuarine analysis area and the LNG Terminal analysis area) are anticipated as human population growth continues in the region. Associated road and commercial development, as well as maintenance and upgrading of existing infrastructure within the estuary, are likely to occur in the foreseeable future. For example, the Port of Coos Bay owns and operates the Charleston Marina, the Charleston Marina RV Park, and Charleston Shipyard. As a component of the Port's economic development, the focus of the Charleston Marina Master Plan is to develop commercial fishing and seafood processing, recreational fishing and boating, tourism, and growth in the retail and commercial sectors. Other, similar economic developments in the region could occur and, if they did, could contribute to the region's human population growth which could be detrimental to western snowy plovers within and around the Coos Bay estuary.

A standard of "reasonably certain to occur" is clarified as "those actions that are likely to occur, bearing in mind the economic, administrative, or legal hurdles which remain to be cleared".

Further, NMFS provides that "speculative actions that are factored into the cumulative effects analysis add needless complexity into the consultation process…" (51 Federal Register 19933). No specific state or private actions have been identified within the action area that meet this standard. Further, activities described above are somewhat speculative in nature and cannot be quantified here. Therefore, a logical conclusion is that there would be no cumulative effects to western snowy plover associated with the proposed action.

Within the action area and estuarine analysis area, gradual habitat and water quality improvements may also occur over time as federal, state and private conservation and habitat enhancement efforts are implemented. There are a number of potential federally permitted projects (e.g. repair of the entrance jetties and widening and deepening of the lower portion of the Federal Navigation Channel) that could result in cumulative effects. However, because these projects would require federal permits, their impacts would be evaluated through the federal permitting process when and if they occur.

Critical Habitat

The northern end of critical habitat on the North Spit, OR-10, is located approximately 2.6 miles from the LNG Terminal. The proposed action would not directly or indirectly affect designated critical habitat or any of the essential physical and biological features within OR-10 that might be utilized by western snowy plovers. Cumulative effects due to increased human presence may occur within the action area.

3.3.2.4 Conservation Measures

Current management activities and use restrictions within the Coos Bay North Spit Recreation Management Area include:

- predator management (i.e., nest exclosures, lethal and non-lethal predator removal and hazing);
- symbolic fencing (ropes and signs installed around nesting areas);
- habitat restoration (removal of European beachgrass, placement of shell hash, maintenance of gaps through the dunes);
- public outreach and education provided by BLM staff;
- monitoring of snowy plover populations;
- recreational use restrictions in place from March 15 – September 15 each year, including:
  - seasonal re-routing of the foredune road;
  - vehicles, camping, and dogs are prohibited;
  - kite flying would be prohibited under the draft conservation plan; and
- non-prohibited recreational use (i.e., jogging, beach combing, horseback riding) is restricted to the wet sand outside of roped and signed breeding areas.

JCEP will work with the agencies to assist with ongoing management activities and recreation use restrictions on the North Spit. Management activities may include fencing, siganage, application of shell hash, tree removal, beach grass elimination, and maintenance.

JCEP would mitigate potential impacts to western snowy plovers, including from increased predator density and increased human presence, through implementation of 1) BMPs, and 2) education and outreach programs.

Best Management Practices

Structures associated with the LNG Terminal would be monitored to discourage use by avian predator species. Frequent inspections would ensure that nests are not being constructed and all nests found would be removed immediately. It is anticipated that there would be sufficient inspections and other activities mandated by safety and security requirements to keep the structures nest free. However, in the unlikely event that a nest becomes established and it is not discovered until young birds are present, the disposition of the nest would be handled in accordance with any applicable statutes including the Migratory Bird Treaty Act.

During construction and operation, the LNG Terminal site would be kept clear of construction debris and food wastes that could attract predators of the western snowy plover. Covered, animal-resistant receptacles would be provided in eating and break areas, parking lots, and at appropriate locations around the construction site. During construction, the site would be monitored on a daily basis to remove any food or other debris left by construction workers. During operations, the facility and grounds would be regularly inspected to ensure that no garbage is allowed to accumulate. These measures will minimize potential predation of snowy plover eggs and chicks from increased predator presence.

The dredged material placement areas would be regularly policed to ensure that no predator denning is occurring in the hillocks. The proposed placement areas would be located near construction activities that would discourage use by individual birds. If necessary, nylon mesh or other exclusion fencing would be installed around the perimeter of the placement areas to prevent the establishment of coyote or skunk dens until the slopes are stabilized or constructed upon.

To prevent plover use of the APCO dredge disposal site, it will be stabilized using American dune grass or other appropriate measures in consultation with USFWS.

Access to Navigation Reliability Improvements dredging areas will be by marine transport. No land-based access near primary snowy plover habitat is planned for pedestrians or vehicles.

The Meteorological Station would be constructed outside the nesting season (March 15 to September 15) to avoid disturbance to snowy plovers. If guy wires are required during final design, bird deterrent measures would be added to the wire to reduce the likelihood of bird collisions. Deterrent measures would also be installed if the final design provides any potential perching habitat for predatory species. Security lighting would be shielded in order to minimize glare while meeting safety requirements. Planned maintenance activities at the Meteorological Station that would generate noise levels above ambient conditions will be scheduled outside of nesting season to minimize potential disruption to western snowy plover. Unplanned activities will be limited to existing pathways and inside fence lines.

Education and Outreach

Surveys conducted in 2002 indicated that 76 percent of beach visitors were unaware of restrictions associated with snowy plovers (OPRD 2007). This indicates that increased education could have a substantial impact on public awareness of issues surrounding snowy plovers. Furthermore, the Forest Service at the Oregon Dunes National Recreation Area and the BLM staff have reported that the majority of contacted individuals are more willing to comply with beach-use restrictions after better understanding the reasons for them (FWS 2007a).

Although snowy plovers do not occur on JCEP property, increased human presence can increase the presence of predators locally which could potentially expand their territory to snowy plover-occupied areas. JCEP would train all construction and operations staff on the need for snowy plover conservation; current snowy plover regulations and recreational use restrictions; and the importance of conservation measures, including: litter control, avoidance of nesting and foraging areas, keeping pets on-leash, and remaining on established roads and trails in designated critical habiat. The training program would be developed based on guidance provided in appendix K of the 2007 Plover Recovery Plan (OPRD 2007). JCEP would consult with agencies prior to implementation.

3.3.2.5 Determination of Effects

Species

The Project **may affect** western snowy plovers because:

- impact hammer noise associated with the Navigation Reliability Improvement temporary facilities may disturb wintering western snowy plovers if present along the eastern edge of the primary nesting area on the North Spit;
- the closest western snowy plover nesting habitat to the Project is on the North Spit approximately 100 feet from the Meteorological Station and 1 miles from LNG Terminal site, and the primary active nesting by western snowy plovers occurs approximately 2.0 miles from the LNG Terminal at its closest location to the Project;
- the Project would result in a large but temporary increase in people employed on the North Spit during construction (1,996 construction workers in the peak months) and a much smaller long-term increase of operations staff (180 permanent employees at the LNG Terminal);
- it is reasonable to assume that the LNG Terminal construction and operations personnel would increase recreational uses of the North Spit, which could result in increased plover disturbance; and
- scavengers and predators (corvids, coyotes, striped skunk, feral cats), most of which are encouraged or attracted by human disturbance such as campsites, garbage dumps, work sites or even footprints in the sand, may increase effects to nesting plovers as human use of the North Spit increases.

The Project is **not likely to adversely affect** western snowy plover because:

- noise at active nest sites (approximately 1 mile) and critical habitat (approximately 2.6 miles) due to the loudest anticipated construction activity (pile driving) is not expected be above ambient levels;
- construction of the Meterological Station would occur outside the nesting season; and
- JCEP would minimize potential indirect effects to the western snowy plover by humans, pets, vehicles or human-attracted predators through implementation of 1) BMPs to minimize predator density related to increased human presence, and 2) education and outreach programs intended to train all construction and operations staff on the need for snowy plover conservation; current snowy plover regulations and

recreational use restrictions; and the importance of conservation measures, including: litter control, avoidance of nesting and foraging areas, keeping pets on-leash, and remaining on established roads and trails in designated critical habitat.

Critical Habitat

The Project **may affect** designated critical habitat for the western snowy plover even though the northern end of critical habitat OR-10 on the North Spit is located approximately 2.6 miles from the LNG Terminal because.

- the Project is expected to require an average of 1,023 construction workers over the five-year construction period (up to 1,996 workers in the peak months). The additional human presence is likely to increase use of the North Spit with concomitant potential increase of pets, vehicles, and/or human-attracted predators.

However, the Project is **not likely to adversely affect** designated critical habitat for the western snowy plover because:

- JCEP would minimize potential secondary effects to the critical habitat PCE that identifies disturbance by humans, pets, vehicles or human-attracted predators through implementation of 1) BMPs to minimize predator density related to increased human presence and habitat removal, and 2) education and outreach programs intended to train all construction and operations staff on the need for snowy plover conservation; current snowy plover regulations and recreational use restrictions; and the importance of conservation measures, including: litter control, avoidance of nesting and foraging areas, keeping pets on-leash, and remaining on established roads and trails.

3.3.3 Marbled Murrelet

3.3.3.1 Species Account and Critical Habitat

Status

Marbled Murrelet (MAMUs) in Washington, Oregon, and California were listed as threatened under the ESA on October 1, 1992 (FWS 1992a), and were subsequently listed as threatened by the State of Oregon under the Oregon Endangered Species Act in 1992. The final rule listing the MAMU cited loss and modification of forest nesting habitats, mostly by commercial timber harvest of Late Successional Old Growth (LSOG) forests, as the principal threat to the species, along with effects of coastal oil spills and gill-net fishing operations off the Washington coast (FWS 1992a).

Threats

Threats to MAMUs include loss of habitat, predation, effects of gill-net fishing, effects of offshore oil spills, and other factors. There are two components of MAMU habitat that are biologically important: 1) terrestrial nesting habitat and associated stands, and 2) marine foraging habitat, including prey spawning and concentration areas. Threats to MAMU can be found in both the terrestrial nesting environment and the marine foraging environment. Extensive harvest of LSOG the primary reason for listing the MAMU as threatened in 1992 (FWS 1992a). In 1992, the amount of old-growth forest in western Oregon and Washington had been reduced by about 82.5 percent from pre-harvest levels. Because MAMUs utilize old-growth forests for nesting, this dramatic loss of older forested habitats is a serious threat to these birds. Harvesting within previously contiguous areas of old-growth forest causes habitat fragmentation on large and small scales. As forest fragmentation increases, the threat of habitat loss due to windthrow is likely to increase. Fire has also affected older coastal forests; however, unlike clearcut timber harvest, fire often allows diverse structural characteristics to develop in regenerating forests, such as scattered surviving old-growth trees that can be utilized by MAMUs for nesting (FWS 1992a).

Predation is expected to be the principal factor limiting MAMU reproductive success and nest site selection (Ralph et al. 1995; Nelson and Hamer 1995). Known predators of MAMU adults, chicks, and eggs in the terrestrial environment include great horned owls, peregrine falcon, sharp-shinned hawk, northern goshawk, bald eagle, Steller's jays, ravens and other corvids. Common ravens account for the majority of egg depredation (Nelson and Hamer 1995). Predation rates are influenced mainly by habitat stand size, habitat quality, nest placement (on the edge of a stand versus the interior of a stand), and proximity of the stand to human activity centers. Fragmentation of forested stands by timber harvest increases the potential for avian predation (FWS 1992a). An increase in susceptibility of adults to predation can have greater impacts on MAMU populations than predation on eggs or young, as demographic modeling for MAMUs demonstrates (McShane et al. 2004).

Because MAMUs feed offshore, gill-net fisheries, especially for salmon, was an important mortality factor in 1992, primarily in Washington and British Columbia. New gill-netting regulations in northern California and Washington have reduced the threat to MAMUs (McShane et al. 2004). Offshore oil spills, such as the *Exxon Valdez*, have also adversely affected MAMUs by causing direct mortality (FWS 1992a). The 1999 oil spill associated with the grounding and wreck of the *New Carissa* on the Oregon coast near Coos Bay killed 252 MAMUs, the highest mortality for any spill during the 1993 to 2003 period (McShane et al. 2004). Oil spills and related mortality of MAMUs are believed to have remained constant since the species was listed. Although there has been a moratorium on offshore oil drilling off the California, Oregon, and Washington coastlines, there has been increased shipping traffic, including oil tankers, carrying the risk of future spills (McShane et al. 2004).

Other factors contributing to demographic threats and population viability include: 1) loss of genetic variation as a result of low population numbers and low immigration rates, 2) low potential for recolonization or recovery from local disturbances due to low immigration rates, and 3) bacterial, fungal, parasitic, and viral diseases, including potentially West Nile Virus (McShane et al. 2004).

The 2004 MAMU 5-year review (FWS 2004a) and the 2009 MAMU 5-year review (FWS 2009c) continue to consider habitat loss, high predation rates, mortality from oil spills, or entanglement in fishing nets as the primary threats to MAMU. Additionally, the 2009 5-year review identified environmental and anthropogenic factors in the marine environment as new threats to MAMU. Another 5-year review was initiated in April 2017 (FWS 2017c).

Species Recovery

FWS published a recovery plan for the MAMU in 1997 for Washington, Oregon, and California (FWS 1997). The objective of the recovery plan is to stabilize population size at or near current levels by increasing population productivity and removing and/or minimizing threats to survivorship. In the short-term, specific actions identified as necessary to stabilize the population included maintaining occupied habitat, maintaining large blocks of suitable habitat, maintaining and enhancing buffer habitat, decreasing risks of nesting habitat loss due to fire and windthrow, reducing predation, and minimizing disturbance. Long-term conservation actions included increasing productivity and population size, increasing the amount, quality, and distribution of suitable nesting habitat, protecting and improving the quality of the marine environment, reducing or eliminating threats to survivorship, reducing predation in the terrestrial environment, and reducing anthropogenic sources of mortality at sea (FWS 1997).

The recovery plan divided the range of the Washington, Oregon, and California MAMU population into six Conservation Zones that extend inland a distance of up to 35 miles, coinciding with the "Inland Zone 1" boundary line described by the Forest Ecosystem Management Assessment Team (FEMAT) for the Northwest Forest Plan (NWFP): Puget Sound (Conservation Zone 1), Western Washington Coast Range (Conservation Zone 2), Oregon Coast Range (Conservation Zone 3), Siskiyou Coast Range (Conservation Zone 4), Mendocino (Conservation Zone 5), and Santa Cruz Mountains (Conservation Zone 6). FEMAT Inland Zone 1 contains large blocks of suitable habitat critical to the recovery of the MAMU within California, Oregon, and Washington. The proposed action occurs within the highest density zones along Oregon's coast (Conservation Zones 3 and 4), although the largest populations of MAMUs are found in Puget Sound and Strait of Juan de Fuca of Washington – Zone 1 (Huff et al. 2006). Management for Conservation Zones 3 and 4 recommend the following: maintain designated occupied sites, minimize loss of unoccupied but suitable habitat, and decrease the time for development of new habitat. The recovery plan also recommended that specific recovery efforts should focus on maintenance of suitable and occupied MAMU nesting habitat in BLM-administered forests (FWS 1997).

FWS (2006c) concluded that the maintenance and/or increase of suitable nesting MAMU habitat in relatively large, contiguous blocks, whether occupied or unoccupied, would be needed to recover the MAMU, since unoccupied suitable habitat in proximity to occupied habitat could be used by dispersing MAMUs. Despite the above protection measures, an approximately 12.1 percent decline (2 percent decline on federal, 27 percent decline on nonfederal lands) in the amount of available, higher suitable nesting habitat has been observed since the NWFP was implemented (1994 to 2012; Raphael et al. 2016). On federal lands, stand-replacing fires are the major cause of of habitat loss, but also timber harvest and insect damage or disease have also caused losses; habitat loss on nonfederal lands is primarily the result of timber harvest (Raphael et al. 2011 and 2016). Together wildfire and timber harvest have been identified as the primary causes of habitat loss since the NWFP was implemented in 1994 (Falxa and Raphael 2016). Based on Maxtent habitat suitability modeling using updated gradient nearest neighbor (GNN) 2012 habitat data and analyses approach, Raphael et al. (2016) estimated that there are approximately 2.2 million acres of moderately high to high suitable habitat available within the following states: Washington (1.3 million acres), California (108,900 acres), and Oregon (774,700 acres).

Life History, Habitat Requirements, and Distribution

The MAMU is a long-lived, small seabird that spends most of its life in the marine environment, but utilizes a distinct nesting habitat type from other Alcidae (guillemots, puffins, auklets and murres), nesting primarily in coastal, old growth forests characterized by large trees, multi-storied stands, and moderate-to-high canopy coverage from Alaska to Monterey Bay, California (FWS 2006c). They are also known to nest in mature forests with old-growth characteristics. Trees must have large branches or deformities such as high, moss-covered branches or branches with growths of dwarf mistletoe, which serve as nest platforms (Binford et al. 1975; Marshall 1988a; Naslund 1993; FWS 1997). Old-growth conifers generally provide the following requisite conditions for MAMU nesting: 1) openings in forest canopies for nest access, 2) nest platforms on large branches or tree deformities, 3) substrate (mosses or epiphytes) for a nest cup, 4) horizontal and vertical cover at the nest site, and 5) enough height above ground to allow for "drop take-offs" and "stalled drop-in" landings (McShane et al. 2004). Generally, forests that provide suitable nesting habitat and nest trees require 200 to 250 years to develop (FWS 2006c).

The distance inland that MAMUs breed is variable and influenced by a number of factors such as habitat availability, climate suitability, foraging range, and predation rates (McShane et al. 2004). In Oregon, MAMU nest sites and occupied stands are located as far as 30 to 40 miles from salt water (Mack et al. 2003), although most often sites are found within 12 miles of the ocean (FWS 1996). Social interactions may also play an important role in determining nesting location, since research has indicated that MAMUs in California and southern Oregon were less likely to occupy old-growth habitat if it was isolated from other nesting MAMUs by more than 3 miles (Meyer et al. 2002).

Murrelets do not form dense colonies, which is atypical for most seabirds; this is most likely to avoid detection by predators (Ralph et al. 1995). Also, in Oregon, MAMU occupied stands and nest sites are generally located away from high-contrast edge created by certain timber harvest practices and adjacent immature forests, most likely to reduce predation risk on eggs and juvenile MAMUs (Ripple et al. 2003), although many MAMU stands on BLM lands are located in highly fragmented landscapes (BLM 2014). Meyer et al. (2002) found at least a few years passed before birds abandoned fragmented forests. In northern California and southern Oregon, Meyer and Miller (2002) concluded that MAMU occupancy was most related to availability of low elevation, unfragmented old-growth forests within the fog zone that were close to highly productive marine areas. Federal lands account for the majority of suitable MAMU habitat in California, Oregon, and Washington (McShane et al. 2004).

These small seabirds spend most of their lives in the marine environment where they forage in shallow off-shore and inland saltwater areas on a variety of small fish and invertebrates, and large pelagic invertebrates (Marshall 1988a, 1988b, and 1989; Becker 2001). MAMUs forage by diving in relatively shallow waters [generally between 20 and 80 meters (65 to 262 feet)], averaging about 16 seconds in the water column per dive (Strachan et al 1995; Burkett 1995). In Oregon and Washington, anchovy, sand lance, and smelt appear to be the major prey types provided to chicks (McShane et al. 2004). MAMUs generally forage within 3 miles of shore in western North America, although during the breeding season they stay closer to the coast, e.g., within 1.2 miles in Oregon (McShane et al. 2004). Courtship, loafing, molting, and preening also occur in near-shore marine waters (Nelson 1997). The largest populations of MAMUs are in the Puget Sound and Strait of Juan de Fuca of Washington (Huff et al. 2006).

MAMUs are usually present year-round in California, Oregon, and Washington, whereas farther north in their breeding range, seasonal migration is common. MAMUs migrate back to breeding grounds in the north in early to mid-April (McShane et al. 2004). Research suggests that MAMUs demonstrate site fidelity (Huff et al. 2006).

Breeding is asynchronous in the MAMU, varying regionally, although generally occurring between April and September (McShane et al. 2004; Huff et al. 2006). Both sexes share the incubation and foraging duties, usually with duty exchanges occurring at dawn. One to two days after hatching the chick will be left alone while both parents forage at sea. The chick will receive 1 to 8 meals per day, with the majority of the meals delivered in the morning, usually before sunrise. Additional meals are delivered at dusk and occasionally throughout the day. Murrelet chicks fledge from the nest 27 to 40 days after hatching, usually at dusk (McShane et al. 2004). Existing data do not provide information on how far or where fledglings disperse.

Sex ratios of juveniles and adults are equal and breeding begins when birds are 2 to 5 years old; only 1 egg is laid per breeding season (McShane et al. 2004). A substantial proportion of nests is known to fail (Nelson and Hamer 1995); breeding success has been documented as high as 0.46 chicks per breeding pair in southern British Columbia but lower in northern California where telemetry studies documented between 0.135 and 0.324 chick per pair (McShane et al. 2004). Such low breeding success is not expected to sustain populations in which adult survivorship ranges from 0.83 to 0.93. The mean lifespan of MAMUs is 10 years (McShane et al. 2004).

Population Status

The exact population size of MAMUs is not known; however, the North American population is currently thought to be about 24,100 birds (with 95% confidence between 19,700 and 28,600 birds), based on counts at sea (Lynch et al. 2017). Within the Pipeline project area (Conservation Zones 3 and 4), the marbled murrelet population is estimated to be 15,556 birds in 2016 (with 95% confidence between 12,798 and 21,946 birds): 6,813 birds in Conservation Zone 3 (with 95% confidence between 5,389 and 8,821 birds) and 8,743 birds in Conservation Zone 4 (with 95% confidence between 7,409 and 13,125 birds).

In the early 1990s, MAMU abundance in Washington, Oregon, and California had been estimated at 18,550 to 32,000 (Ralph et al. 1995). In the late 1990s, population survey protocols were established to provide a consistent methodology for estimating MAMU population and population trends. Using the data and trends provided in Lynch et al. (2017), the trend in murrelet densities off-shore in Conservation Zones 3 and 4 has increased significantly ($P<0.05$) between 2000 and 2016. While this research indicates a positive trend, this positive trend in Conservation Zone 3 is uncertain (lower confidence interval overlaps zero). Using that trend, the predicted estimate of marbled murrelet densities within Conservation Zones 3 and 4 by proposed Pipeline in-service year (2022) is 5.77 birds per km^2 but could range from 3.30 to 8.24 birds per km^2 using the 95% prediction intervals (see table 3.3.3-0). Figure 3.3.3-1 shows the increasing population trend from 2000 to 2016 in Conservation Zones 3 and 4, combined, as well as projections of murrelet populations through construction and initial operation of the Pipeline (through 2022) using data from Lynch et al. (2017) which also shows an increasing trend in marbled murrelet density from 2000 to 2016 for all of Oregon (see Figure 4 in Lynch et al., 2017).

TABLE 3.3.3-0

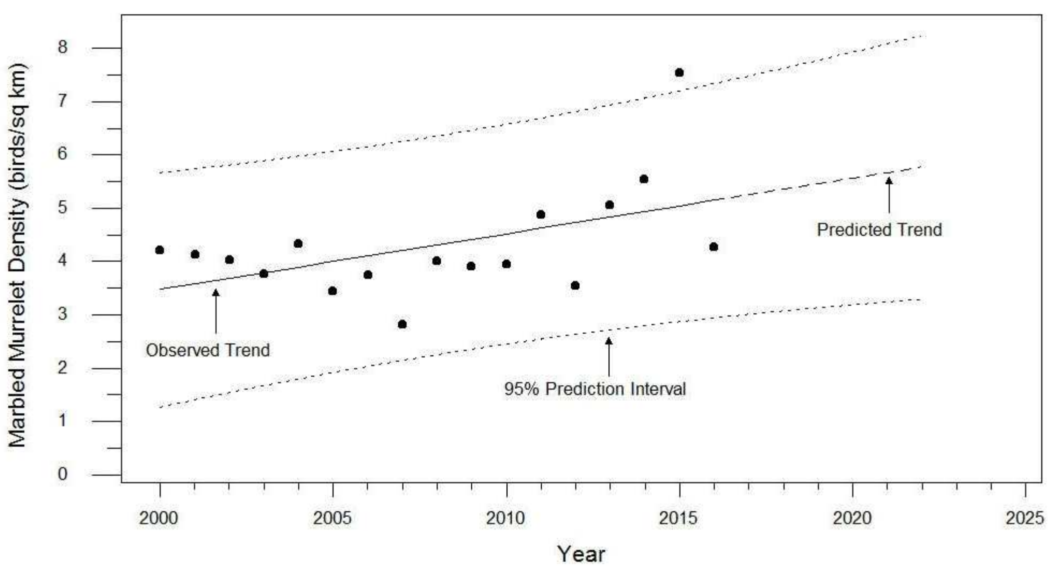

Figure 3.3.3-1 Density trend from 2000 to 2016 and predicted density estimates through 2022, the first year of operation of the Pipeline Project. The linear relationship is significant (r^2 = 0.253, P<0.05). (Data from Lynch et al. 2017)

Critical Habitat

Critical habitat for the MAMU was first designated in Washington, Oregon, and California on May 24, 1996 and included 3,887,000 acres in 32 critical habitat units (CHUs) (FWS 1996). On July

31, 2008, FWS proposed a revision to the 1996 critical habitat designation, proposing to remove approximately 254,070 acres in northern California and Oregon. This proposal was based on new information indicating that these areas do not meet the definition of critical habitat (FWS 2008b). Based on proposed revisions in 2008 critical habitat for the MAMU was revised in 2011, removing approximately 189,671 acres in northern California and southern Oregon from the 1996 designation (FWS 2011b and 2016b). Currently, designated critical habitat includes approximately 3,698,100 acres in 22 CHUs within Washington, Oregon, and California (FWS 2016b).

There are two components of MAMU habitat that are biologically important: 1) marine foraging habitat, including prey spawning and concentration areas, and 2) terrestrial nesting habitat and associated stands. Because FWS is unable to define specific marine areas essential to the conservation of the species, only terrestrial habitat is considered for designation as critical habitat. Throughout the forested portion of their range, MAMU habitat use is positively associated with the presence and abundance of mature and old-growth forests, large core areas of old-growth, low amounts of edge and fragmentation, proximity to the marine environment, and increasing forest age and height, although the presence of platforms is the most important characteristic of nesting habitat (FWS 2006c). As a result, the FWS designated the following as PCEs (FWS 2006c) that remain applicable to the revised critical habitat designated for the MAMU (FWS 2008b, 2011b): 1) forested stands containing large-sized trees, generally greater than 32 inches in diameter with potential nesting platforms at sufficient heights (≥ 33 feet); and 2) surrounding forested areas within 0.5 mile of these stands with a canopy height of at least one-half the site-potential tree height. In Oregon, MAMU nests have been located in trees with platforms greater than 19 inches diameter at breast height (dbh) and at least 98 feet tall (FWS 2006c).

Late-Successional Reserves

Additional habitat protection for the MAMU was established when the BLM and Forest Service in Washington, Oregon, and northern California adopted the NWFP in 1994 (Forest Service and BLM 1994). The NWFP divided the nesting portion of the MAMU range into two inland zones: 1) Inland Zone 1, which is a 10- to 35-mile zone closer to the coast where the majority of MAMU nests and detections are located, and 2) Inland Zone 2 where detection data indicated only a small fraction of the MAMU population nests (FEMAT 1993). Large amounts of NFS and BLM lands were allocated for LSRs, with the primary objective of protecting and enhancing conditions of late-successional and old-growth forest ecosystems. These lands could then serve as habitat for old-growth-related species including the MAMU, while maintaining diversity associated with native species and thus providing a network of fully functioning LSRs in National Forests throughout the Pacific Northwest (Forest Service and BLM 1994). The NWFP Standards and Guidelines also state that sites occupied by marbled murrelets but within Matrix lands are considered “unmapped LSRs” and are managed as lands allocated as LSRs by the NWFP.

In August 2016, the BLM issued two Records of Decision for tow Resource Management Plans (RMPs) for Southwestern Oregon and Northwestern and Coastal Oregon (BLM 2016a and 2016b). The NWFP no long applies on BLM-managed lands under the terms of the 2016 RMPs. The 2016 RMPs have similar land allocations that continue to contribute to the conservation of marbled murrelet habitat within BLM-administered lands, including an increase in designated LSRs within the range of the marbled murrelet. The NWFP still applies to lands managed by the Forest Service and is still in effect on the three National Forests crossed by the Pipeline.

The goals for LSR management for both Forest Service and BLM-managed lands are consistent with the function of federally-designated CHUs to contribute to the recovery of marbled murrelets. Management of LSRs should not only protect habitat currently suitable to marbled murrelets, but also promote the development of additional marbled murrelet habitat. Approximately 25 percent of the LSRs crossed overlap with federally designated critical habitats for marbled murrelets. The Pipeline would cross 8.65 miles of lands managed as LSRs within the marbled murrelet range, including 6.35 miles in Coos Bay BLM District and 2.30 miles in Roseburg BLM District; no lands managed by Forest Service are crossed within the marbled murrelet range.

The NWFP Standards and Guidelines also state that occupied MAMU sites and Known Owl Activity Centers (KOAC: 100-acre areas identified by BLM and Forest Service on January 1, 1994) that occur within NWFP-designated Matrix lands, are considered “unmapped LSRs” and managed as lands allocated as LSRs by the NWFP. Coos Bay and Roseburg BLM Districts also provide more specific management direction to protect marbled murrelets and their habitat on BLM-managed lands within the updated RMPs in all land allocations within Inland Zone 1, and within LSRs and Riparian Reserves within Inland Zone 2 unless otherwise directed through concurrence with the FWS, including (BLM 2016a and 2016b): 1) assess the project area for marbled murrelet nesting structure and conduct pre-project surveys following protocol; 2) prohibit activities that disrupt marbled murrelets nesting at occupied sites; and 3) restrict timber harvest within occupied marbled murrelet stands and all forest within 300 feet of a stand, with the exception of linear and nonlinear rights-of-way as long as the stand continues to support murrelet nesting. The 2016 RMPs also require future allocation of marbled murrelet occupied stands to LSR if occupied stands are identified within marbled murrelet Zone 1 within another land use allocation.

3.3.3.2 Environmental Baseline

Analysis Area

MAMU habitat can be categorized into various components, based on the life cycle needs of the species. Three main areas in which MAMU could be affected by the Project are outlined below.

Terrestrial Nesting Analysis Area

The first area in which MAMU could be affected by the Project is the terrestrial nesting analysis area. Per direction provided by FWS in the Revised Conservation Framework (*Revised Conservation Framework for the Northern Spotted owl and Marbled Murrelet: Jordan Cove Energy and Pacific Connector Gas Pipeline Project*, FWS 2014c), the terrestrial nesting analysis area consists of two components that consider effects from: 1) habitat removal or modification, and 2) disturbance/disruption of MAMU during the breeding season, as described below. The terrestrial nesting analysis area extends inland along the Pipeline route to include MAMU Inland Zone 1 – MPs 0.00 to 53.76 - and MAMU Inland Zone 2 – MPs 53.76 to 75.40 and is shown in figure 3.3.3-2.

The FWS (FWS 2008b and 2011b and 2014c) and BLM (BLM 2016a and 2016b) have recognized that forested habitat within 0.5 mile of an occupied stand, or 0.25 mile of occupied murrelet behavior, are important to recruit additional nesting habitat for the marbled murrelet in the future (e.g., “recruitment habitat” which has been defined by FWS as habitat that has the potential to become nesting habitat within 25 years; FWS 1997). To identify areas of higher importance for the marbled murrelet that could play an important role in maintaining and expanding marbled murrelet populations in the Pipeline project area, PCGP delineated marbled murrelet suitable habitat units (SHU), as directed by FWS (2014c) in the Conservation Framework.

The marbled murrelet SHU consists of three elements (FWS 2014c): 1) marbled murrelet occupied and unsurvyed suitable habitat (i.e., "presumed occupied" stands – forested stand identified as potential nesting habitat that has not been ground-truthed for suitable nesting structures and/or surveyed following the 2-year protocol); 2) a 300-foot buffer around each marbled murrelet occupied or presumed occupied stand; and 3) federally-designated critical habitat that occurs within a 0.5-mile buffer of marbled murrelet stands that are within 0.5 mile of critical habitat removal. Critical habitat located within the 0.5-mile buffer is an area considered important to the recovery of the species (FWS 2011b and 2014c). The 300-foot buffer incorporates an area that should maintain the integrity of the marbled murrelet stand from windthrow or other environmental disturbances as well as provide protection from potential predation (FWS 1997, ODF 2004). A protective 300-foot buffer of marbled murrelet stands is also recognized within the updated BLM RMPs (see Option 1 in BLM 2016a and 2016b). Areas included in defined SHUs represent areas of higher importance for the preservation of forested habitat for marbled murrelets. Within the Pipeline project area where marbled murrelet occupied stands are in close proximity to each other (i.e., less than 300 feet or adjacent), SHUs overlap. Approximately 15.71 miles of SHUs (occupied or presumed occupied stand, 300-foot buffer, and 0.5 mile buffer) would be crossed by the Pipeline: 14.08 miles in Inland Zone 1 and 1.63 mile in Inland Zone 2.

Habitat Removal or modification: This portion of the terrestrial nesting analysis area applies to all Project components that have the potential to remove or modify habitat, including construction of the LNG facilities and Pipeline , as well as a 100-meter (328-foot) wide buffer along each edge of the area of habitat impact (e.g., edge of right-of-way, TEWAs, new roads built for access, etc.) in recruitment or capable habitat throughout the entire range of MAMU. It also includes MAMU SHUs that are included for analysis within this APDBA.

Disturbance/Disruption (breeding season only): The terrestrial nesting analysis area also includes all lands within 0.25 mile of the Project components (including identified access roads). Access roads considered do not include paved roads that are used regularly by the public (i.e., county roads and state highways). The size of this analysis area considers the maximum distance (0.25 mile) at which MAMUs could be harassed during the breeding season (April 1 through September 15) by noise generated from general construction, operation, and maintenance activities, smoke from burning slash piles, blasting (with mitigation measures), and/or Boeing Chinook (CH-47) or Boeing Vertol 107 (CH-46) helicopter use (with mitigation measures) during construction, or use of access roads (FWS 2014c; see also PCGP's Blasting and Helicopter Noise Analysis & Mitigation Plan in appendix P).

Estuarine Analysis Area

The second area in which MAMU could be affected by the proposed action is the Coos Bay estuarine analysis area (see figure 3.3.3-3) which encompasses all estuarine waters (and substrates) that are within the estuary between the North Jetty and South Jetty at the Coos Head entrance to the bay. The estuarine analysis area includes: 1) the existing Federal Navigation Channel which forms part of the waterway for LNG carrier traffic to and from the LNG Terminal, 2) the proposed access channel to the terminal slip and pile dike rock apron, 3) the Navigation Reliability Improvements, 4) the area of North Slough adjacent to the Trans Pacific Parkway/U.S. Highway 101 (US-101) Intersection Widening, 5) the Eelgrass Mitigation site, 6) the Kentuck Project site, and 7) sites temporarily occupied during construction activities (see figure 2.1.1-2 under section 2.1.1.1, Jordan Cove Energy Project Component Description .

Marine Analysis Area

The third area in which MAMU could be affected by the proposed action is the marine analysis area (see figure 3.2-1), which extends to the edge of the continental shelf, approximately 12 nmi offshore. Within the marine analysis area, effects to MAMU would be associated with LNG vessels, which are assumed to transect the marine analysis area perpendicularly – east and west – as they approach and depart from Coos Bay (see the discussion above under section 3.2.1).

Species Presence

The Project occurs within Marbled Murrelet Inland Zone 1 and Marbled Murrelet Inland Zone 2; MAMU nesting has been documented within the two inland zones in and near the terrestrial nesting analysis area. MAMU nesting behavior is cryptic, however, resulting in few nests being located by biologists. As a result, documented behaviors assumed to be associated with nesting, such as MAMUs flying into the canopy or circling very close above the canopy are used to infer nesting activity and thus occupancy of MAMU stands. Since these occupied behaviors are not detected during every visit to a stand, the Pacific Seabird Group inland MAMU survey protocol (Mack et al. 2003) recommends several visits to a stand that contains potential MAMU nest trees (up to 9 per year) for a duration of two years in order to determine with some certainty that a timbered stand is occupied or unoccupied (probable absence). When occupied behavior is identified, the managing agency delineates the occupied stand and provides a master site number (MSNO). That stand is then considered "occupied" in perpetuity. If after two years of protocol surveys MAMU occupancy has not been determined in potential suitable MAMU habitat, then the site would be considered unoccupied (probable absence) for five years after completion of protocol surveys (Mack et al. 2003).

To determine presence of occupied stands in the vicinity of the Pipeline , PCGP used survey data from 2-year protocol surveys conducted for the Pipeline, as well as GIS data layers with known occupied MAMU stands or areas of suitable MAMU nesting habitat from BLM (2017) and private timber companies (Weyerhauser 2007). Areas identified within the vicinity of the Pipeline that are either known to have suitable nesting structures present but have not been surveyed in accordance with the applicable survey protocol or suitable nesting habitat has been presumed based on age of forested stand or height of trees but actual habitat has not been ground-truthed (i.e., landowners did not permit surveys) are considered "presumed occupied stands."

<u>Known Occupied MAMU Stands</u>

GIS data layers were obtained from Coos Bay and Roseburg BLM Districts (BLM 2017) to determine areas with known MAMU occupancy; 277 occupied stands were provided within the Coos Bay (249 stands) and Roseburg (28 stands) BLM Districts, including 10 stands identified during surveys conducted by PCGP in 2007 and 2008, six stands identified during surveys conducted by PCGP in 2013, and two stands identified during surveys conducted by PCGP in 2014 (see PCGP survey details, below). MAMU survey data were requested from private landowners within the Project area and in 2007 Weyerhaeuser Timber Company provided GIS files with areas of known MAMU occupancy (Weyerhauser 2007); none of the stands identified by Weyerhauser occur within 0.25 mile of the Pipeline or proposed access roads.

<u>Pipeline Project-Specific Marbled Murrelet Surveys</u>

No suitable MAMU nesting habitat occurs at the LNG Terminal site (LBJ Enterprises 2006; SHN 2013c); therefore, MAMU nesting surveys were limited to the Pipeline project area.

Habitat Assessment: To determine species presence within the proposed Pipeline project area, PCGP contracted surveyors (SBS and Rogers & Associates [R&A]) to conduct two-year surveys within habitat containing suitable nesting structures as described by Mack et al. (2003). Prior to surveys, SBS assessed habitat within 0.25 mile of the Pipeline to identify areas with potential suitable marbled murrelet nesting habitat to determine where marbled murrelet protocol surveys should be conducted for the Pipeline project. Delineation of suitable habitat was accomplished using a combination of aerial photographs, BLM Federal Operations Inventory (FOI) GIS data, local knowledge of on-the-ground habitat, and light detection and ranging (LiDAR) that was flown in a corridor including 0.25 mile on either side of the proposed Pipeline. The LiDAR data set was used to display all trees with a canopy height greater than 107 feet. Polygons were derived from these data to indicate possible suitable MAMU nesting habitat and/or trees. Within 20 miles of the coastline a single tree qualified as potential nesting habitat, whereas further inland, clusters of 6 or more large trees within a floating 5 acre window were considered potential habitat as directed by FWS (see SBS 2008a). These polygons were reviewed using aerial photos and BLM FOI data to determine which areas could provide potential suitable nesting habitat for MAMU.

Based on further direction provided by FWS and BLM Districts (Roseburg and Coos Bay), additional areas within 0.25 mile of construction activities and proposed existing access roads for the Pipeline were delineated that could provide potential suitable nesting habitat for MAMU. On BLM-managed lands, potential habitat was delineated from GIS layers provided by Coos Bay and Roseburg BLM Districts (BLM 2017) that identified suitable MAMU habitat. On private land, additional areas were delineated where the NWFP MAMU habitat model that uses maximum entropy (Maxent models) developed by Raphael et al. (2016) had a dense grouping of modeled "value 4" pixels ("highest suitability") and forested habitat was present in an obvious stand that could be delineated.

As the proposed route changed, habitat was reassessed with updated GIS layers, photography, and LiDAR where available and included additional survey efforts, if necessary.

PCGP Surveys (2007 – 2015): In areas where permission to survey was granted, R&A conducted on-the-ground surveys to determine whether timber stands exhibited the characteristics of nesting habitat outlined in the Pacific Seabird Group protocol (Mack et al. 2003). MAMU survey stations were set up on property where access was allowed and timber stands exhibited the characteristics of nesting habitat outlined in the Pacific Seabird Group protocol (Mack et al. 2003). Survey stations were positioned in such a manner that all of the potential habitat in a given stand could be seen, and that any MAMUs present would be able to be seen against the sky.

In areas identified with potentially suitable nesting structures where survey permission had been granted, R&A conducted protocol surveys in 2007 and 2008 and observed occupied behavior in 10 stands on BLM lands; data was provided to BLM to delineate "occupied stands." Full protocol surveys were conducted in nine other stands with suitable nesting structures in 2007 and 2008 but surveyors did not detect occupied behavior and they were considered "unlikely to be occupied" through 2013; five of these stands were resurveyed in 2013 and 2014. Protocol surveys were also initiated in three other areas with suitable nesting structures that were either included because of a pipeline reroute or had only received one year of protocol surveys; all eight areas were determined occupied in 2013 (six stands) or 2014 (two stands). Coos Bay and Roseburg BLM Districts were provided the appropriate survey results after occupied behavior was detected; each District delineated the occupied stands and provided an MSNO for each MAMU stand that are included in analysis for this APDBA.

In 2007 and 2008, 65 of 118 identified stands were examined, of which 46 of 65 (71 percent) timber stands and/or trees were determined not to exhibit the necessary nest tree characteristics and were removed from the list of stands/acreage to be surveyed.

Protocol surveys were also initiated along the Blue Ridge route in 2015 where MAMU occupied behavior was detected in 13 stands with suitable nesting structures present. To-date, only one year of survey effort has occurred in this portion of the Pipeline project. Although occupied behavior was detected in 13 of the stands (sub-canopy murrelet behavior detected), Coos Bay BLM determined that survey results were difficult to interpret and additional survey information was needed in this area since Blue Ridge is the first significant north-south ridge that MAMU encounter as they fly inland from the ocean and behavior documented could have been MAMU flying low over the ridgeline to conserve energy (BLM 2017b). Therefore, stands along the Blue Ridge portion of the proposed Pipeline with occupied behavior detected during 2015 protocol surveys are considered presumed occupied, with presence detected for this APDBA.

PCGP Surveys (2017 – 2018): In 2017 and 2018, additional on-the-ground surveys were conducted in potential habitat (presumed occupied stands) where survey permission was granted to determine whether timber stands exhibited the characteristics of nesting habitat, as outlined in the MAMU protocol (Mack et al. 2003). Surveys in fall 2017 assessed eight presumed occupied MAMU stands for suitable nesting structures, of which six stands were determined to provide suitable nesting structures for MAMU; two stands were removed from further consideration as presumed occupied, of which one was along a previously proposed route. Surveys in late spring (May and June) 2018 assessed 12 additional presumed occupied stands to determine if the forested stands provided suitable structure for nesting: three stands were determined to not provide suitable nesting structures and have been removed from analysis as a presumed occupied stand in this revised APDBA.

Two-year protocol surveys were also initiated in late spring 2018 in nine presumed occupied stands on BLM-managed lands to determine if the stands were occupied by MAMU: occupied behavior was observed in six occupied stands on both Coos Bay and Roseburg BLM lands, MAMU presence was detected above canopy during survey visits at one other stand where survey efforts were increased from five visits to nine visits in 2018 but no occupied behavior was observed, and two other stands did not detect MAMU presence. Survey data where occupied behavior was detected has been provided to BLM to review and officially delineate occupied stands where and if necessary. Second year survey efforts in these nine stands will continue as required by the protocol and be completed in 2019.

Additional Stands Delineated – No Survey

Areas of potentially suitable habitat that have been delineated in the Project area, as described above, but have not been ground-surveyed or not surveyed following the 2-year protocol, are considered “presumed occupied stands” and included for analysis within this APDBA as if they are occupied by marbled murrelets. Some of these areas have been ground-truthed and suitable nesting habitat was observed, but 2-year protocol surveys have not been completed (see table Q-1 in appendix Q). Other areas either did not receive survey permission, or survey permission was not requested due to the habitat location in relation to the Project (i.e., greater than 100 meters from habitat removal or along an existing, proposed access road). The areas greater than 100 meters from habitat removal were included for analysis within this APDBA to assess direct effects from disturbance of the proposed action. PCGP will continue to conduct additional on-the-ground surveys to determine if habitat within delineated presumed occupied stands that are crossed by the Pipeline provide suitable nesting structures. If the habitat is determined suitable nesting habitat through ground reconnaissance, PCGP would continue to presume occupancy. If the habitat is determined to not be suitable for marbled murrelet nesting, then PCGP would not continue to analyze the area as "presumed occupied," but would consider habitat within the delineated stand as "recruitment" habitat for subsequent analyses. Ground reconnaissance survey results would be provided to FWS to update impact analysis categories.

Marbled Murrelet Stands Considered for Analysis within the Terrestrial Nesting Analysis Area

Overall, 175 MAMU stands have been included for analysis within this APDBA: 51 occupied MAMU stands and 124 presumed occupied MAMU stands. MAMU stands were included if located within 0.25 mile of the proposed action, including 0.25 mile from proposed existing access roads (excluding paved public roads used regularly by the public – i.e., county roads or state highways). MAMU stands were also included for analysis if located within 0.5 mile of federally-designated critical habitat that would be affected by the proposed action. Fifty-one occupied stands (as defined by occupied behavior and delineated by BLM) are considered for analysis, including 18 stands detected during survey efforts by PCGP within the proposed Pipeline project area in 2007, 2008, 2013, and 2014. Twenty-six occupied stands are only included because they are within 0.25 mile of proposed existing access roads, including two stands determined to be occupied during PCGP 2007/2008 MAMU survey efforts. The other 124 stands included for analysis in this APDBA are "presumed occupied" – they either have been incorporated into the analysis based on Coos Bay and Roseburg BLM suitable habitat GIS data layers (71 stands; BLM 2017), or have been incorporated into the analysis considering high suitability values in the NWFP MAMU habitat model (Raphael et al. 2016) and/or LiDAR flown for the Project identifying trees greater than 107 feet in height (53 stands).

The number of "presumed occupied" stands deemed to be present within the analysis area is an extremely conservative number resulting in an overestimation. PCGP does not expect presumed occupied stands to have suitable habitat present, especially habitat located on private lands based on 1) on-the-ground surveys adjacent to those stands with no suitable nesting habitat (see maps included in appendix Z1), 2) location of those identified stands within narrow riparian buffers surrounded by clear-cuts and/or residences, 3) extent of timber stand harvests adjacent or near identified stands, and/or 4) proximity of presumed occupied stands greater than 3.0 miles from known occupied stands. For example in regards to #1, in 2007 and 2008, 46 of 65 (71 percent) timber stands and/or trees examined on the ground as potential MAMU nesting habitat were determined not to exhibit the necessary nest tree characteristics and were removed from the list of stands/acreage to be surveyed. Additionally, FWS (2006d) indicated that generally forests that provide suitable nesting habitat and nest trees require 200 to 250 years to develop. The majority of stands identified as "presumed occupied" do not occur in old-growth forest.

Table 3.3.3-1 below summarizes the number of MAMU stands (and status) considered for this analysis within each Marbled Murrelet Zone, by landowner in the terrestrial nesting analysis area. The table also tallies the number of stands that are included because of the stand's proximity to proposed habitat removal and/or access roads for each Zone. Table Q-1 in appendix Q provides details for each stand, including location in relation to proposed action, distance from proposed action including access roads, landowner, land allocation, and overall acres in stand by Marbled Murrelet Inland Zone. Figure 1 in appendix Q shows an overview of occupied and presumed occupied stands within the terrestrial nesting analysis area (occupied stands provided by Coos Bay and Roseburg BLM Districts (BLM 2017) are also depicted beyond the analysis area).

Marbled Murrelet Presence within the Estuarine and Marine Analysis Areas

Because occupied MAMU stands have been documented within the proposed terrestrial nesting analysis area (see table 3.3.3-1), and MAMUs have been recorded on the National Audubon Society's CBCs in the Coos Bay count circle that occurs within the delineated estuarine and marine analysis areas (National Audubon Society 2017), MAMUs are expected to forage within the Project's estuarine and marine analysis areas throughout the year. The most MAMUs reported in any survey were 16 counted during 95 observation hours (0.2 counted per hour) in 1992. On average, MAMUs have been recorded 3.1 times per count since 1977.

a/ "Occupied:" delineated stand that has identified occupied behavior during protocol surveys; " "Presumed Occupied:" forested stand has not been surveyed and habitat present is may provide suitable nesting structures.

b/ BLM includes Coos Bay and Roseburg Districts; three presumed occupied stands with mixed landowner (BLM and private) in MAMU Inland Zone 1 have been included in this category. Other includes private and Bureau of Indian Affairs (BIA); one presumed occupied stand with mixed landowner (private and BIA) in MAMU Inland Zone 1 have been included in this category.

c/ Stand Affected by Construction considers MAMU stands located within 0.25 mile of all proposed disturbance, including uncleared storage areas (UCSAs), as well as stands within 0.5 mile of federally-designated critical habitat removal.

d/ Access roads considered does not include paved roads that are used regularly by the public (i.e., County Roads, State Highways). MAMU stands are included if the stand is within 0.25 mile of a proposed access road.

e/ One occupied MAMU stand occurs in both Marbled Murrelet Inland Zones 1 and 2 but has been included in tabluations for Inland Zone 2.

Table Q-1 in appendix Q provides details for each stand, including location in relation to proposed action, distance from proposed action including access roads, landowner, land allocation, and overall acres in stand by Marbled Murrelet Inland Zone.

Habitat

The proposed action traverses two MAMU habitat inland zones designated by FEMAT. Inland Zone 1 encompasses a strip of land along the coast approximately 0 to 35 miles from the coast, and Inland Zone 2 includes areas along the western fringe of the species' range, about 35 to 50 miles from the coast (figure 3.3.3-2). The most suitable habitat is expected to occur within MAMU habitat Inland Zone 1, and recent surveys provide evidence to support this (Raphael 2006). The proposed action also occurs within Conservation Zones 3 and 4 as described by the MAMU Recovery Plan (FWS 1997). Figure Q-1 in appendix Q provides the location of each MAMU Inland Zone and Conservation Zone within the terrestrial nesting analysis area.

Three categories of MAMU habitat have been identified within the terrestrial nesting analysis area within MAMU Inland Zones 1 and 2: suitable nesting habitat, recruitment habitat, and habitat capable of becoming suitable nesting habitat (capable habitat). The following definitions were considered to classify MAMU habitat considering direction provided in several documents (FWS 1996, 2014c; BLM 1995a, 1995b) to provide standardization of terms for habitat categories: 1) suitable habitat includes coniferous forest that provides structures, or may provide structures and/or a forested buffer necessary for nesting MAMUs, and generally consist of late seral forest; 2) recruitment habitat is coniferous forested stands greater than 60 years of age that do not provide suitable nesting structures for MAMUs and could become suitable habitat within 25 years; and 3) capable habitat is coniferous forested stands from 0 to 60 years of age that could become suitable habitat.

Potential MAMU habitat within the Terrestrial Nesting Analysis area was identified in four steps, building upon each layer. Suitable nesting habitat was identified first, then recruitment; all other coniferous forest not included in the previous two categories was considered capable habitat. Non-forested habitat and deciduous forest was considered non-capable habitat. The vegetation file developed for the Pipeline project was used as the base file. Vegetation cover types were digitized with GIS from 2016 aerial photography and delineated based on the predominate vegetation physiognomy (e.g., trees, shrubs, herbaceous vegetation) and the dominant species present. Forested vegetation was assigned an age class using available GIS data (BLM FOI database, Gradient Nearest Neighbor raster data set [developed by Landscape Ecology, Modeling, Mapping & Analysis, or LEMMA: http://lemma.forestry.oregonstate.edu/], Moeur et al. (2006) LANDSAR late successional old-growth coverage, and an index called the old-growth structure index (OGSI) that further assisted monitoring the abundance of old-growth forest across large landscapes, including the NWFP area in the 20-year late successional and old-growth forest status and trend report (see Davis et al. 2015). Age class within previous versions of mapped vegetation for the Pipeline was also reviewed by BLM and Forest Service biologists on their respective lands with specific focus on verifying/classifying late seral forest stands (Habitat Quality subtask group, 2007 through 2008), as well as verified/revised by SBS who conducted biological surveys for PCGP. Age class for forested stands was categorized within five age ranges: clearcut (0-5 years), regenerating (5-40 years), mid-seral (40-80 years), late successional (80-175 years), and old-growth (175+ years) (Lint 2005). Areas of regenerating forest that appear to be "clearcut" on the aerial photography were identified as "early-regenerating" forest. The PCGP vegetation file extends at least 100 meters (328 feet) from the proposed action and consists of smooth polygons following obvious vegetation breaks. Outside of the Pipeline project vegetation layer and outside BLM-managed lands, the MAMU habitat file becomes more pixelated (25-meter by 25-meter squares) and less refined because it relied on MAMU habitat modeled from Raphael et al. (2016) (see Habitat Modeling, Pacific Northwest Research Station below).

Table 3.3.3-2 provides a summary of MAMU habitat within the terrestrial nesting analysis area by MAMU Inland Zone, Recovery Plan Conservation Zone, general landownership, and within SHUs and outside of SHUs that was developed for the proposed action.

<u>Estimate of Suitable Habitat</u>

For this APDBA, suitable habitat includes all habitat that occurs within BLM delineated occupied stands (BLM 2017) including where BLM-delineated occupied stands include younger forest (e.g., regenerating forest) or non-forested habitat (e.g., roads). Habitat that is included within "presumed occupied stands" analyzed within this APDBA (see species presence section, above) was also included in the MAMU habitat file as suitable habitat, including potential habitat areas identified by Coos Bay and Roseburg BLM Districts (2017 suitable habitat GIS files), or potential habitat based on LiDAR and habitat modeling developed by the Pacific Northwest Research Center (Raphael et al. 2016). Based on the vegetation file developed for the Pipeline project, these “presumed occupied” stands include coniferous forest ranging from mid-seral to old-growth.

TABLE 3.3.3-2

a/ Federal Landowners include Coos Bay BLM and Roseburg BLM Districts, Non-federal Landowners include private and State lands.
b/ Suitable Habitat: generally late-seral forested stands that provide or are presumed to provide nesting structures for marbled murrelet based on modeling and other available GIS data.
c/ Recruitment Habitat: forested land not currently suitable for marbled murrelet nesting that may be capable of becoming suitable marbled murrelet habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).
d/ Capable Habitat: forested land that has the capability of becoming suitable nesting marbled murrelet habitat, generally includes forest stand age 0 to 60 years (FWS 2014c).
e/ Total MAMU Habitat does not include "non-capable habitat" that occurs within the Marbled Murrelet Terrestrial Nesting Analysis Area.

Suitable habitat was incorporated into the MAMU habitat GIS file first. On BLM lands, additional suitable habitat was incorporated into the MAMU habitat file where GIS data provided by Coos Bay and Roseburg BLM Districts (BLM 2017) identified suitable habitat based on BLM FOI coverage (includes coniferous stands at least 80 years of age); these areas correspond to presumed occupied stands described above for species presence. On non-federal lands, additional suitable habitat was identified using a MAMU habitat model developed by the Pacific Northwest Research Center (see Raphael et al. 2011). Within 0.25 mile of the proposed action, areas modeled with "highest" suitable habitat potential (value 4 in the Raphael et al. 2016 model) and where obvious late seral stands were present (2016 aerial photography and PCGP GIS vegetation layer) were included in the MAMU habitat file developed for the proposed action. Additional description of the MAMU habitat model developed at the Pacific Northwest Research Center is included, below. Suitable habitat included in the MAMU habitat GIS file consists of coniferous forest in the following age classes: old-growth (175+ years), late successional (80 to 175 years), and mid-seral (40 to 80 years), with the exception of some habitat within BLM-delineated MAMU stands that include lower seral and nonforested habitat.

Based on the proportion of suitable habitat known to be occupied by nesting MAMUs either as surveyed per protocol (see Mack et al. 2003), or expected to be occupied based on survey history in the area and the application of an occupancy index to unsurveyed areas, FWS estimated that approximately 408,621 acres of suitable MAMU habitat (51 percent of reported suitable habitat) are likely occupied in Oregon (McShane et al. 2004). Also, 97 percent of the stands identified by SBS that were potential MAMU nesting habitat were determined to be non-suitable nesting habitat after on-the-ground habitat surveys by R&A in 2007; most of those areas are uniform 40-60 year old stands. Therefore, the estimates of suitable nesting habitat included in the MAMU habitat file and summarized in table 3.3.3-2 are most likely an over-estimation.

<u>Estimate of Recruitment Habitat</u>

Recruitment habitat was included into the MAMU habitat file next and only included areas not considered "suitable habitat," as described above. Delineation of recruitment habitat relied on several sources: Roseburg BLM District's MAMU-specific GIS layer (BLM 2017), BLM FOI database, SBS habitat delineation for the Pipeline project and on-the-ground survey results, PCGP's delineated vegetation GIS file, Pacific Northwest Research Center's MAMU habitat model developed by Raphael et al. (2016), and nesting, roosting, and foraging (NRF) and High NRF modeled for the NSO habitat model (discussed below in section 3.3.4 for NSO).

First, areas that were identified as potential suitable nesting habitat (gray habitat) based on LiDAR and aerial photography by SBS but had subsequently been ground-truthed and determined to not provide suitable nesting structures were included as "recruitment" habitat. Next, habitat was identified as recruitment habitat on BLM lands where forest had not been recently harvested (review of 2016 aerial photography) and 1) coniferous forest and mixed forest habitat was 60 years or greater (BLM 2016), and/or 2) where Roseburg BLM District's MAMU-specific GIS layer identified the area as recruitment habitat (BLM 2017).

On non-federal lands not included in the previous steps, the PCGP vegetation GIS file was used to identify additional recruitment habitat. All coniferous late successional and old-growth forest not previously incorporated into the MAMU habitat GIS file as suitable habitat were included as recruitment habitat. Mid-seral habitat included in the vegetation GIS file located on non-federal lands and not previously identified as suitable habitat was included as "recruitment habitat." Outside of PCGP vegetation GIS file, recruitment habitat was incorporated in the MAMU habitat file where Raphael et al. (2016) pixel values were classed as "moderately high" potential to be suitable MAMU habitat (pixel value 3). Recruitment habitat included in the MAMU habitat GIS file consists of coniferous forest in the following age classes: old-growth (175+ years), late successional (80 to 175 years), and mid-seral (40 to 80 years).

Estimate of Capable Habitat

Capable habitat incorporated into the MAMU habitat GIS file includes all other coniferous forested habitat not previously identified as suitable or recruitment habitat (see above). This includes coniferous forest areas that have been clearcut and are regenerating. On BLM lands, mid-seral coniferous forest between 40 and 60 years of age not previously included as suitable or recruitment habitat was also included as capable in the MAMU habitat file. Capable habitat included in the MAMU habitat GIS file consists of coniferous forest in the following age classes: mid-seral (40 to 60 years), regenerating (5 to 40 years), and clearcut (0 to 5 years).

Non-Capable Habitat

This category includes all areas that are non-forested habitat (i.e., waterbodies, agriculture fields, existing rights-of-ways and corridors, grasslands/shrublands) and deciduous forest, as delineated within PCGP's vegetation GIS layer.

Habitat Modeling, Pacific Northwest Research Station

Modeling of potential suitable MAMU nesting habitat has been generated by the Pacific Northwest Research Station (see Raphael et al. 2016; General Technical Report PNW-GTR-933) with the objective to estimate a baseline amount and distribution of potential nesting habitat since the inception of the NWFP in 1994 (Forest Service and BLM 1994). Methods to determine the baseline of MAMU habitat suitability within the NWFP area on both federal and nonfederal lands have been improved and updated during the 10-year (Raphael et al., 2006), 15-year (Raphael et al 2011), and 20-year (Raphael et al. 2016) monitoring reports. Raphael et al. (2006) used vegetation data derived from satellite imagery to model MAMU habitat suitability to establish the habitat baseline. Raphael et al (2011) updated the baseline model focusing on results of a new approach for estimating baseline potential nesting habitat, and on changes to date from the original 2006 baseline. To model relative suitability of MAMU nesting habitat, Raphael et al. (2011) used recently developed habitat suitability modeling software called Maxtent (Phillips et al. 2006; Phillips and Dudík 2008), which estimates probabilities of occurrence at unobserved locations by using information at the observed locations and assuming as little as possible about background sites for which there is not information (Baldwin 2009). The newest model (Raphael et al. 2016) relies on updated spatial habitat data from 1993 through 2012 using GNN methods, updated vegetation disturbances using Landsat-based detection of Trends in Disturbance and Recovery Methodes (LandTrendr), and a slightly expanded set of murrelet nest and occupied sites in Oregon and California. The resulting model includes four habitat classes: highest (value 4), moderately high (value 3), marginal (value 2), and lowest (value 1). In many instances where the earlier models had indicated high or moderately high potential for suitable nesting habitat, the newer model indicated marginal or low. Because available LiDAR indicated trees greater than 107 feet (which was one factor considered to identify presumed occupied stands; see Species Presence section, above), PCGP continued to include presumed occupied MAMU stands that had been previously analyzed, even though the updated MAMU habitat model may not have identified the area as highly suitable habitat. This allowed PCGP to continue with a conservative approach in analyzing impacts to MAMU.

Critical Habitat

Marbled murrelet critical habitat unit OR-06-d has been designated within the Pipeline project area (FWS 2011b and 2016c). Approximately 2.17 miles of marbled murrelet critical habitat are crossed by the Pipeline on BLM-administered lands, although CHUs OR-06-b and OR-06-c are within the terrestrial nesting analysis area located on lands of the Coos Bay and Roseburg BLM Districts (FWS 2011b and 2016c). No designated critical habitat is affected by the LNG Terminal. Habitat modeled for the proposed action (see discussion, above) was intersected with each CHU to determine the amount of MAMU habitat available within the terrestrial nesting analysis area and CHU. Table 3.3.3-3 summarizes the MAMU habitat associated with the CHUs, and identifies known occupied stands from data provided by BLM (2017) within each CHU (both within the entire CHU and CHU within the terrestrial nesting analysis area). PCEs are included in table 3.3.3-3 and below:

- PCE 1 includes individual trees with potential nest platforms, including supporting trees delineated as occupied or suitable (comparable to suitable habitat); and
- PCE 2 includes forest lands of at least one half site-potential tree height, within 0.5 mile of individual trees/suitable habitat stand that are recruitment or capable habitat (comparable to recruitment habitat) not currently suitable for MAMU nesting that may be capable of becoming suitable MAMU habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).

Suitable MAMU nesting habitat within the terrestrial nesting analysis area is considered equivalent to the MAMU critical habitat designation PCE 1 for analysis within this APDBA – individual trees (and delineated stands) with potential nesting platforms. Recruitment habitat (or PCE 2) is defined by FWS (2011b) as coniferous forested land not currently suitable for MAMU nesting that may be capable of becoming suitable MAMU habitat within the next 25 years, generally forested stands 60 years or greater (FWS 2014c). FWS (2011b) considers all forests within 0.5 mile of an occupied stand containing trees with at least one-half the site-potential tree height of the occupied stand to be recruitment habitat. Recruitment habitat is essential to provide and support suitable nesting habitat for successful reproduction of the MAMU. Benefits of this habitat include reducing the differences in microclimates associated with forested and unforested areas, reducing the potential for windthrow during storms, and providing a landscape that has a higher probability of occupancy by MAMUs. FWS (Trask & Associates 2013) requested that for this APDBA, PCE 2 consider recruitment and capable habitat as defined above in the habitat section.

Only 8,417 acres, or 11.2 percent of 75,334 acres available within MAMU CHUs OR-06-b, OR-06-c, and OR-06-d, occur within the terrestrial nesting analysis area, of which approximately 4,301 acres (50.7 percent of the analysis area) are presumed to provide suitable nesting habitat for MAMUs (see table 3.3.3-3). The other portion of CHUs consists of recruitment habitat and forested stands capable of becoming suitable habitat (approximately 28.6 percent and 19.9 percent of available CHU in the terrestrial analysis area, respectively). The majority of CHU within the analysis area (5,431 acres or 64.5 percent) is located on federal lands designated as LSRs. The overlap of CHU with LSR affords a greater degree of protection to the designated critical habitat as the BLM RMP protections for LSRs are automatically imposed on those LSR acres that are found within a CHU. Thus, MAMUs located within these land allocations also benefit from increased protection. Ten occupied MAMU stands occur within CHU OR-06 (b, c, and d) within the proposed terrestrial analysis area, including six occupied stands detected during PCGP survey efforts in 2007, 2008, 2013, and 2014. Twenty-four other stands have also been delineated as presumed occupied stands within designated critical habitat in the terrestrial analysis area: OR-06-b (one stand), OR-06-c (three stands), and OR-06-d (20 stands). Table Q-1 in appendix Q provides land allocations, including CHU that each MAMU stand (occupied and presumed occupied) analyzed within this APDBA is associated with, if applicable.

a/ Total Acres within CHU Subunit in the terrestrial nesting analysis area

b/ Occupied stands consider only known occupied stands (BLM 2017); the number in parenthesis identify stands that occur within the terrestrial nesting analysis area.

c/ PCE1/Suitable habitat: individual trees with potential nest platforms, including supporting trees delineated as occupied or suitable (comparable to suitable habitat)

d/ PCE2/Recruitment habitat: forest lands of at least one half site-potential tree height, within 0.5 mile of individual trees/suitable habitat stand that are recruitment or capable habitat (comparable to recruitment habitat) not currently suitable for marbled murrelet nesting that may be capable of becoming suitable marbled murrelet habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).

e/ PCE2/Capable Habitat: forested land that has the capability of becoming suitable nesting marbled murrelet habitat, generally includes forest stand age 0 to 60 years (FWS 2014c).

Late-Successional Reserves

BLM has designated LSR within BLM checkerboard lands on Coos Bay and Roseburg BLM Districts. Approximately 18,065 acres of LSR occur within the terrestrial nesting analysis area, of which 12,045 acres (66.7 percent) provide suitable nesting habitat; 3,903 acres (21.6 percent) provide recruitment habitat; and 1,941 acres (10.7 percent) consist of forested areas capable of becoming suitable habitat. Table 3.3.3-4, below, provides a summary of MAMU habitat that occurs within lands allocated as LSRs in the terrestrial nesting analysis area.

Approximately 5,431 acres of the LSRs within the terrestrial nesting analysis area overlap the FWS designated CHUs for MAMU. The overlap of LSRs with federally designated MAMU critical habitat affords a greater degree of protection to the MAMU and its critical habitat as the protections for LSRs are automatically imposed on those LSR acres that are found within a CHU. Thus, MAMUs located within these land allocations also benefit from increased protection. Table Q-1 in appendix Q provides land allocations, including LSRs that each MAMU stand (occupied and presumed occupied) analyzed within this APDBA is associated, if applicable.

a/ Suitable Habitat: generally late-seral forested stands that provide or are presumed to provide nesting structures for MAMU based on modeling and other available GIS data.
b/ Recruitment Habitat: forested land not currently suitable for marbled murrelet nesting that may be capable of becoming suitable MAMU habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).
c/ Capable Habitat: forested land that has the capability of becoming suitable nesting MAMU habitat, generally includes forest stand age 0 to 60 years (FWS 2014c).

3.3.3.3 Effects of the Proposed Action

Effects of the proposed action include direct and indirect effects within the marine analysis area, estuarine analysis area, and terrestrial nesting analysis area, and are described below.

Direct Effects – Marine and Estuarine Analysis Areas

MAMUs that forage offshore (marine analysis area) and/or within Coos Bay (estuarine analysis area) could be directly affected by 1) underwater noise generated during construction of the LNG Terminal and noise generated by LNG carriers transiting the marine analysis area and estuary, 2) disturbance during feeding by LNG carrier traffic, and 3) injury or mortality due to fuel spills from LNG carriers.

Underwater Noise

Propeller cavitations produce most carrier broadband noise, especially if damaged, operating asynchronously, or operating without nozzles. Engines and auxiliary machinery can also radiate noise during operation that is related to ship size (larger ships are noisier than small ones), speed (noise increases with ship speed), and mode of operation (ships underway with full loads, towing or pushing loads, are noisier than unladen ships) (Greene and Moore 1995).

The Federal Highway Administration, FWS, and WSDOT (2012) developed and agreed to underwater noise level criteria for injury to MAMUs from noise. The criteria are for underwater sound resulting from impact pile driving of steel piles and/or repetitive impulsive underwater sounds (see table 3.3.3-5). However, FWS considers the sound levels in table 3.3.3-5 to be used as guidelines in effects analysis rather than threshold criteria for foraging MAMUs. Other factors, including duration, are important when considering whether exposure in the zones would result in adverse effects. The thresholds do not apply to non-impact, non-impulsive underwater sounds such as ship noise. In this analysis, however, they serve as references for potential effects of ship noise produced by LNG carriers on diving MAMUs.

TABLE 3.3.3-5

Current In-water Acoustic Thresholds for Marbled Murrelets

Criterion Zone	Threshold a/
Auditory Injury Threshold	202 dB SEL b/
Non-auditory Injury Threshold	208 dB SEL
Non-injurious Hearing Threshold Shift Zone	183 dB SEL
Potential Behavioral Effects Zone	150 dB_{rms} c/

a/ All decibels (dB) referenced to 1 micropascal (re: 1 μPa).
b/ SEL – sound level exposure – reported as the cumulative amount of exposure for a single pile driving event.
c/ rms – the root mean squared for pile driving during a single pile driving impulse pressure event.

A review of LNG carriers in service during 2013 (Colton 2013; MarineTraffic 2013) revealed there are 267 carriers with capacities of 148,000 m^3 or less, the current size limit for LNG carriers utilizing the LNG Terminal. Hatch et al. (2008) determined underwater noise levels from various commercial ships while transiting the Stellwagen Bank National Marine Sanctuary off the Massachusetts coast. Estimates of sound levels from one ship, an LNG carrier (the Berge Everett also known as the BW Suez Everett) built in 2003 with 138,028 m^3 capacity (93,844 gross tonnage), are used here to estimate exposure of MAMU to project-related shipping noise. Also, Hatch et al. (2008) reported noise for three tugs in the same area, and they are used here as the standard for the following analysis of noise effects on MAMUs within the marine analysis area.

The ocean or waterway offshore from the entrance to Coos Bay is partially within the southern portion of offshore Conservation Zone 3 and partially within the northern portion of offshore Conservation Zone 4, as defined by Miller et al. (2012). In those portions of the Northern California- Oregon coast, the researchers estimated at-sea densities of MAMUs per km^2 of ocean surveyed from 2000 through 2016.As discussed in section3.3.3.1, the predicted estimate of marbled murrelet densities within Conservation Zones 3 and 4 shows an increasing trend for all of Oregon (see Figure 4 in Lynch et al., 2017).

The LNG carrier in the Hatch et al. (2008) study produced sound levels (with one standard error) of 182 ± 2 dB re: 1 µPa at 1 meter that attenuated to 160 dB at 35 ± 11 meters and to 120 dB at 16,185 ± 5,359 meters (Hatch et al. 2008). MAMUs diving and feeding in the marine analysis area are not expected to be exposed to ship propulsion noise that would cause harm (see table 3.3.3-5), although MAMUs would likely detect noise from LNG carriers transiting the analysis area. MAMU could be exposed to propulsion related noise levels of 160 dB, which could cause potential behavioral effects due to LNG carrier noise. However, since MAMUs forage in shallow offshore areas, they would not be expected to be exposed to LNG carrier noise but would be in areas of potential exposure to tug noise.

Three tractor tugs would guide each LNG carrier from a point approximately five nmi offshore the entrance to Coos Bay and to the LNG Terminal. Noise produced by tugs would attenuate to 160 dB at 11 ± 4 meters (upper end) and to 120 dB at 4,992 ± 1,599 meters (upper end) (Hatch et al. 2008). MAMU diving and foraging would be exposed to noise levels of 160 dB, which could cause potential behavioral effects due to tug noise, such as flushing or avoidance (Bellefleur et al 2009; Agness et al 2008; Teachout 2013). Exposure to noise levels of 120 dB would not be expected to cause potential behavioral effects due to tug noise, as indicated in table 3.3.3-5, although may interfere with communications between MAMUs in the vicinity of the tug (Teachout 2013).

As discussed in section 3.5.1.3, Green Sturgeon, underwater noise can be generated by driving piles on land (dry piles). The propagation of underwater construction noise from the "dry" impact pile driving associated with the MOF was modeled for marine mammals in several reports prepared by JASCO Applied Sciences (Wladichuk et al. 2018). The Phase 5 modeling study examined the threshold radii from driving a pile at the MOF face and at 98.4 feet (30 meters) set-back distance behind the MOF. Based on analysis for listed fish, the model results indicate the 187dB SEL injury level threshold extends a maximum range of 5,653 feet (1,723 meters) for piles at the MOF face and 2,890 feet (881 meters) for pile at the 98.4 feet (30 meter) set-back. The fish noise analysis indicates the MAMU 183dB SEL non-injurious Hearing Threshold Shift Zone (see table 3.3.3-5) may be exceeded. Pile driving of the 8 mooring bollards located at the MOF is anticipated to take 14 days to install. Pile driving associated with the MOF may reduce foraging efficiency by impairing communication between individual MAMU within the impact area shown in figure 3.5.1-2. Based on species presence information above, the number of MAMU in the impact area are anticipated to be low on both a seasonal and annual basis thereby resulting in minimal potential impacts to MAMU from underwater noise..

Underwater noise harassment or potential injury to MAMU could occur from pile driving associated with in-water temporary piles within the estuarine analysis area. However, the low abundance and density of murrelets and the limited number and area of in-water pile installation would make these effects unlikely. The harassment and injury area would be determined by the pile installation methods used and the number of pile driven within in a given area and period of time. Using the NMFS pile driving effects calculator, vibratory installation of piles, presumed to be the primary installation type for pipe piles would exceed harassment thresholds within 328 feet (100 meters) of pile installations from cumulative sound exposure levels for the installation of up to 85 temporary pipe pile. The NMFS pile driving calculator established that impact driven piles, if utilized could produce injurious peak level sound within approximately 40 feet (12 meters) and harassment levels of sound created from cumulative sound exposure extending to 5.3 miles (8,577 meters).

LNG Carrier Traffic

MAMUs are expected to forage in the estuarine analysis area and probably within the marine analysis area at the same time LNG carriers would be in transit to and from the LNG Terminal. No information has been found that describes MAMU response to ships' presence and/or ship above-water noise. However, responses of Kittlitz's murrelet (*Brachyramphus brevirostris*, a congeneric of MAMU) to ships' approach were studied in Glacier Bay, Alaska (Agness et al 2008). The study reported that Kittlitz's murrelets were observed to immediately fly away from carriers; they flew 30 times more from carriers than in the absence of carriers and non-breeding birds (birds not holding fish) were more likely to take flight than breeding birds (those holding a fish; Agness et al 2008) Applying the behavioral response of the MAMU congener to MAMU would suggest that the species may also avoid and disperse from approaching carrier vessels, disrupting foraging and other behaviors in the process.

Modeled estimates of energy expense showed that non-breeding murrelets had a greater increase in energy expenditure when disturbed (up to 30 percent increase under the average scenario of ship traffic and greater than 50 percent increase under the peak scenario of ship traffic) than breeders (up to 10 percent and 30 percent increases under the average and peak carrier traffic scenarios, respectively). Likewise, non-breeding birds were more likely to experience chronic increases in energy expense (i.e., a greater percentage of days with an increase in energy expenditure) than breeding birds which would be expected to adversely affect energy partitioning for reproduction and survival behaviors (Agness et al. 2013).

Similar responses by foraging MAMUs to LNG carrier traffic would be expected once the LNG Terminal is in operation. MAMUs foraging within the marine and estuarine analysis areas could potentially fly away from approaching carriers. This could result in expenditure of additional energy and thus reduce energy available for reproduction and other survival behaviors.

Ship-Strike

There are no records or any indication that MAMUs offshore are susceptible to ship-strikes. Collisions of seabirds with stationary objects (including off-shore wind energy turbines) are possible, either by collisions of ships with birds on the ocean surface or collisions of birds in flight with ship structures although empirical data are limited (Wilson et al. 2007). Collisions between MAMUs and LNG carriers are possible but highlyunlikely within the marine analysis area.

Fuel Spills

MAMUs are adversely affected by spills of oil and other pollutants, primarily as a result of death at the spill site, although reduced breeding success of seabirds due to various forms of marine pollution are also well-known (FWS 1997). Because of their extensive use of nearshore waters for foraging, MAMUs are especially susceptible to the impacts of offshore oil spills (Carter and Kuletz 1995) and industrial pollution (Fry 1995), and have been given one of the highest oil spill vulnerability index values among seabirds (King and Sanger 1979).

Fuel or lubricants accidentally spilled from LNG carriers at sea could adversely affect MAMUs if feathers became coated with these petroleum products, causing death or injury. These products are kept in relatively small quantities on LNG carriers and therefore spills would not result in the types of effects associated with a spill from an oil tanker, as was observed from the grounding and wreck of the *New Carissa* on the Oregon coast near Coos Bay in 1999. However, oiled MAMUs have been reported in the absence of known large and medium spills, indicating that chronic oil pollution from sources such as cleaning of tanks at sea, bilge pumping, and smaller accidental spills can affect MAMUs (FWS 1997; Carter and Kuletz 1995). Mortality from spills, large and small, is poorly documented throughout the range of the species, and impacts are often difficult to demonstrate, requiring detailed pre-event baseline data, careful injury determination, and detailed follow-up data, especially to determine population-level impacts (Carter and Kuletz 1995). Impacts to MAMU from fuel and lubricant spills as a result of the 120 LNG carrier transits per year are unlikely given the relatively low density of MAMUs within the marine and estuarine analysis areas (see figure 3.3.3-1). Implementation of SPCC plans in the event of fuel or lubricant spills will likely reduce the potential effects of spills depending on the size and severity of incidents. Additionally, LNG carriers calling on the LNG Terminal would be required by the Coast Guard to have a vessel response plan in order to be adequately prepared for accidental spills. As a result, effects to MAMU from accidental spills are expected to be insignificant and discountable.

Indirect Effects – Marine and Estuarine Analysis Areas

Foraging Habitat

MAMUs forage in shallow offshore and inland saltwater areas on a variety of small fish and invertebrates, including large pelagic invertebrates (Marshall 1988a, 1988b, and 1989; Becker 2001). In Oregon and Washington, anchovy, sand lance, and smelt appear to be the major prey types provided to chicks (McShane et al. 2004).

Turbidity associated with dredging activities within Coos Bay may affect MAMU forage/prey species and their habitat. Turbidity from dredging at the Navigation Reliability Improvements dredge sites are modeled to extend from 2,170 to 2,880 feet upstream beyond each of the dredging footprints and from 2,820 to 4,600 feet downstream from each of the dredging footprints. Dredging could be conducted through up to four in-water work windows. Dredging taking place at the access channel and MOF are expected to produce turbidity plumes approximately half the area of the LNG Terminal slip and access channel prism. This plume may reach the existing navigation channel where currents would influence its shape up and downstream. Dredging at the eelgrass mitigation site is expected to be completed in one in-water work window and is not expected to extend beyond the dredge prism as it is a low energy part of the bay. Dredging is planned from October 1 through February 15 following ODFW's recommendation, and timing of these activities will minimize impact to MAMU forage/prey species.

Fuels or lubricants spilled from LNG carriers could decrease forage species abundance and quality. Many MAMU prey species are intertidal spawners, and are more susceptible to oil pollution than pelagic spawners (Carter and Kuletz 1995). However, fuels and lubricants are kept in relatively small quantities on LNG carriers and therefore spills are unlikely to result in impacts to forage species. Mitigation measures (SPCC plans) will further reduce potential effects of any spills on MAMU within the proximity of such an incident. For example, LNG carriers calling on the LNG Terminal would be required by the Coast Guard to have a vessel response plan in order to be adequately prepared for accidental spills. LNG carriers would also be required to obtain a vessel general permit from the EPA that would outline regulations for avoiding release of even small quantities of fuel or lubricants during normal operations such as washing the vessel deck. As a result, effects to MAMU prey species from accidental spills are expected to be insignificant and discountable.

Direct Effects – Terrestrial Nesting Analysis Area

MAMUs nesting within the terrestrial nesting analysis area could be directly affected by 1) removal of nest trees or potential nest trees during the breeding season (April 1 through September 15) and 2) human presence and noise disturbance during the breeding period. No direct effects to nesting MAMU are expected from construction or operation of the LNG Terminal. Analysis of potential direct effects to MAMU by the Pipeline project within the terrestrial nesting analysis area followed guidance provided by FWS included in the Revised Conservation Framework developed for the Project (see *Revised Conservation Framework for the Northern Spotted owl and Marbled Murrelet: Jordan Cove Energy and Pacific Connector Gas Pipeline Project*, FWS 2014c).

Nest Removal During Breeding Season

Removal of habitat during the breeding season within an occupied or presumed occupied stand could result in the potential death of nestlings if the nest tree is removed. Removing suitable nesting habitat outside of the entire breeding season (September 16 through March 31) would eliminate any direct impact to individual MAMUs or nestlings. PCGP met with FWS on June 5, 2008, to review and discuss the proposed action and construction schedule and identify areas where the project and schedule could be adjusted to avoid or further decrease the disturbance impacts to MAMUs while allowing for a constructible Pipeline project that considered 1) MAMU seasonal and daily timing restrictions, 2) safety of the construction crew, and 3) meeting the targeted in-service date within a two-year construction period. FWS provided a preference of activities associated with timber removal and construction, including the following specific to habitat removal, listed below in descending order of importance:

- Felling nest trees outside the entire breeding season.
- No removal of habitat within an occupied stand during the entire breeding season.
- No fragmentation of an occupied stand (i.e., clipping the edge of the stand is not as bad as dissecting through the middle).

PCGP moved and adjusted the Pipeline to avoid and/or minimize effects to MAMU, where feasible. Appendix V1 (Marbled Murrelet and Northern Spotted Owl Avoidance and Minimization Plan) identifies the additional measures that have been incorporated into the design of the Pipeline in relation to occupied MAMU stands or potentially suitable MAMU habitat. Maps within appendix V1 show the timing constraints that would be applied in relation to each MAMU stand for timber felling and Pipeline construction.

Also, considering the factors above, PCGP developed a timber removal and construction schedule that would minimize effects to MAMU, as well as ensure the safety of the timber removal and construction crew and meet the in-service date (see section 2.1.2.3). PCGP would remove forested habitat within 300 feet of an occupied stand, or presumed occupied stand outside of the entire breeding season to eliminate direct impact to individual MAMUs or nestlings. Timber would be removed beginning fourth quarter prior to initiating construction and, if necessary, continue the following fall after the breeding season. This includes habitat that would be removed or potentially removed from 37 MAMU stands (19 occupied and 18 presumed occupied stands) and 300-foot buffers of 59 MAMU stands (21 occupied stands and 38 presumed occupied stands). Habitat would also be removed within 0.25 mile of an NSO activity center outside of the breeding season (from October 1 through February 28); within the range of the MAMU, this includes forested habitat between MPs 37.33 and 37.86, MPs 53.74 and 54.04, and MPs 64.02 and 64.43. Elsewhere in the range of the MAMU, timber removal would precede construction and could occur during the breeding season; however, direct effects to MAMUs or nestlings would not be expected because suitable nesting habitat would have been removed outside of the breeding season.

Table 3.3.3-6 tabulates the number of occupied and presumed occupied stands by Murrelet Inland Zone that would have timber cleared within 300 feet of the MAMU Stand (i.e., the SHU) outside of the breeding season, including 37 MAMU stands that would have suitable habitat removed from the stand.

TABLE 3.3.3-6

Number of Occupied and Presumed Occupied Stands that Would Have Habitat Removed Outside of the Breeding Season, Including the 300-foot Buffer (i.e., the Suitable Habitat Unit)

	Number of MAMU Stands		
Status Of Marbled Murrelet (MAMU) Stand	**Stand**	**300-foot Buffer**	**Total**
Marbled Murrelet Inland Zone 1			
Occupied	16	18	18
Presumed Occupied	19	39	39
Total	**35**	**57**	**57**
Marbled Murrelet Inland Zone 2			
Occupied a/	2	2	2
Presumed Occupied	0	0	0
Total	**2**	**2**	**2**
Overall Total			
Occupied	18	20	20
Presumed Occupied	19	39	39
Total	**37**	**59**	**59**

a/ One occupied MAMU stand occurs in both Marbled Murrelet Inland Zones 1 and 2 but has been included in tabluations for Inland Zone 2.

No suitable MAMU nesting habitat would be removed during the construction of the LNG Terminal because no suitable nesting habitat exists within the LNG Terminal site; therefore, no direct effects to MAMUs would be result from the construction of the LNG Terminal.

Noise and Visual Effects

In the Revised Conservation Framework, FWS (2014c) provided guidance on determining potential impacts to NSO and MAMU from noise. This guidance included disturbance and disruption distances based on noise thresholds (as described in FWS 2003b and 2006a; discussed below), and prescribed associated impact levels (No, Low, Moderate, or High) based on Project timing and activity.

Disruption and Disturbance – Available Literature

Noise associated with timber clearing and other construction and operation activities associated with the proposed Pipeline could disturb nesting MAMUs and negatively affect productivity. The term "disruption" was alluded to in the ESA, under the definition of "harassment" (50 CFR 17.3) as:

> "an intentional or negligent act or omission which creates the likelihood of injury by annoying it (the organism) to such an extent as to significantly disrupt normal behavior patterns which include but are not limited to, breeding, feeding or sheltering."

The term "disturbance" was not included in the ESA but a reasonable working definition was provided by Leal (2006) and has been incorporated into this APDBA:

> "any potential auditory or visual stimuli or deviation from ambient/baseline conditions [that] an individual bird, at a given site, is likely to detect and potentially react to."

There is limited information on distances from noise and/or visual stimuli at which MAMUs react or flush from the nest, or the effect of such disturbance on productivity (FWS 2003b). Most data gathered for disturbance on MAMUs have been obtained from observations incidental to other research (e.g., Long and Ralph 1998). The sensitivity of an individual MAMU to noise and/or visual disturbance is likely related to levels of disturbance to which the bird is accustomed, including the level and proximity of the disturbance (Hamer and Nelson 1998) as well as the timing of disturbance (time of day, time of year, and time within breeding season). The available research and anecdotal accounts show that the effects of noise and vehicles on roads can elicit disturbance as well as disruption responses from MAMUs, including responses such as flushing, flight, and/or missed feedings of chicks in nests that would be to a level that could interfere with normal behavior patterns including but not limited to, breeding, feeding or sheltering. The following are brief summaries of available research and anecdotal accounts.

- No visible response to vehicles driving past MAMU nests 70 meters (230 feet) away from a paved, "well traveled park road" (Singer et al. 1995 in Long and Ralph 1998).
- MAMU in nests in Big Basin Redwoods State Park showed no response to passing cars during several days of observation in 1989 (Nelson, personal communication, in Long and Ralph 1998).
- MAMU nests 70 meters (230 feet) from lightly used logging road show little to no response when observers drove by in light trucks (Chinnici, personal communication, in Long and Ralph 1998).
- MAMU in nests across river from road with moderate traffic (30 cars/day) showed no reactions when vehicles passed (Nelson, personal communication, in Long and Ralph 1998).
- In a study comparing responses to four types of disturbance (automobiles, trucks, cars, humans), adult MAMU reacted least to trucks and automobiles on U.S. Highway 101 even though truck noise averaged 84 dB and auto noise averaged 72 dB, although one or more vehicles passing by the nest sometimes caused adults to abort a nest visit and return later; MAMU chicks showed only low response to cars/trucks (Hamer and Nelson 1998). The authors concluded that visual disturbances may be of much more concern to nesting birds than noise, which they note is not surprising given the fact they hunt prey solely by visual means.
- There is evidence of MAMU flushing from car doors/people talking within 32.8 yards. (FWS 2006a, 2014d), although Hébert and Golightly (2006) found that trail use does not appear to influence the behavior of MAMU adults or chicks on the nest.
- Field study to measure behavioral responses of MAMU adults and chicks to disturbance produced by trail users, proximity to paved highways, and experimental disturbances produced by maintenance activities (chainsaws) (Hébert and Golightly 2006):
  - Ambient sound at nest sites was less than 50 dB before and after exposure to chainsaw noise. Experimental noise was greater than 65 dB generated by chainsaws.
  - MAMU chicks and adults in nests exposed to significantly louder experimental noise than before or after trial.
  - Adult MAMU spent less time at rest during disturbance than before and after.
  - Adult MAMU spent more time with head raised during disturbance than before and after.

- MAMU chicks spent similar times at rest before, during, and after chainsaw noise trials.
- Controlled for temporal variations, hatching success at control nests (69 percent) was not significantly different than hatching success at experimental nests (exposed to chainsaw noise; 67 percent).
- Fledging success at control nests was 25 to 50 percent; fledging success at experimental nest did not show a statistically significantly difference.
- Overall, MAMU avoided nesting close to high volume roads (U.S. Highway 101).
- Concluded that in some instances vehicular traffic noise may have little or no effect on MAMU nesting success.

Available research suggests that MAMUs may be more sensitive to visual disturbances than to auditory disturbance conditioned by predators in the vicinity that may cause aborted or delayed feedings (Phifer 2003; Hamer and Nelson 1998; Bednarz and Hayden 1994). Human presence attracts corvids, which increases the predation risk at MAMU nest sites that are located near project activities. Studies from other bird species suggest that disturbance can affect productivity by causing nest abandonment, egg and hatchling mortality due to exposure and predation, longer periods of incubation, premature fledging or nest evacuation, depressed feeding rates of adults and offspring, reduced body mass or slower growth of nestlings, and avoidance of otherwise suitable habitat (Henson and Grant 1991; Rodgers and Smith 1995 as cited in BLM and Forest Service 2008). Additionally, increased vigilance or non-resting behaviors can increase energetic expenditures or decrease food deliveries such that energetic costs exceed energy supply (Hébert and Golightly 2006).

Auditory and Visual Disturbance - FWS Guidance

Based on analysis of published literature and anecdotal accounts of harassment of MAMUs, the FWS (2003b, 2006a, 2014c) established distances within which sound levels and visual disturbance for various activities may result in injury or harassment of MAMUs by disrupting the normal behavior pattern of individuals or breeding pairs. FWS determined that visual disturbances within 100 yards of MAMU nest sites could lead to increased predation of nests by corvids when humans are present during project-related activities and would constitute a disruption of the nest site (Phifer 2003).

FWS identified distances within which activities may “disrupt” nesting MAMUs (noise and/or visual disturbance). Disruption distances identify a distance from activities that FWS have determined would likely cause a MAMU to be distracted to such an extent as to substantially disrupt normal behavior and increase the likelihood of breeding season failure. Activities that occur beyond the disruption distances may “disturb” MAMU but the effects should be minimal and not result in harm or “disrupt” reproductive activities. Activities may disturb MAMU if the activities occur within 0.25 mile of MAMU; disturbance distances have often been applied as seasonal buffers to minimize impacts of projects to nesting MAMUs. FWS determined that activities occurring beyond these disturbance distances would not likely cause MAMUs to be distracted from their normal activity. This direction is consistant with guidance provided in the FWS Conservation Framework prepared for this Project (FWS 2014c).

Table 3.3.3-7 provides the threshold distances beyond which noise and visual disturbances are unlikely to result in disruption or disturbance to nesting MAMUs during the breeding season (April 1 through September 15), which are generally based on distances to which noise levels and/or human presence are expected to disrupt or disturb nesting MAMU. In addition to the temporal and spatial restrictions presented in table 3.3.3-7, FWS also recommends limiting Project-related disturbance to two hours after sunrise until two hours before sunset near occupied and presumed occupied stands. Adhering to this daily timing restriction (DTR) minimizes the potential to disrupt adult MAMUs delivering meals to chicks at dawn and dusk. Application of DTRs during the breeding season should minimize effects from project activities, and would result in no disturbance or disruption for most activities if applied in the late breeding period, as identified in table 3.3.3-7.

TABLE 3.3.3-7

Threshold Distances Beyond which Noise and Visual Disturbances are Unlikely to Result in Disruption or Disturbance to Nesting Marbled Murrelets during the Breeding Season a/

	Disruption Threshold Distances From Occupied or Presumed Occupied Stands			Disturbance Threshold Distance From Occupied or Presumed Occupied Stands

a/ Sources: FWS 2003b; Michael Minor & Associates 2008 (appendix P); FWS 2014c; Phifer 2003.
b/ MAMU breeding period is from April 1-September 15; critical breeding period is considered from April 1-August 5; late breeding season is considered from August 6 – September 15.
c/ DTRs (Daily Timing Restrictions) – restricting activity to between 2 hours after sunrise until 2 hours before sunset.
d/ Existing Low Use Roads include federal roads designated as local/resource and private roads that appear to receive light traffic and periodic maintenance.
e/ Existing High Use Roads include federal roads that are designated as arterial and collector roads. Includes some federal roads local/resources roads that are paved or receive regular traffic/maintenance and are the primary access routes within checkerboard (federal/private) ownership. Also includes other private residential roads driveways or other roads that provide access to multiple rural residences.
f/ Heavy equipment includes: back trackhoes, side-booms, bulldozers, semi-trucks, pneumatic hammers.
g/ Rock Ditching Equipment includes: auger drill rig, mounted impact hammer, rock drill, and blasting (mitigated or less than 2 lbs).
h/ Transport helicopters proposed for use during construction of the Pipeline include: Boeing Chinook (CH-47) and Boeing Vertol 107-II (CH-46)

FWS (2003b and 2006a) reviewed available scientific literature on behavioral and physiological responses of different bird species to various noise sources. They determined that birds would likely detect noises that were 4 decibels or more above ambient noise levels. FWS (2006a) defined an “injury threshold” of 92 dBA, and a “tolerance threshold” of 82 dB for MAMUs and NSOs.

The tolerance threshold assumes that respective nest sites become "intolerable" to the species and harassment occurs due to the total sound level the species must endure. FWS (2006a) did recognize that a tolerance threshold of 92 dB for aircraft (e.g., helicopters) would be applicable due to the usually slow onset of aircraft noise approaching, but otherwise FWS (2006a) applied the threshold of 82 dB as a sound-related injury threshold level. Based on Delaney et al. (1999) and Brown (1990), FWS (2006a) subtracted the noise level that elicited a harassment-indicating behavior (flight or flushing) from the minimum ambient noise at the respective sites and deduced that action-generated noise levels that are 25 dB above ambient levels constitute the sound level threshold above which harassment is likely to occur. From that exercise, FWS (2006a) deduced that a noise level of 70 dB would be a disturbance threshold and noise greater than 70 dB would be disruptive.

FWS (2003b) did not analyze injury threshold distances for noise associated with blasting or large helicopters. Rather, a conservative assumption was used for blasting with charges of 2 pounds or less; for larger blasts (greater than 2 pounds) a conventional one-mile distance was considered due to the lack of dB information. During informal consultation with FWS (Smith et al. 2007; Wille et al. 2006), restricting the use of large helicopters to remove large timber and transport pipe to the construction right-of-way to a one-mile disturbance threshold distance was considered as well. However, FWS also suggested that if additional studies could demonstrate that use of larger blasts (greater than 2 pounds) and large helicopters attenuated to less than 92 dB, and preferably 70 dB (disturbance threshold versus 92 dB disruption threshold) within a mile, the report and additional data demonstrating this would be considered to reduce the disturbance threshold distances for those activities (Smith et al. 2007; Wille et al. 2006).

Blasting and Helicopter Noise Levels

PCGP prepared a noise report (see appendix P) that analyzes the distances at which conventional blasting required for trenching within rock substrate for construction and transport helicopters attenuates to 92 dB, the threshold for injury to individual MAMUs and is the sound level above which MAMU are likely to respond with behavior that indicate harassment (FWS 2006a). Under the worst case conditions, with common and appropriate mitigation measures applied to trench blasting operations (greater than 2 pounds of explosives), it is expected that blasting noise would attenuate to 92 dB within 200 feet of the source and to 70 dB within 1,025 feet of the blast source in soft rock. Large transport helicopters would attenuate to 92 dB within 700 feet. The greater distance for helicopter use is due to the directional aspects of blade slap noise that is directed toward the ground.

Mitigation for helicopter noise includes operational restrictions such as maintaining a high altitude and keeping away from noise sensitive areas whenever possible. Analyses for MAMUs in this APDBA consider the distances for larger blasts and large helicopters to be more conservative than what the noise report suggests. A disruption threshold distance for blasting greater than 92 dB has been used but with mitigation measures discussed in appendix P applied to be the same disruption distance expected for smaller blasts (less than 92 dB) – 120 yards or 360 feet – more conservative than the noise report describes, and the disturbance threshold distance associated with large blasts to be expected within 0.25 mile of blasting activity (see table 3.3.3-7). It is expected that these distances be considered throughout the entire breeding season (April 1 – September 15), regardless of the application of DTRs, because of the sudden onset of noise associated with blasting activities. A disruption threshold distance for large/transport helicopter use has been used with proposed mitigation techniques discussed in appendix P to be slightly farther than the report suggests, considering a disruption distance of 240 yards or 720 feet and a disturbance threshold distance of 0.25 mile (see table 3.3.3-7).

Even though FWS (2003b) provided some evidence suggesting that noise that builds in intensity, such as a helicopter approaching from a distance, may result in less risks and does not anticipate effects for smaller aircraft after the critical breeding period with DTRs applied, for analysis within this assessment, it is anticipated that similar to large blasts (greater than 2 pounds) use of large/transport helicopters may disrupt or disturb MAMUs throughout the entire breeding season (April 1–September 15), regardless of the application of DTRs. In a memorandum provided to Tetra Tech, contractor to FERC (FWS 2008h), FWS indicated that if noise level above 92 dB is recorded at 0.25 mile of the blasting activities, that blasting operations should cease until more effective mitigation measures can be employed.

Noise Evaluation Procedure

In the Revised Conservation Framework, FWS (2014c) provides the threshold distances beyond which noise and visual disturbances are unlikely to result in disruption or disturbance to nesting MAMUs during the breeding season (April 1 through September 15), which are generally based on distances to which noise levels and/or human presence are expected to disrupt or disturb nesting MAMU (see table 3.3.3-7). PCGP is aware of the temporal and spatial restrictions recommended by FWS (see table 3.3.3-7) and would adhere to them where feasible; however, due to construction constraints within the range of the MAMU and safety of construction crew, PCGP cannot adhere to all recommended restrictions. No suitable nesting MAMU habitat is within 0.25 mile of proposed construction of the LNG terminal and no disruption or disturbance to nesting MAMU is expected, including construction at the Kentuck Project site.

Disruption and Disturbance – Timber Clearing, Pipeline Construction, Existing Road Use

To avoid direct effects to MAMUs, chicks, or eggs within MAMU stands and adjacent habitat, PCGP would clear timber within MAMU Stands and a 300-foot buffer of MAMU stands outside of the entire breeding season (between September 16 and March 31): this includes at least 15.0 miles of forested habitat within 300 feet of 59 occupied and presumed occupied MAMU stands (tables 3.3.3-6 and 3.3.3-8). Timber removal is expected to begin the fourth quarter prior to construction, and if timber removal within 300 feet of MAMU stands is not completed prior to the MAMU breeding season (April 1), timber removal would continue the following fall outside of the breeding season (between September 16 and March 31). Noise, visual disturbance, and in some instances large helicopter use associated with timber removal within 300 feet of MAMU stands outside of the breeding season would be consistent with the temporal restrictions recommended by FWS to protect nesting MAMUs (see table 3.3.3-7) and would not be expected to disturb or disrupt MAMUs. However, to safely construct the Pipeline within two years, PCGP could not commit to removing timber within the entire 0.25-mile spatial buffer recommended by FWS outside of the breeding season; therefore, some disturbance would be expected from timber removal outside of the 300-foot buffer. An additional 15.1 miles of timber clearing (greater than 300 feet but within 0.25 mile of MAMU Stand) could occur during the MAMU breeding period within 0.25 mile of 25 occupied and 57 presumed occupied MAMU stands (see tables 3.3.3-8 and 3.3.3-9). As a result, acoustic and visual disturbances from timber removal could affect MAMU nesting and rearing activities.

After timber has been cleared, approximately 37.5 miles of construction activities along the Pipeline route could occur during the MAMU breeding period within 0.25 mile of 25 occupied and 57 presumed occupied MAMU stands (see tables 3.3.3-8 and 3.3.3-9), including mitigated blasting along the trenchline and across waterbodies, and use of large transport helicopters for pipe delivery (see table Q2 in appendix Q). As a result, acoustic and visual disturbances from construction of the Pipeline project could affect MAMU nesting and rearing activities.

PCGP has proposed to apply DTRs recommended by FWS for timber removal and construction activities that occur within 0.25 mile of a MAMU stand through the critical breeding period (April 1 through August 5), which would reduce direct effects from noise and visual disturbance. PCGP has indicated that DTRs would also be applied to large transport helicopters in the late breeding period (August 6 through September 15), if use of helicopters is necessary during that time period. Although timber removal and construction activities would likely occur within one breeding season in the proximity of each MAMU stand, PCGP conservatively assumes that each MAMU stand could experience effects from activities for 2 years.

Informal consultations with FWS (June 5, 2008 meeting; see NSO and MAMU Avoidance Plan, appendix V1) identified disturbance from travel on existing roads to be less of an impact than other actions associated with the construction, especially if farther than 35 yards (105 feet). In the Revised Conservation Framework, FWS (2014c) identified that use of existing low use roads within 35 yards (105 feet) of an active MAMU nest has the potential to disrupt normal behavior patterns and lead to harassment, whereas use of existing high use roads would not be expected to disrupt normal behavior at an active MAMU nest. However, utilization of high or low traffic use access roads would be expected to disturb MAMU up to 0.25 mile of the road (see table 3.3.3-7). For the purposes of this analysis, existing low use roads include federal roads designated as local/resource and private roads that appear to receive light traffic and periodic maintenance. Existing high use roads include federal roads that are designated as arterial and collector roads as well as some local/resources roads that are paved or receive regular traffic/maintenance and are the primary access routes within checkerboard (federal/private) ownership. Existing high use roads also include other private residential roads driveways or other roads that provide access to multiple rural residences.

TABLE 3.3.3-8

Total Miles Crossed by the Pipeline within the MAMU Stand, and the 300-foot and 0.25-mile Buffer of MAMU Stands

	Marbled Murrelet Habitat (miles crossed)				
Location of Project Activity	**Suitable**	**Recruitment**	**Capable**	**Not Capable**	**Total Miles Crossed**
Total MAMU Inland Zone 1					
MAMU Stand a/	4.9		0.1	<0.1	5.1
300-foot Buffer a/, b/		3.4	4.8	2.4	10.7
0.25-mile Buffer c/		3.7	10.1	3.4	17.1
MAMU Inland Zone 1 Total	**4.9**	**7.2**	**15.0**	**5.9**	**32.9**
MAMU Inland Zone 2					
MAMU Stand a/	0.9				0.9
300-foot Buffer a/, b/		0.3	0.5	<0.1	0.8
0.25-mile Buffer c/		0.8	0.1	1.1	1.9

Overall MAMU Range					
MAMU Stand a/	5.8		0.1	<0.1	6.0
300-foot Buffer a/, b/		3.7	5.3	2.4	11.4
0.25-mile Buffer c/		4.6	10.2	4.5	19.0
Overall Total MAMU Range	**5.8**	**8.3**	**15.5**	**6.9**	**36.4**

a/ Timber would be harvested outside of the entire breeding season (between September 16 and March 31); this includes habitat associated with 59 MAMU stands (see table 3.3.3-6).
b/ Miles provided for 300-foot buffer exclude the MAMU stand.
c/ Miles provided for 0.25-mile buffer exlude the MAMU stand and the 300-foot buffer.

Expected Disturbance Effects

Impact assessments were prepared following guidance from FWS's Revised Conservation Framework (FWS 2014c) for each MAMU stand analyzed within this APDBA (appendix Z1) that identify existing access roads within 0.25 mile of occupied or presumed occupied stands, including distance from roads, expected improvements within the stand or 0.25-mile buffer, and surface of existing roads, including maps of the particular stand. The impact assessments in appendix Z1 also identify the distance between a MAMU stand and proposed construction activities, including large helicopter use and blasting (>2 pounds explosives). Many of the MAMU stands occur in areas with higher existing disturbance (i.e., residential, commercial, and agricultural areas) and although noise associated with construction would be detectable, but often times not disruptive, PCGP has conservatively applied direction provided by FWS to determine possible effects to MAMU if nesting in the stand (see table 3.3.3-7).

Table Q-2 in appendix Q provides distances from actions and timing of those actions that are expected to occur within the occupied or presumed occupied stands during Pipeline project activities (timber clearing, construction activities, road use) and through the life of the Pipeline (i.e., maintenance and operation activities). Since nest locations within MAMU stands are not known, analyses in this APDBA have assumed that MAMUs are nesting along the closest edge to disturbance or existing road from the MAMU stand which is unlikely but, absent specific nest locations, is the most conservative approach. Additionally, table Q-2 in appendix Q provides the expected effect from noise and visual presence of construction activities (disruption, disturbance, no disturbance, or no effect) and rationale for each occupied or presumed occupied stand based on timing and distance from the activities for each proposed activity (based on disturbance distances from table 3.3.3-7).

Maps 1 through 10 in appendix Q show the locations of occupied and presumed occupied stands in relation to different Project components and identify spatial buffers (360 feet and 0.25-mile buffers) associated with a MAMU stand. The rationale for location of the proposed Pipeline within each known occupied stand and presumed occupied stand is provided in PCGP's *Marbled Murrelet and Northern Spotted Owl Avoidance and Minimization Plan* (see appendix V1).

Table 3.3.3-9 provides a summary of occupied and presumed occupied stands within the terrestrial nesting analysis area that may be affected by the Pipeline and is based on the timing of activities (summarized from table Q-2 in appendix Q). Forested stands that may provide suitable habitat for MAMU that have not had ground surveys conducted to date to determine presence of nesting structues have been presumed occupied for this analysis, resulting in a conservative estimate of potential effects. If stands are surveyed and no suitable nesting structures are present, then no disturbance effect would be expected. Table 3.3.3-9 provides a conservative estimate of the stands likely to be disturbed by activities associated within the proposed action, because PCGP does not expect the majority of presumed occupied stands on private lands to have suitable nesting habitat present based on the following:

1. on-the-ground surveys adjacent to those stands with no suitable nesting habitat identified,
2. location of those identified stands within narrow riparian buffers surrounded by clear-cuts and/or residences, and/or
3. proximity of presumed occupied stands greater than 3.0 miles from known occupied stands.

Additionally, activities would not occur simultaneously along the Pipeline route, and as a result some activities near MAMU stands may occur outside of the breeding period and/or within the latter part of the breeding season within the DTR timing window. Also, disturbance or disruption associated with construction activities would likely only occur in one year; however, PCGP cannot guarantee that activities would only occur in one year (there may be unforeseeable circumstances that result in two years of activities), therefore, PCGP has identified that disruption and disturbance activities could occur in both Years 1 and 2.

MAMU stands identified in the timber and removal/construction column could also experience effects during reclamation; however, reclamation activities within 0.25 mile of MAMU stands would occur outside of the MAMU breeding season (September 15 through March 31). Effects by reclamation to nesting MAMUs would not be expected.

The FWS (2014c) provided a method in the Revised Conservation Framework to categorize direct effects to MAMU stands within a disruption and/or disturbance distance (0.25 mile) of project activities, including use of access roads, into the following Disruption-Disturbance (D/D) Impact Categories: High Impact, Moderate Impact, Low Impact, Low Impact – no mitigation, and No Impact. The assessment considers the timing, types, and location of project-related activities in relation to MAMU stands that could result in disturbance or disruption of nesting MAMU to assist in determining a D/D Impact Category for each activity for each MAMU stand. In many instances a MAMU stand is provided more than one D/D Impact Category because of different project effects and different locations of effects on the MAMU stand (i.e., construction effects and proposed use of existing access roads).

The Revised Conservation Framework (FWS 2014c), guided individual assessments included in appendix Z1 for each MAMU stand (occupied and presumed occupied) to determine the amount of acres by D/D Impact Type; the resulting D/D Impact Category(ies) is also included for each stand in table Q2 in appendix Q. In May 2018, FWS reviewed the D/D impact categories provided for each MAMU stand and agreed with the categories provided by PCGP. Table MAMU-1 in the introduction to appendix Z1 summarizes the acres of MAMU stands (occupied and presumed occupied) within 0.25 mile of proposed activities that would be categorized as Moderate Impact, Low Impact, and No Impact. No MAMU stand was assigned a "High" category, because PCGP would adhere to DTRs during the critical breeding period for construction and timber removal activities that occur within 0.25 mile of MAMU stands.

Maintenance and Operation

No activities associated with general maintenance and operations of the Pipeline project are expected to affect occupied MAMU stands. Vegetation maintenance activities would occur only between August 1 and April 15 of any year (see appendix C); generally, outside of the critical breeding season. PCGP would apply DTRs during activities within 0.25 mile of MAMU stands during the late breeding season (August 5 through September 15) to ensure no effects to MAMU (see table 3.3.3-7); therefore, no disturbance is expected. Routine clearing of vegetation within the 30-foot permanent right-of-way would not occur more frequently than every 3 years. A 10-foot corridor centered over the pipeline would be maintained annually in an herbaceous state to facilitate periodic corrosion and leak surveys. PCGP would also require pilots conducting annual aerial inspection (small plane/helicopter) of the pipeline to adhere to the spatial restrictions recommended in the vicinity of occupied stands (no overflight within 1,300 feet agl during the critical breeding season (April 1 through August 5), resulting in no adverse effect from aerial pipeline inspection. However, some routine activities such as right-of-way inspection may require pipeline personnel to visit the right-of-way at any time; these visits along the right-of-way would be by a vehicle or via walking and would adhere to DTRs.

a/ Summarized from table Q-2 in appendix Q.; see appendix Z1 for D/D Impact Categories for each MAMU stand applying guidance provided by FWS (2014c) in the Revised Conservation Framework.

b/ BLM includes Coos Bay and Roseburg Districts; three presumed occupied stands with mixed landowner (BLM and private) in MAMU Inland Zone 1 have been included in this category. Other includes private and Bureau of Indian Affairs (BIA); one presumed occupied stand with mixed landowner (private and BIA) in MAMU Inland Zone 1 have been included in this category.

c/ Construction Activities (see d/) and Road use (see e/): both proposed activities occur within 0.25 mile of MAMU Stands

d/ Construction Activities Only: includes general construction activities, blasting (> 2lbs explosives), and large transport helicopter use; no proposed road use within 0.25 mile of MAMU Stands

e/ Road use only: does not include paved roads that are used regularly by the public (i.e., County Roads, State Highways). MAMU stands are included if the stand is within 0.25 mile of a proposed access road; no construction activities proposed within 0.25 mile of MAMU Stand

f/ None: construction and proposed road use > 0.25 mile of MAMU Stands but within 0.5 mile of critical habitat removal (see appendix Z-1).

g/ One occupied MAMU stand occurs in both Marbled Murrelet Inland Zones 1 and 2 but has been included in tabluations for Inland Zone 2.

Helicopter Rotor Wash

Strong winds can adversely affect MAMUs (FWS 1990) by directly removing habitat from windthrow that could fragment forests and increase edge effects (risk of predation, microclimatological changes). Wind can also cause direct mortality by blowing chicks out of nests (FWS 1992a). Helicopter drive rotors produce high velocity vortices (winds) that extend from the center of the helicopter outward in all directions. Vertical downwash of air (rotor wash) close enough to the ground produces surface winds that dissipate with distance away from the helicopter (sidewash). Induced winds caused by helicopter rotor wash may exceed hurricane force velocities that would be expected to adversely affect nesting MAMUs on a local level. Since induced rotor downwash and surface sidewash are functions of helicopter size, rotor surface area, helicopter weight, flight speed, and height above ground (Teske et al. 1997; Gordon et al. 2005), effects to nesting birds can be minimized or avoided by routing helicopter flight paths and staging locations far enough away from nests so that induced winds would not adversely affect nests or nestlings.

Maximum induced surface velocities produced by downwash and sidewash from various helicopters were measured in the field to determine the decay function of rotor-produced vortices near ground level (Teske et al. 1997). Field studies included measurements on three helicopter models that might be utilized during construction of the Pipeline: 1) the twin-rotor CH-47 (civilian variant is the Boeing HH-47 Chinook) with rotor diameter 59.1 feet, 2) the single rotor CH-54 with a rotor diameter of 72 feet (civilian variant is the Sikorsky S-64 Skycrane), and 3) the twin-rotor CH-46 (civilian variant Boeing Vertol 107) with a rotor diameter of 49.9 feet (Teske et al. 1997). Using parameters derived from the field trials, estimates of maximum induced surface velocities were made for each of the three helicopter models at varying heights above ground while flying at different ground speeds. In general, maximum induced surface velocities increase with rotor diameters, decrease with distance above ground, and decrease with faster ground speeds.

Results of modeling maximum induced surface velocities (model described in Teske et al. 1997) produced by a Chinook helicopter are shown in figure 3.3.3-4 for drop heights (heights above ground level at which the helicopter would discharge a payload of foam, water, or retardant during wild fire control) ranging from 10 to 320 feet while flying at ground speeds ranging from 5 to 25 mph. Included in figure 3.3.3-4 are four wind speed categories on the Beaufort Scale (NOAA 2015) which was developed to describe damage associated with wind forces ranging from calm to hurricane forces. On the Beaufort Scale, induced surface winds of 9 to 11 mph produced by rotor wash would be equivalent to a “gentle breeze” during which leaves and small twigs would be constantly moving and light flags would be extended. Wind velocities of 19 to 24 mph are classified as a “fresh breeze” (small trees in leaf would sway). Winds 39 to 46 mph are “gale” force strength: difficult to walk against, twigs and small branches blown off trees. Winds greater than 74 mph are classified as a hurricane.

Figure 3.3.3-5 shows the heights above ground that Chinook helicopters would produce maximum induced surface winds with velocities equivalent to a “fresh breeze” while traveling at ground speeds of 5, 10, 15, 20 or 25 mph. For example, if traveling at a ground speed of 5 mph, the Chinook would have to be approximately 185 feet above ground to produce a maximum induced surface velocity of 24 mph, equivalent to a “fresh breeze.” If traveling at ground speed of 25 mph, the Chinook could be 75 feet above ground and still induce a maximum surface velocity of 24 mph.

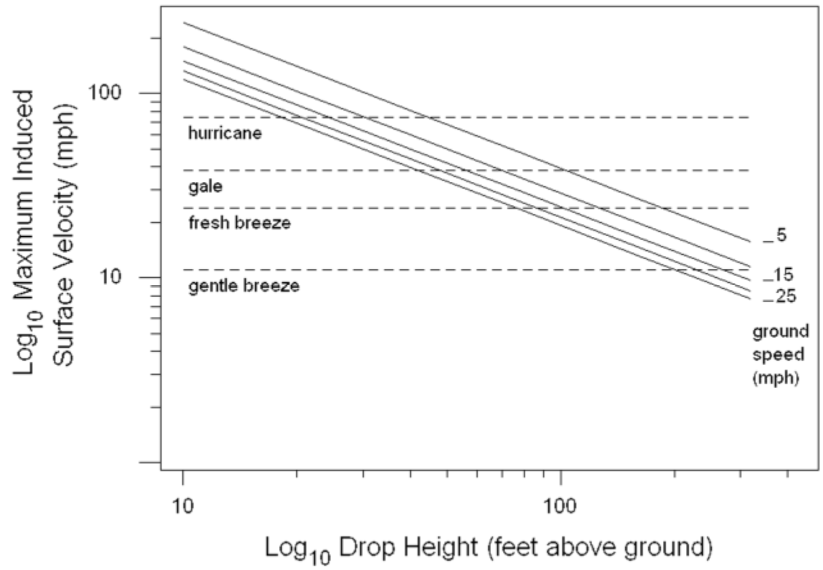

Figure 3.3.3-4 Modeled Maximum Surface Velocities Induced by Chinook C-47 Helicopters while Flying at Ground Speeds From 5 to 25 mph at Heights From 10 to 320 feet Above Ground. (Modeled from data in Teske et al. 1997)

In the Pipeline project area, wind speeds reported by the Western Regional Climate Center (2015) at the North Bend airport averaged 10.2 mph in June, 11.2 mph in July and 9.9 mph in August, the three months with highest average wind velocities during the period from 1996 to 2006. During the same period, winds in Roseburg averaged 5.0 mph in June, 5.2 mph in July, and 4.4 mph in August. These data indicate that winds as strong as a fresh breeze (19 to 24 mph) would be expected along the Oregon Coast and most likely inland during the period when MAMUs are nesting. It is assumed that induced winds the strength of a fresh breeze would not adversely affect young or nests.

Incoming or outgoing Chinook helicopters flying at 5 mph while 185 feet above a tree with a nest would most likely produce winds with velocities less than a fresh breeze at the tree top because there would be no resistance by the ground to induce maximum sidewash vortices.

Similar results were produced by the Boeing Vertol 107 (see figure 3.3-8) even though it is smaller than the Chinook (rotor diameter 49.9 feet compared to 59.1 feet). The Vertol 107, flying at a ground speed of 5 mph, would have to be approximately 200 feet above ground to produce a maximum induced surface velocity of 24 mph, equivalent to a fresh breeze. If traveling at ground speed of 25 mph, the Vertol 107 could be 82 feet above ground and still induce a maximum surface velocity of 24 mph. Overall, the Vertol 107 produces slightly greater maximum induced surface velocities than the Chinook CH-47 even though its maximum equipment weight is less than the Chinook.

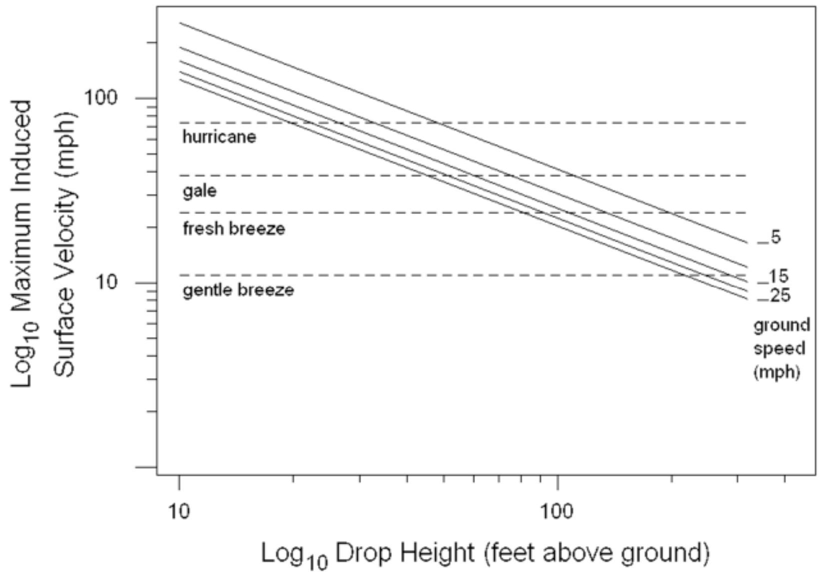

Figure 3.3.3-5 Modeled Maximum Surface Velocities Induced by Boeing Vertol 107 Helicopters while Flying at Ground Speeds From 5 to 25 mph at Heights From 10 to 320 feet Above Ground (Modeled from data in Teske et al. 1997)

The single rotor S-64 Skycrane has the largest rotor diameter (72 feet diameter) of the three models. As modeled in figure 3.3.3-6, the Skycrane would produce greater maximum induced surface velocities while flying at the same ground speeds and same drop heights as the other two helicopter models.

Flying at a ground speed of 5 mph, the Skycrane would have to be approximately 233 feet above ground to produce a maximum induced surface velocity of 24 mph, equivalent to a fresh breeze. The Chinook and Vertol 107 helicopters would induce similar maximum surface velocities flying at heights of 185 feet and 200 feet above ground, respectively. If traveling at ground speed of 25 mph, the Skycrane could be 95 feet above ground to induce a maximum surface velocity of 24 mph.

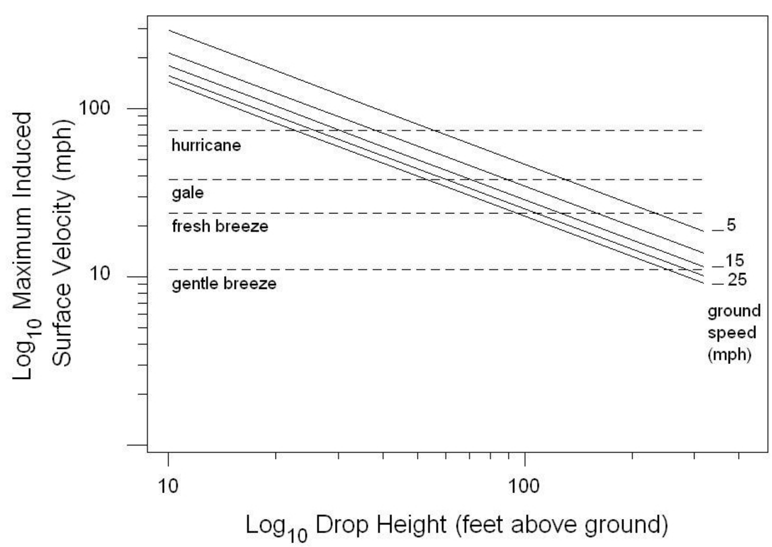

Figure 3.3.3-6 Modeled Maximum Surface Velocities Induced by Skycrane S-64 Helicopters while Flying at Ground Speeds From 5 to 25 mph at Heights From 10 to 320 feet Above Ground. (Modeled from data in Teske et al. 1997)

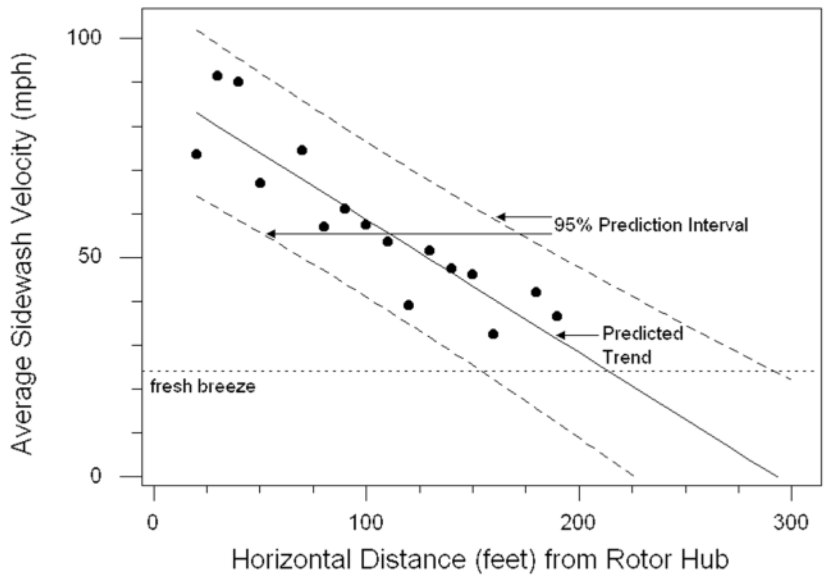
Actual downwash and sidewash vortices produced by Chinook CH-47 and Skycrane (CH-54) helicopters were measured during field tests (Leese and Knight 1974) while aircraft were hovering at 40-50 feet and 80-90 feet above ground level (agl) while under maximum loads of 36,000 pounds (CH-47) and 45,000 to 47,000 pounds (CH-54). The Vertol 107 (CH-46) was not included in the field tests.

With a 47,000-pound load, the single rotor CH-54 hovering at 40 feet agl produced a maximum sidewash velocity of 87 mph 50 feet away from the rotor hub; at 80 feet agl, the maximum sidewash was 74 mph, also measured at 50 feet from the hub though the gross weight was 45,000 pounds during that particular trial. Both maximum sidewash measurements were at heights of 0.3 feet above ground (Leese and Knight 1974). Under the specified load conditions, the CH-54 produced a sidewash of 11 mph 170 feet away from the rotor hub while hovering at 40 feet agl and a sidewash of 9 mph 150 feet away from the hub while hovering at 80 feet agl. Maximum sidewash velocities of 74 to 87 mph that were associated with the CH-54 helicopter while it was hovering, are within the range of hurricane force winds on the Beaufort Scale while winds of 9 to 11 mph produced by rotor sidewash would be described as a "gentle breeze." Sidewash velocities between 9 and 11 mph at distances 150 to 170 feet away from a CH-54 helicopter (Skycrane) would be unlikely to blow young MAMUs from their nests.

Downwash and sidewash velocities measured for the CH-47 helicopter (Chinook) were greater than 100 mph up to 70 feet horizontally from the rotor hub when it was hovering at 90 feet agl with maximum load of 36,000 pounds (Leese and Knight 1974). The twin rotor CH-47 produced sidewash velocities as high as 56 mph 190 feet away from the rotor hub when it was hovering at 90 feet agl. The Beaufort Scale classifies winds between 55 and 63 mph as a "storm," with trees uprooted and structural damage likely. The greater strength of winds produced by the CH-47 is likely due to the interaction of descending air produced by the two rotors (Fabey 2008); sidewash winds are generally strongest at 120 and 240 degrees (4 o'clock and 8 o'clock, respectively) relative to the helicopter's heading (data in Leese and Knight 1974).

Sidewash wind velocities produced by the CH-47 at various distances away from the rotor hub (Leese and Knight 1974) were used to predict the distance at which the helicopter would be far enough to avoid adversely affecting MAMU nests and young. The prediction is based on the sidewash wind velocities produced by the CH-47, averaged for wind measurements made 0.3 feet above ground at angles of 120 and 240 degrees while the helicopter was hovering 90 feet agl under a load of 36,000 pounds. The prediction is shown below in figure 3.3.3-7 in which a sidewash velocity of 0 mph would occur 293 feet away from the rotor hub. Due to the observed variation in sidewash winds at different distances away from the rotor hub (solid circles in figure 3.3.3-7), the upper 95 percent prediction interval on that predictive estimate of 0 mph at 293 feet from the hub would be 23.8 mph. A wind velocity of 23.8 mph is classified as a fresh breeze on the Beaufort Scale. One can be 95 percent certain that a stronger wind, potentially adversely affect nesting MAMUs, would not occur.



Source: Leese and Knight 1974

Figure 3.3.3-7 Average Sidewash Wind Velocities Produced by the CH-47 at Varying Horizontal Distances from the Rotor Hub While Hovering 90 feet agl Under a Load of 36,000 pounds. The observed averages (solid circles) were used to predict sidewash winds at distances out to 300 feet.

These estimates clearly suggest that greater distances would be required to avoid adverse effects to MAMUs if Chinook helicopters, rather than Skycranes, are employed for heavy lifting along remote sections of the construction right-of-way. Based on the similarities of maximum induced surface velocities between Chinook and Vertol 107 helicopters, sidewash velocities induced while hovering are likely to be similar as well. However, if known nest trees or stands can be avoided by at least 200 feet above tree tops by heavy-lifting helicopters in transit, and avoided horizontally by at least 300 feet while helicopters hover above staging sites, no adverse effects to the species from rotor downwash and induced sidewash would be expected.

Eight MAMU stands occur within 0.25 mile of proposed helicopter use, of which six occupied stands are within 300 feet of proposed helicopter use (C3073, C3090, C3094, C3095, R3035 [EAR 46.51_A], and R3051 [B14]). Helicopter use for timber extraction within 300 feet of a MAMU stand would occur outside of the entire breeding season (between September 16 and March 31); no adverse effects from rotor wash of large helicopters are expected during timber extraction. Adverse effects to MAMUs in the six stands identified above could occur from rotor wash of large helicopters during pipe delivery during construction of the proposed action, since activity could occur during the entire breeding season and may be within 200 feet above nest trees and horizontally within 300 feet of nest trees (the nest site is unknown within these stands but potential nest trees have been identified adjacent to the construction right-of-way and rotor wash could affect MAMU if present).

Burning and Smoke

Whether by prescribed burning as a habitat enhancement procedure or by burning slash, effects of smoke on MAMUs have not been studied. However, FWS et al. (2007) have declared (see Table 15, FWS et al. 2007) "that smoke can cause [NSO] adults to move off nest sites, therefore leaving eggs or young exposed to predation or resulting in lost feedings reducing the young's fitness." In the absence of reliable information, one would reasonably assume that the same effects apply to MAMUs.

According to BLM and Forest Service (2008, page 35), MAMUs "are potentially affected by fire control activities and drifting smoke during burning. The threshold distance for disturbance from smoke is 0.25 mile for MAMUs," which also would be subject to smoke-related disturbance during the critical breeding period (April 1 through August 5). PCGP would not conduct slash burning on any land during the critical breeding season within 0.25 mile of an occupied or presumed occupied MAMU stand. No direct effect to MAMUs due to slash burning is expected.

Indirect Effects – Terrestrial Nesting Analysis Area

A primary indirect effect to MAMUs would be removal of suitable nesting habitat, and could also include removal of recruitment or capable habitat. Removal of MAMU habitat would be a long-term impact to MAMUs and would be expected to last at least 5 years or more. Short-term impact is expected with the use of UCSAs and is likely to last from the initiation of timber clearing until 1 to 5 years after restoration/revegetation. Other indirect or secondary effects by the Pipeline could include increased human presence as a result of the requirements of the action itself (the workforce needed to construct or operate the Pipeline), increased recreation (including ORV use, hunting), and habitat degradation, including a reduction of those habitats that are capable of achieving higher quality habitat status but for the Pipeline's impacts within LSR, Riparian Reserves, or within MAMU SHUs (Comer 1982). No effects to MAMU habitat is expected from construction of the LNG Terminal; the following section is specific to construction fo the Pipeline.

Analysis of indirect effects to MAMU habitat by Pipeline construction and operation within the terrestrial nesting analysis area followed guidance provided by FWS included in the Revised Conservation Framework developed for the Project (see *Revised Conservation Framework for the Northern Spotted owl and Marbled Murrelet: Jordan Cove Energy and Pacific Connector Gas Pipeline Project*, FWS 2014c).

Focus of Effects Analyses

Indirect effects from construction of the Pipeline analyzed within this APDBA are considered within three habitat areas defined by FWS as an SHU (FWS 2014c), which include habitat that could play an important role in maintaining and expanding MAMU populations: 1) the MAMU Stand with known or presumed suitable nesting structures; 2) a 300-foot buffer around the MAMU stand that includes forested habitat to protect/provide a buffer to nesting MAMUs as described by the MAMU Recovery plan (FWS 1997); and 3) federally-designated critical habitat within a 0.5-mile buffer around a MAMU stand that is within 0.5 miles of critical habitat removal by the proposed action. The FWS (2008b, 2011b) recognize that forested habitat within 0.5 mile of an occupied stand is important to recruit additional nesting habitat for the MAMU in the future (e.g., coniferous forested stands greater than 60 years of age that are capable of becoming potential nesting habitat within 25 years; FWS 2014c; BLM 1995a, 1995b). Therefore, this latter defined area includes forested habitat proximal to the MAMU stand that could provide suitable nesting structures in the future for the MAMU and has been federally protected through critical habitat designation. Within the terrestrial nesting analysis area where MAMU stands are in close proximity of each other (i.e., less than 300 feet or adjacent), SHUs overlap. Therefore, analyses provided in this APDBA consider the SHUs within the terrestrial nesting analysis area collectively to eliminate duplication of acres of impact. Impacts to individual MAMU SHUs are included in appendix Z1. Figure 1 in appendix Z1 shows the MAMU SHUs in relation to the proposed action and Marbled Murrelet Inland Zones 1 and 2.

Nesting Habitat Removal/Modification

Long-Term Effects to Habitat. Removal of suitable nesting habitat by harvest of old-growth timber has been cited as the primary reason for the species' decline (FWS 1992a). Implementation of the NWFP and management of late successional reserves, and the designation of critical habitat were designed to increase the amount of late successional forest habitat available for the long term, thus increasing potential nesting habitat for MAMUs. The BLM RMPs (BLM 2016a and 2016b) also identify the importance of forested habitat within 0.25 mile of occupied MAMU stands and state that removal of habitat within occupied stands should not occur and other forested habitat within a 0.25-mile radius of any occupied stand should be protected for recruitment of nesting habitat for MAMUs (i.e., stands that are capable of becoming MAMU habitat). Since 2003, effects to MAMU suitable habitat have been minimal (BLM and Forest Service 2006). Suitable MAMU nesting habitat takes a long time to develop (more than 250 years on average); therefore, any removal of suitable habitat or recruitment habitat may affect the recovery of the MAMU since recent trends indicate that MAMUs may be declining (see section 3.3.3.1).

Based on MAMU habitat delineated for the Pipeline, construction of the Pipeline would remove approximately 806.45 acres of MAMU habitat, including 78.04 acres of "suitable habitat" removed from 37 MAMU stands (19 occupied MAMU stands and 18 presumed occupied stands; see tables 3.3.3-6 and 3.3.3-10). Removal of 78.04 acres of suitable MAMU habitat amounts to approximately 0.5 percent of the 14,310 acres of suitable habitat available in the terrestrial nesting analysis area (see table 3.3.3-11) and accounts for 0.09 percent of potential nesting habitat in Conservation Zones 3 and 4 in Oregon (approximately 867,219 acres of higher suitable nesting habitat; (Falxa and Raphael 2016). It is expected that recruitment habitat within SHUs, especially forested habitat greater than 60 years located on federally-managed lands, would provide potential nesting habitat for MAMUs in the future (BLM 1995a, 1995b; FWS 2008a, 2011b, 2014c). The removal of suitable habitat would indirectly affect MAMUs over the long term, for longer that the expected 40-year life of the Project.

Short-Term Effects to Habitat. Additionally, 157.13 acres of MAMU habitat (23.51 acres of suitable habitat) have been identified for use by the Pipeline project as UCSAs that may be used to store forest slash, stumps, and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration (see UCSA Column in table 3.3.3-10). Use of the UCSAs would be a short-term modification of understory species and would not affect the nesting habitat or characteristics.

Summary of Effects to Habitat. Table 3.3.3-10 below summarizes the amount of suitable habitat, recruitment habitat, and capable habitat that would be directly removed or used as UCSAs within and outside of SHUs within the range of the MAMU.

Table 3.3.3-10 (summarized from table Q-3 in appendix Q) also identifies 192.71 acres of MAMU habitat that occur within the designated 30-foot maintenance corridor (21.33 acres of suitable habitat, 75.65 acres of recruitment habitat, and 95.73 acres of capable habitat) within Marbled Murrelet Inland Zones 1 and 2. After construction of the Pipeline, a maximum of 613.74 acres of forested habitat within Marbled Murrelet Inland Zones 1 and 2 outside of the 30-foot maintenance corridor (see Suitable, Recruitment, and Capable in table 3.3.3-10, computed by subtracting areas in the 30-foot Corridor from areas in the Removed columns) would be replanted with trees. This acreage represents a maximum because replanting may not occur or be maintained on non-federal lands and federal lands slated for timber harvest. In areas where trees are planted and maintained as forested habitat, edge effects would decrease over time, although these areas would provide minimal benefit to MAMUs because it would take decades at a minimum to restore replanted forests to recruitment or suitable habitat conditions. Douglas-firs (12-inch seedlings in one-gallon containers or bare root) would be planted on dry sites and western hemlock (12-inch seedlings in one-gallon containers) would be planted on moist sites (see ECRP in appendix F). It is expected that 12-inch Douglas-firs and western hemlocks planted the year of or year after construction could be approximately 70 feet tall in 50 years (expected end of the Pipeline project life). During the first 30 years or so, coastal Douglas-fir are expected to grow at an average rate of 24 inches per year and may grow at a continuous rate of 6 to 9 inches per year to age 120 (McArdle et al. 1961; Hermann and Lavender 2004). Young, unthinned stands of Douglas-fir (38 to 70 years old) were documented between 115 and 154 feet tall while young, thinned stands (40 to 73 years old) were 121 to 151 feet tall (Tappeiner et al. 1997). Western hemlock are highly productive; trees in Oregon were 140 feet tall at 100 years old (an approximate height growth rate of 16-17 inches per year). MAMU habitat within the 30-foot corridor would remain in an early seral state, maintained free of vegetation greater than 6 feet in height, through the life of the project.

Figure 1 in appendix Q provides an overview of MAMU habitat (suitable, recruitment, and capable) within the proposed terrestrial nesting analysis area and includes known occupied and presumed occupied stands, designated critical habitat, and LSRs within Marbled Murrelet Zones 1 and 2 and Conservation Zones 3 and 4. Table 3.3.3-11 summarizes the amount of MAMU habitat affected by the Pipeline project within the terrestrial nesting analysis area pre- and post-action. The proposed action would remove the greatest percentage of available MAMU habitat within the terrestrial nesting analysis area on non-federal lands; however, only a small amount of habitat on non-federal lands is expected to provide suitable nesting structures, and a majority of capable or recruitment habitat is not expected to mature to provide suitable MAMU nesting structures based on review of timber harvest practices in Oregon (Zhou et al. 2005; Rasmussen et al. 2012). These studies noted that forest harvest practices on non-federal lands typically occur between 45 and 65 years of age.

TABLE 3.3.3-10

Summary of Marbled Murrelet Suitable, Recruitment, and Capable Habitat Impacted during Pipeline Project Construction and Operation (30-foot Corridor) within Marbled Murrelet Inland Zones 1 and 2, Recovery Plan Conservation Zones, and within/outside Marbled Murrelet SHUs by Landowner

a/ General Location identifies areas within Marbled Murrelet SHUs – marbled murrelet stands – occupied and presumed occupied, and appropriate buffers and areas outside of Marbled Murrelet SHUs within the range of the marbled murrelet.
b/ Suitable Habitat: generally late-seral forested stands that provide or are presumed to provide nesting structures for marbled murrelet based on modeling and other available GIS data.
c/ Recruitment Habitat: forested land not currently suitable for marbled murrelet nesting that may be capable of becoming suitable marbled murrelet habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).
d/ Capable Habitat: forested land that has the capability of becoming suitable nesting marbled murrelet habitat, generally includes forest stand age 0 to 60 years (FWS 2014c).
e/ Non-Capable habitat: not forested and not capable of becoming forest, or deciduous forest stands.
f/ Pipeline project components considered in calculation of habitat "Removed:" construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), and pipe storage yards.
g/ Acres identified as UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.
h/ Acres of habitat that would be maintained in an early seral / shrub state during the life of the project within the 30-foot maintenance corridor.

Summarized from table Q-3 in appendix Q, which also provides project effects by land allocation and within and outside of interior forest.

a/ Federal Landowners include Coos Bay BLM and Roseburg BLM Districts; Non-federal Landowners include Private and State.
b/ Suitable Habitat: generally late-seral forested stands that provide or are presumed to provide nesting structures for marbled murrelet based on modeling and other available GIS data.
c/ Recruitment Habitat: forested land not currently suitable for marbled murrelet nesting that may be capable of becoming suitable marbled murrelet habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).
d/ Capable Habitat: forested land that has the capability of becoming suitable nesting marbled murrelet habitat, generally includes forest stand age 0 to 60 years (FWS 2014c).

Habitat Impact Categorization. PCGP used the Revised Conservation Framework (FWS 2014c) to guide categorizing effects to MAMU habitat within SHUs into Habitat Impact Categories (Severe, High, Moderate, and Low categories) based on the amount and type of MAMU Habitat removed, as well as the area from which the habitat is removed within the MAMU SHU (see MAMU habitat impact categorization for each MAMU stand in appendix Z1).

The Habitat Impact Category assigned to each MAMU SHU (appendix Z1 and table Q-1 in appendix Q) was applied to acres of MAMU habitat affected by the proposed action (summarized in table 3.3.3-10 from table Q-3 in appendix Q). Where MAMU SHUs overlapped, the higher impact category was considered. MAMU habitat affected outside of MAMU SHUs or within a MAMU SHU that were provided a "No Impact Category" in appendix Z1 are considered areas of "Low Impact," as well. Table MAMU-3 in the introduction to appendix Z1 provides a summary of MAMU habitat affected by Habitat Impact Category within and outside of interior forest.

Temporary Loss of Habitat – Noise and Human Presence

There is a potential for MAMU that may be present within 0.25 mile of Pipeline activities to be disturbed or disrupted from normal activities due to associated noise or human presence from Pipeline project activities, which could cause MAMU to temporarily avoid or flush from suitable nesting habitat (i.e., temporary habitat loss). Approximately 7,145 acres of suitable nesting habitat (occupied and presumed occupied MAMU stands) within the terrestrial nesting analysis area could occur within 0.25 mile of the Projectwhich could result in temporary loss of habitat due to noise and visual disturbance where construction activities, including existing road use (nonpublic) occur within 0.25 mile of suitable habitat within MAMU stands during the breeding season (April 1 through September 15; table 3.3.3-12). Construction activities within the range of the MAMU could occur during the breeding season for up to two years, with DTRs applied for timber removal and construction during the critical breeding season (April 1 through August 5) to minimize direct effects to MAMU. PCGP would continue to apply DTRs in the late breeding season for use of large transport helicopter, if use of large transport helicopters is still necessary, to further minimize disturbance and disruption effects. Proposed activities would not occur simultaneously within MAMU Inland Zones 1 and 2, and therefore, actual temporary, indirect habitat loss would be less than estimated within table 3.3.3-12, and potential direct effects to MAMU utilizing habitat would be short in duration.

TABLE 3.3.3-12

a/ Acres of suitable habitat (MAMU Stands – occupied and presumed occupied, including non-capable and early regenerating habitat within BLM-delineated occupied stands) includes only the area of MAMU stands considered for analysis within this APDBA within 0.25 mile of proposed activities.
b/ Access Roads do not include roads currently identified as public access roads; only nonpublic access roads within 0.25 mile of MAMU stands (occupied and presumed occupied) that have been identified for use by the Pipeline project.

Table 3.3.3-12 identifies that approximately 7,145 acres of potentially suitable MAMU nesting habitat (occupied and presumed occupied stands) could become effectively unavailable on a temporary basis due to noise and/or human presence during Pipeline construction. This overestimates potential Pipeline project effects, because conservative assumptions are used by PCGP, as explained above. Additionally, BLM-delineated occupied stands include habitat not suitable for nesting (non-capable habitat and early seral forested habitat). If considering the occupancy index (see McShane et al. 2004), approximately 3,643.84 acres (51 percent of available suitable habitat in terrestrial nesting analysis area; 7,144.79 acres in table 3.3.3-12) is likely occupied and could be indirectly impacted. Use of existing access roads (nonpublic) could disrupt or disturb MAMU to the extent of expected nest failure during the breeding season (see discussion above in Direct Effects section).

Habitat Fragmentation

In addition to impact by surface disturbances, fragmentation of connected, contiguous habitats would occur. Fragmentation of MAMU habitat can reduce the amount and heterogeneous nature of the habitat, forest patch size, and amount of interior or core habitat, and can increase the amount of edge, isolate remaining habitat patches, and create "sink" habitats (FWS 2006c). The ecological consequences of these habitat changes to MAMUs can include effects on population viability and size, local or regional extinctions, displacement, fewer nesting attempts, failure to breed, reduced fecundity, reduced nest abundance, lower nest success, increased predation and parasitism rates, and reduced adult survival (FWS 2006c).

Habitat Edge. One manifestation of fragmentation is the amount of edge created through otherwise contiguous habitats. In the context of habitat fragmentation, edge is the portion of habitat (or ecosystem on a larger scale) "near its perimeter, where influences of the surroundings prevent development of interior environmental conditions" (page 38 in Forman 1995). As compared to interior habitats, edge habitats generally support different species composition, structure, and species' abundance (Forman and Godron 1986). For example, higher levels of flower and fruit production often occur along the edge (Forman 1995) and vertebrate species richness (bird and amphibian) has positively associated with edges in fragmented Douglas-fir forests (Rosenberg and Raphael 1986). Edges play a crucial role in controlling ecosystem interactions and landscape function, including the distribution of plants and animals, fire spread, vegetation structure, wildlife habitat conservation, and physical environments.

Research indicates that MAMUs within southern Oregon tend to nest in stands that are generally located away from high-contrast edge created from timber stand harvests and adjacent immature forests (Ripple et al. 2003; Meyer et al. 2002). In Canada, Zharikov et al. (2006) found MAMUs commonly nesting in stands near edges, although when edge increased in the nest stand, more nests failed (Zharikov et al. 2007). Nest failure observed by Zharikov et al. (2007) could be a result of increased risk of nest predation by corvids, since Raphael et al. (2011) and McShane et al. (2005) indicated that MAMU have reduced nest success along forested edges as a result of nest predation, predominantly by species of corvids. Alternatively, a study conducted in British Columbia found no evidence suggesting that nesting near forest edges, especially natural edges, reduced reproductive success in MAMUs (Bradley 2002). In addition, nests at edges of clearcuts, old-growth, and second-growth transitional forests were generally more successful than not successful. In that study, increased reproductive success at natural edges compared to interior forest stands was thought to be related to the ease of nest tree accessibility having a greater benefit to MAMUs than the risk of nest predation (Bradley 2002).

Increase in edge within SHUs from construction of the Pipeline may result in reduced nest success as a result of increased nest predation by corvids (Raphael et al 2011, McSchane et al. 2005; Meyer et al. 2002). Fragmentation of an SHU may also result in eventual abandonment of the stand. For example, Meyer et al. (2002) reported that fragmentation may result in increased predation on nests near forest edges, which could cause the birds to abandon small old-growth stands with high edge/area ratios. Meyer et al. (2002) determined that stands with large core areas over 50 to 100 meters from edge had higher occupancy and abundance than patches with little or no core area, and on average, occupied old-growth stands were 136 acres (55 hectares) in size. However, since the terrestrial nesting analysis area has already been subjected to extensive fragmentation by past land uses including transportation corridors, timber harvest and associated activities (i.e., road construction), and urban development, occupied and presumed occupied stands analyzed within this APDBA are generally smaller than 136 acres (see overall acres in the stand in table Q1 in appendix Q). To minimize further fragmentation to MAMU stands in the terrestrial analysis area from construction and operation of the Pipeline, PCGP routed the Pipeline in or adjacent to existing edge (forested or non-forested) or corridors. Within MAMU Inland Zone 1 and Zone 2 (MP 0.0 to MP 75.40), the Pipeline would be located within or parallel to existing corridors for approximately 30.5 miles (40 percent of proposed action in MAMU range; see table Q-4 in appendix Q), thus minimizing fragmentation within known or potential suitable MAMU nesting habitat. Table Q-4 in appendix Q identifies the location of MAMU Stands and associated SHU habitat areas in relation to existing rights-of-ways and corridors. However, additional fragmentation would occur within suitable nesting habitat (occupied and presumed occupied stands), as well as recruitment and capable habitat due to the Project.

Table 3.3.3-13 identifies 39 MAMU stands (occupied and presumed occupied) that overlap the Pipeline. The 39 affected stands range in size from 0.86 acre (presumed occupied stand on edge of right-of-way and uncapable habitat on private land) to 326.96 acres in an occupied stand, of which most stands (20 presumed occupied stands and 9 of 19 occupied stands) are currently smaller than 124 acres (table 3.3.3-13). With the exception of 14 MAMU stands (eight occupied and six presumed occupied), most suitable habitat that would be removed by construction of the Pipeline project either occurs on the edge of the MAMU stand or between the interface of the older occupied stand and an adjacent young, regenerating stand and/or existing access roads. Additionally, five presumed occupied stands occur on the extreme edge of the Pipeline project footprint and would not be expected to have suitable habitat or large trees removed from the stand and two other occupied MAMU stands would have in-road construction that would minimize or avoid removing potentially suitable nesting habitat (see underlined stands in table 3.3.3-13). Table 3.3.3-13 summarizes the length that each of the 39 MAMU stands is crossed by the proposed Pipeline, how much each stand is reduced in size, and the resulting habitat patches for the 14 stands bisected by the Pipeline.

The Pipeline would bisect eight occupied stands and six presumed occupied stands (see asterisk in table 3.3.3-13), although some stands identified with an asterisk would remove additional habitat adjacent to existing roads, essentially creating two lobes of the stand. Five of the MAMU stands that would be bisected are currently 136 acres or greater, and within those occupied stands, construction of the Pipeline would create habitat patches smaller than 136 acres (C1080, C3073, and R3051; see table 3.3.3-13). Although these stands would be reduced below 136 acres, a mean patch size that Meyer et al. (2002) indicated was generally occupied by MAMUs, most stands analyzed in the terrestrial nesting analysis area are below the 136 acres as a result of the currently fragmented landscape but still have observed MAMU nesting.

Table Q-1 in appendix Q, as well as the MAMU Impact Categorization for each MAMU Stand in appendix Z1 identifies the suitable, recruitment, and/or capable MAMU habitat that would be removed within the 300-foot Buffer of each MAMU Stand outside of the MAMU breeding season (see also maps of each MAMU Stand located within appendix Z1). The proposed Pipeline occurs in MAMU recovery plan Conservation Zones 3 and 4, of which the recommended management to aid in recovery includes maintaining designated occupied sites and minimizing loss of unoccupied but suitable habitat (FWS 1997). PCGP has adjusted the proposed route to minimize impact to MAMU stands by 1) rerouting the Pipeline to avoid occupied stands documented during 2007 and 2008 survey efforts, 2) incorporating minor alignment adjustments to reduce habitat removed in occupied stands, 3) modifying or moving temporary extra work areas, and 4) restricting the construction right-of-way to roads within occupied and presumed occupied stands. Approximately 78.04 acres of suitable habitat would be removed from occupied and presumed occupied stands, removing a total of 0.5 percent from available suitable habitat within the analysis area (14,345 acres; see table 3.3.3-11, above). Overall, 2.6 percent of MAMU habitat (suitable, recruitment, and capable) within delineated MAMU stands would be removed as a result of construction (see table 3.3.3-13).

TABLE 3.3.3-13

Suitable Nesting Habitat Removed from Occupied and Presumed Occupied Stands Affected by the Proposed Action

MSNO or Site ID a/	Status b/	Project Location (MP range in stand)	Landowner	Land Allocation c/	Overall Acres in the Stand	Length Crossed		Edge Created	Suitable Habitat Affected in MAMU Stand d/		Additional Description (see Maps in appendix Z1)
						Feet	Miles		Acres	Percent of Stand	
Marbled Murrelet Zone 1											
WC1A-C	Presumed (No Permission)	8.24R - 8.25R	Private	None	0.86	0	0	0	0.01	1.2	Stand adjacent to non-capable habitat (pasture); no trees within the presumed occupied stand would be removed.
WC1A-G	Presumed (No Permission)	8.79R-8.85R	Private	None	3.11	307.92	0.06	0	0.62	19.9	Habitat on edge of 100' powerline corridor and surrounded by recent clearcut (habitat previously considered a part of the presumed occupied stand) and early regenerating forest; ROW follows existing road ~ 50-100 feet from powerline corridor; would remove habitat either side of two-track road, generally reducing or removing all potential habitat in WC1A-G between road and powerline corridor; other permitted 'gray' habitat around stand determined "not suitable'; no new edge created.
C1027*	Occupied (Coos Bay BLM)	12.83BR - 13.17BR	Coos Bay BLM	LSR	43.40	153.18	0.03	2	2.22	5.1	ROW follows edge of one lobe of occupied stand following a two-track road between late seral and early seral forested habitat; ROW continues to follow road (EAR 13.15BR-13.66BR) between two lobes of occupied stand. Does not fragment stand but would increase fragmentation along existing access road, essentially creating two lobes (17.5 acres and 23.6 acres after construction).
C1042	Occupied (Coos Bay BLM)	13.17BR - 13.31BR 13.46BR - 13.58BR	Coos Bay BLM	LSR	76.61	1,006.33	0.19	1	1.55	2.0	ROW generally follows an existing road (EAR 13.15BR-13.66BR; BLM 26-12-4.1) through outer portion of northern lobe of the occupied stand and then skirts the outer edge of southern lobe of the occupied stand. ROW increases existing edge along road within the northern lobe of stand and creates a harder edge along southern lobe between early regen and late seral forest in the stand.
G102	Presumed (Ground Survey)	TEWA 13.79BR	Private	None	4.01	0	0	1	<0.01	<0.1	The ROW and TEWA are located on the edge of the presumed occupied stand and generally occur within existing roads and adjacent early seral habitat; it is not expected that suitable MAMU habitat would be removed from the delineated stand. The project would not fragment the stand but would create a hard edge.
C1040	Occupied (Coos Bay BLM)	13.46BR - 13.78BR	Coos Bay BLM	LSR	72.87	856.55	0.16	1	2.14	2.9	This occupied stand is adjacent to occupied stand C1042. The ROW follows existing Road (EAR 13.15BR-13.66BR, BLM 26-12-4.1) for approximately 1,290 feet on the north edge of the stand, between late seral and early regenerating forest. The ROW would not fragment the stand but would create a hard edge along the north edge of the stand between late seral habitat in the Stand and early regeneration forests.
BR 01	Presumed (Presence – 2015)	14.06BR - 14.15BR	Coos Bay BLM	Other	1.88	0.76	<0.01	1	0.64	34.0	Small stand adjacent to EAR 13.83BR-14.42BR (BLM 26-12-4.4) and surrounded by early seral forest. The ROW would follow the existing road on the edge of the stand. Does not fragment stand but would create a harder edge between stand and early seral forest. Although trees greater than 107 feet that could provide suitable habitat would be removed by the Project (LiDAR coverage), the stand would continue to provide potentially suitable nesting habitat including within at least four trees greater than 200 feet.
G109	Presumed (No Permission)	15.40BR-15.50BR	Private	None	3.17	384.37	0.07	1	1.00	31.5	The ROW removes habitat from eastern portion of small presumed occupied stand and would create a hard edge between early seral forest and the remaining late seral forest in the delineated stand. Based on LiDAR coverage, the Project could remove potentially suitable nesting habitat (trees > 107 feet); however, at least three additional trees greater than 107 feet within the delineated stand would remain.
BR 02A*	Presumed (Ground Survey)	16.44BR - 16.71BR	Coos Bay BLM / Private	LSR / None	81.94	1,456.47	0.28	2	3.78	4.6	ROW generally follows an existing access road (EAR 16.09BR-16.97BR, BLM 26-12-15.2) through the middle of the presumed occupied stand. The ROW generally occurs in smaller trees within the stand but would fragment the stand where it deviates from the existing road; two resulting lobes = 45.9 acres and 32.2 acres. The project would also increase fragmentation along the existing access road.
BR 03*	Presumed (Presence – 2015)	17.13BR - 17.56BR	Coos Bay BLM	LSR	70.29	2,263.56	0.43	2	4.78	6.8	ROW generally follows or parallels an existing road (EAR 16.97BR-18.14BR, Blue Ridge Road) through the stand and would remove forested habitat either side of road. Where the ROW deviates from the existing road, additional edge in the stand would be created; resulting two lobes = 50.85 acres and 14.09 acres. Stand is surrounded by clearcut and early seral forest.
BR 04	Presumed (Presence – 2015)	17.60BR-17.90BR	Coos Bay BLM	LSR	32.13	0	0	1	0.17	0.5	ROW parallels existing access road (EAR 16.97BR-18.14BR, Blue Ridge Road) and removes potential habitat within extreme point of finger-like lobe of presumed occupied stand. Project does not fragment stand but creates harder edge on the narrow stand finger between stand and early seral habitat that surrounds stand.
G120	Presumed (Presence – 2015)	18.86BR - 19.02BR	Coos Bay BLM	LSR	13.06	861.69	0.16	1	2.16	16.5	Stand consists of two lobes separated by existing access road (EAR 10.20BR-19.61BR, Blue Ridge Road). Project generally parallels Blue Ridge Road within the larger, eastern lobe of G120, where habitat is removed on the edge of the lobe between the road and the stand and creates a hard edge.
BR 05	Presumed (Presence – 2015)	19.02BR - 19.13BR 19.18BR - 19.25BR	Coos Bay BLM	LSR	51.00	0	0	1	0.87	1.7	Large stand consists of three lobes separated by Blue Ridge Road. ROW generally parallels Blue Ridge Road and removes habitat between early/mid-seral

TABLE 3.3.3-13

Suitable Nesting Habitat Removed from Occupied and Presumed Occupied Stands Affected by the Proposed Action

MSNO or Site ID a/	Status b/	Project Location (MP range in stand)	Landowner	Land Allocation c/	Overall Acres in the Stand	Length Crossed		Edge Created	Suitable Habitat Affected in MAMU Stand d/		Additional Description (see Maps in appendix Z1)
						Feet	Miles		Acres	Percent of Stand	
											forest and far eastern edge of two lobes of the presumed occupied stand. Project does not further fragment stand but creates harder edge from stand and access road and/or early/mid-seral forest.
BR 06	Presumed (Presence – 2015)	19.50BR - 19.62BR	Coos Bay BLM Bay	LSR	60.79	0	0	0	0.01	<0.1	Large stand consists of two lobes. ROW is generally located over 300 feet west of presumed occupied stand, but is adjacent to the southern edge of the stand for approximately 670 feet where the ROW follows existing access road (EAR 19.20BR-19.61BR, Blue Ridge Road). Although the ROW intersects the Stand at this location, it is not expected that the project would remove suitable nesting habitat – only early regenerating forest along the edge of the existing road.
G122*	Presumed (Presence – 2015)	19.63BR - 20.2BR	Coos Bay BLM	LSR	42.11	1,956.49	0.37	2	5.64	13.4	ROW divides stand for approximately 0.25 mile and then follows the edge of the stand, following an existing access road (EAR 19.88BR-20.05BR) for a portion. Project would fragment the stand and would also create a harder edge along the edge of the stand; resulting two lobes = 9.79 acres and 26.42 acres. Based on LiDAR coverage, the Project could remove potentially suitable nesting habitat (trees > 107 feet); however, the remaining portion of the stand would continue to provide potential nesting habitat (trees > 107 feet).
G128	Presumed (Presence – 2015)	22.69BR - 22.95BR	Coos Bay BLM	LSR	11.34	17.39	<0.01	1	0.25	2.2	ROW traverses the western edge of the presumed occupied stand. Project would not fragment stand but create a harder edge between early seral forest and delineated stand. Although project removes a small amount of habitat from the edge of the stand, it is not expected to remove the larger, potentially suitable trees.
G129	Presumed (Presence – 2015)	23.06BR - 23.08BR	Coos Bay BLM	LSR	1.42	0	0	0	<0.01	<0.1	ROW traverses the western edge of a small presumed occupied stand. Although the ROW is adjacent to the stand and just intersects the delineated stand, the project is not expected to remove suitable MAMU habitat.
G133*	Presumed (No Permission)	24.49BR - 24.5BR	Private	None	1.87	77.90	0.01	2	0.17	9.1	This presumed occupied stand incorporates potentially suitable habitat within a strip of habitat adjacent to an existing access road (EAR 24.50BR) and early regenerating forest. The ROW would bisect the stand in two lobes creating two additional edges; resulting lobes = 1.21 acres and 0.49 acre. Based on available LiDAR, no trees greater than 107 feet would be removed and potential nest trees would remain in the existing stand.
G134*	Presumed (No Permission)	24.58BR - 24.72BR	Private	None	12.84	736.65	0.14	2	1.62	12.6	The ROW bisects this presumed occupied stand that is adjacent and/or near early seral/clearcut forest; resulting two lobes = 5.02 acres and 6.20 acres. One existing road (EAR 24.72BR) traverses across the south eastern portion of the stand. Based on LiDAR coverage, the Project could remove potentially suitable nesting habitat (trees > 107 feet); however, the remaining portion of the stand would continue to provide potential nesting habitat (trees > 107 feet).

a/ Underlined MSNO or Site ID indicates that the project is not expected to remove suitable nesting habitat from the stand. Asterisk (*) indicates Pipeline would bisect stand and create at least two new edges.
b/ "Occupied" – areas/stands delineated that occupied marbled murrelet behavior has been documented. Stands have been provided by BLM Coos Bay and Roseburg districts (BLM 2017). ""Presumed" – these are areas that may provide suitable MAMU nesting habitat as determined through 1) LiDAR, 2) identified by Coos Bay and/or Roseburg BLM Districts, 3) suitable habitat modeling (Raphael 2015; habitat value 4), or 4) ground-truthed by SBS/PCGP..
c/ Land Allocation: LSR = late-successional reserves; CHU = Marbled Murrelet Critical Habitat Unit OR-06-d; Other = other BLM land use allocations except for LSR; None = marbled murrelet stand on Private or Native American lands and do not have BLM LUA or designated CHU.
d/ MAMU Habitat includes suitable, recruitment, and/or capable habitat affected in the MAMU Stand; non-capable habitat is not tallied. Overall, 78.04 acres of suitable habitat is removed from occupied and presumed occupied stands (see table 3.3.3-10).

PCGP surveyed 17 occupied and presumed occupied stands located on BLM lands in fall 2013 to identify potential nest trees that may occur within proximity of the proposed Pipeline (see R&A and SBS 2014). Trees with adequate nesting platform structures, as outlined in the Pacific Seabird Group protocol (Mack et al. 2003) were considered "potential nest trees" and included: 1) mature (with or without an old-growth component) and old-growth coniferous trees, or 2) younger coniferous trees that have platforms. A nesting platform consists of a relatively flat surface (at least 4 inches in diameter) that occurs at least 33 feet from the ground in the live crown of a coniferous tree and can include a wide bare branch, moss or lichen covered a branch, mistletoe, witches brooms, or other deformities (i.e., squirrel nests).

In October 2013, PCGP cruised/surveyed nine stands that would be affected by the Pipeline, where permitted, of which six stands would be bisected by the Pipeline. LiDAR was available for the stands located in Coos Bay, and based on height of trees (> 107 feet, > 200 feet), there are several potential nest trees within the stands, both within and outside of the right-of-way. Potential nest trees (large trees with deformities) were documented within the construction right-of-way.

Additional description in table 3.3.3-13 describes the potential nest trees that were identified within the proposed construction area, if any. Additional maps have been prepared and included in appendix Z1 for the 39 MAMU stands that would potentially have suitable habitat removed by construction. The maps include locations of potential nest trees located within the vicinity of the proposed Pipeline during survey efforts in fall 2013, and were available (23 of 37 MAMU stands), are produced with a LiDAR background that depicts the structure and height of the MAMU stand, where available. Based on these maps and the potential nest trees documented within the vicinity of the Pipeline right-of-way, it can be assumed that each stand contains trees outside of the Pipeline project area that could provide suitable nesting habitat (i.e., trees greater than 200 feet in height). Although PCGP would remove potential nesting trees, it is expected that the biological viability would remain intact after construction activities have occurred since remaining habitat in the stands adjacent to the Pipeline would continue to provide potentially suitable nesting structures that could be used by the MAMU. In close proximity to the coast (within 20 miles), only one potential nest tree within a stand is considered necessary to provide nesting habitat for MAMU, whereas further from the coast (greater than 20 miles), at least six potential nest trees within a forested stand is considered necessary to be suitable for nesting MAMU. PCGP will evaluate the following possible opportunities during the detailed design phase that would further reduce impact to MAMU nesting habitat and reduce fragmentation, in particular where the Pipeline traverses Blue Ridge: 1) in-road construction where the right-of-way occurs on an edge of a MAMU stand in an existing road, or 2) reduce the width of the construction right-of-way, similar to wetland minimization measures.

Interior Forest Habitat. Indirect effects from construction of the Pipeline are also expected within habitat adjacent to the construction right-of-way, including within interior forest that the MAMU relies on for nesting habitat. The conversion of large tracts of old-growth forest to small, isolated forest patches with large edge areas can create changes in microclimate, vegetation species, and predator-prey dynamics. In general, microclimates along edges differ from those in forest interiors. Two main physical factors affecting and creating an edge microclimate are sun and wind (Forman 1995; Chen et al. 1995; Harper et al. 2005). Compared to the forest interior, areas near edges receive more direct solar radiation during the day, lose more long-wave radiation at night, have lower humidity, and receive less short-wave radiation. Other physical factors affecting edge includes edge orientation (Chen et al. 1995). For example, the general orientation of the Pipeline project is from northwest to southeast. Therefore, edge effects would be most pronounced on the southwest-facing edges and weakest along the northeast-facing edges (see discussion in Chen et al. 1995). Harper et al. (2005) reported that the mean distance of edge influence could occur to approximately 100 meters (328 feet) and result, on average, in 1) increased tree mortality and damage, increased recruitment, increased growth rate, decreased canopy foliage, increased understory foliage, and increased seedling mortality; 2) decreased amounts of canopy trees, reduced canopy cover, increased abundance of snags and logs, increased understory tree density, increased herbaceous cover, and increased shrub cover; and 3) increased stand composition metrics such as species, exotics, individual species, and species diversity. In other younger coniferous forests or mixed forests with deciduous species, edge effects compared to interior forests have been much less pronounced (Heithecker and Halpern 2007; Harper and Macdonald 2002). The importance of interior forest habitat to MAMUs is unclear. Suitable nest trees may be present within interior forest but reproductive success may be lower than at forest edges if access to interior forest nest trees is problematic, decreasing site suitability (Bradley 2002).

To determine indirect effects to MAMU habitat (suitable, recruitment, capable) from construction of the Pipeline project, PCGP assessed effects to MAMU habitat within 100 meters (328 feet) of proposed habitat removal, including effects to interior forest. This distance has been recommended by FWS (2014c), and is similar to the 300 feet considered in discussions within the Habitat Quality subtask force to analyze effects to interior forests (2007 and 2008), and the 295 feet used as an edge assessment by Raphael et al. (2011) within the NWFP 15-Year Monitoring Report for nesting MAMU habitat. This assessment considers the indirect effects of the newly constructed right-of-way on MAMU habitat within 100 meters (328 feet) of habitat removal, including interior forest. To determine which tracts of forested land (late regenerating, mid-seral, late successional, and old-growth) should be considered interior forest, existing edges, such as wide-surface roads, large rivers, early seral forest, and nonforested habitat were buffered by 100 meters (328 feet), and forested habitat included in the buffered area was identified as forested habitat currently affected by existing edge (FWS 2014c). Smaller roads with existing canopy cover were buffered by 50 feet per direction of FWS (2014c). Forested habitat (late regenerating to old-growth forest) that was not included in buffered "currently affected" area was classified as "interior forest" and incorporated into an interior forest GIS layer created for analysis of the Pipeline project.

Table 3.3.3-14 identifies the distance that MAMU habitat is crossed by the proposed Pipeline within and outside of interior habitat, summarizes the acreage of MAMU habitat directly removed and indirectly affected within 100 meters (328 feet) of the Pipeline project (habitat removal) by Marbled Murrelet Inland Zones 1 and 2, landowner, and within and outside of SHUs (summarized from table Q-3 in appendix Q). Approximately 5,163 acres of MAMU habitat (656 acres of suitable habitat, 2,058 acres of recruitment habitat, and 2.449 acres of capable habitat) occur within 100 meters (328 feet) of habitat removal, of which 1,455 acres (28.2 percent) of interior MAMU habitat would be indirectly affected (364 acres of suitable habitat, 644 acres of recruitment habitat, and 447 acres of capable habitat; table 3.3.3-14). The majority of MAMU habitat indirectly affected occurs outside of SHUs: 3,762 acres (72.8 percent) of all MAMU habitat within 100 meters (328 feet) of habitat removal, which includes 840 acres of interior MAMU habitat and 2,922 acres of MAMU habitat currently affected by existing edge.

Table Q-3 in appendix Q identifies the acres of MAMU habitat affected 100 meters (328 feet) from habitat removal by Marbled Murrelet Inland Zone, Recovery Plan Conservation Zone, land allocations (critical habitat and LSR effects), and landowner within SHUs and interior forest. Effects to MAMU habitat adjacent to the construction right-of-way would decrease as the forested area (a maximum of approximately 483 acres; table 3.3.3-14) outside of the 30-foot maintenance corridor are replanted with trees and return to early regenerating stands, except for those habitats on non-federal or Matrix/Harvest Land Base lands where there is less certainty that replanting would occur or be maintained on the landscape. Additionally, if allowed to regrow, these areas would provide minimal benefit to MAMUs because it would take decades at a minimum to restore replanted forests to recruitment or suitable habitat conditions.

Based on table 3.3.3-14, it can be assumed that at least 15.1 miles of interior forest would experience fragmentation as a result of construction and operation of the Pipeline, creating at least 30.2 miles (15.1 miles x 2) of additional edge in approximately 53 miles of MAMU habitat crossed by the Pipeline; this considers interior forest crossed by the Pipeline within older regenerating forest to old-growth forest (see FWS 2014c). Additional fragmentation of approximately 10.3 miles within forest currently affected by existing disturbance ("other" forest in table 3.3.3-14) could occur since approximately 40 percent (30.5 miles) of the Pipeline within the range of MAMU occurs within or is adjacent to/parallels existing disturbance (see co-locate table Q-4 in appendix Q; 40.8 miles minus 30.5 miles), creating approximately 20.6 miles of additional edge in forest already affected by existing disturbance. In addition to MAMU habitat crossed and affected within the MAMU range, approximately 24.3 miles of non-capable habitat would be crossed and remove approximately 676 acres (see table Q-3 in appendix Q). Figure 3.3.3-8 below provides an example of how indirect effects to MAMU habitat, both within and outside of interior forest are considered within the range of the MAMU.

Predation and Edge

A long-held tenet of bird conservation is that habitat fragmentation with concomitant exposure of nests at habitat edges increases risks of nest predation and/or nest parasitism and ultimately affects species' population growth. While various reviews of available literature have supported that relationship (Paton 1994), other reviews have found no relationships or ambiguous associations between fragmentation and nest predation (Murcia 1995; Lahti 2001). A common theme among reviews is poor representation of studies with tested hypotheses on the edge-predator hypothesis (Chalfoun et al. 2002). Some of the disparate results among studies come from forest characteristics, predator species, and predated species which makes generalizations about effects of fragmentation difficult; in western forests, fragmentation may reduce the abundance of some nest predating species while increasing the abundance of others (Tewksbury et al. 1998).

Early studies of fragmentation effects on predation of MAMU nests yielded mixed results (Meyer and Miller 2002). In British Columbia, MAMU nests greater than 150 meters (492 feet) from the edge of fragmented nest stands did not fail because of nest predation (Manley and Nelson 1999 in Nelson 2005). Nelson and Hamer (1995) found that MAMU nest success was higher for nests greater than 50 meters (164 feet) from forest edge. However, an experimental study using artificial nests in Washington did not detect differences in nest predation within fragmented or continuous forest stands (Marzuluff and Restani 1999 cited in Meyer and Miller 2002).

More recent investigations have given new support for the relationship between fragmentation, edges, and predation on MAMU nests. Predation at experimental MAMU nests located at fragment edges and at forest interiors was recorded by cameras. Disturbances by avian predators (Steller's jay, *Cyanocitta stelleri*) were more frequent at hard edges (between old growth and clearcut forest) relative to interiors, but less frequent at soft edges (between old growth and regenerating forest). There were no edge effects at natural-edged sites associated with riparian forest (Malt and Lank 2007).

TABLE 3.3.3-14

a/ Landowner: Federal includes Coos Bay and Roseburg BLM Districts; Non-federal includes State and Private lands.
b/ General Location identifies areas within Marbled Murrelet SHUs—occupied and presumed occupied—and areas outside of Marbled Murrelet SHUs but within the range of the marbled murrelet.
c/ Interior Forest: forested habitat farther than 100 meters (328 feet) from existing disturbance (i.e., wide-surface roads, existing corridors) or adjacent land use/vegetation type (i.e., agriculture, non-forest, early regenerating forest), and/or farther than 50 feet from smaller roads with existing canopy cover (FWS 2014c). Other Forest Type includes forested habitat that is currently affected by existing disturbance or adjacent land use/vegetation types within 100 meters (328 feet) of disturbance
d/ Suitable Habitat: generally late-seral forested stands that provide or are presumed to provide nesting structures for marbled murrelet based on modeling and other available GIS data.
e/ Recruitment Habitat: forested land not currently suitable for marbled murrelet nesting that may be capable of becoming suitable marbled murrelet habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).
f/ Capable Habitat: forested land that has the capability of becoming suitable nesting marbled murrelet habitat, generally includes forest stand age 0 to 60 years (FWS 2014c).
g/ Total Habitat: only includes forested MAMU habitat
h/ Pipeline project components considered in calculation of habitat "Removed:" construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), pipe storage yards, and rock source and disposal site.
i/ Acres identified as UCSAs have been incorporated into the 100-meter indirect effects. Indirect Effects considers habitat within 100-meters (328 feet) of habitat removal as measured from the edge of habitat removal/edge of right-of-way/TEWA.
j/ UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.
k/ 30-foot-wide Maintenance Corridor would be kept in a shrub/sapling state for the life of the project; all other habitat outside of the 30-foot maintenance corridor would be revegetated, except for those habitats on non-federal or matrix lands where there is less certainty that replanting would occur or be maintained on the landscape.
Note: Table summarized from table Q-3 in appendix Q, which includes effects by general landowner, by Conservation Zones 3 and 4 and Marbled Murrelet Inland Zones 1 and 2. Habitat effects are also broken out marbled murrelet habitat type and within and outside of marbled murrelet SHUs (occupied and presumed).

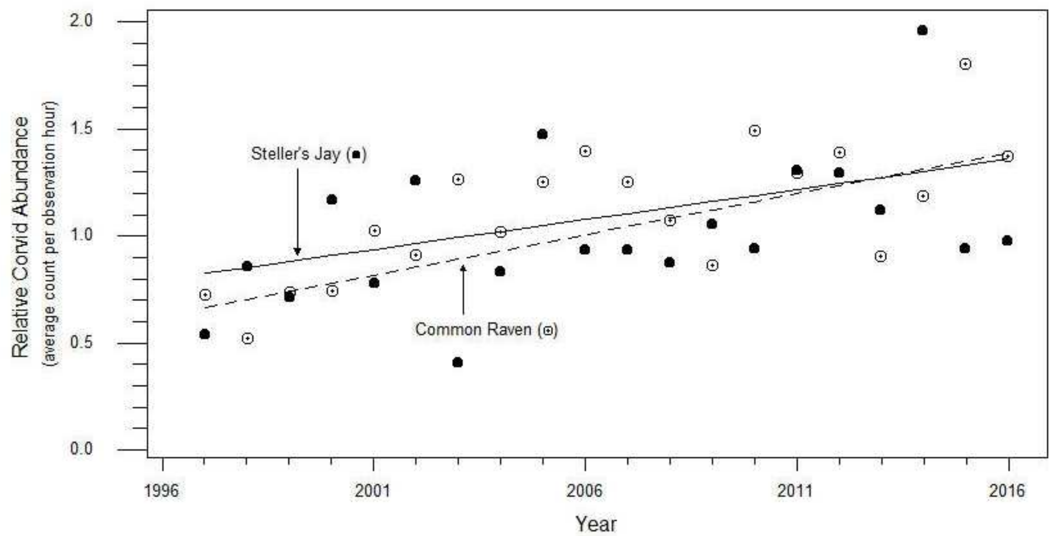
Nest disturbance probability at hard edges was 2.5 times that of interior sites, but soft edges had less than half the disturbance probability of interiors (Malt and Lank 2009). The study also showed that the negative effects of fragmentation decrease over time as managed forests regenerate, changing edge characteristics from hard to soft contrasts with older forest stands. Further, the study found Steller's jay to be the dominant avian predator of simulated nests and abundance of Steller's jay increased across the landscape as old-growth forest cover declined (Malt and Lank 2009). That study and another by Marzluff et al. (2004) demonstrated that Steller's jays prefer fragmented habitat and high contrast edges, often sites associated with residential sites and campgrounds, locations where jays are more likely to successfully forage and fledge young. Study results reported by Malt and Lank (2009) suggested that larger areas of habitat would lessen negative effects of hard edges, including surrounding or embedding small reserves of suitable MAMU nesting habitat within a protective matrix of surrounding regenerating forest that would reduce predation risks to nesting MAMUs as well as to the conservation of other old-growth associated bird species (Malt and Lank 2009). However in Oregon, Luginbuhl et al. (2001) found that predator densities and rates of nest predation are higher in areas with a variety of tree ages, so nest success is reduced in areas intermixed with young trees or brush habitat (Raphael 2006).

In addition to Steller's jay, common ravens (Corvus corax) have been observed preying on MAMU nestings and eggs (Nelson and Hamer 1995; Peery and Henry 2010). Statistically significant increasing regional trends of corvids within the Pipeline vicinity, specifically Steller's jay and common ravens which have been observed during the National Audubon Society CBCs since the early 1990s (see figure 3.3.3-9) and have likely contributed to existing but undocumented nest predation of MAMUs and other bird species (see Liebezeit and George 2002 for a comprehensive review of corvid predation). Population viability modeling of MAMUs in central California included various nest predation rates by corvids (Peery and Henry 2010). With only a 40 percent reduction in predation, the extinction risk was dramatically reduced from 96 percent to 5 percent over 100 years and a 60 percent reduction resulted in a stable MAMU population with assumed modest proportion of breeders, renesting rates, and corvid predation rates. The modeled population viability analysis revealed that nest predation would only need to be reduced by 40 percent to produce a stable population if corvid management was coupled with a modest increase in after-hatch-year survival rate (Peery and Henry 2010). Corvid control resulted in greater gains in MAMU population size when the maximum number of breeders was allowed to increase over time, similar to what would be expected if the amount of old-growth nesting habitat increased over time (Perry and Henry 2010). The authors and others (Liebezeit and George 2002) advocate evaluating local corvid populations, local conditions that may subsidize artificially high population levels (e.g., food, garbage), and MAMU nest site vulnerability to develop a corvid management plan that may or may not include lethal removal if an immediate short-term solution to predation is required (e.g., Liebezeit and George 2002).



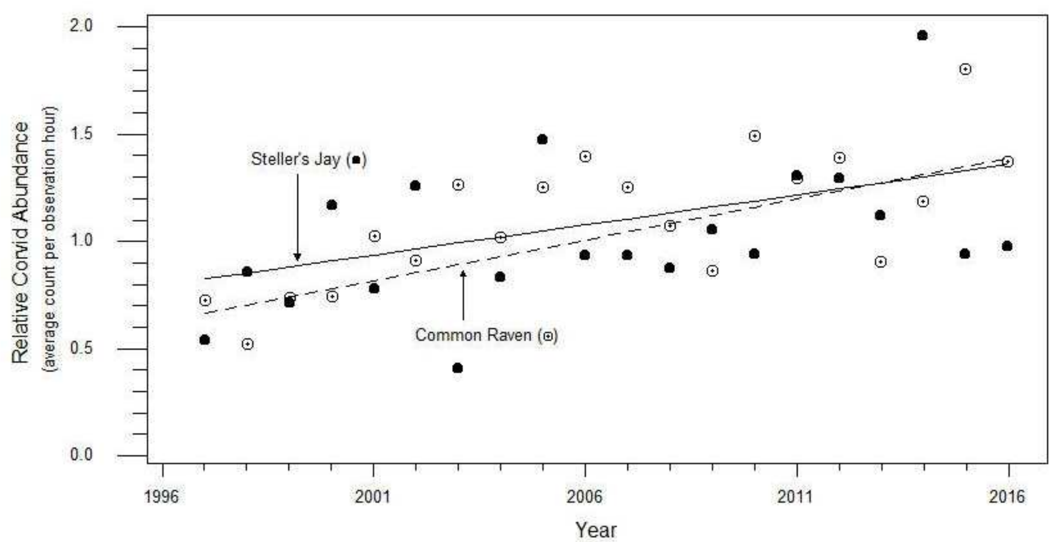


Figure 3.3.3-9 Relative Abundance for Two Species of Corvids Surveyed During the National Audubon Society Christmas Bird Counts within the Pipeline Vicinity, 1997 through 2016, with Significant Increasing Trends (Steller's Jay, P<0.05; Common Raven, <0.001).

Creation of a 30-foot shrub/grass utility corridor could increase current corvid densities and result in reduced nest success, although, where feasible, revegetation (tree planting) outside of the 30-foot maintenance corridor on certain federal lands and non-federal lands and subsequent regrowth may reduce the effects of a hard edge and minimize predation on nesting MAMU. Food enticements associated with human presence during construction activities could also increase predator populations within the vicinity of the Pipeline. All trash, food waste, and other items attractive to ravens, jays, magpies, and other corvids would be picked up and removed from the construction areas on a daily basis to minimize potential predation of MAMU nestlings.

Critical Habitat/Late Successional Reserves

The FWS (1996, 2011b) determined the physical and biological habitat features associated with the terrestrial environment that support nesting, roosting, and other normal behaviors essential to the conservation of the MAMU. Within areas essential for successful MAMU nesting, FWS utilized the following physical and biological habitat features to identify critical habitat: PCE 1 – individual trees with potential nest platforms (comparable to suitable habitat within this APDBA); and PCE 2 – forest lands of at least one half site-potential tree height, within 0.5 mile of individual trees/suitable habitat stand that are recruitment or capable habitat (within a MAMU Group/SHU). Within this analysis, PCE 2 is comparable to recruitment habitat delineated (FWS 2013g).

A variety of ongoing or proposed activities that disturb or remove physical and biological habitat features may adversely affect, remove or modify MAMU critical habitat. Such activities include, but are not limited to: 1) forest management activities that greatly reduce stand canopy closure, appreciably alter the stand structure, or reduce the availability of nesting sites; 2) land disturbance activities such as mining, sand and gravel extraction, and road building; and 3) harvest of certain types of commercial forest products (e.g., moss).

Those activities have the following effects on the PCEs of MAMU critical habitat:

1. Removal or degradation of individual trees with potential nesting platforms, or the nest platforms themselves, that results in a substantial decrease in the value of the trees for future nesting use. Moss may be an important component of nesting platforms in some areas.
2. Removal or degradation of trees adjacent to trees with potential nesting platforms that provide habitat elements essential to the suitability of the potential nest tree or platform, such as trees providing cover from weather or predators.
3. Removal or degradation of forested areas with a canopy height of at least one-half the site-potential tree height and regardless of contiguity, within 0.5 mile of individual trees containing potential nest platforms. This includes removal or degradation of trees currently unsuitable for nesting that contribute to the integrity of the potential nest area (e.g., trees that contribute to the canopy of the forested area). These trees provide the canopy and stand conditions important for MAMU nesting (FWS 1996).

The proposed Pipeline crosses one federally designated CHU (OR-06-d) five times for a total of 2.14 miles, although not all habitat within designated critical habitat is forested MAMU habitat (i.e., "non-capable" in table Q-3 in appendix Q; see table 3.3.3-15). Additionally five rock source and disposal sites occur within critical habitat: Signal Tree Road Quarry (Section 3, MP 45.86), Signal Tree Road Quarry (Section 15, MP 47.00), Weaver Road Quarry Sites 1 and 2 (MP 47.00), and Signal Tree Road Quarry (Section 35, MP 47.00). These are existing quarries and although GIS indicates the quarries provide recruitment (0.97 acre) and capable (4.90 acres) MAMU habitat, no forested habitat would be removed within these sites. Overall, construction of the Pipeline project would remove 4.33 acres of suitable MAMU nesting habitat (PCE-1) and 11.77 acres of recruitment (PCE-2) within CHU OR-06-d (see table 3.3.3-15), all within MAMU SHUs. Additionally, approximately 1.64 acres of suitable habitat (PCE-1), and 0.95 acre of recruitment habitat within CHU OR-06-d have been identified for use by the Pipeline project as UCSAs that may be used to store forest slash, stumps, and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration (see UCSA Column, table 3.3.3-15).

Use of the UCSAs would be a short-term disturbance of understory vegetation within suitable and potentially suitable habitat and would not affect potential nesting stand structures or characteristics. After construction, approximately 19.44 acres of MAMU habitat within CHU OR-06-d outside of the 30-foot maintenance corridor would be replanted with tree species and effects of edge would decrease over time. A detailed table of CHU OR-06-d affected by the Pipeline within and outside of MAMU SHUs and interior forest is provided in appendix Q (table Q-3); non-capable habitat that is affected in designated critical habitat can be reviewed in table Q-2, appendix Q.

Designated critical habitat only occurs within MAMU Inland Zone 1. Approximately half (54.1 percent) of forested habitat within CHU OR-06-d affected by the proposed action overlaps with BLM RMP designated late successional reserves (LSRs) in Coos Bay and Roseburg BLM Districts (see table Q-3 in appendix Q). The Pipeline project would remove approximately 176.5 acres of MAMU habitat (65.37 acres of suitable, 55.93 acres of recruitment, and 55.19 acres of capable habitat) within LSRs, of which 100.61 acres of forested habitat within LSRs would be replanted with trees outside of the 30-foot maintenance corridor which would reduce the effects of edge over time (see table 3.3.3-16). Table 3.3.3-16 identifies the MAMU habitat that would be affected within LSRs from construction. A detailed table of LSRs affected by the Pipeline project within and outside of MAMU SHUs and interior forest, as well as non-capable habitat that is affected and occurs in LSRs is provided in table Q-6 in appendix Q. Table Q-3 in appendix Q provides the acres of MAMU habitat affected within Marbled Murrelet Inland Zones 1 and 2 and Recovery Plan Conservation Zones 3 and 4, including landowner, and identifies the area that FWS-designated CHU OR-06-d overlaps with LSRs within and outside of MAMU SHUs.

Within Murrelet Inland Zones 1 and 2 where federal land is checker-boarded, PCGP considered locations of LSRs, occupied MAMU stands, and/or late successional / old-growth forest when routing the Pipeline and tried to avoid those tracts of lands if another constructible route was feasible to minimize impacts to MAMU habitat (see MAMU and NSO Avoidance Plan). Minimizing effects to LSRs also minimizes effects to MAMU designated critical habitat since overlap of MAMU CHU OR-06-d and LSRs occurs. Table 3.3.3-17 summarizes the location of the Pipeline project and MAMU habitat affected in relation to MAMU designated CHU OR-06-d.

In addition to direct loss of critical habitat and effects to PCEs due to construction, the Pipeline project's indirect effects to MAMU that were discussed above (fragmentation, edge, and effects to interior forest) indirectly affect designated critical habitats and PCEs. Edge effects and effects to interior forest may induce changes to forest characteristics later in time and would indirectly affect PCEs. Such effects may induce changes at individual nest trees and/or trees with potential nest platforms (PCE-1). Long-term effects on edges and interiors of recruitment habitat (PCE-2) are less well defined and over time, edge effects would diminish as edges evolve from "hard" to "soft" after revegetation occurs in the construction right-of-way, and in particular, trees are planted outside of the 30-foot maintenance corridor (see for example, Peery and Henry 2010).

a/ Suitable Habitat: generally late-seral forested stands that provide or are presumed to provide nesting structures for marbled murrelet based on modeling and other available GIS data.
b/ Recruitment Habitat: forested land not currently suitable for marbled murrelet nesting that may be capable of becoming suitable marbled murrelet habitat within the next 25 years (FWS 2006c; BLM 1995a, 1995b); generally forested stands 60 years or greater (FWS 2014c).
c/ Capable Habitat: forested land that has the capability of becoming suitable nesting marbled murrelet habitat, generally includes forest stand age 0 to 60 years (FWS 2014c).
d/ Pipeline Project components considered in calculation of habitat "Removed:" construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), pipe storage yards, and rock source and disposal sites.
e/ Acres identified as UCSAs have been incorporated into the 100-meter indirect effects. Indirect Effects considers habitat within 100 meters (328 feet) of habitat removal as measured from the edge of habitat removal/edge of right-of-way/TEWA.
f/ UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.
g/ 30-foot-wide Maintenance Corridor would be kept in a shrub/sapling state for the life of the project; all other habitat outside of the 30-foot maintenance corridor would be revegetated, except for those habitats on non-federal or matrix lands where there is less certainty that replanting would occur or be maintained on the landscape.

Summarized from table Q-7 in appendix Q. Non-Capable habitat (not forested and not capable of becoming suitable habitat, or deciduous forest) that occurs in LSRs is included in table Q-7 in appendix Q.

TABLE 3.3.3-17

Summary of Habitat Affected in Marbled Murrelet Designated Critical Habitat Unit OR-06-d from the Proposed Action

Critical Habitat Unit	Land Ownership	Land Use Allocation	Total acres of PCE1 that would be removed a/	Total Acres of PCE2/Recruitment removed b/	Total Acres of PCE2/Capable c/	Length of Pipeline through CHU (miles)	Additional Comments
OR-06-d	Coos Bay BLM	LSR / Harvest Land Base	1.02	5.3	2.27	0.67	1st crossing (MPs 41.44-42.01): Pipeline routed through mostly regenerating (capable) and mid-seral (recruitment) forest, with a portion crossing through the edge of an old-growth/occupied (suitable) stand; crosses corner of critical habitat section. Follows or occurs within an existing road for a small portion.
		Harvest Land Base / Riparian Reserve	0.0	3.50	0.0	0.32	2nd crossing (MPs 43.20-43.50): route mostly parallels a road through regenerating (capable) forest.
			0.0	0.0	3.49	N/A	Rock Sources (Signal Tree Road Quarry Section 35 – MP 47.00, Weaver Road Quarry Site 1 and 2 – MP 47.00): within previously disturbed quarries.
OR-06-d	Roseburg BLM	LSR / Harvest Land Base	2.43	0.55	0.04	0.26	3rd crossing (MPs 46.91-47.17) – Weaver Ridge reroute: crosses mosaic of old-growth (suitable) and regenerating (capable) forest; parallels a road for approximately 0.06 mile.
		LSR	0.0	1.32	3.04	0.33	4th crossing (MPs 52.61-52.94): crosses mid-seral (recruitment) and regenerating (capable) forest; crosses corner of critical habitat section.
			0.88	0.15	4.90	0.59	5th crossing (MPs 53.10-53.70): generally follows a road between regenerating (capable) and late successional (suitable) stands.
			0.0	0.97	1.40	N/A	Rock Sources (Signal Tree Road Quarry Section 15 – MP 47.00, Signal Tree Road Quarry Section 3 – MP 45.86): within previously disturbed quarries - no recruitment habitat would be removed.

a/ PCE 1 = suitable habitat
b/ PCE 2 = recruitment habitat
c/ PCE 2 = capable habitat, which includes early mid-seral forest, as well as clearcut and regenerating coniferous forest.

Long-term effects from removal of interior forest within critical habitat, LSRs, and unmapped LSRs by the Pipeline could occur from clearing MAMU habitat. Tables 3.3.3-15 and 3.3.3-16 identify the distance that MAMU habitat is crossed by the Pipeline within and outside of interior habitat, and summarize the acreage of MAMU habitat directly removed and indirectly affected within 100 meters (328 feet) of the Pipeline project (habitat removal) by Marbled Murrelet Inland Zones 1 and 2, and landowner within CHUs and NWFP LSRs and unmapped LSRs, respectively. Tables Q-5 and Q-6 in appendix Q provide detailed effects to MAMU Habitat within CHU OR-06-d and LSRs, respectively, including MAMU habitat affected within and outside of MAMU SHUs and interior forest. Most indirect effects to forested habitat within 100 meters (328 feet) of habitat removal occur in MAMU habitat that has been previously affected by existing edge, such as roads, waterbodies, early seral forest, and nonforested habitat.

Cumulative Effects

Habitat removal and construction disturbance from the Pipeline are expected to be complete one year before the in-service date due to the longer construction period for the LNG Terminal, access channel, and slip (figure 2.1.1-1). Consequently, the foreseeable future required for cumulative effects analysis would actually occur before implementation of the proposed action, not after its implementation, which is more often the case.

Cumulative effects to MAMUs would be generated by timber harvesting and other sources of habitat losses on non-federal lands in the foreseeable future. Areas of MAMU habitat-capable land have been monitored as a component of the NWFP. Habitat-capable lands are capable of supporting forest structure with the potential to provide MAMU nesting habitat (Raphael et al. 2016). In Oregon, the evaluation of habitat-capable land was limited to Marbled Murrelet Zone 1 (of the NWFP) and did not include any analysis of habitat within Marbled Murrelet Zone 2.

In 2017, there were 465 acres of suitable habitat and 7,411 acres of recruitment habitat on non-federal lands within the terrestrial nesting analysis area (see table 3.3.3-2 in section 3.3.3.2, above). Recruitment habitat and suitable habitat, used here, are considered equivalent to habitat Class 3 (moderately high likelihood of suitability) and habitat Class 4 (highest likelihood of suitability), respectively. Those two habitat classes were included in modeling changes in MAMU habitat availability from 1996 (baseline conditions) to 2012 (Raphael et al. 2015).

Within Marbled Murrelet Zone 1, which coincides with the Coast Range physiographic province, there were 254.3 thousand acres of Class 3 and Class 4 habitats in 1993; by 2012 there were 198.3 thousand acres in those habitat classes on non-federal lands (see Table 2-7 in Raphael et al. 2016). There was a net loss of 56.0 thousand acres of Class 3 and Class 4 habitats (-22.0 percent), declining by 22.0 percent during the 19-year period (Table 2-10 in Raphael et al. 2011), and used here as an annual loss of suitable and recruitment habitats at 1.16 percent per year. That rate of decline on non-federal lands is assumed to be constant over time within the terrestrial nesting analysis area. Areas of suitable and recruitment habitats present in 2017 would be expected to decline at that annual rate; therefore, within 2020, there would be 449 acres of suitable habitat and 7,153 acres of recruitment habitat expected within the analysis area on non-federal land in 2020.

The Pipeline would remove 10.75 acres of suitable habitat and 61.74 acres of recruitment habitat on non-federal (state and private) lands in Marbled Murrelet Zone 1 (see table 3.3.3-10 in section 3.3.3.3, above). The amount of suitable habitat removed in Marbled Murrelet Zone 1 would be 2.51 percent of the suitable habitat remaining on non-federal lands (429 acres) in the analysis area by 2020 and represents less than 0.01 percent of higher quality suitable habitat available on non-federal lands in Oregon (approximately 221,131 acres; Falxa and Raphael 2016). Likewise, the amount of recruitment habitat removed would be 1.98 percent of the habitat remaining on non-federal lands (3,121 acres) in the analysis area by 2020. When compared to the estimated amount of suitable and recruitment habitat on non-federal land within the analysis area, the Pipeline project would affect a total of 72.49 acres within Marbled Murrelet Zone 1, which would be 2.04 percent of the total suitable and recruitment habitat available within Marbled Murrelet Zone 1 within the foreseeable future in 2020.

Although Raphael et al. (2016) limited their evaluation of habitat-capable land to Marbled Murrelet Zone 1 (of the NWFP), the same analysis was included, as described above, for Zone 2 using the annual loss of 1.16 percent, which is included in table 3.3.3-18.

Cumulative effects to MAMUs could also occur within the marine and estuarine analysis areas from fuel spills and disturbance, including underwater noise. NMFS (2008a) reports that chronic small-scale discharges of oil into oceans greatly exceed the volume released by major spills (Clark 1997). Fuel or lubricants spilled from the 120 LNG carriers transiting the marine analysis area could adversely affect foraging MAMUs, especially in combination with other small spills or accidental releases. On board mitigation measures, including the SPCC plans would minimize potential inadvardent spills. However, as discussed above for blue whales, the background rate of spills off the Oregon coast by fishing carriers, recreation carriers, and other carrier types is generally low, a frequency that would be expected to continue.

As discussed above in section 3.2.1.3 for blue whales, ship traffic at the Port has declined in the past two decades and is not expected to increase significantly relative to historical levels. . Therefore, the foreseeable cumulative effect of 120 LNG carriers per year would exceed current carrier-related disturbance, including disturbance from underwater noise and avoidance of ships, to foraging MAMUs in the Coos Bay estuary and nearshore habitats in the vicinity of the Coos Bay channel in the marine analysis area.

TABLE 3.3.3-18

Estimates for Losses of Marbled Murrelet Suitable and Recruitment Habitat on Non-Federal Land within the Terrestrial Nesting Analysis Area by 2020, with Pipeline Project-Related Effects on Non-Federal Land Compared to Cumulative Effects

Marbled Murrelet Inland Zone	Marbled Murrelet Habitat Areas on Non-Federal Land in Analysis Area in 2017 a/			Loss of Marbled Murrelet Habitat Between 1993 and 2012 b/		Marbled Murrelet Habitat on Non-federal Land in Analysis Area Expected in 2020			Marbled Murrelet Habitat Removed by the Project on Non-federal Land in Analysis Area c/			Percent of Marbled Murrelet Habitat in Analysis Area Expected in 2020 to be Affected by the Project

3.3.3.4 Conservation Measures

PCGP and JCEP have implemented or proposed conservation measures including avoidance, minimization, and rehabilitation/restoration, as described below.

Avoidance, Minimization, and Rehabilitation / Restoration

Conservation measures have been proposed by PCGP and JCEP to minimize construction and operations impact to the terrestrial nesting analysis area. Those measures have been compiled in table 2C in appendix N. Specific conservation measures that would benefit MAMUs include those that:

- avoid timber clearing during the breeding and nesting season;
- apply DTRs for construction activities within 0.25 mile of occupied or presumed occupied stands during the critical breeding season (April 1 through August 5);
- route the Pipeline through existing disturbance or previously disturbed forested lands to minimize impact to higher quality MAMU habitat;
- minimize removal of forest by incorporating UCSAs into the project design;
- utilize two-year construction window to minimize the overall TEWAs;
- flag large diameter trees on edges of construction right-of-way or temporary work areas where feasible to save from clearing, as outlined in the Plan of Development's Leave Tree Protection Plan;
- ensure that all trash, food waste, and other items attractive to crows, jays, and other corvids would be contained and removed from the construction areas on a daily basis to minimize potential predation on MAMU nestlings;
- use logging methods that would minimize damage to adjacent trees when clearing the right-of-way to reduce potential infestation from forest pathogens and insects; and
- minimize potential for establishment of invasive vegetation and establish control of noxious weeds.

Conservation measures have been proposed by JCEP to minimize construction and operation impacts to foraging marbled murrelets in the marine and estuarine analysis areas. Measures to reduce ship speeds once inside the Coos Bay navigation channel to between 4 to 6 knots and within the marine analysis area when pods or large assemblages of cetaceans are observed near an underway ship would provide protection to MAMU as well. Those measures have been compiled in tables 2A and 2B in appendix N. Specific conservation measure that would benefit MAMUs include:

- The contractor will develop and implement a turbidity monitoring and management plan (TMMP) that describes measures to reduce and monitor turbidity impacts resulting from dredging activities. Water quality monitoring will be performed during active in-water work operations in Coos Bay to ensure compliance with federal and state water quality standards.
- JCEP has prepared a Spill Prevention, Control, and Countermeasure (SPCC) Plan for both construction and operational phases of the LNG Terminal to minimize the potential for accidental releases of hazardous materials and to establish proper protocol concerning minimization, containment, remediation, and reporting of any releases that occur.

- All in-water work associated with the LNG Terminal will be conducted during the ODFW-approved in-water work window for Coos Bay (October 1 to February 15) unless otherwise approved by the appropriate agencies.
- Whenever feasible, a vibratory hammer will be used during in-water piling installation. If not feasible, an appropriately sized drop or impact hammer will be used to complete the job following the manufacturers' recommendations to drive the piling. If an impact hammer is used to drive or proof steel piling within fish-bearing waters, then sound attenuation devices would be used to effectively dampen sound in accordance with the guidance in NMFS' and USFWS' Impact Pile Driving Sound Attenuation Specifications, Western Washington Fish and Wildlife Office, Revised October 13, 2006, which is the standard NMFS applies in Oregon.
- Vibratory equipment will be used during installation of land-based sheet pile. Pre-drilling of sheet pile for the Slip and MOF and for pipe pile within a 30 meter setback will also be completed. Installation of piles will use an appropriately sized impact hammer.

Plans included in the appendices of PCGP's POD would also minimize effects to MAMU habitat and/or nesting MAMUs. The *Leave Tree Protection Plan* describes the preconstruction surveys that would be completed to clearly mark the boundaries of the Pipeline project's certificated working limits, and procedures to identify individual trees within and along the edges of the certificated work limits that can be conserved or left standing, as well as BMPs that would be employed to minimize damage to trees within UCSAs and protect trees not removed from the construction right-of-way (see appendix P to the POD, available upon request). An *Integrated Pest Management Plan* (see appendix N to the POD, available upon request) describes BMPs to address the control of noxious weeds, invasive plants, forest pathogens, and soil pests, as well as describes measures to minimize the potential spread of invasive species and potential adverse effects of control treatments. The *Blasting Plan* and *Air Noise and Fugitive Dust Plan* (see Appendices C and B to the POD, respectively – available upon request) provide mitigation measures and monitoring plans to minimize noise effects to nesting MAMUs during construction of the Pipeline project.

PCGP prepared an *Avoidance and Minimization Plan for MAMU and NSO* (see appendix V1) that identifies the additional measures that have been incorporated into the project design to reduce impacts to both MAMUs and NSOs. This avoidance plan was developed through consultations with the FWS and the cooperating agencies (Interagency Habitat Quality Subgroup-Micro Siting Working Group, June 4, 2008). Application of measures outlined in the plan would minimize potential impacts to suitable MAMU habitat by 1) converting TEWAs to UCSAs to reduce the amount of suitable habitat removed by the Pipeline project, 2) moving TEWAs to avoid impacts to suitable habitat within occupied or presumed occupied stands, and 3) moving the alignment to avoid MAMU occupied or presumed occupied stands. A "Standard Rules Set" was developed during the meeting to further minimize effects to MAMU, and this Standard Rules Set would be implemented prior to or concurrent with tree felling. The Standard Rules Set measures include:

- identify potential nest trees that would be allowed to remain standing within TEWAs or edge of right-of-way;
- identify TEWAs to be reduced in size or eliminated to reduce removal of suitable habitat;

- identify any additional minor route adjustments that would not alter constructability but further reduce removal of suitable habitat;
- identify any previously unknown nest tree discovered and assure that it is properly protected by applying the appropriate seasonal limitations or daily timing restrictions associated with similar locations along the alignment; and
- EIs would be supported by qualified biologists to identify potential nest trees.

To avoid direct effects to MAMU, PCGP would remove timber outside of the entire MAMU breeding season (after September 15 but before March 31) within 300 feet of MAMU stands to ensure that trees with active MAMU nests and chicks are not felled. Additionally, to minimize disturbance within forested areas, PCGP has designated nearly 165 acres (see table 3.3.3-10) of UCSAs within Marbled Murrelet Inland Zones 1 and 2 that would not be cleared of trees but be used to store forest slash, stumps, and dead and downed log materials during construction that would be scattered across the right-of-way after construction and during restoration. The UCSAs would be used for construction of the Pipeline project while not requiring removal of trees or understory vegetation, as well as allow the maintenance of suitable or potentially suitable and recruitment habitat function.

Construction of the Pipeline would occur within Marbled Murrelet Inland Zones 1 and 2, including within MAMU occupied stands during the entire breeding season. Construction would occur after timber has been felled outside of the breeding season and would adhere to daily timing restrictions (DTRs, activity limited to 2 hours after sunrise and 2 hours before sunset) within 0.25 mile of MAMU stands (occupied and presumed occupied) at least through the critical breeding season to minimize risk of disturbance to adult MAMUs entering and leaving the stand, as well as possible dispersal of juveniles. DTRs would continue to be applied to large transport helicopter use in the late breeding season within 0.25 mile of a MAMU stand if helicopter use is necessary.

Within known occupied stands, PCGP has proposed the route within existing roads that traverse the stand or situated the right-of-way within existing edge (i.e., within clearcut or regenerating forest adjacent to a stand) to avoid or minimize habitat removal from the stand, where feasible. In other areas, PCGP has rerouted the Original 2007 Route (FERC 2009) to avoid removing habitat and further fragmenting suitable MAMU stands – occupied and presumed occupied (surveyed/no survey). Also, to minimize impacts to MAMU stands and suitable nesting habitat, PCGP has incorporated minor alignment adjustments or TEWA modifications into the Pipeline project. Other major and minor route alternatives that further minimize effects to MAMUs and habitat have been considered and included in the Pipeline route, which are discussed in the *Marbled Murrelet and Northern Spotted Owl Avoidance and Minimization Plan* (appendix V1 to this APDBA).

When PCGP acquires survey access in stands identified to have potential nesting habitat (presumed occupied stands), where survey permission has been denied, PCGP would evaluate the stands for trees with suitable nesting structures. If suitable nesting structures are identified and time permits for 2-year protocol surveys prior to beginning the proposed Project, PCGP may survey those stands for occupied MAMU behavior. If protocol surveys are not conducted, PCGP will continue to presume occupancy and apply conservation measures to those presumed occupied stands. When additional information on the status of these presumed occupied MAMU stands is acquired, PCGP would advise the FWS of their updated status, including whether they are determined to have suitable nesting structures, determined to be occupied or unlikely occupied, or determined to not be suitable habitat for nesting MAMUs.

During construction, PCGP would ensure that the construction contracts include stipulations ensuring that all trash, food waste, debris, and other items attractive to crows, jays, and other corvids would be picked up and removed from the construction areas on a daily basis year round to minimize potential predation of MAMU nestlings. PCGP's EIs would be responsible for overseeing that the construction contractor is adequately following these stipulations.

PCGP has also proposed measures to rectify, repair, rehabilitate, and otherwise reduce impact to forested habitats once construction of the Pipeline is complete. Those measures have been compiled in table 3C in appendix N. Specific conservation measures that would benefit MAMUs include those that:

- replant conifer species outside of the 30-foot-wide maintenance corridor after construction, where allowable, which would contribute to the reestablishment of native vegetation and soften the edge effect created from construction of the Pipeline project if the area is allowed to revegetate;
- contribute to forest habitat structural diversity (e.g., snags and downed timber); and
- minimize potential for increased human use of the reclaimed construction right-of-way and intrusion into undisturbed habitats.

Following construction, affected forested lands (the construction right-of-way and TEWAs outside of the 30-foot maintenance right-of-way) would be replanted and allowed to return to the pre-construction condition where possible, with tree species in the approximate proportion to those species removed. This replanting would occur on certain federal lands and non-federal lands on a case- by-case basis. Replanted trees may also be harvested from non-federal lands or federal lands slated for timber harvest. Tree establishment would be allowed to occur up to 15 feet on either side of the centerline. Over the short term, replanting a maximum of approximately 1,211 acres on the edge of the 30-foot maintenance corridor within the range of the MAMU would provide a soft edge to adjacent forested habitat and minimize effects of edge, as well as reduce predator presence (see table 3.3.3-10). However, if allowed to regrow, these areas would provide minimal benefit to MAMUs because it would take decades to restore replanted forests to recruitment or suitable habitat conditions. Over the long term (200 to 250 years to become MAMU suitable nesting habitat), revegetated areas outside of the 30-foot maintenance corridor may achieve tree structural characteristics comparable to trees that would be removed, had they not been affected.

3.3.3.5 Determination of Effects

Species

The Project **may affect** MAMUs because:

- suitable habitat is available within the terrestrial nesting analysis area;
- MAMUs have been located within the terrestrial nesting analysis area during survey efforts for the proposed action and
- MAMUs are expected to forage offshore in the marine analysis area, and within Coos Bay in the estuarine analysis area.

The Project is **likely to adversely affect** MAMUs because:

- disturbance associated with Pipeline project activities and construction of Kentuck Mitigation Site would occur within the critical breeding season and within 0.25 mile of known MAMU stands. Proposed actions which generate noise above local ambient levels might disturb or disrupt MAMUs and interfere with essential nesting behaviors.
  - 82 MAMU stands (25 occupied and 57 presumed occupied) are within 0.25 mile of the proposed construction right-of-way that could be constructed during the breeding season.
  - 168 MAMU stands (50 occupied and 118 presumed occupied) are within 0.25 mile of proposed access roads that could be used during the breeding season.
- blasting activities (>2 pounds explosives) may occur within 0.25 mile of MAMU stands between April 1 and September 30.
- helicopter use within 0.25 mile of eight occupied MAMU stands during the breeding period (between April 1 and September 15) could occur and disturb MAMU adults and nestlings, as well as potentially blow nestlings out of the nest tree within six occupied MAMU Stands from rotor wash.
- the proposed Pipeline would remove and modify potential suitable nesting habitat and recruitment habitat within the range of the MAMU, which does not support the recovery of the species. Approximately 78 acres of suitable MAMU habitat would be removed, or approximately 0.5 percent of the 14,310 acres of suitable habitat available in the terrestrial nesting analysis area.

Critical Habitat

A **may affect** determination is warranted for MAMU critical habitat because:

- the Pipeline crosses designated MAMU critical habitat, and
- the Pipeline would result in habitat impacts within designated critical habitat area.

A **likely to adversely affect** determination is warranted for MAMU critical habitat because:

- the proposed action could remove or degrade individual trees with potential nesting platforms or the nest platforms themselves, resulting in a decrease in the value of the trees for future nesting use (PCE-1, or suitable or potentially suitable habitat); and
- the proposed action could remove or degrade trees adjacent to trees with potential nesting platforms that provide habitat elements essential to the suitability of the potential nest tree or platform, such as providing cover from weather or predators (PCE-2, or recruitment/capable habitat).

3.3.4 Northern Spotted Owl

3.3.4.1 Species Account and Critical Habitat

Status

The NSO was listed by the FWS as threatened on June 26, 1990 (FWS 1990), including populations in Oregon. Declining populations due to loss and adverse modification of suitable habitat from timber harvest and natural catastrophes (wild fire, windthrow), as well as inadequate regulatory mechanisms to protect the owl or its habitat (FWS 1990) were the basis for the listing decision.

Threats

As of 1990 when NSO was listed as threatened by the FWS, an estimated 60 percent of suitable NSO habitat present in the Pacific Northwest in 1800 had been eliminated with 90 percent of all remaining suitable habitat occurring on public lands (less than 5 percent of old-growth habitats occurred on private, state, or tribal lands in 1990). At the time of listing, FWS (1990) indicated that given the current trends, remaining unprotected NSO habitat could be eliminated in 10 to 30 years Although timber harvest on federal lands has been greatly reduced since NSO habitat has been protected through designated critical habitat (FWS 1992c), as well as additional habitat protection from the Forest Service and the Bureau of Land Management through the Northwest Forest Plan (NWFP), Further, at the time of listing, the quality of 50 percent of total remaining NSO habitats across the range of the NSO was judged to be affected by reduction of individual stand size, fragmentation, and edge effects so that successful NSO reproduction was at risk (FWS 1990). Continued logging practices were chiefly responsible for the loss and degradation of habitat, and public forest lands that are intensively managed for timber production generally are not able to achieve old-growth characteristics, which may require 200 years to develop (FWS 1990). Although timber harvest on federal lands has been greatly reduced since implementation of the NWFP in 1994, documented loss of NSO habitat on federal lands has contined, mostly as a result of wildfies (Davis et al 2016); from 1993 through NSO habitat on feeral lands has decreased by 1.5 percent range wide (approximately 135,700 acres; Davis et al 2016). Residual habitat loss and continued timber harvest on private lands across the range of NSO continues to threaten this species (FWS 2011c, Davis et al. 2011). Past NSO habitat loss and current NSO habitat loss are still considered pressing threats to the NSO (FWS 2011d).

Natural events and logging create a fragmented landscape that is utilized less by NSO than more intact landscapes (FWS 1990). Further, fragmentation reduces potential metapopulation dynamic interactions between NSO-inhabited patches (extinction, colonization within patches), resulting in potential adverse genetic effects (FWS 1990). High levels of fragmentation, particularly fragmentation found on BLM lands interspersed with private lands forming a "checkerboard," adversely affect adult survivorship and fecundity (FWS 1990), which are the major drivers influencing population growth.

In addition to the relationship of habitat quality and quantity to NSO population declines, in 1990, barred owls were recognized as a potential threat to NSO due to their aggressiveness and potential to displace NSO through competitive interactions (FWS 1990); however, by 2006, FWS (2007c) recognized that competition from barred owls was a significant "pressing" threat to NSO throughout its range. Threats from barred owls had developed within the context of habitat loss and diminished distribution of habitat by past logging activities and other catastrophic disturbances, as well as ongoing habitat losses from timber harvest, albeit reduced harvest levels since implementation of the NWFP (FWS 2007c, 2008c; Dugger et al. 2016). Hazards to NSO from barred owl include competition for resources and displacement from suitable habitat (Kelley et al. 2003; Kelley and Forsman 2004) and to a lesser degree than thought in the 1990 listing, hybridization with NSOs (Courtney et al. 2004; Kelley and Forsman 2004). Dugger et al. (2016) report that barred owls have negatively affected spotted owl populations, primarily by decreasing apparent survival and increasing local territory extinction rates.

Another threat to NSO populations is loss of habitat from wildfires, especially within forests that demonstrate succession toward climax communities in the absence of fires (FWS 2011c; Courtney et al. 2004). In drier portions of the NSO range, such as the Eastern Oregon Cascades and Klamath Mountains provinces, wildfire has become more of a threat (FWS 2011c, 2004b). Davis et al. (2016) report 85,900 acres of non-reserved lands in the northern spotted owl range had burned since 1993, which represents approximately 48.8 percent of habitat loss reported since 1993. Climate change is expected to increase the risk of large, high-intensity wildfire in the Pacific northwest (Dugger et al. 2016).

Other potential threats to the NSO and its habitat include West Nile virus and tree diseases, respectively (FWS 2004b; FWS 2006d, 2011c). West Nile Virus has the potential to reduce population numbers beyond what was anticipated from other causes, although to date, no mortality of NSO has been recorded from the West Nile virus (Lint 2005). The revised northern spotted owl recovery plan did not consider West Nile virus as a significant threat to spotted owls (FWS 2011c). At this time, no avian diseases, including West Nile Virus, are significantly affecting spotted owls (FWS 2011c).

Species Recovery

1992 Draft Recovery Plan (FWS 1992b)

The 1992 Draft Recovery Plan for the Northern Spotted Owl considered threats to NSO populations within the proposed project area to include: low and declining populations, loss and fragmentation of habitat, poor population connectivity within each province and with adjacent provinces, and high levels of predators. As a result of these threats, the 1992 Draft Recovery Plan established 196 designated conservation areas (DCAs), of which 56 were considered category 1 DCAs (having the potential to support at least 20 NSO pairs), and the other 140 were considered category 2 DCAs (potential to support 1 to 19 NSO pairs). DCAs were derived from concepts presented by Thomas et al. (1990) in "A Conservation Strategy for the Northern Spotted Owl" that focused on the establishment of large habitat blocks that could support self-sustaining populations of 15 to 20 pairs and protected lands for dispersal of juveniles.

2008 Final Recovery Plan (FWS 2008c)

In April 2007, the FWS released a NSO draft recovery plan for public review, identifying criteria and actions needed to stop NSO decline, reduce threats, and return the species to a stable, well-distributed population in Washington, Oregon, and California over the next 30 years (FWS 2007c). In May 2008, FWS approved the Final Recovery Plan for the Northern Spotted Owl. The recovery plan recommended specific actions that address the threats to the NSO, including threats posed by barred owls, as well as actions to maintain habitat for the recovery and long-term survival of the NSO including dry-forest landscape management strategies. The recovery plan built off strategies set forth in the 1992 Draft Recovery Plan for NSO (FWS 1992b) and the NWFP (Forest Service and BLM 1994), using a network of Managed Owl Conservation Areas (MOCAs) on federal lands and Conservation Support Areas (CSAs) on federal and non-federal lands where recovery actions and criteria would be targeted. MOCAs are larger tracts of lands within non-fire-dominated provinces that are expected to support a stable number of breeding pairs of NSOs over time and allow for movement of NSOs across the network. Within the drier forests of the Eastern Cascades Province, the recovery plan did not identify MOCAs or CSAs since it is expected that the rate of loss of older forests to stand-replacing wildfires would continue or increase in the coming years as the climate changes (Westerling et al. 2006 in FWS 2008c). Rather, the recovery plan recommended treatments to older forests to reduce risks of fires and insect outbreaks even though the strategy could have short-term impacts on NSO habitat, but would achieve the long-term goal of creating more sustainable NSO habitat.

2011 Revised Final Recovery Plan (FWS 2011c)

The 2008 Northern Spotted Owl Recovery Plan was revised in 2011, which continues to address threats of barred owl and habitat loss, and integrates an adaptive management approach to achieve results focusing on the most important actions for recovery, including maintaining and restoring high value habitat for the recovery and long-term survival of the NSO. Recovery criteria have been identified to serve as objective, measureable guidelines to assist in determining if the NSO has recovered and may be delisted, which include: 1) stable population trend, 2) adequate population distribution, and 3) continued maintenance and recruitment of spotted owl habitat. Thirty-three recovery actions were included to guide activities needed to accomplish the four recovery criteria. In some instances, recovery actions are specific to physiographic provinces, which have been identified as recovery units within the 2011 Revised Recovery Plan to assist managers in measuring the objectives of the recovery criteria.

The 2011 Revised Recovery Plan discontinued the recommendation of DCAs, MOCA networks, and CSAs included in previous NSO recovery plans; rather, these areas were considered in revised critical habitat designation in 2012 (FWS 2011c).

Life History, Habitat Requirements, and Distribution

The NSO is a medium-sized owl that occurs in coniferous or mixed coniferous-hardwood forests from southwestern British Columbia through western Washington, Oregon, and northern California south to San Francisco Bay (FWS 1990). Although NSO habitat is variable over its range, to support NSO reproduction, a home range requires appropriate amounts of nesting, roosting, and foraging (NRF) habitat arrayed so that nesting pairs can survive, obtain resources, and breed successfully. NSOs primarily occur in old-growth and mature forests because these habitat types provide the structure and characteristics required for nesting, but they may also inhabit younger forests with the appropriate structural, vegetation, and prey characteristics, including:

- moderate to high canopy cover (60 to 80 percent);
- multi-layered, multi-species canopy dominated by large overstory trees (greater than 30 inches dbh;
- a high incidence of large trees with various deformities,
- numerous large snags;
- large accumulations of fallen trees and other woody debris on the ground; and
- sufficient open space below the canopy to fly (FWS 1990).

High canopy closure is important to help NSOs thermoregulate and reduce potential predation (FWS 1990 and 2007c). Dispersing NSOs, whether adults moving between blocks of suitable NRF habitat (generally 15 miles for females and 9 miles for males; Forsman et al. 2002), or juveniles dispersing from natal areas (a range of 0.3 to 69 miles; Forsman et al. 2002), utilize a wider array of forest types and structures including more open and fragmented habitat. Although forest attributes needed for successful dispersal have not been thoroughly evaluated, they generally consist of conifer and mixed mature conifer-hardwood habitats with canopy cover greater than or equal to 40 percent and conifer trees averaging at least 11 inches dbh (FWS 1992b). Dispersal habitat may occur in NRF habitat, but it lacks the optimal structural characteristics needed for nesting.

Foraging and dispersal habitats may be in younger, more open and fragmented forests than those associated with nesting and roosting (FWS 1992b). Foraging habitat may also be consistent with areas that NSO prey is found. Northern spotted owls are primarily nocturnal, foraging between dusk and dawn, with peak activity occurring two hours after sunset and two hours prior to sunrise (Delaney et al. 1999; Forsman et al. 1984). NSO feed primarily on small mammals, especially northern flying squirrels and woodrats in southwestern Oregon (citations in Anthony et al. 2006).

Northern spotted owls have been reported to occur in the following forest types: Douglas-fir and western hemlock in the coastal forests of Washington and Oregon, Pacific silver fir on the west slope of the Cascades in Washington and Oregon, mixed conifer stands including Douglas-fir, grand fir, and ponderosa pine on the east slope of the Cascades, dry Douglas-fir and mixed conifer in southern interior Oregon, and Douglas-fir, mixed-conifer, and coastal redwood or mixed conifer-hardwood habitat types in California (FWS 1992b; Forsman et al. 1984). The NSO has been reported in a variety of elevations, from 70 feet on the Olympic Peninsula in Washington to more than 6,000 feet in California (FWS 1990).

NSOs are territorial and remain on their home range throughout the year. As a result, NSO have large home ranges that provide all the habitat components and prey necessary for the survival and successful reproduction of a territorial pair. Home ranges vary in size by physiographic province, forest type, and heterogeneity but generally increase in size from south to north where habitat quality decreases and/or becomes more fragmented (Courtney et al. 2004; FWS 1990, 1992b; Forsman et al. 1984). Courtney et al. (2004) determined that the home range size of NSOs appeared to be influenced by a variety of factors including proportion of mature and old-growth forest within the home range, forest fragmentation, and the availability of dominant prey species (larger home ranges where flying squirrels dominated the diet compared to smaller home ranges where wood rats dominated the diet). Within the Pipeline project area, NSO home ranges typically encompass an area within the following radii around the nest site: 1.5 miles within Coast Range Physiographic Province, 1.3 miles within Klamath Mountains Physiographic Province, and 1.2 miles within East and West Cascades Physiographic Provinces from a nest or roost site (FWS 1992c). Home ranges within the Coast Range physiographic province are much larger where a lot of fragmentation from urban development, timber harvesting, and transmission corridors has occurred (Courtney et al. 2004).

Home ranges contain three distinct use areas: 1) the nest patch, which research has shown to be an important attribute for site selection by NSOs and includes approximately 70 acres of usually contiguous forest (300-meter radius around an activity center; FWS et al. 2008), 2) the core area, which is used most intensively by a nesting pair and varies considerably in size across the geographic range, but on average encompasses approximately 500 acres around the nest site (1/2 mile radius around the activity center), and is generally made up of mostly mature/old-growth forest (FWS 2007c; Courtney et al. 2004), and 3) the remainder of the home range which is used for foraging and roosting and is essential to the year-round survival of the resident pair (FWS 2007c).

NSOs are relatively long-lived. They are sexually mature at the age of 1, but rarely breed until they are 2 to 5 years of age. Females will lay one to four eggs per clutch, with an average of two eggs. However, most NSOs do not nest every year (FWS 2011c). Fecundity in NSOs appears to follow a biennial cycle of high fecundity in even-numbered years and low fecundity in odd-numbered years; however, it is not known what causes the synchronization across the range of the NSO (Dugger et al. 2016). Nesting and fledging varies with latitude and elevation (FWS 1990), although, courtship usually occurs in February or March and eggs are laid in late March or April. Although juveniles flege in late May or June, parental care continues into September when natal dispersal may begin (FWS 2011).

Population Status

Demographic data collected from 11 study areas throughout the range of the northern spotted owl in Washington, California, and Oregon have been used to monitor NSO populations in their geographical range from 1985 through 2013, of which five sites occur in Oregon (Anthony et al. 2006; Dugger et al. 2016). The primary objectives of these studies were to estimate fecundity, apparent survival, and annual population rate of change, and to determine if there were any temporal trends in these population parameters. Recently, studies have also been reporting barred owl activity and its potential effects on the spotted owl population (Dugger et al. 2016). Three of the study sites in Oregon, Tyee, Klamath, and southern Oregon Cascades (South Cascades), are located within and/or adjacent to the Pipeline: Klamath and South Cascades study areas are located in Douglas County (approximately MP 94.13 to MP 98.9) and in Jackson and Klamath counties (approximately MP 153.87 to MP 172.25), and the Tyee study site is located north of the Pipeline. Forests on these study sites were mostly characterized by mixtures of Douglas-fir and western hemlock or by mixed-conifer associations of Douglas-fir, grand fir, western white pine, and ponderosa pine (Anthony et al. 2006; Dugger et al. 2016).

Estimates of fecundity, apparent survival rates, and population change for five study sites within Oregon are included in table 3.3.4-1 (Dugger et al. 2016). Within Oregon, apparent adult survival rates are declining on all but the Oregon Coast Range and Klamath study areas; most annual rates of decline have been increasing. Decreased local extinction rates of NSOs were attributed to barred owl presence in all 11 study areas. In Oregon, increased fecundity was associated with higher annual estimates of the amount of suitable habitat. Overall, demographic declines in study sites were attributed to the increased numbers of barred owls and loss of habitat (Forsman et al. 2011; Davis et al. 2011; Dugger et al. 2016).

In 2009, a barred owl removal pilot program was initiated in the Green Diamond Resources (GDR) study area in California where barred owls were removed from a portion of the study area to assess the effectiveness of this program on northern spotted owl survival and population change. Based on the study to-date, removal of barred owls has had a positive effect on northern spotted owl survival and rate of population change, at least at a localized scale (Dugger et al. 2016). Annual rate of decline in all study areas (excluding the GDR treatment area) indicated an average rate of decline of 3.8 percent per year.

Barred owl presence has increased significantly within each NSO demographic study area in Oregon (Dugger 2016; Lesmeister and Reid 2016; Lesmeister 2016; Dugger 2015; Hollen 2015). In 2013, FWS (2013e) released an Environmental Impact Statement (EIS) for the experimental removal of barred owls in four study areas including the Klamath study area in the Pipeline project area to determine if removal of barred owls can improve localized populations trends of spotted owls (FWS 2013e). Experimental removals following a before-after-control-impact (BACI) experimental design were initiated in 2015 on three demographic study areas in Oregon and Washington with at least 20 years of pre-treatment demographic data on spotted owls (Wiens et al. 2017). The first 21 months (March 2015 – December 2016) of the planned 5-year experiment has removed 643 individual barred owls outside of the breeding season; treatments are expected to continue through 2020 in the Klamath study area, and through 2019 within the Cle Elum and Coast Ranges study areas. A preliminary analysis of the demographic response of spotted owls to experimental removal of barred owls in Oregon and Washington is scheduled to occur after a full 3 years of removal has been completed by March 2018/2019.

TABLE 3.3.4-1

Estimates of Fecundity, Apparent Survival Rates and Population Change for the Five Northern Spotted Owl Demographic Study Sites on Federally-Managed Lands in Oregon from 1985-2013 [1]

Study Area	Land-ownership	Fecundity [2] %	Fecundity [2] Trend	Apparent Survival [2] %	Apparent Survival [2] Trend	Population Rate of Change (λ)	Population Trend	Overall Trend

South Cascades [5]	Federal	32.3	gNo Trend [6]	85.1	Declining	0.963	No Trend [6]	Declining

[1] Source: adapted from Dugger et al. 2016.
[2] Provides rates for adults greater than 3 years.
[3] Trends based on data collected between 1990 – 2013
[4] Trends based on data collected between 1988 – 2013
[5] Trends based on data collected between 1991 – 2013
Although study sites appeared stationary throughout the study period (1985-2013), data through 2015 for this study area suggests that fecundity and populations are declining (Dugger 2016).

Critical Habitat

Critical habitat for the NSO was originally designated on January 15, 1992 and included approximately 6.9 million acres in California, Oregon, and Washington, of which 3.3 million acres occurred in Oregon (FWS 1992c). The 1992 designation was revised in 2008 (FWS 2008e), and more recently in 2012 (FWS 2012d). The 2012 final rule (FWS 2012d) designates approximately 9.6 million acres within 11 CHUs and 60 critical habitat subunits in California, Oregon, and Washington. Eight CHU and 58 subunits are identified in Oregon on a little more than 4.5 million acres. The FWS (2012d) relied on recovery criteria set forth in the 2011 Recovery Plan for the NSO (FWS 2011c) to ensure that designated CHUs met the following criteria: 1) ensures sufficient habitat to support stable, healthy populations across the range and within each CHU, 2) ensures distribution of NSO populations across the range of habitat conditions used by the species, and 3) incorporates uncertainty, including potential effects of barred owls, climate change, and wildfire disturbance risk.

The FWS (1992c) determined that the physical and biological habitat features, the primary constituent elements (PCEs) that are essential for the recovery of the spotted owl are forested lands used or potentially used for nesting, roosting, foraging, and dispersal; more specificity to PCEs was provided in the revised critical habitat rule in 2012. Based on more current information on the life history, biology, and ecology of the species, the revised PCEs are (FWS 2012d):

- PCE 1: Forest types that may be in early-, mid-, or late-seral stages and that support NSOs across its geographical range, primarily: Sitka spruce, western hemlock, grand fir, Pacific silver fir, Douglas-fir, white fir, Shasta red fir, redwood/Douglas-fir (in coastal California and southwestern Oregon), and the moist end of the ponderosa pine coniferous forest zones. This PCE must occur in concert with at least one of the following PCEs.
- PCE 2: Forested habitat (see PCE1) that provides for nesting and roosting, and could provide for foraging. Nesting and roosting habitat provides structural features for nesting, protection from adverse weather conditions, and cover to reduce predation risks for adults and young. Across the owl's range, habitat requirements are nearly identical and are associated with a high incidence of large trees with various deformities (large cavities, broken tops, mistletoe infections) or large snags suitable for nest placement. Patches of nesting habitat, in combination with roosting habitat, must be sufficiently large and contiguous to maintain NSO core areas and home ranges, and must be proximate to foraging habitat.
- PCE 3: Habitat that provides for foraging, which varies widely across the NSO range. It can consist of nesting and roosting habitat, and provide for dispersal, but its primary function is to provide a food supply for survival and reproduction. Foraging habitat is closely tied to the prey base and in some cases can include more open and fragmented forests, especially in the southern portion of the owl's range. NSO feed primarily on small mammals, especially northern flying squirrels and wood rats in southwestern Oregon (citations in Anthony et al. 2006).
- PCE 4: Habitat that supports dispersal of spotted owls, which could provide NRF habitat, but could also be composed of other forest types between larger blocks of NRF habitat. Dispersal habitat must, at a minimum, provide stands with adequate tree size and canopy cover to provide protection from avian predators and at least minimal foraging opportunities. It is essential to maintaining genetic and demographic connections among populations across the range of the species.

Because not all life history functions require all the PCEs, not all critical habitat would contain all four PCEs described above. Some CHUs contain all PCEs and support multiple life processes, while other units contain only one or two (FWS 2012d). All CHUs have had or have presence of NSO.

Activities that disturb or remove the PCEs within designated CHUs might adversely modify the owls' critical habitat. These activities could include actions that would reduce the canopy closure of a timber stand, reduce the average dbh of trees in the stand, appreciably modify the multi-layered stand structure, reduce the availability of nesting structures and sites, reduce the suitability of the landscape to provide for safe movement, or reduce the abundance or availability of prey species (FWS 1992c).

<u>NWFP Late Successional Reserves</u>

Additional habitat protection for the NSO was established when the Forest Service and BLM adopted the NWFP in 1994. The NWFP (Forest Service and BLM 1994) was designed to protect habitat for NSO and other species associated with late-successional forests while allowing a reduced amount of commercial logging on federal lands. Large amounts of federal land within the range of NSO were allocated for riparian and late successional reserves; the primary objective for these lands was to maintain or restore habitat for NSO and other fish and wildlife species. Riparian Reserves and other NWFP land use allocations provide connectivity between LSRs and federally designated critical habitat. Additionally the NWFP states that sites currently occupied by MAMUs, and KOAC (100-acre areas identified by BLM and Forest Service) that are within Matrix lands are considered "unmapped LSRs" and managed as LSRs by the NWFP.

In August 2016, the BLM issued two Records of Decision and Approved Resource Management Plans (RMPs) for Southwestern Oregon and Northwestern and Coastal Oregon (BLM 2016a and 2016b). These 2016 RMPs supersede the NWFP on BLM-managed lands. The new 2016 RMPs have similar land allocations to those in the NWFP that continue to contribute to the conservation of northern spotted owl habitat within BLM-administered lands, including LSRs and riparian reserves. The NWFP still applies to lands managed by the Forest Service and is still in effect on the three National Forests crossed by the Proposed Route. A good portion of the federally designated critical habitat overlaps with LSR land allocations; however, some lands do not and therefore LSRs afford additional habitat protection for listed species.

3.3.4.2 Environmental Baseline

Provincial Analysis Area

The proposed action is located within four Physiographic Provinces: Oregon Coast Range, Oregon Klamath Mountains, West Oregon Cascades, and East Oregon Cascades. NSO home ranges vary across provinces as a result of habitat heterogeneity and type, and prey availability (Courtney et al. 2004), and are generally larger on the west coast of Oregon and become smaller in eastern Oregon. Described below are two components of the action area within which Project-related activities could affect NSOs—one for habitat removal or modification that relate to NSO home ranges and a second for disturbance/disruption of NSO during the breeding season. The two components have been combined together to consider all components of the provincial analysis area (see figure 3.3.4-1).

Habitat Removal or Modification

The habitat removal or modification analysis area applies to all proposed action components that have the potential to remove or modify habitat, including construction of the Pipeline and aboveground facilities; no NSO habitat occurs at the LNG Terminal site (LBJ Enterprises 2006; SHN 2013c). The provincial analysis area also includes a 100-meter (328-foot) wide buffer along the edge of the area of habitat impact (e.g., edge of right-of-way or edge of new roadway corridor). In addition to the 100-meter buffer, the provincial analysis area includes any NSO Home Range with an activity center located between the outer edge of the 100-meter (328-foot) wide buffer of the proposed action components out to the distance equal to the applicable NSO physiographic home range radius: 1.5 miles, 1.3 miles, or 1.2 miles of the proposed Project.

Disturbance/Disruption

Harassment that could occur from proposed construction, including blasting (greater than 2 pounds) and/or large transport helicopter use by the proposed action has been analyzed within a 0.25-mile radius of the proposed activity. A 0.25-mile analysis area would be considered for construction and timber removal activities, as well as existing access roads that have been identified for access to the proposed action (excluding paved roads used regularly by the public – County Roads and State Highways) to account for potential disturbance from noise generated from traffic or road improvements.

Species Presence

NSO populations consist of resident owls (adult and subadult) that defend a territory vocally, and non-territorial owls (adult, subadult, and juvenile owls) that generally move through habitats in search of vacant territories or available mates and rarely vocalize. Surveys to determine if potential suitable NSO habitat is occupied are accomplished by imitating NSO calls to elicit a response, generally from the territorial owls. This is usually more effective at night, as NSOs would defend their territory more readily at night (Hobbs et al. 2004; Courtney et al. 2004; Forsman 1983). Generally sites identified at night would be visited the following day to determine status (i.e., pair, nesting, resident single). Reproduction information for territorial owls is obtained by feeding an individual adult owl live mice to determine if it is a member of a nesting pair or not, based on the owl's behavior (Lint 2001; FWS 1992d). FWS (2012i) recommends conducting at least six visits a year for two years prior to a proposed action to determine site occupancy and potential reproductive success, although the survey protocol for NSOs suggests that this information can be gathered during six visits to a site in one year if the only disturbance expected from a project is noise.

Northern spotted owls are known to occur within the vicinity of the Pipeline (ORBIC 2017a) and designated critical habitat for the species is present in each county crossed by the Pipeline (FWS 2012d) see Critical Habitat Units ORC-6, KLE-1, KLE-2, KLE-3, KLE-4, KLE-5, and ECS-1). Additionally, the Pipeline will pass through BLM and Forest Service LSRs in Coos Bay, Roseburg, and Medford BLM Districts, and through LSR units RO 223 on Umpqua NF and RO 227 on Rogue River-Siskiyou NF.

To determine species presence and/or absence within the provincial analysis area, GIS data of historical and current NSO locations were obtained from BLM Districts and National Forests crossed by the Pipeline, as well as from the demographic studies occurring within the Pipeline project area (BLM 2006, 2012, and 2017; Forest Service 2006, 2012, 2017a, 2017b, and 2017c; FWS 2008d). Additionally, PCGP contracted SBS (Eagle Point, Oregon) to conduct 2 years of surveys in 2007 and 2008 to determine species presence within the proposed construction right-of-way. Taking a conservative approach for purposes of this APDBA, all owl sites (known, best location, and PCGP assumed) are analyzed as if occupied and reproductive.

PCGP Spotted Owl Surveys (2007 and 2008)

To determine nesting NSO presence and/or absence, as well as nesting status (if possible) within the analysis area, NSO surveys were conducted by PCGP between March 15 and August 31 in 2007 and 2008 as defined by the *Protocol for Surveying Proposed Management Activities that May Impact Northern Spotted Owls* (FWS 1992d); NSO absence data could be considered accurate for two breeding seasons following complete survey efforts. Surveys were conducted by SBS and were carried out within suitable NRF habitat and outside of ongoing NSO demographic and monitoring survey efforts. In general, surveys were conducted within 0.5 mile of the proposed construction right-of-way where suitable NRF habitat would be removed by the Project. Otherwise, surveys were conducted within 0.25 mile of the proposed construction right-of-way if suitable NRF habitat was present, but would not be removed (as advised by Smith et al. 2007). In areas that were identified as requiring blasting and/or timber removal and construction by helicopter, surveys within suitable NSO habitat were conducted 1 mile from the proposed alignment in 2008 (Smith et al. 2007; Wille et al. 2006).

The 0.25-mile disturbance and the 0.5-mile habitat alteration survey areas followed the 1992 FWS two-year survey protocol (three visits per year) in 2007 and 2008. Surveys conducted out to 1 mile from potential blasting (greater than 2 pounds) and/or large transport helicopter disturbance areas in 2008 followed the 1992 one-year survey protocol (six visits per year). Surveys conducted within the Project area took extra precautions to reduce negative effects of barred owls on NSO, following guidance provided by the FWS in March 2007, which dictate that if a barred owl responds to a NSO call, stop calling for the NSO. This guidance is similar to the direction provided in the 2012 revised and updated survey protocol (FWS 2012i). To further reduce NSO harassment from multiple survey efforts, PCGP did not conduct surveys where other survey efforts by agency biologists were ongoing, including demographic and monitoring studies in the Roseburg BLM District (approximately MP 46.8 through MP 100.7), South Cascades demographic study conducted in Jackson and Klamath counties (MP 155.2 through MP 170.7), and a NSO monitoring study area in Lakeview BLM District.

Within the defined survey area for 2007, approximately 28,774 acres were identified as suitable NRF habitat and were organized into 61 separate survey areas. Of that acreage, 8,562 acres identified were located on private lands but permission to survey was granted on only 3,713 acres (access was denied for 4,849 acres). Overall, 83 percent or approximately 23,925 acres were surveyed in 2007 following the 1992 two-year survey protocol. In 2008, an additional 32,221 acres were identified as potential suitable NRF habitat within 1 mile of areas that may require blasting (greater than 2 pounds) and large transport helicopter use. Of the 58,652 acres identified as suitable NRF habitat, permission to survey was granted for 47,679 acres (81 percent), and these were surveyed in 2008. New habitat identified in 2008 followed the 1992 one-year survey protocol.

NSO surveys conducted in 2007 detected NSO 115 times in 29 of the 61 survey areas. Twelve NSO pairs and one resident single (located at least three times on separate survey visits) were detected. No nest sites were located in 2007; however, at one site fledglings were observed with their parents, suggesting a nest location in the vicinity. During 2008 surveys, NSO were detected 190 times and were found in 26 of the 54 survey areas established. NSO pairs were detected at 20 locations and two nests were located. Resident singles were identified at six sites. Approximate activity centers were drawn around the pairs and resident singles documented in 2007 and/or 2008 based on detection date and time, the age and sex of owls observed, the owls' behavior, and occasionally the habitat of a detection location. Seven NSO pairs documented within the survey area were assumed to be NSO activity sites previously documented and/or monitored by other agencies, and seven pairs were incorporated as new activity sites within agency management areas considering activity documented during 2007 and/or 2008 survey results. NSO pairs or resident singles that were not associated with previous known NSO activity centers or were not incorporated by agencies as new activity sites are considered Pipeline project "best location" activity centers for analysis within this APDBA.

Although survey design was not intended to locate or census barred owls, this species was documented 36 times in 14 survey areas in 2007, and 115 times in 14 survey areas in 2008, including 8 pairs.

For full description and information on NSO surveys and detections, see the 2007–2008 Northern Spotted Owl Survey Report (available upon request).

PCGP Spotted Owl Surveys (2015)

Protocol surveys were initiated along the Blue Ridge route in 2015 following the revised 2012 survey protocol – two years of surveys, six visits each year (FWS 2012i). No NSO were documented; however, barred owls were documented 19 times, including three pairs. The presence of barred owls detected during survey efforts decreases the likelihood that NSO are nesting along the Blue Ridge portion of the Proposed Route. To-date, only one year of survey effort has occurred in this portion of the Pipeline project.

Northern Spotted Owl Activity Sites Considered for Analysis

Initially in 2008, PCGP received a Northern Spotted Owl Occupancy Map (NSOOM) from FWS that included both historical and recent NSO sites provided by BLM Districts and National Forests within the proposed Project area that were combined with survey data collected for the Pipeline by SBS in 2007/2008. Additionally, the NSOOM provided areas of potential NSO nests sites modeled or "predicted" to occur on the landscape based on current NSO occupancy and available NSO habitat (see appendix 1 in appendix A of Trapper Timber Sale Biological Opinion). Agency biologists reviewed the data and revised NSO activity centers considered for the Pipeline based on local knowledge prior to providing the final data to PCGP. The objective of the collaborative process was to generate a clean but complete NSO map that could be used for analyses purposes for the proposed Pipeline. Some areas where owl activity was less certain, such as where resident single or pair activity was identified by SBS that may be associated with other known activity sites but not enough information was available (i.e., no band color collected), were included for analysis (i.e., Pipeline project best location sites). If an agency-provided alternate nest site was closer to the Pipeline route, the alternate site was considered rather than the site with the most recent activity for a more conservative analysis. By using this conservative approach, the analysis reflects a "worst case scenario" and likely results in an overestimation of potential impacts to the NSO.

The 2008 NSOOM was revised in 2013 and again in 2014 as part of the previous iteration of the Pipeline project, and subsequently revised in 2017 to account for new data and new direction by agencies since 2008 for the Pipeline. To revise previous NSOOM and account for new data and new survey efforts since 2008, PCGP requested and obtained new NSO data from each of the BLM Districts and National Forests crossed by the Pipeline, including demographic study data (Forest Service 2017a, 2017b, 2017c; BLM 2017) Using the same methodology that was applied to the 2008 NSOOM, a revised NSOOM was created for this APDBA. The NSOOM methodology is intended to facilitate a reasonable, but conservative basis for estimating potentially occupied NSO habitat within the proposed analysis area, especially where surveys have not been conducted or not completed as required by the survey protocol, or barred owl presence may have negatively affected the response of NSOs during calling surveys.

In June 2013, the use of the Owl Estimation Model (OEM) that produced "predicted" owls provided in the 2008 NSOOM was challenged in federal district court. As a result of this challenge, FWS, BLM, and Forest Service requested that the use of "predicted owls" utilizing the OEM no longer be used by PCGP. PCGP had used the predicted owl sites and had previously included 18 possible NSO activity centers to produce a more conservative analysis for habitat effects and disturbance disruption effects by the Project. As a result of the recent court activity and agency requests, PCGP removed 18 predicted owls created using the OEM that had been previously included in the 2008 NSOOM. In order for PCGP to continue with a conservative analysis approach for spotted owls (similar to PCGP's approach for MAMUs – presumed occupied stands), PCGP identified nine areas (referred to hereafter as "PCGP assumed sites") within 1.2 to 1.5 miles of proposed Project disturbance (Cascades to Coast Range physiographic province home range radii distances) that could potentially support NSO pairs. PCGP assumed sites were established in areas that were either surveyed in 2007/2008 with NSO presence but no pair or resident single determined, or an area that could support a NSO pair based on suitable habitat available in an assumed nest patch/core area that is located farther than the average "nearest neighbor" distance from a known or best location NSO site, as reported by FWS et al. (2008) for each physiographic province crossed (see Table 5 in FWS et al. 2008: more than 2,084 meters [6,837 feet] in Coast Range; more than 2,078 meters [6,817 feet] in Klamath Mountains; more than 2,333 meters [7,654 feet] in West Cascades; and more than 2,446 meters [8,024 feet] in East Cascades).

PCGP took into consideration the general habitat characteristics of known NSO sites in the vicinity of potential "assumed" locations to review the current status of available NRF within known home ranges, since available NRF habitat within a potential PCGP assumed site often did not meet the FWS-recommended NRF threshold of more than 40 percent and more than 50 percent NRF in the home range and core area, respectively. Past predicted owl sites previously analyzed were also reviewed for consideration because PCGP survey efforts had targeted those areas. In five instances, PCGP assumed sites were established in the vicinity of previously "mapped" / "predicted" owl sites based on survey efforts or the amount of available high quality NRF habitat that was also contiguous, interior forest. PCGP assumed sites have been placed in contiguous high NRF/NRF habitat at least 100 meters (328 feet) from the edge of a forested stand resulting in the site being placed in interior forest. These areas are PCGP assumed NSO sites and have been provided a site ID (i.e. PCGP A-8) No PCGP assumed sites were established between MPs 0.00 and 32.47 because this area consists of checkerboard BLM/private land ownership where commercial timber harvest is prevalent and surveys conducted within this MP range for the Pipeline in areas of higher quality NRF habitat did not document NSO. Three of the PCGP-assumed sites established in 2014 were replaced by known or historic owl sites provided by BLM or Forest Service in 2017 that were in close proximity to the PCGP-assumed sites.

Sites considered for analysis within this APDBA are either 1) known pairs or resident singles provided by BLM and Forest Service (historic or current), 2) best location (pair documented by PCGP survey efforts in 2007/2008 but nest site not located, or 3) PCGP-assumed (site analyzed where no pair has been documented, but available NRF habitat present could provide habitat for nesting or future nesting NSO). Approximately 105 northern spotted owl home ranges – known current/historic (84), best location (15), and PCGP-assumed (6) occur within the vicinity of the proposed Pipeline, including existing access roads (excluding paved, public roads) identified for use for construction and operation of the Pipeline, pipe yards, and rock storage areas, of which 97 home ranges will be affected by construction of the proposed Pipeline, and 78 home ranges will be crossed by proposed access roads. Table 3.3.4-2 provides a summary of NSO home ranges, core areas, and nest patches (known, best location, or PCGP assumed) that intersect the proposed Pipeline and/or proposed access roads within each physiographic province. Table Q-7 in appendix Q provides additional details for each NSO Home Range included in the provincial analysis area, including available NSO habitat (high NRF, NRF, dispersal only, and capable) within each Home Range pre-action.

TABLE 3.3.4-2

a/ Habitat Affected considers all proposed disturbance, including uncleared storage areas (UCSAs), pipeyards, rock sources, and PARs/TARs.
b/ Access roads considered does not include paved roads that are used regularly by the public (i.e., County Roads, State Highways). Home ranges are included if the activity center is within 0.25 mile of a proposed access road.
c/ Best Location Sites – areas identified with pair activity during PCGP survey efforts in 2007 and/or 2008 but the nest was not located; SBS and local agency biologists determined best potential nest site based on survey data and available habitat.
d/ PCGP Assumed Sites - area identified by PCGP that may provide habitat for NSO pair.

FWS et al. (2008) consider core areas with 50 percent or greater NRF habitat and home ranges with at least 40 percent NRF habitat to be necessary to maintain NSO life history function. Based on FWS et al. (2008) guidelines 39 of 97 spotted owl sites identified that will have habitat removed by the Proposed Route are above the threshold of available NRF habitat within both their core area (greater than 50 percent) and home range (greater than 40 percent): 32 known NSO sites and 7 best location sites. The remaining 58 spotted owl activity centers (45 known, 8 best location, and 5 PCGP assumed) are below NRF thresholds for the core area and/or home range (table 3.3.4-3).

Table 3.3.4-3 provides a summary of the current habitat condition by Physiographic Province and owl status (known, best location, or PCGP assumed) of the 97 NSO sites within the provincial analysis area that will have habitat affected by the Proposed Route. Note that calculations of habitat conditions for each owl site in table 3.3.4-3 considered suitable habitat located on both federal and non-federal lands. The amount of NRF habitat currently available for each NSO within each habitat type (nest patch, core area, and home range) can be reviewed in table Q-7 in appendix Q. Amount of NRF habitat in table Q-7 in appendix Q is specific to each habitat type in its entirety;

acres provided for the home range include acres that also occur within the core area and nest patch, and acres included in the core area also include acres within the nest patch. Table Q-7 in appendix Q provides the amount of suitable habitat for each individual owl in federal and non-federal lands, regardless of overlap with adjacent home ranges and the habitat condition determined pre-action for each NSO home range. A description of how NSO habitat was determined is addressed in the Habitat section below.

[1] For detailed suitable NRF habitat available for each individual northern spotted owl and its habitat type (nest patch, core area, home range), refer to suitable habitat acres in table Q-7 in appendix Q.
[2] FWS et al. (2008) consider core areas with 50 percent or greater suitable NRF habitat and home ranges with at least 40 percent suitable NRF habitat to be necessary to maintain NSO life history function.
[3] Owl Status: 1) Known sites represent pairs or resident singles - historic or current; 2) Best Location are sites documented during survey efforts for the Pipeline project but nest site was not located; and 3) PCGP-assumed sites are areas identified by PCGP that may provide habitat for NSO pair.

PCGP requested guidance from FWS in November 2012 to determine what additional surveys for NSO should be conducted for the proposed action, considering the survey protocol was revised in February 2010 (see FWS 2010h) and finalized in January 2012 (see FWS 2012i), and surveys for the Pipeline project were conducted in 2007 and 2008 following the 1992 survey protocol. FWS (McCorkle 2012; appendix S – ROC) stated that additional full protocol NSO surveys across the entire project were not necessary, but recommended pre-construction "spot check" surveys with at least three site visits occurring prior to construction to confirm occupancy status, and to inform additional opportunities to fine-tune timing or distance buffers around active NSO activity centers. PCGP would conduct "spot check" surveys one year prior to scheduled timber removal in NRF habitat that is within 0.25 mile of the construction right-of-way to detect spotted owls that may have recently established territories in the project area or are utilizing another site for nesting (see "spot check" surveys in the revised NSO survey protocol; FWS 2012i). Surveys would target NRF habitat within home ranges analyzed for the Pipeline project, as well as additional NRF habitat outside of NSO home ranges that was included in previous survey efforts for the Pipeline (2007, 2008, and 2015 survey efforts) and may be capable of supporting a single or pair of territorial

NSO. Surveys would not occur where annual monitoring survey efforts are on-going in the proposed action area to minimize NSO harassment.

Habitat

FWS identified four categories of NSO habitat that should be used to assess impacts to spotted owls and habitat for the proposed action (2014c): highly suitable NRF (high NRF), NRF, dispersal habitat, and capable habitat. High NRF is considered habitat that is characterized by large trees (greater than 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species (FWS 2014c). Other habitat definitions include (FWS; 2012d, 2014c; North et al. 1999): 1) NRF that consists of conifer-dominated stands older than 80 years, and are multi-storied in structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, high basal area (greater than 240 square feet/acre), high diversity of different diameters of trees, high incidence of large live trees with various deformities (e.g., large cavities, broken tops, mistletoe infections), sufficient snags and down wood, and sufficient open space below the canopy for NSO to fly but does not meet the definition of High NRF; 2) dispersal habitat is composed of conifer and mixed mature conifer-hardwood habitats with a canopy cover greater than or equal to 40 percent in moist forests and greater than 30 percent in dry forests, conifer trees greater than or equal to 11 inches average diameter-breast-at-height, and sufficient open space below the canopy to fly; and 3) capable habitat that is forested habitat that could provide NSO suitable NRF in the future (including recently harvested stands – i.e., clearcut) but currently does not provide the structures described above for NSO High NRF, NRF, or dispersal habitat. Non-capable habitat has been defined as areas that will never provide habitat for NRF or dispersal habitat, such as agriculture fields, grasslands, rivers, rock outcroppings, roads, etc. (FWS 2006d), as well as forested areas that are non-capable largely because of the natural expression of vegetation patterns resulting from edaphic, topographic, and climatic constraints; such areas may include serpentine dominated soils or dry, south-facing slopes, and could also include oak woodlands.

In the analysis conducted for the previously proposed project (FERC 2009), PCGP used the BioMapper Habitat Model created by the Forest Service Northwest Research Station and used in the 10-year Monitoring Report (see Lint 2005) per recommendations by FWS and Forest Service, as the foundation to determine suitable habitat within the project area. Davis et al. (2011) determined that the BioMapper model overestimated owl habitat suitability in portions of the range, including pine-dominated forests of the eastern Cascades, and young stands in the Coast Range and western Cascades. Since the previous analysis (FERC 2009), improved NSO habitat models have been developed to monitor status and trends of the NSO populations and habitat within the past 15 and 20 years in the NWFP area and were introduced in the 15-year and 20-year NWFP NSO habitat monitoring documents; the habitat suitability models represent NSO habitat as of 2006 and 2012 in Oregon, respectively (see Davis et al. 2011 and 2016). In 2012, FWS and Forest Service suggested that PCGP use these models developed for the 15-year NWFP NSO habitat monitoring efforts to assist in categorizing NSO habitat (high NRF, NRF, dispersal, and capable habitat; see FWS 2014c) within the proposed action project area, rather than the BioMapper model. The updated model used in the 20-year NWFP NSO habitat monitoring effort has been used for developing NSO habitat for this APDBA.

In addition to the updated GIS NSO habitat models developed for the 20-year NWFP monitoring documents (Davis et al. 2016), PCGP received agency-specific NSO habitat GIS data from National Forests crossed by the Pipeline [Umpqua (Forest Service 2017a), Rogue River – Siskiyou

(Forest Service 2017b), and Fremont-Winema (Forest Service 2017c)] and BLM Districts crossed by the Pipeline (Coos Bay, Roseburg, Medford, and Lakeview [BLM 2017a]). In order to standardize the available GIS data throughout the provinicial analysis area, and create a NSO habitat GIS file with the four recommended NSO habitat categories for for this BAAPDBA (see FWS 2014c), PCGP used the available GIS NSO Habitat files in conjuction with the vegetation GIS coverage that was delineated for the Pipeline. The vegetation GIS coverage for the Pipeline was delineated at a finer scale using 2016 aerial photography, and available agency data (i.e., BLM FOI coverage, late successional Gradient Nearest Neighbor coverage) to classify age of forest, generally within 300 meters (984 feet) of the proposed action and particularly in the affected area, and has been reviewed by local agency biologists; forested habitat was classified by type and age classes (clear-cut – 0 to 5 years, regenerating forest—5 to 40 years, mid-seral—40 to 80 years, late successional—80 to 175 years, and old-growth—greater than 175 years; see discussion in Vegetation, Section 3.3.1.1 in PCGP's FERC Certificate application).

NSO habitat was initially delineated using the vegetation GIS file created by PCGP for the proposed action using age classes and forest type: clearcut and regenerating forest was considered "capable;" mid-seral coniferous and mixed forest lands, as well as deciduous forests were considered "dispersal only;" and late successional coniferous and old-growth forest were considered NRF habitat. Next, the seven NSO habitat coverages obtained from the National Forests and BLM Districts crossed by the Pipeline were used to further refine NSO habitat classification, and expand the PCGP NSO habitat coverage beyond the vegetation GIS file delineated for the Pipeline. Where NSO habitat categories differed between the NSO habitat identified from the vegetion GIS file, or from other agency data, PCGP conservatively used the higher habitat category (i.e., an area that was identified as NRF, dispersal, and non-capable was categorized as NRF), especially outside of the finely delineated vegetation GIS file created for the Pipeline project. Within closer vicinity of the Pipeline, NSO habitat was generally classified using the vegetation GIS file created for the proposed action since forested vegetation on the ground had been updated from 2016 aerial photography to consider recent clearcuts and the 2015 Stouts Creek fire; available agency NSO habitat data often did not reflect changes in forested habitat since 2015 or earlier.

The 2012 nesting/roosting model created for the 20-year NWFP Habitat monitoring provided a pixelated coverage that identified areas of highly suitable, suitable, marginal, and unsuitable habitat throughout the NWFP area. The pixelated areas identified as "highly suitable" were used to classify areas of "high NRF" in the NSO habitat file where the previous steps using the vegetation GIS and agency data determined NSO habitat to be NRF. Further, unclassified NSO habitat within the provincial analysis area was classified using areas identified in the 2012 nesting/roosting model ("suitable" areas were used to classify NSO habitat as NRF and "highly suitable" areas were used to classify high NRF), and previously modeled habitat from the 2015 FERC BA.

Within the resulting modeled areas for the provincial analysis area, 2016 aerial photography was used to delineate obviously young stands (i.e., clearcuts or early regenerating forest) and identify the habitat as capable (in many instances high NRF and NRF modeled from available data and the 2012 NWFP model were located in clearcuts). In 2015, Stouts Creek fire burned through a large quantity of high quality NSO habitat in the provinicial analysis area in Klamath Mountain physiographic provice; the modeled habitat and agency GIS data often identified this area as providing NRF and high NRF habitat. PCGP consulted with FWS (Stone, 2017), Forest Service

(Hadwen, 2017) and BLM (McGraw, 2017) to determine how to proceed with classifying NSO habitat in the affected area. Based on direction received from the agencies, PCGP conservatively classified NSO habitat in the area affected by the fire as follows:

- areas that had been clearcut or burned to the ground were considered capable habitat;
- mid-seral to late successional habitat that that had standing trees but had burned to some degree (trees brown in patches, based on visually reviewing 2016 aerial photography) continued to be considered their modeled NSO habitat type – diserpsal, NRF, high NRF; and
- areas that were charred from a high intensity burn, but still had trees standing (contiguous stand of black, standing trees) were considered NRF, but not high NRF if the 2012 NWFP model identified that area as high NRF. Agencies indicated that these areas would be considered areas for NSO foraging and/or roosting, but to include the habitat in the "NRF" category, as defined in the FWS Conservation Framework document (FWS 2014c). In the NSO GIS file, this NSO habitat type is classified as "post-fire NRF" and is incorporated in subsequent tables to identify the NRF habitat that is likely standing dead trees. Post-fire NRF is a term used in the Roseburg BLM District NSO habitat GIS file provided to PCGP.

The resulting NSO Habitat file described above provides a good, but conservative approximation of the NSO habitat (high NRF, NRF, dispersal only, and capable) within the proposed action area that would be affected by construction of the Pipeline. The model was used to determine the amount of high NRF, NRF, dispersal, and capable habitat within the Physiographic analysis area by Physiographic Province and jurisdiction (see table 3.3.4-4). Figures 2, 3, and 4 in appendix Q provide an overview of NSO habitat within the Project analysis area in relation to spotted owl home ranges, NSO critical habitat, and NWFP LSRs. Table Q-7 in appendix Q identifies the amount of NSO Habitat (high NRF, NRF, dispersal only, and capable habitat) available within each NSO Home Range.

Both federal and non-federal land occurs within the defined provincial analysis area, and based on acres of high NRF and NRF habitat available within each (see table 3.3.4-4), it is apparent that federally-managed lands provide substantially more suitable NRF habitat than non-federal lands. Therefore, it can be expected that non-federal land within the provincial analysis area plays a minor role in supporting NSOs and aiding in their recovery. Overall, approximately 52 percent of federal lands within the provincial analysis area provide suitable NRF (including High NRF) habitat; this is greater than the 40 percent NRF habitat threshold per home range that FWS et al. (2007) consider necessary to maintain NSO life history function. Also note, the majority of available NRF occurs within NSO home ranges. If physiographic provinces are reviewed individually, less than 40 percent of federal and non-federal lands together provide suitable NRF within each physiographic province; however, federal lands within individual physiographic province (except for the Coast Range) collectively consist of more than 40 percent NRF habitat which is above the recommended threshold. On all lands (federal and nonfederal), the Coast Range provides 18.1 percent NRF; Klamath Mountains, 37.5 percent NRF; West Cascades, 37.8 percent NRF; East Cascades, 32.6 percent NRF.

TABLE 3.3.4-4

Summary of NSO Suitable Nesting, Roosting, and Foraging, Dispersal, and Capable Habitat Available within the Provincial Analysis Area by Physiographic Province

a/ Landowner is summarized by Federal (BLM Districts and National Forests) and Non-Federal (Private, State, Corps of Engineers, and Bureau of Indian Affairs Land).

b/ Total acres available within the entire analysis area, including non-capable habitat, is not identified in this table.

c/ High NRF (FWS 2014c): forested habitat characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species. Generally includes late successional and old-growth forest (greater than 80 years).

d/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., "post-fire NRF").

e/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.

f/ Capable Habitat (FWS 2014c: habitat that is forested or could become forested (i.e., including recently harvested timberlands) that do not provide dispersal or NRF characteristics

Discussion at the Task Force - ESA Consultation Subgroup meeting on April 2, 2008, indicated that NSO dispersal habitat could be considered adequate, or sufficient to support dispersing NSO, if at least 50 percent of the analysis area (in the Project's case, the defined provincial analysis area) consists of dispersal habitat. Within the provincial analysis area, dispersal habitat comprises dispersal-only habitat, as well as high NRF and NRF. Calculating the overall high NRF, NRF, and dispersal habitat from table 3.3.4-4, approximately 168,443 acres (52.4 percent) of dispersal habitat are available within the provincial analysis area. Overall, the provincial analysis area provides sufficient levels of dispersal habitat to support dispersing NSO (greater than 50 percent). Using the same method to calculate the available dispersal habitat within each physiographic province, the following acres of dispersal habitat are available within each province: 34,594 acres (37.5 percent) in the Coast Range, 73,156 acres (56.8 percent) in Klamath Mountains, 50,176 acres (65.3 percent) in West Cascades, and 10,517 acres (44.0 percent) in East Cascades. Two of the physiographic provinces within the provincial analysis area - Klamath Mountains and West Cascades physiographic provinces - provide adequate levels of dispersal habitat (greater than 50 percent).

Critical Habitat

Four federally-designated CHUs occur within the provincial analysis area (FWS 2012d): Oregon Coast Ranges – OCR (Unit 2) totaling 859,864 acres and six subunits, East Cascades South – ECS (Unit 8) totaling 368,381 acres and three subunits, Klamath West – KLW (Unit 9) totaling 1,197,389 acres and nine subunits, and Klamath East – KLE (Unit 10) totaling 1,052,731 acres and seven subunits. Eight subunits occur within the provincial analysis area (OCR-6, ECS-1, KLW-1, KLE-1, KLE-2, KLE-3, KLE-4, and KLE-5). All subunits are expected to function primarily for demographic support to the overall population, as well as connectivity between subunits and CHUs. Special management consideration or protection required for each subunit is to address threats from current and past timber harvest and competition from barred owls, as well as losses due to wildfire and the effects on vegetation from fire exclusion (with the exception of OCR-6).

- OCR (Unit 2): forest is dominated by western hemlock, Sitka spruce, and Douglas-fir. NSO nesting habitat tends to be limited to stands providing very large trees with cavities or deformities because Douglas-fir dwarf mistletoe is unusual in this region. Woodrats comprise an increasing proportion of the diet. One subunit occurs in the provincial analysis area: OCR-6.
  - OCR-6: consists of approximately 81,900 acres in Coos and Douglas Counties, Oregon and comprises lands managed by the BLM. 97 percent of the area was used by NSO at the time of listing.
- KLW (Unit 9): forest is a highly diverse mix of mesic forest communities such as Pacific Douglas-fir, Douglas-fir tanoak, and mixed evergreen forest interspersed with more xeric forest types; tanoak is a dominant factor. Douglas-fir dwarf mistletoe is uncommon and seldom used for nesting platforms by NSO. Prey is diverse, but dominated by woodrats and flying squirrels. One subunit occurs in the provincial analysis area but would not be affected by the Pipeline project: KLW-1.
  - KLW-1: consists of approximately 147,326 acres in Douglas, Josephine, Curry, and Coos Counties, Oregon and managed by the State of Oregon and BLM. 96 percent of the area was used by NSO at the time of listing.

- KLE (Unit 10): forest is a mixed-conifer/evergreen hardwood forest type and grades into the western hemlock forest. High summer temperatures and a mosaic of open forest conditions and Oregon white oak woodlands influence NSO distribution in this region. Dwarf mistletoe provides an important component of nesting habitat, enabling NSO to occasionally nest within stands of relatively younger, small trees. Five subunits occur in the provincial analysis area: KLE-1, KLE-2, KLE-3, KLE-4, and KLE-5.
  - KLE-1: consists of 242, 338 acres in Jackson and Douglas Counties, Oregon and managed by Forest Service and BLM; 84 percent of the area was used by NSO at the time of listing.
  - KLE-2: consists of 101,942 acres in Josephine and Douglas Counties, Oregon and is managed by BLM and the Forest Service; 92 percent of the area was used by NSO at the time of listing.
  - KLE-3: consists of 111,410 acres in Jackson, Josephine, and Douglas Counties, Oregon and is managed by Forest Service and BLM; 97 percent of the area was used by NSO at the time of listing.
  - KLE-4: consists of 254,442 acres in Jackson, Klamath, and Douglas Counties, Oregon and is managed by the Forest Service and BLM; 81 percent of the area was used by NSO at the time of listing.
  - KLE-5: consists of 38,283 acres in Jackson County, Oregon and is managed by the BLM and Forest Service; 86 percent of the area was used by NSO at the time of listing.
- ECS (Unit 8): ponderosa pine is dominant at mid-to-lower elevations, with a narrow band of Douglas-fir and white fir at middle elevations providing the majority of NSO habitat. Dwarf mistletoe provides an important component of nesting habitat, enabling NSO to nest within stands of relatively younger smaller trees. One subunit occurs in the provincial analysis area: ECS-1.
  - ECS-1: consists of approximately 127,801 acres in Klamath, Jackson, and Douglas Counties, Oregon and comprises lands managed by the BLM and Forest Service; 78 percent of the area was used by NSO at the time of listing.

The current status of NSO habitat (high NRF, NRF, dispersal only, and capable, as determined through the process for the Pipeline project identified in the "Habitat" sub-section above) within designated CHUs and subunits located in the Project analysis area is shown in table 3.3.4-5. The baseline information shows that not all designated critical habitat is currently functioning as suitable NRF habitat. However, table 3.3.4-5 also provides the number of NSO that are known to occur in the CHUs located in the analysis area (based on NSO activity centers provided to PCGP by FWS, BLM, and Forest Service). Given that suitable habitat acres within all affected CHUs currently support NRF habitat at levels that are adequate to support pairs of nesting NSOs, these CHUs are considered to be functional with respect to their recovery roles.

Of the 84 known, 15 best location, and 6 PCGP assumed NSO activity centers within the analysis area, 59 activity sites occur in Critical Habitat Units (48 known, 8 best location, 3 PCGP assumed). Table 3.3.4-6 summarizes the number of activity sites analyzed within this APDBA that occur within each critical habitat subunit, and the condition of the home range (see table Q-7 in appendix Q). More than half the activity centers (39 of 59) have suitable NSO habitat above the recommended level of 50 percent suitable NRF habitat in the core area and 40 percent suitable NRF habitat in the home range to support nesting and NSO survival.

TABLE 3.3.4-5

a/ Number of Known Owls in entire CHU Subunit: known owl sites obtained from known owl locations provided by BLM (2017a), Forest Service (2017), and FWS (2008d) and 2007/2008 surveys conducted by PCGP.

b/ High NRF (FWS 2014c): forested habitat that is characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species.

c/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., “post-fire NRF”).

d/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.

e/ Capable Habitat (FWS 2014c): habitat that is forested or could become forested (i.e., recently harvested timberlands) that do not provide dispersal or NRF characteristics.

f/ Total NSO Habitat within CHU Subunits that occur within the provincial analysis area; does not include non-capable habitat.

g/ Percent total: percent of habitat available in entire critical habitat unit, not just the provincial analysis area.

Late Successional Reserves

BLM and Forest Service LSRs occur within the provincial analysis area. LSRs on Forest Service lands are provided an LSR unit identified within the NWFP (Forest Service and BLM 1994): RO 223 is a large LSR unit and occurs within Umpqua NF, and RO 227 occurs within Rogue River National Forest and Winema National Forest and is generally contiguous. Additionally, approximately 568 acres of unmapped LSRs on National Forest Service lands associated with known NSO activity centers (KOAC) occur within the provincial analysis area. Table 3.3.4-7 includes a summary of NSO habitat that occurs within LSRs (and respective LSR units on National Forest Service lands) within the provincial analysis area by BLM District and National Forest, as well as NSO habitat within unmapped LSRs.

Much of the LSRs (and unmapped LSRs) within the provincial analysis area overlap the FWS designated CHUs for NSO. The overlap of LSRs with federally designated NSO critical habitat affords a greater degree of protection to the NSO and its critical habitat as the protections for LSRs are automatically imposed on those LSR acres that are found within a CHU. Thus, NSOs located within these land allocations also benefit from increased protection.

TABLE 3.3.4-7

Summary of High NRF, NRF, Dispersal, and Capable Habitat Available within LSRs and Forest Service Unmapped LSRs by Physiographic Province and Landowner within the Provincial Analysis Area

a/ Unmapped LSRs consider MAMU occupied stands and Known Owl Activity Centers (KOAC) on NWFP Matrix lands on Forest Service-Managed lands.
b/ High NRF (FWS 2014c): forested habitat that is characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species.
c/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., “post-fire NRF”).
d/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.
e/ Capable Habitat (FWS 2014c): habitat that is forested or could become forested (i.e., recently harvested timberlands) that do not provide dispersal or NRF characteristics.
f/ Total NSO Habitat within NWFP LSRs and unmapped LSRs that occur within the provincial analysis area; does not include non-capable habitat.
g/ Percent total: percent of habitat available in LSR units withint the provincial analysis area.

3.3.4.3 Effects of the Proposed Action

Effects of the proposed action include direct and indirect effects within the provincial analysis area, as described below. Analysis of potential direct and indirect effects to NSO by the Pipeline project within the provincial analysis was guided by the Revised Conservation Framework developed for the Project (see *Revised Conservation Framework for the Northern Spotted owl and Marbled Murrelet: Jordan Cove Energy and Pacific Connector Gas Pipeline Project*, FWS 2014c).

Direct Effects

Potential Project-related effects to NSOs that could be caused by the action and occur at the same time and place, including the following within the provincial analysis area: 1) removal of a known nest tree during the breeding season (March 1 through September 30), and 2) human and noise disturbance due to right-of-way clearing, construction, and road use during the breeding period, including noise due to blasting and helicopter support during construction, and smoke from burning slash. These effects would extend over the short term.

Habitat Removal During Breeding Season

Removal of habitat during the breeding season within a nest patch could result in the potential death of nestlings if the nest tree is felled. Removing habitat outside of the entire breeding season (outside of March 1 through September 30) would eliminate any direct impact to individual NSOs or nestlings. Because habitat removal within 0.25 mile of an activity center within the Pipeline route, including subsequent NSO activity centers detected within 0.25 mile of the Pipeline prior to construction, would occur outside of the entire breeding season (outside of March 1 through September 30), no direct effect to NSOs through habitat removal is expected. Maps within appendix V1 show the timing constraints that would be applied in relation to NSO activity centers for timber felling (and Pipeline construction).

Noise and Visual

In their Revised Conservation Framework, FWS (2014c) provided guidance on determining Project impacts to NSO from noise. This guidance included disturbance and disruption distances based on noise thresholds (as described in FWS 2003b and 2006a; discussed below), and prescribed associated impact levels (No, Low, Moderate, or High) based on Project timing and activity.

Disruption and Disturbance – Available Literature

NSOs could be directly affected by noise and disturbance related to proximate human-related activities associated with timber removal, construction, and operation and maintenance of the Pipeline that could result in diminished reproductive success and survival (if behavior response to construction makes them more vulnerable to injury). Disturbance (both visual and noise) would include use of chainsaws and heavy equipment during vegetation clearing and construction, explosives to trench through rock, helicopters and/or small aircraft to inspect the pipeline once per year during the life of the Pipeline, and brush control (i.e., mowing and cutting) within the 30-foot maintenance right-of-way every three to five years for the life of the Pipeline. The term "disruption" was alluded to in the ESA, under the definition of "harassment" (50 CFR 17.3) as:

"an intentional or negligent act or omission which creates the likelihood of injury by annoying it (the organism) to such an extent as to significantly disrupt normal behavior patterns which include but are not limited to, breeding, feeding or sheltering."

The term "disturbance" was not included in the ESA but a reasonable working definition was provided by Leal (2006) and has been incorporated into this APDBA:

"any potential auditory or visual stimuli or deviation from ambient/baseline conditions [that] an individual bird, at a given site, is likely to detect and potentially react to."

Reactions of NSOs from human presence and excessive noise levels in the immediate vicinity of owls could include the following if project activities occur during the breeding season: 1) flushing from the nest site, which would leave eggs or young exposed to predation; 2) causing juveniles to prematurely fledge, which would increase juveniles' risk of predation; 3) interrupting foraging activities, which would result in the reduced fitness or even mortality of an individual; and/or 4) disrupting roosting activities which would cause a NSO to be displaced and possibly relocate. In the Northern Spotted Owl Status Review, none of these types of disturbance were considered a threat to the species (Courtney et al. 2004). However, at the individual level, based on anecdotal information and effects to other bird species (Wesemann and Rowe 1987; Delaney et al. 1999; Delaney and Grubb 2001; Swarthout and Steidl 2001; FWS 2003b; FWS 2005d), disturbance to NSOs could occur.

Disturbance to owls would be expected to be inversely related to stimulus distance and positively related to noise level, similar to results reported for bald eagles (Grubb and King 1991), gyrfalcon (Platt 1977), and other raptors (Awbrey and Bowles 1990). Therefore, for a significant disruption of NSO behavior to occur as a result of disturbance caused by an action, the disturbance and the NSO must be in close proximity to one another (FWS 2003b; FWS 2005d). Human presence on the ground is not expected to cause a significant disruption of behavior because NSOs do not seem to be startled by human presence (FWS 2005d); however, increased human presence in an area that previously had minimal human presence may be an indirect effect of the proposed Project.

NSOs disturbed at a roost site are presumably capable of moving away from disturbance without a substantial disruption of behavior. Since NSOs are primarily nocturnal predators, projects that occur during the day are not likely to disrupt foraging behavior and the potential for effects is mainly associated with breeding behavior at an active nest site.

In the late breeding period, potential effects from Pipeline project activities decline because juvenile NSOs are increasingly more capable of moving as the nesting season progresses. Once capable of sustained flight, young owls are presumably able to distance themselves from disturbance and minimize their risk of predation. To ensure that more than 86 percent of juvenile NSOs in the Oregon Western Cascades Physiographic Province are able to move away from disturbances without increasing their risk of predation or harm, the critical nesting period is considered to be March 1 through July 15. This is based on fledge data (Turner 1999) and includes an additional two weeks to allow for development of flight skills. After July 15, most fledgling NSOs are assumed to be capable of sustained flight and can move away from harmful disturbances. The critical breeding period for the Oregon Western Cascades Physiographic Province is applied to the entire provincial analysis area (March 1 through July 15), even though research has provided data that indicate NSOs fledge earlier in other Physiographic Provinces within the analysis area.

The available research and anecdotal accounts show that the effects of noise from a variety of sources can elicit disturbance as well as disruption responses from spotted owl subspecies (including MSO, NSO, and California spotted owls [CSO]), including responses such as flushing or flight that would be construed as interference with normal behavior patterns including but not limited to, breeding, feeding, or sheltering. The following are brief summaries of available spotted owl research:

- All NSO foraged adjacent to roads and appeared undisturbed by the occasional passage of vehicles on narrow secondary gravel forest roads (Forsman et al. 1984).
- Male NSOs within 0.25 mile of a major logging road or timber harvest had higher fecal corticosterone levels indicating that the NSO was more stressed than males farther away; no differences found for females related to distance from roads or timber harvest (Wasser et al. 1997).
- Proximity to roads (paved, improved surface, any type) was not correlated with fecal corticosterone in CSO (Tempel and Gutiérrez 2004).
- CSO exposure to chainsaw noise did not result in a detectable increase in fecal corticosterone level; CSO can tolerate low-intensity human sound in their environment without eliciting a physiological stress response (Tempel and Gutiérrez 2003).
- MSO nest occupancy less than 1 mile from firing sites was higher than nest occupancy more than 1 mile away; MSO not affected by explosives but were affected by hikers (Hathcock et al. 2010).
- MSO response to military aircraft overflights (noise levels 78, 92 and 95 dB during sequential exposures) ranged from none to sudden head turning; behaviors during flights were no different than pre- and post-flight periods (Johnson and Reynolds 2002).
- Relationships of NSO baseline physiology, nutritional stress, and reproductive success to exposures to high and low levels of routine OHV traffic (Hayward et al. 2011).
  - Male NSO showed high fecal glucocorticoid (GC) response to OHV trials during incubation period, indicating a higher level of stress.
  - Male NSO 164 to 2,625 feet (50 to 800 meters) from loud roads showed lower fecal GC response to motorcycle trials than males 164 to 2,625 feet (50 to 800 meters) from quiet roads in July (fledging period).
  - Female NSO with good nutrition but no young showed high fecal GC response to OHV trials.
  - Female NSO with 2 young and poor nutrition showed low fecal GS response to OHV trials.
  - NSO close to roads had better nutrition but levels of fecal GC were not related to proximity to roads or noise.
  - NSO within 328 feet (100 meters) of quiet roads fledged more young than NSO farther from roads; NSO within 328 feet (100 meters) of noisy roads fledged fewer young.

These studies to date show a mixed spotted owl response to noise. The majority of these studies focus on short-term measures of fecal steroids and do not necessarily account for potential longer term effects of noise over a breeding season. However, Hayward et al. (2011) did measure the effects on reproductive success of OHV traffic and found that that proximity to busy roads resulted in lower reproduction, which by definition is a measure of disruption. The literature summarized above indicates that while in the short term responses to noise may not be measureable, over a breeding season noise from roads has the potential to result in disruption.

Auditory and Visual Disturbance – FWS Guidance

FWS (2003b, 2006a) indicated that the disturbance behaviors noted above may occur when 1) the project-generated sound level substantially exceeds existing ambient noise levels by 20 to 25 dB; 2) when the total sound level (project and ambient noise levels combined) exceeds 90 dB; or 3) when the visual proximity of human disturbance occurs within 130 feet of an active nest site. FWS concluded that noise and human presence can result in a significant disruption of breeding, feeding, and/or sheltering behavior of NSOs such that it creates the potential for injury to the individuals (i.e., incidental take in the form of harassment).

FWS (2006a) established distances within which sound levels and visual disturbance for various activities may result in injury or harassment of NSOs by significantly disrupting the normal behavior pattern of individuals or breeding pairs. Table 3.3.4-8 (Disruption Threshold Distance) provides the distances at which FWS (2003b, 2006a, and 2014c) indicate that NSOs could be disrupted or "harassed" by certain activities during the critical breeding period and late breeding period. Within the Revised Conservation Framework, FWS (2014c) provided distances from a project boundary within which NSOs could potentially be distracted, or "disturbed" from their normal activity. Those distances are often applied as seasonal buffers to minimize impacts of projects on nesting NSOs (Disturbance Threshold Distance; table 3.3.4-8).

TABLE 3.3.4-8

Threshold Distances where Noise and Visual Disturbances are Unlikely to Occur to Nesting Northern Spotted Owls during the Breeding Season a/

g/ Transport helicopters proposed for this Project include: Boeing Chinook (CH-47) and Boeing Vertol 107-II (CH-46)				

FWS (2003b, 2006a) reviewed available scientific literature on behavioral and physiological responses of different bird species to various noise sources. They determined that birds would likely detect noises that were ≥4 decibels or more above ambient noise levels. FWS (2006a) defined an "injury threshold" of 92 dBA, and a "tolerance threshold" of 82 dB for NSOs and MAMUs. The tolerance threshold assumes that respective nest sites become "intolerable" to the species and harassment occurs due to the total sound level the species must endure. FWS (2006a) did recognize that a tolerance threshold of 92 dB for aircraft (e.g., helicopters) would be applicable due to the usually slow onset of aircraft noise approaching, but otherwise FWS (2006a) applied the threshold of 82 dB as a sound-related injury threshold level. Based on Delaney et al. (1999) and Brown (1990), FWS (2006a) subtracted the noise level that elicited a harassment-indicating behavior (flight or flushing) from the minimum ambient noise at the respective sites and deduced that action-generated noise levels that are 25 dB above ambient levels would constitute the sound level threshold above which harassment is likely to occur (FWS 2006a). From that exercise, FWS (2006a) deduced that a noise level of 70 dB would be a disturbance threshold and noise ≥70 dB would be disruptive.

The FWS typically considers the disturbance threshold for general noise-generating activities within a 0.25-mile radius (125-acre area) of the activity during the critical breeding season (March 1 to July 15). For louder disturbance activities such as open air blasting using more than a 2 pound charge or large aircraft, FWS generally applies a 1.0-mile radius (2,176-acre area) around NSO sites during the entire breeding season (March 1 to September 30) to minimize disturbance to nesting NSO (FWS 2003b; Smith et al. 2007; Wille et al. 2006). However, FWS suggested that if additional studies could demonstrate that use of larger blasts (greater than 2 pounds) and large helicopters with mitigation measures proposed for the Project attenuated to less than 92 dB, and preferably below 70 dB (disturbance threshold versus 92 dB disruption threshold) within a mile, to provide a report and additional data would be considered to reduce the threshold distances for those activities (Smith et al. 2007; Wille et al. 2006).

Blasting and Helicopter Noise Levels

PCGP prepared a report (see appendix P) that analyzes the distances at which conventional blasting required for trenching within rock substrate for construction and transport helicopters attenuate to 92 dB. Appendix P shows empirical noise data evaluations for trench blasting and heavy transport helicopters and was used to determine the distances for which noise levels remain below 92 dB during construction activities with appropriate mitigation measures applied. Under the worst-case conditions with common and appropriate mitigation measures applied to trench blasting operations, it is expected that blasting noise would attenuate to 92 dB within 200 feet of the source, and to 70 dB within 1,025 feet of the blast source in soft rock. Likewise, large transport helicopters would attenuate to 92 dB within 700 feet. The greater distance for helicopter use is due to the directional aspects of blade slap noise that is directed toward the ground.

Mitigation for helicopter noise includes operational restrictions, such as maintaining a high altitude and flight paths away from noise sensitive areas whenever possible. Analyses for NSOs in this APDBA consider the distances for larger blasts and large helicopters to be more conservative than what the noise report suggests. A disruption threshold distance for blasting greater than 92 dB has been used but with mitigation measures applied to be the same disruption distance expected for smaller blasts (less than 92 dB)—120 yards or 360 feet—more conservative than the noise report describes, and the disturbance threshold distance associated with large blasts to be expected within 0.25 mile of blasting activity (see table 3.3.4-8). It is expected that these distances be considered throughout the entire breeding season (March 1–September 30) because of the sudden onset of noise associated with blasting activities. A disruption threshold distance for large/transport helicopter use has been used with proposed mitigation to be slightly farther than the report suggests, considering disruption distance of 240 yards (720 feet) and a disturbance threshold distance of 0.25 mile (1,320 feet) (see table 3.3.4-8).

Even though FWS (2003b) provided some evidence suggesting that noise that builds gradually, such as a helicopter approaching from a distance, may result in less risk, and even though FWS does not anticipate effects from smaller aircraft use after the critical breeding period, it is anticipated that use of large/transport helicopters may disrupt or disturb NSOs throughout the entire breeding season (March 1 – September 30) and therefore the analysis within this assessment makes the same assumption. In a memorandum provided to Tetra Tech (September 16, 2008), FWS indicated that if noise levels above 92 dB are recorded at 0.25 mile of the blasting activities, that blasting operations should cease until more effective mitigation measures can be employed.

Disruption and Disturbance – Timber Clearing, Pipeline Construction, Existing Road Use

Approximately 7.7 miles of timber clearing and construction would occur within 0.25 mile of 12 NSO activity centers (nine known sites, two best location sites, and one PCGP assumed site. PCGP proposes to clear timber within 0.25 mile of NSO activity centers between October 1 and February 28, outside of the NSO breeding season (March 1 through September 30); therefore, noise, visual disturbance, and in some instances large helicopter use would not be expected to disturb or disrupt NSO breeding activities at these 12 activity centers (see Habitat Removal during Breeding Season, above). However, due to construction constraints and safety of construction crew, PCGP has indicated they would need to construct and install the pipe within 0.25 mile of activity centers during the breeding season. To minimize disturbance, though, PCGP would construct within 0.25 mile of activity centers after the critical breeding season (after July 15).

With the exception of large transport helicopter activities to deliver pipe to inaccessible areas that could occur within 0.25 mile of three NSO activity centers (2317B, PCGP 095.3, and assumed PCGP A-3) and/or potential blasting activities (greater than 2 pounds of explosives) that could occur within 0.25 mile of five additional NSO activity centers (four known sites and one best location sites), acoustic and visual disturbances from the proposed action are not expected to disrupt NSO nesting and rearing activities because they would occur after the critical breeding season (see table 3.3.4-8). Therefore, activities from Pipeline construction during the late breeding period (July 16 through September 30) could disrupt or disturb NSO at 10 NSO activity centers within 0.25 mile of the Pipeline right-of-way, and construction activities off the right-of-way would occur during the entire breeding season and could disturb NSO at two known activity centers (0071 and 4052A) located within 0.25 of Pipeline project components, if NSO are present (see table 3.3.4-9). Table Q-8 in appendix Q provides distances from proposed project activities (timber clearing, construction activities, road use, operations/maintenance) and timing of those actions, including large transport helicopter use and blasting more than 2 pounds of explosives that are expected to occur within 0.25 mile of known, best location, and PCGP assumed NSO sites. Additionally, table Q-8 in appendix Q provides the expected direct effect (disruption, disturbance, no effect) and rationale for each known, best location, and PCGP assumed NSO site based on timing and distance from the Project activities for each proposed activity (based on disturbance distances from table 3.3.4-8).

a/ Summarized from table Q-8 in appendix Q; see appendix Z2 for D/D Impact Categories for each NSO activity center applying guidance provided by FWS (2014c) in the Revised Conservation Framework.
b/ Construction Activities and Road use: both proposed activities occur within 0.25 mile of NSO activity center
c/ Construction Activities Only: includes general construction activities, blasting (> 2 lbs explosives), and/or large transport helicopter use; no proposed road use within 0.25 mile of NSO activity centers
d/ Road use only: includes non-public roads that will be used by for the Pipeline project; no construction activities proposed within 0.25 mile of NSO activity centers.
e/ None: construction and proposed road use > 0.25 mile of NSO activity center
f/ Best location site PCGP 090.2 is also located within 0.25 mile of Pipeline construction but no large transport or mitigated blasting (> 2lbs explosives) would occur; no disturbance or disruption would be expected since construction could occur during the late breeding season.

Informal consultations with FWS (June 5, 2008, meeting; see NSO and MAMU Avoidance Plan, appendix V1) identified disturbance from travel on existing roads to be less of an impact than other actions associated with the proposed Project, especially if farther than 35 yards (105 feet) from an NSO activity center. Based on the Revised Conservation Framework (FWS 2014c) that includes guidance provided by FWS, as well as available scientific literature, use of existing high use roads may be detectable by NSO within 0.25 mile but it is not expected that use of every existing high-use road would disturb nesting NSOs and use of existing high-use roads would not substantially disrupt normal behavior patterns and lead to harassment under the ESA. However, use of existing low-use roads has the potential to disrupt normal behavior patterns during the breeding season (March 1 through September 30) and lead to harassment under the ESA within 35 yards of an activity center. Use of public, high-volume access roads (i.e., State highways and county roads) are not expected to disturb NSO.

For the purposes of this analysis, existing low-use roads include federal roads designated as local/resource and private roads that appear to receive light traffic and periodic maintenance. Existing high-use roads include federal roads that are designated as arterial and collector roads as well as some local/resources roads that are paved or receive regular traffic/maintenance and are the primary access routes within checkerboard (federal/private) ownership. Existing high-use roads also include other private residential roads driveways or other roads that provide access to multiple rural residences. Use of existing low volume access roads would potentially disrupt NSO at two activity centers within 35 yards of the access roads and would potentially disturb NSO at 36 activity centers located within 0.25 mile, including seven activity centers that would experience disturbance from Pipeline construction during the late breeding season, if present.

Expected Disturbance Effects

Impact assessments were prepared following guidance from FWS's Revised Conservation Framework (FWS 2014c) for each NSO activity center analyzed within this APDBA (see appendix Z2) that identify how far a NSO activity center is in relation to proposed construction activities, including large transport helicopter use and blasting (greater than 2 pounds of explosives). The impact assessments in appendix Z2 also identify existing access roads by high or low traffic use within 0.25 mile of known, PCGP assumed, or best location NSO sites, including distance from the access road(s) and expected road improvements within the nest patch or 0.25-mile buffer of the activity site. Each NSO activity center has a series of maps with the analysis that show the NSO home range in relation to the proposed actions and include a 0.25-mile spatial buffer around each activity center (see appendix Z2); maps in appendix V1 identify the seasonal constraints that would be applied to minimize impact to NSO during timber felling and Pipeline construction. Additionally, maps 1 through 39 in appendix Q show the locations of NSO activity centers in relation to different Project components and identify spatial buffers (360 feet, 720 feet, and 0.25-mile buffers) associated with a NSO activity site.

Table 3.3.4-9 summarizes the effects (disruption, disturbance, no effect) to known, best location, or PCGP assumed NSO sites located within 0.25 mile of proposed project activities, including use of access roads within the provincial analysis area affected by the proposed Project based on the timing of activities and distance from proposed activity to NSO activity center (summarized from table Q-8 in appendix Q and described in appendix Z2).

The FWS (2014c) provided a method in the Revised Conservation Framework to categorize direct effects to NSO pairs within a disruption and/or disturbance distance (0.25 mile) of project activities, including use of access roads, into the following Disruption-Disturbance (D/D) Impact Categories: High Impact, Moderate Impact, Low Impact, Low Impact – no mitigation, and No Impact. The assessment considers the timing, types, and location of Project-related activities in relation to NSO activity centers that could result in disturbance or disruption of NSO to assist in determining a D/D Impact Category for each Project activity for each NSO activity center.

Using the Revised Conservation Framework (FWS 2014c) as guidance, PCGP determined the D/D Impact Category for each NSO activity center within 0.25 mile of proposed project activities in appendix Z2, and included a list of factors considered when determining if an activity would be considered a disruption, a disturbance, or have no effect on each NSO activity center. In many instances an NSO activity center could experience disturbance from more than one proposed activity (e.g., construction effects and proposed use of existing access roads; see D/D Impact Categorization in appendix Z2). In May 2018, FWS reviewed the D/D impact categories provided for each NSO activity center and agreed with the categories provided by PCGP. The resulting D/D Impact Category is included for each NSO activity center in table Q-8 in appendix Q, and within appendix Z2.

Table NSO-1 in the introduction to appendix Z2 summarizes the number of NSO activity centers by D/D Impact Category and status of NSO activity center. No NSO activity center was assigned a "High" category because within 0.25 mile of an NSO activity center, PCGP would remove timber outside of the entire breeding period and construct outside the critical breeding period (March 1 to July 15).

Temporary Habitat Loss Due to Disturbance

There is a potential for NSO present within 0.25 mile of Pipeline activities to be disturbed or disrupted from normal activities due to associated noise from Pipeline project activities, which could cause NSO to temporarily avoid or move away from habitat within 0.25 mile of Pipeline project activities (i.e., temporary habitat loss). Approximately 16,051 acres of suitable NRF habitat (high NRF and NRF) within the provincial analysis area occur within 0.25 mile of the proposed action, of which 12,687 acres occur within NSO home ranges analyzed within this APDBA that could result in temporary loss of habitat due to associated noise disturbance from construction and pipelay activities within the NSO breeding season (March 1 through September 30; table 3.3.4-10). Within 0.25 mile of NSO activity centers, timber removal would occur outside of the entire breeding season beginning in October and continuing through February and continue the following year outside of the NSO breeding season, if necessary (see table Q-9 in appendix Q for specific timing within individual owl home ranges), so direct effects to NSO would not occur. Timber removal and construction activities could occur during the entire NSO breeding season when beyond 0.25 mile of NSO activity centers. Activity would not occur simultaneously within the 192.1 miles of the proposed Pipeline project within the range of the NSO, and therefore, any temporary habitat loss would be less than estimated in table 3.3.4-10, and potential effects to NSO utilizing habitat would be short in duration. PCGP would conduct additional "spot-check" surveys within the NSO provincial analysis area one year prior to scheduled timber removal/construction in NRF habitat that is within 0.25 mile of the construction right-of-way to detect, if possible, spotted owls that may have recently established territories in the Pipeline project area and adjust the schedule, if necessary, further minimizing direct effects to NSO during the breeding season.

TABLE 3.3.4-10

Amount (acres) of Nesting, Roosting, and Foraging Habitat (acres) within 0.25 mile of Pipeline Project Activities that Could Directly Impact NSO during the Breeding Season (March 1 through September 30)

Physiographic Province	Miles of Proposed Pipeline	Suitable NRF within 0.25 mile of Proposed Activities a/	Suitable NRF within 0.25 mile of Proposed Activities within NSO Home Ranges a/	Percent of NRF Habitat within NSO Home Ranges
Coast Range	53.0	2,522	1,664	66.0
Klamath Mountains	71.0 (1.8)	7,022 (805)	6,405 (805)	91.2
West Cascades	45.0	5,309	3,977	74.9
East Cascades	23.1	1,199	641	53.5
Total	**192.1 (1.8)**	**16,051 (805)**	**12,687 (805)**	**79.0**

a/ Suitable NRF Habitat includes both high NRF and NRF habitat within 0.25 mile of proposed habitat removal. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., "post-fire NRF").

Helicopter Rotor Wash

Strong winds can adversely affect NSOs (FWS 1990) by directly removing habitat from windthrow that could fragment forests and increase edge effects (risk of predation, microclimatological changes). Wind can also cause direct mortality by blowing chicks out of nests (FWS 1992b). Helicopter drive rotors produce high velocity vortices (winds) that extend from the center of the helicopter outward in all directions. Vertical downwash of air (rotor wash) close enough to the ground produces surface winds that dissipate as they move away from the helicopter (sidewash). Induced winds caused by helicopter rotor wash may exceed hurricane force velocities and would be expected to adversely affect nesting NSOs in the area. Induced rotor downwash and surface sidewash are functions of helicopter size, rotor surface area, helicopter weight, flight speed and height above ground (Teske et al. 1997; Gordon et al. 2005), effects to nesting birds can be minimized or avoided by routing helicopter flight paths and staging locations far enough away from nests so that locally induced winds would not adversely affect nests or nestlings.

Maximum induced surface velocities produced by downwash and sidewash from various helicopters were measured in the field to determine the decay function of rotor-produced vortices near ground level (Teske et al. 1997). Field studies included measurements on three helicopter models that might be utilized during construction of the Pipeline: 1) the twin-rotor CH-47 (civilian variant is the Boeing HH-47 Chinook) with rotor diameter 59.1 feet, 2) the single rotor CH-54 with a rotor diameter of 72 feet (civilian variant is the Sikorsky S-64 Skycrane), and 3) the twin-rotor CH-46 (civilian variant Boeing Vertol 107) with rotor diameter of 49.9 feet (Teske et al. 1997). Using parameters derived from the field trials, estimates of maximum induced surface velocities were made for each of the three helicopter models at varying heights above ground while flying at different ground speeds. In general, maximum induced surface velocities increase with rotor diameters, decrease with distance above ground, and decrease with faster ground speeds.

Results of modeling maximum induced surface velocities (model described in Teske et al. 1997) produced by a Chinook helicopter are shown in figure 3.3-4-2 for drop heights (heights above ground level at which the helicopter would discharge a payload of foam, water, or retardant during wild fire control) ranging from 10 to 320 feet while flying at ground speeds ranging from 5 to 25 miles per hour (mph). Included in figure 3.3.4-2 are four wind speed categories on the Beaufort Scale (NOAA 2015) which was developed to describe damage associated with wind forces ranging from calm to hurricane forces. On the Beaufort Scale, induced surface winds of 9 to 11 mph produced by rotor wash would be equivalent to a "gentle breeze" during which leaves and small twigs would be constantly moving and light flags would be extended. Wind velocities of 19 to 24 mph are classified as a "fresh breeze" (small trees in leaf would sway). Winds 39 to 46 mph are "gale" force strength—difficult to walk against, while twigs and small branches would be blown off trees—and winds greater than 74 mph are classified as a "hurricane."

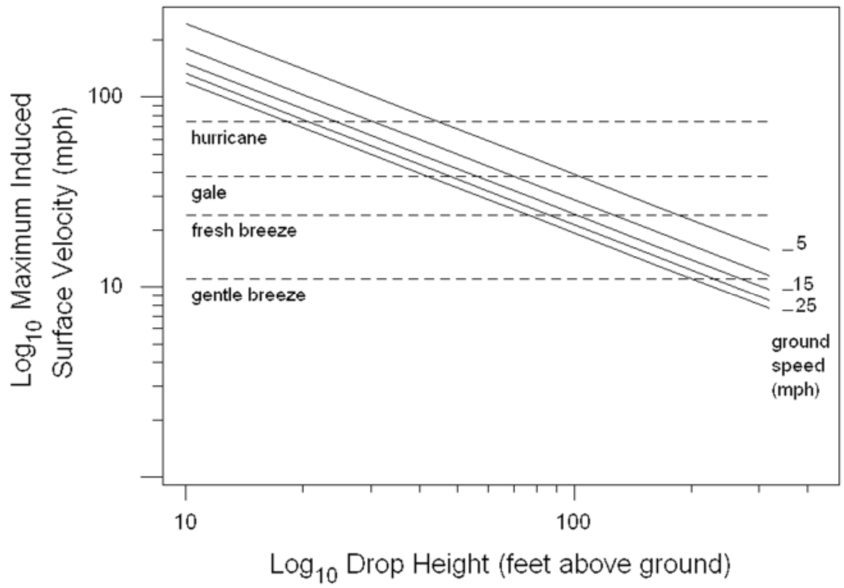

Figure 3.3.4-2 Modeled Maximum Surface Velocities Induced by Chinook C-47 Helicopters while Flying at Ground Speeds From 5 to 25 mph at Heights from 10 to 320 feet Above Ground. (Modeled from data in Teske et al. 1997)

Figure 3.3.4-2 shows the heights above ground that Chinook helicopters would produce maximum induced surface winds with velocities equivalent to a "fresh breeze" while traveling at ground speeds of 5, 10, 15, 20 or 25 mph. For example, if traveling at a ground speed of 5 mph, the Chinook would have to be approximately 185 feet above ground to produce a maximum induced surface velocity of 24 mph, equivalent to a "fresh breeze." If traveling at ground speed of 25 mph, the Chinook could be 75 feet above ground and still induce a maximum surface velocity of 24 mph.

In the project area, wind speeds reported by the Western Regional Climate Center (2015) at the North Bend airport averaged 10.2 mph in June, 11.2 mph in July and 9.9 mph in August, the three months with highest average wind velocities during the period from 1996 to 2006. During the same period, winds in Roseburg averaged 5.0 mph in June, 5.2 mph in July, and 4.4 mph in August. These data indicate that winds as strong as a fresh breeze (19 to 24 mph) would be expected along the Oregon Coast and most likely inland during the period when NSOs are nesting. It is assumed that induced winds the strength of a fresh breeze would not adversely affect young or nests. Incoming or outgoing Chinook helicopters flying at 5 mph while 185 feet above a tree with a nest would most likely produce winds with velocities less than a fresh breeze at the tree top because there would be no resistance by the ground to induce maximum sidewash vortices.

Similar results were produced by the Boeing Vertol 107 (see figure 3.3.4-3) even though it is smaller than the Chinook (rotor diameter 49.9 feet compared to 59.1 feet). The Vertol 107, flying at a ground speed of 5 mph, would have to be approximately 200 feet above ground to produce a maximum induced surface velocity of 24 mph, equivalent to a fresh breeze. If traveling at a ground speed of 25 mph, the Vertol 107 could be 82 feet above ground and still induce a maximum surface velocity of 24 mph. Overall, the Vertol 107 produces slightly greater maximum induced surface velocities than the Chinook CH-47 even though its maximum equipment weight is less than the Chinook.

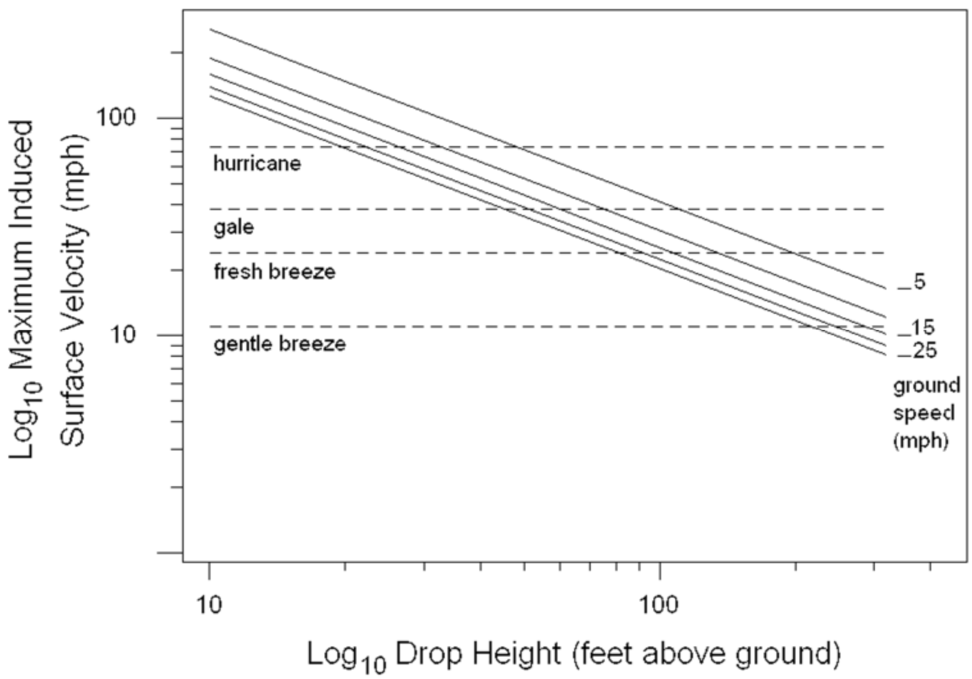

Figure 3.3.4-3 Modeled Maximum Surface Velocities Induced by Boeing Vertol 107 Helicopters while Flying at Ground Speeds From 5 to 25 mph at Heights From 10 to 320 feet Above Ground (Modeled from data in Teske et al. 1997)

The single rotor S-64 Skycrane has the largest rotor diameter (72 feet diameter) of the three models. As modeled in figure 3.3.4-4, the Skycrane would produce greater maximum induced surface velocities while flying at the same ground speeds and same drop heights as the other two helicopter models.

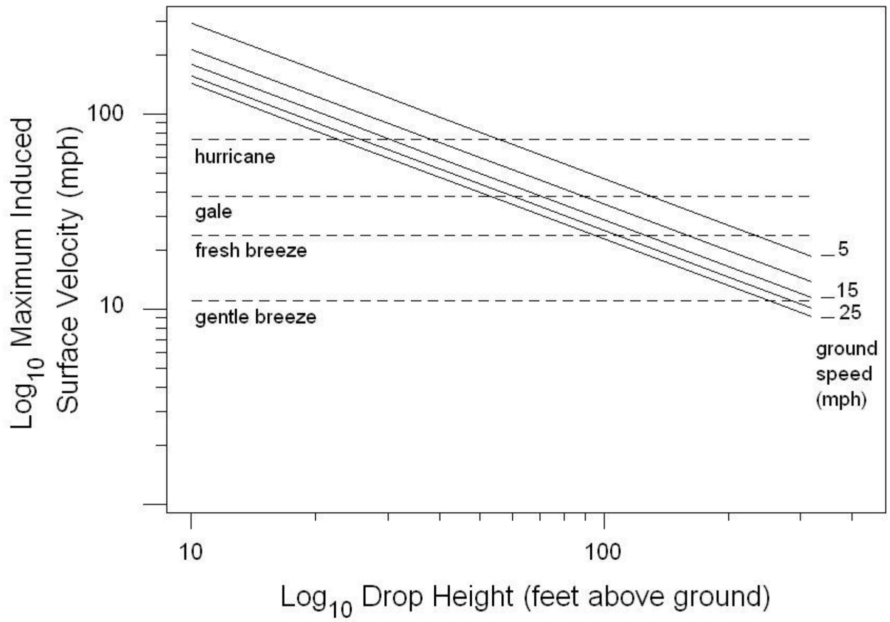

Figure 3.3.4-4 Modeled Maximum Surface Velocities Induced by Skycrane S-64 Helicopters while Flying at Ground Speeds From 5 to 25 mph at Heights From 10 to 320 feet Above Ground. (Modeled from data in Teske et al. 1997)

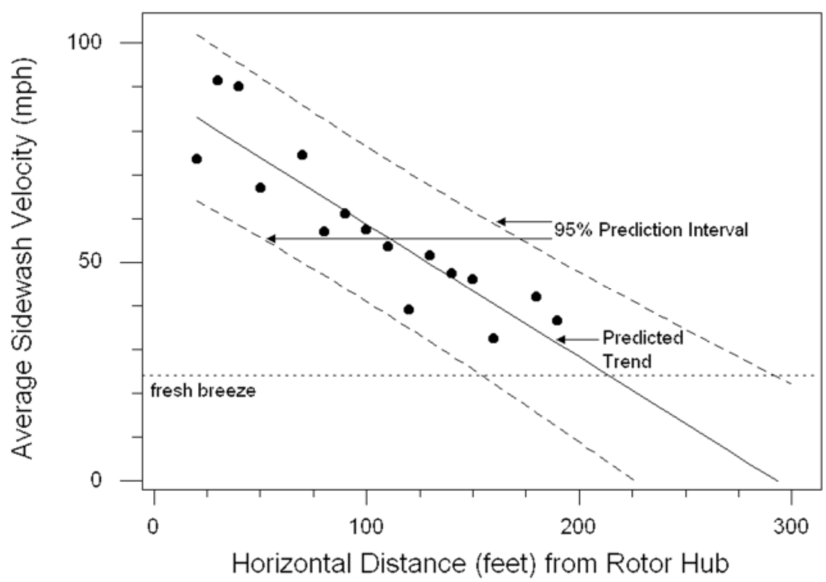
Flying at a ground speed of 5 mph, the Skycrane would have to be approximately 233 feet above ground to produce a maximum induced surface velocity of 24 mph, equivalent to a fresh breeze. The Chinook and Vertol 107 helicopters would induce similar maximum surface velocities flying at heights of 185 feet and 200 feet above ground, respectively. If traveling at ground speed of 25 mph, the Skycrane could be 95 feet above ground to induce a maximum surface velocity of 24 mph.

Actual downwash and sidewash vortices produced by Chinook CH-47 and Skycrane (CH-54) helicopters were measured during field tests (Leese and Knight 1974) while aircraft were hovering at 40–50 feet and 80–90 feet agl while under maximum loads of 36,000 pounds (CH-47) and 45,000 to 47,000 pounds (CH-54). The Vertol 107 (CH-46) was not included in the field tests.

With a 47,000-pound load, the single rotor CH-54 hovering at 40 feet agl produced a maximum sidewash velocity of 87 mph 50 feet away from the rotor hub. At 80 feet agl, the maximum sidewash was 74 mph, also measured at 50 feet from the hub though the gross weight was 45,000 pounds during that particular trial. Both maximum sidewash measurements were at heights of 0.3 feet above ground (Leese and Knight 1974). Under the specified load conditions, the CH-54 produced a sidewash of 11 mph 170 feet away from the rotor hub while hovering at 40 feet agl and a sidewash of 9 mph 150 feet away from the hub while hovering at 80 feet agl. Maximum sidewash velocities of 74–87 mph that were associated with the CH-54 helicopter while it was hovering, are within the range of hurricane force winds on the Beaufort Scale while winds of 9–11 mph produced by rotor sidewash would be described as a "gentle breeze." Sidewash velocities between 9 and 11 mph at distances 150 to 170 feet away from a CH-54 helicopter (Skycrane) would not create a risk of young NSOs being blown out of nests.

Downwash and sidewash velocities measured for the CH-47 helicopter (Chinook) were greater than 100 mph up to 70 feet horizontally from the rotor hub when it was hovering at 90 feet agl with maximum load of 36,000 pounds (Leese and Knight 1974). The twin rotor CH-47 produced sidewash velocities as high as 56 mph 190 feet away from the rotor hub when it was hovering 90 feet agl. The Beaufort Scale classifies winds between 55 and 63 mph as a "storm", with trees uprooted and structural damage likely. The strength of winds produced by the CH-47 is likely due to the interaction of descending air produced by the two rotors (Fabey 2008); sidewash winds are generally strongest at 120 and 240 degrees (4 o'clock and 8 o'clock, respectively) relative to the helicopter's heading (data in Leese and Knight 1974).

Sidewash wind velocities produced by the CH-47 at various distances away from the rotor hub (Leese and Knight 1974) were used to predict the distance at which the helicopter would be far enough away from adversely affecting NSO nests and young. The prediction is based on the sidewash wind velocities produced by the CH-47 averaged for wind measurements made 0.3 feet above ground at angles of 120 and 240 degrees while the helicopter was hovering 90 feet agl under a load of 36,000 pounds. The prediction is shown below in figure 3.3.4-5 in which a sidewash velocity of 0 mph would occur 293 feet away from the rotor hub. Due to the observed variation in sidewash winds at different distances away from the rotor hub (solid circles in figure 3.3.4-5), the upper 95 percent prediction interval on that predictive estimate of 0 mph at 293 feet from the hub would be 23.8 mph. A wind velocity of 23.8 mph is classified as a fresh breeze on the Beaufort Scale. One would be 95 percent certain that a stronger wind would not occur which could potentially adversely affect nesting NSOs.



Source: Leese and Knight 1974

Figure 3.3.4-5 Average Sidewash Wind Velocities Produced by the CH-47 at Varying Horizontal Distances from the Rotor Hub While Hovering 90 feet agl Under a Load of 36,000 pounds. The Observed Averages (solid circles) were used to Predict Sidewash Winds at Distances Out to 300 feet.

These estimates clearly suggest that greater distances would be required to avoid adverse effects to NSOs if Chinook helicopters, rather than Skycranes, are employed for heavy lifting along remote sections of the Pipeline construction right-of-way. Based on the similarities of maximum induced surface velocities between Chinook and Vertol 107 helicopters, sidewash velocities induced while hovering are likely to be similar as well. However, if known NSO activity centers can be avoided by at least 200 feet above tree tops by heavy-lifting helicopters in transit and avoided horizontally by at least 300 feet while helicopters hover above staging sites, no adverse effects to the species would be expected due to rotor downwash and induced sidewash.

Three activity centers occur within 0.25 mile of proposed helicopter use (known 2317B, best location site PCGP 095.3, and assumed PCGP A-3), of which two sites (2317B and PCGP 095.3) could have helicopter activity within their nest patch (see table Q-8 in appendix Q, and individual NSO impact assessments, appendix Z2). Helicopter use for timber extraction within 0.25 mile of an NSO activity center would occur outside of the entire breeding season (between October 1 and February 28); no adverse effects from rotor wash of large helicopters are expected during timber extraction. Helicopter activity could occur within two nest patches (2317B and PCGP 095.3) and adverse effects could occur from rotor wash of large helicopters during pipe delivery for construction of the proposed action if the activities occur within 200 feet above nest trees and horizontally within 300 feet of nest trees; however, the activity centerscenter analyzed for both NSO sites are located further than 300 feet, but the nest site is unknown for PCGP 095.3 (best location site). Helicopter use would only occur after the critical breeding season (after July 15), minimizing risk to NSO.

Burning and Smoke

Effects on NSOs from smoke, whether by prescribed burning as a habitat enhancement procedure or by burning slash have not been studied. However, FWS et al. (2007) have declared (see Table 15 in, FWS et al. 2007) that "smoke can cause [spotted owl] adults to move off nest sites, therefore leaving eggs or young exposed to predation or resulting in lost feedings reducing the young's fitness."

According to BLM and Forest Service (2008, page 34), NSOs "are potentially affected by fire control activities and drifting smoke during burning. The threshold distance for disturbance from smoke is 0.25 mile for spotted owls," which would be subject to smoke-related disturbance during the critical breeding period (March 1 to July 15). PCGP would not conduct slash burning during the critical breeding season within 0.25 mile of an occupied NSO activity center. No direct effect to NSOs due to slash burning is expected.

Maintenance and Operations

No activities associated with general maintenance and operations of the proposed action are expected to affect NSO sites. Vegetation maintenance activities within the operational right-of-way would occur only between August 1 and April 15 of any year (see appendix C). To further reduce impacts to nesting NSOs, PCGP would conduct vegetation maintenance activities within the operational right-of-way after the entire breeding season within known, best location, and PCGP assumed nest patches and after the critical breeding season within 0.25 mile of NSO activity centers. Routine clearing of vegetation within the 30-foot operational right-of-way would not occur more frequently than every 3 years. A 10-foot corridor centered over the pipeline may be maintained annually in an herbaceous state to facilitate periodic corrosion and leak surveys. PCGP would also require pilots conducting annual aerial inspection (small plane/helicopter) of the pipeline to adhere to the spatial restrictions recommended in the vicinity of known, best location, or PCGP assumed sites (no overflight within 1,300 feet of ground level during the critical breeding season [March 1 through July 15]); therefore, no effects from aerial pipeline inspection would be expected.

Indirect Effects

Habitat loss and modification, whether to nesting, roosting or foraging habitats, due to forest clear-cutting has been the primary factor causing declines of the NSO (FWS 1992b). Habitat losses and habitat fragmentation have indirect impacts that can affect survival and reproduction of NSOs. Short-term impact is expected with UCSAs and is likely to last from the initiation of use until 1 to 5 years afterward. Long-term impact to NSOs and NSO habitat is expected to last at least 5 years or more.

Other indirect effects to NSOs that are often related to habitat loss or modification are increased predation, increased competition, and effects to prey utilized by NSOs. Other indirect effects to NSOs also include increased edge and decreased interior forest habitats, as well as reduction of those habitats that are capable of achieving higher quality habitat status but for the Project's impacts within LSR, Riparian Reserves, or within NSO home ranges. In addition, secondary effects (Comer 1982) due to an increased human population base are expected as a consequence of the action (i.e., the need for ancillary goods, services, recreational opportunities resulting from the Project). Potential indirect or secondary effects by the proposed Pipeline project include increased recreation demand (including off-road vehicle use), increased habitat conversion, and habitat degradation by human intrusion and encroachment (Comer 1982).

To determine potential indirect effects to known, best location, and PCGP-assumed owl home ranges within the provincial analysis area, 14 NSO groups (note that WC-L and EC-M are in the same group) were created that included all known, best location, and PCGP assumed owls whose home ranges overlapped. Table 3.3.4-11 summarizes the number of owls by status (known, best location, and PCGP assumed) and physiographic province that occur within each owl group. The number of owls included in each group varied from one to 45 NSO activity centers (see table Q-7 in appendix Q for specific information on each NSO site included in each owl group). Owl groups have been used to identify the area of habitat being affected within and outside of NSO home ranges in the project area.

Analysis of indirect effects to NSO habitat by Pipeline construction and operation within the physiographic analysis area followed guidance provided by FWS included in the Revised Conservation Framework developed for the Project (see *Revised Conservation Framework for the Northern Spotted owl and Marbled Murrelet: Jordan Cove Energy and Pacific Connector Gas Pipeline Project*, FWS 2014c).

Habitat Removal and Modification

The decline of NSOs has been linked to the removal and degradation of available suitable NRF habitat. Appropriate vegetation and structural components are necessary to maintain suitable habitat, and the removal of these components can potentially have adverse effects on NSO populations. These effects could include displacement from traditional nesting areas, increased concentration of NSOs into smaller, fragmented areas of suitable habitat, and diminished reproductive success (FWS 2011c).

In the provincial analysis area, NSO habitat needs and home ranges vary based on physiographic provinces and forest type. In the Coast Range Physiographic Province (MP 0.00 to MP 51.74), the home range is assumed to be circular with a radius of 1.5 miles. Within the Klamath Mountains Physiographic Province (MP 51.74 to MP 122.67), the home range radius is 1.3 miles, and in the West Cascades (MP 122.67 to MP 167.76) and East Cascade Physiographic Provinces (MP 167.76 to MP 190.64) the home range radius is 1.2 miles (FWS 1992d). Although differences exist in natural stand characteristics that influence provincial home range size, habitat loss and forest fragmentation caused by timber harvest effectively reduce habitat quality in the home range. A reduction in the amount of suitable habitat reduces NSO abundance and nesting success (Bart and Forsman 1992; Bart 1995), and recent studies have indicated that NSOs' home ranges are substantially larger in more heavily fragmented stands (Courtney et al. 2004).

a/ Summarized from table Q-7 in appendix Q.
b/ Owl status: known (provided by BLM Districts, Forest Service, or FWS within the project area), PCGP assumed (area identifed by PCGP that may provide habitat for NSO activity center), best location (no nest located during PCGP survey efforts but survey results determined best potential site for nest).

Effects to Habitat. The Pipeline would affect NSOs over the long-term by habitat removal and modifications. Table 3.3.4-12 summarizes effects to NSO habitat from construction and operation (30-foot maintenance corridor) of the proposed Pipeline by physiographic province, land owner, and Project component (see table Q-9 in appendix Q for detailed information on habitat impact including amount removed/modified from CHUs, LSRs, and interior forest, by landowner within and outside of NSO groups). Habitat cleared outside of the 30-foot-wide operational right-of-way would be revegetated after construction where possible, although non-federal and Matrix or Harvest-land based lands may be harvested before they reach dispersal or NRF characteristics and thus would provide minimal benefit to NSO.

In total, construction of the Pipeline would remove approximately 517 acres of suitable NRF habitat (high NRF and NRF which include 26 acres of "post-fire NRF" removed) (see table 3.3.4-

12; table Q-9 in appendix Q), of which approximately 134 acres (includes 7 acres of "post-fire NRF") would be within the 30-foot operational easement and maintained free of forested vegetation for the life of the Pipeline (table 3.3.4-12; table Q-9 in appendix Q). A maximum of approximately 383 acres of suitable NRF habitat cleared outside the 30-foot operational right-of-way (including 19 acres of "post-fire NRF") would be revegetated, at least on federal land, and considered capable of becoming NRF habitat in approximately 80 years, although some of it may become functional foraging or roosting habitat prior to 80 years. However, replanted or naturally seeded trees may be harvested from non-federal lands or federal lands slated for timber harvest (i.e., Matrix or Harvest-based lands) before becoming NRF habitat. Removal of 517 acres of NRF habitat across the four physiographic provinces crossed represents approximately 0.5 percent of the 101,810 acres of suitable NRF/high NRF habitat in the provincial analysis area (see table 3.3.4-4, above) or less than 0.01 percent of the 5,091,800 acres available within Oregon (Davis et al 2016). Additionally, 214 acres of suitable NRF habitat (including 37 acres of "post-fire NRF") have been identified for use by the proposed project as UCSAs, which would not have vegetation removed but may be used to store forest slash, stumps, and dead and downed log materials between existing trees during construction and before they are scattered across the right-of-way after construction during restoration (see table 3.3.4-12; table Q-9 in appendix Q). Use of the UCSAs would be a short-term modification of suitable NRF habitat, and habitat function should be maintained following construction.

Discussion at the Task Force–ESA Consultation Subgroup meeting on April 2, 2008, indicated that NSO dispersal habitat could be considered adequate, or sufficient to support dispersing NSO, if at least 50 percent of the analysis area (in the Project's case, the defined provincial analysis area) consisted of dispersal habitat. Table 3.3.4-4 shows the amount of dispersal habitat available (High NRF, NRF, and Dispersal Only habitat) and its percentage for each physiographic province, and overall, within the defined provincial analysis area. Approximately 1,158 acres of dispersal habitat (high NRF, NRF, and dispersal only habitat) would be removed by the Proposed Action, which represents approximately 0.7 percent of all total available dispersal habitat (168,443 acres) within the provincial analysis area (see high NRF, NRF, and dispersal only habitat in table 3.3.4-4). After construction of the Pipeline project, approximately 167,285 acres (52.0 percent) of dispersal habitat would be available within the provinicial analysis area and would continue to provide sufficient habitat to support NSO dispersal.

Two physiographic provinces currently provide more than 50 percent available dispersal habitat – Klamath Mountains (56.8 percent) and West Cascades (65.3 percent). Removal of 515.95 acres of dispersal habitat from the Klamath Mountains Physiographic Province and 287.09 acres of dispersal habitat from the West Cascades Physiographic Province would still provide more than 50 percent dispersal habitat for both physiographic provinces within the defined provincial analysis area (approximately 72,604 acres or 56 percent in the Klamath Mountains Physiographic Province and 49,889 acres or 65 percent available in the West Cascades Physiographic Province). Removal of dispersal habitat in two physiographic provinces currently with less than 50 percent available dispersal habitat – Coast Range (37.5 percent) and East Cascades (44.0 percent) – would further reduce the amount of dispersal habitat available within those provinces: approximately 34,363 acres (37.2 percent) of dispersal habitat would remain in the Coast Range province after removal of 231.42 acres, and approximately 10,394 acres (43.5 percent) of dispersal habitat would remain in the East Cascades province after removal of 123.13 acres. Removal of dispersal habitat would not be in one locale, but would be removed along 192.1 miles of proposed Pipeline in the range of the NSO. After the Pipeline project is completed, neither the temporary 95-foot-wide construction right-of-way and associated temporary extra work areas or the permanent 30-foot-wide operational right-of-way would impede the movement of juveniles and adults.

Construction and permanent effects to habitat that is not currently NRF habitat, but is capable of becoming suitable NRF habitat (capable habitat) are also included in table 3.3.4-12. Approximately 919 acres of NSO capable habitat would be removed by construction of the proposed Project, of which 216 acres would remain in a permanent herbaceous/shrub state within the 30-foot operational right-of-way for the life of the Pipeline. Approximately 632 acres of capable habitat removed on private lands is not expected to mature to provide suitable NRF or high NRF habitat for NSO based on review of research on timber harvest practices in Oregon (Zhou et al. 2005; Rasmussen et al. 2012). These studies noted that forest harvest practices on non-federal lands typically occur between 45 and 65 years of age.

The majority of NRF habitat (high NRF and NRF) removed by the Pipeline project (approximately 386 acres) occurs within known, best location, or PCGP assumed home ranges of NSOs within the analysis area (see NSO Groups in table 3.3.4-11) and could affect NSO over the long term; this is approximately 75 percent of all suitable NRF habitat removed or modified by the proposed Project (517 acres total) within the range of the NSO. Table Q-10 in appendix Q provides a summary of suitable, dispersal, and capable habitat affected by the proposed Project within NSO groups by nest patch, core area, and home range. Suitable but unoccupied habitat removed outside of known, best location, or PCGP assumed home ranges may reduce the physical, geographical, and/or demographic connectivity between habitat and population reserves.

Davis et al. (2011) observed increased extinction rates of spotted owls in response to decreased amounts of old forest within the core area and higher colonization rates when old-forest habitat was less fragmented in the Southern Cascades Study Area, which is situated within the project area on federal lands (see Population Status section, above). The proposed action would affect NSO high NRF and NRF habitat within approximately 40 core areas (30 known sites, seven best location sites, and three PCGP assumed sites, see talleys in table 3.3.4-14) mostly within the Klamath Mountains Physiographic Province (21 core areas affected, see table 3.3.4-13), potentially increasing habitat abandonment and/or barred owl competition and encroachment (see Davis et al. 2011). Table Q-7 in appendix Q identifies the location and distance of each spotted owl site center from construction of the Pipeline, as well as identifies the current condition of each spotted owl nest site and the amount of habitat removed from the nest patch, core area, and home range for each NSO activity center, where applicable. It would be expected that spotted owl sites with less habitat available within their core area (i.e., Habitat Condition 2 or 4 in table Q-7 in appendix Q) would be affected more by habitat removal within their core area including: three PCGP assumed sites, four best location sites, and 13 known spotted owl sites (table 3.3.4-14).

a/ General Location identifies areas within Northern Spotted Owl Groups (areas within NSO home ranges; see table Q-10 in appendix Q) and areas outside of NSO groups (outside of NSO home ranges).
b/ High NRF (FWS 2014c: forested habitat that is characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species.
c/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., “post-fire NRF”).
d/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.
e/ Capable Habitat (FWS 2014c): habitat that is forested or could become forested (i.e., recently harvested timberlands) that do not provide dispersal or NRF characteristics.
f/ Noncapable Habitat: not forested and not capable of becoming forested.
g/ Project components considered in calculation of habitat “Removed”: construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), pipe storage yards, rock source/disposal sites, and hydrostatic test locations.
h UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.
i/ 30-foot Maintenance Corridor would be kept in a shrub/sapling state for the life of the project; all other habitat outside of the 30-foot maintenance corridor would be revegetated, except for those habitats on non-federal or matrix lands where there is less certainty that replanting would occur or be maintained on the landscape.

Note: More detailed information on BLM Districts and National Forests impacted, as well as critical habitat, NWFP late successional reserves, is located in table Q-9 in appendix Q.

a/ Nest patch: includes an area that is 300 meters (984 feet) from the site center (70 acres occur within a nest patch).
Core area: generally 502 acres occur within a core area.
Home range: generally 4,525 acres, 3,398 acres, and 2,895 acres occur within the Oregon Coast Range, Klamath Mountains, and Cascades NSO home ranges, respectively.

b/ High NRF (FWS 2014c): forested habitat that is characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species.

c/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., "post-fire NRF").

d/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.

e/ Capable Habitat (FWS 2014c): habitat that is forested or could become forested (i.e., recently harvested timberlands) that do not provide dispersal or NRF characteristics.

f/ Noncapable Habitat: not forested and not capable of becoming forested.

g/ Project components considered in calculation of habitat "Removed": construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), pipe storage yards, rock source/disposal, and hydrostatic test locations.

h/ UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.

i/ 30-foot Maintenance Corridor would be kept in a shrub/sapling state for the life of the project; all other habitat outside of the 30-foot maintenance corridor would be revegetated, except for those habitats on non-federal or matrix lands where there is less certainty that replanting would occur or be maintained on the landscape.

NOTE: Summarized from table Q-10 in appendix Q.

a/ For detailed NRF/High NRF habitat available for each NSO and its habitat type (nest patch, core area, home range), refer to "pre-action" suitable habitat acres in table Q-7 in appendix Q.

b/ FWS et al. (2008) consider core areas with 50 percent or greater suitable NRF habitat and home ranges with at least 40 percent suitable NRF habitat to be necessary to maintain NSO life history function. Habitat condition for each NSO affected is summarized from table Q-7 in appendix Q.

c/ Owl Status: 1) Known sites represent NSO activity sites provided by BLM and Forest Service biologists within the provincial analysis area; 2) Best Location sites represent pairs or resident singles documented by PCGP during surveys in 2007 and 2008 with no nest site/activity center located, and; 3) PCGP assumed sites respresents an area identifed by PCGP that may provide habitat for NSO pair.

Habitat Impact Categorization. PCGP used the Revised Conservation Framework (FWS 2014c) to guide categorizing effects to NSO habitat within home ranges into Habitat Impact Categories (Severe, High, Moderate, and Low categories), considering the amount and type of NSO Habitat removed, as well as where the NSO habitat is affected within an NSO home range, core area, and/or nest patch (see NSO habitat impact categorization for each NSO home range in appendix Z2). No NSO home range was provided a "Severe Impact" category because PCGP would not remove a known nest site or activity center or cause a NSO home range to become nonfunctional (loss of the territory).

The Habitat Impact Category assigned to each NSO home range (appendix Z2, table Q-7 in appendix Q) was then applied to acres of NSO habitat affected by the Pipeline project (summarized in table 3.3.4-12 from table Q-9 in appendix Q). Where home ranges overlapped, the higher impact category was considered. NSO habitat affected outside of NSO home ranges or within NSO home ranges that were provided a "No Impact Category" in appendix Z2 are considered areas of "Low Impact". Table NSO-3 in the introduction to appendix Z2 provides a summary of NSO habitat affected by Habitat Impact Category within and outside of interior forest.

<u>Known, Best Location, or PCGP Assumed Owl Sites</u>

There are 105 known, best location, or PCGP assumed owl home ranges that overlap the proposed Project. Of these, 8 NSO home ranges would not have habitat removed or modified because they are only intersected by existing roads to be used to access the right-of-way or are within 100 meters (328 feet) of habitat removal. The effects of habitat changes to the other 97 known, best location, or PCGP assumed NSO activity centers within the provincial analysis area as a result of the proposed action were evaluated at three scales: the nest patch, the core area, and the home range. The pre-action and post-action habitat conditions are provided in table Q-7 in appendix Q for each NSO home range; the amount of NSO habitat is specific to each habitat type in its entirety; acres provided for the home range include acres that also occur within the core area and nest patch, and acres included in the core area also include acres within the nest patch. Also, the amount of suitable NRF habitat removed within each owl habitat type does not consider overlap with neighboring owl sites.

Table 3.3.4-14 summarizes the number of NSO activity centers and acres of NSO habitat by physiographic province that would have NSO habitat removed from their nest patch, core area, and/or home range (summarized from table Q-7 in appendix Q). NSOs that are below the FWS recommended suitable habitat thresholds or are near those thresholds, either in the core area or home range, and would have suitable habitat removed could be impacted more by the Project than those above the recommended FWS suitable habitat thresholds (greater than 50 percent and/or greater than 40 percent available high NRF/NRF in their core area or home range, respectively). Table 3.3.4-14 tabulates the number of NSO home ranges/core areas below threshold, by physiographic province, that would have habitat removed and identifies the habitat use area (nest patch, core area, home range) for each owl group affected. Generally, removal of habitat from home ranges already below threshold represents less than 0.2 percent of available suitable habitat within the owls' home range (see table Q-7 in appendix Q). Since removal of habitat represents such a small percentage of available suitable NRF habitat (high NRF and NRF) within the core area and/or home range, removal of habitat within owl site core areas and home ranges should not adversely impact those NSO pairs or resident singles. However, habitat removed in closer proximity to the nest site or nest patch may have a greater impact to the NSO pair or resident single.

NSOs with suitable habitat availability within their core area and/or home range below the FWS recommended threshold of suitable habitat (less than 40 percent suitable habitat in home range/less than 50 percent suitable habitat in core area) could be considered adversely affected, especially if habitat is removed during the breeding season within 0.25 mile of an activity center. Habitat would be removed from 97 home ranges (including 40 core areas) within the four physiographic provinces crossed, of which 58 home NSO activity centers are below the recommended habitat thresholds in the core area and/or home range (table 3.3.4-3). Habitat removal within 0.25 mile of 13 NSO activity centers (9 known, 3 best location, and one PCGP assumed), of which nine are below recommended NRF threshold (core area and/or home range), would occur outside of the entire breeding period (between October 1 and February 28); disturbance associated with timber removal should not adversely affect spotted owls. If survey efforts prior to construction identify additional NSO reproductive activity within 0.25 mile, habitat removal would occur outside of the breeding season within 0.25 mile of those sites.

Eight nest patches would be crossed by the proposed action; suitable NRF habitat (high NRF, NRF, post-fire NRF (4008B)) would be removed from seven nest patches, of which five NSO home ranges have suitable habitat below the recommended NRF threshold in the core area and/or home range (see table 3.3.4-15). Timber would be removed outside the entire breeding season (after September 30 but before March 1) within each nest patch and 0.25 mile of that activity center; therefore, no direct impact to those NSOs is expected. Removal of habitat from the nest patches, however, could have an indirect, negative impact on those NSOs, especially in the four sites below recommended FWS NRF threshold for core area and/or home range. Three NSO sites represent pairs documented during 2008 survey efforts (best location sites); however, none of the sites had a nest tree identified. As a result, these nest patches represent a 300-meter radius around the "best location" as determined by the surveyors and local agency biologists based on detection date and time, individual owls (age and sex) present at particular detections, behavior of owls at a particular detection, and occasionally the habitat of a detection location. In discussions with various agency biologists (table S-1 in appendix S), it was thought that these sites were associated with other monitored pairs and that nesting at the "best location" sites was not occurring, but not enough information was available to be sure of this. Therefore, PCGP continues to include these best location NSO pair sites for analyzing worst case scenarios. If additional surveys conducted prior to construction and timber clearing indicate that these are not active, PCGP would revise the schedule accordingly. Table 3.3.4-15 provides details specific for each NSO nest patch crossed by the Pipeline. These details include the length of proposed Pipeline within each nest patch, how much suitable habitat would be removed, and the pre-action NRF habitat status of each NSO home range. Within the "additional description" column, information is provided about the effects to habitat in the nest patch and its location relative to existing disturbance and/or the creation of new edge in the nest patch.

Habitat Fragmentation

In addition to impact by surface disturbances, fragmentation of connected, contiguous habitat would occur. Fragmentation of NSO habitat is considered a cause for poor demographic performance, although the threat posed by fragmentation is still not fully understood (Courtney et al. 2004) and, as described below, NSO fecundity has also been positively correlated with forest edge, which is associated with fragmentation (Franklin et al. 2000; Olson et al. 2004; Hayward et al. 2011). FWS (2004b) indicated that habitat fragmentation was the "aggregate of effects of historical habitat loss, continuing habitat loss due to uncharacteristic wildfire, and continuing timber harvest, albeit at reduced levels," and that habitat fragmentation remained a threat in the northern part of the NSO's range but was reduced in the southern part. Courtney et al. (2004) indicated that typically a larger area is required for NSO home ranges in more fragmented habitats. Based on this assumption, the Provincial Home Range Radii provided in the 2012 Northern Spotted Owl Survey Protocol would be indicative of more fragmented habitats in the northern part of the NSO's range than in the southern portion (1.8-mile radius in the Washington Cascades, 2.2 miles on the Olympic Peninsula, 1.2 miles in the Oregon Cascades, 1.5 miles in the Oregon Coast Ranges, and 1.3 miles in Klamath Province).

TABLE 3.3.4-15

Summary of NSO Nest Patches Crossed by the Proposed Action

MSNO or Site ID	Site Name	Nest Patch Location (MP)	Landowner	Land Allocation	Available High NRF/NRF a/ (acres)	Length Crossed b/ (feet)	High NRF/NRF Affected c/		Pre-Action Habitat Condition d/	Additional Description
							Area (acres)	Percent of Available NRF		
Coast Range Physiographic Province										
2317B	Brewster Valley	35.90-39.41	Coos Bay BLM	LSR	69.63	2,068	4.77	6.9	<40% Home Range, >50% Core	Coos Bay BLM provided a newly documented alternate NSO activity center to PCGP in January 2014; this area had been surveyed in previous years by Coos Bay BLM and PCGP and spotted owl activity was identified in area, but no nest location or pair was documented (see Raymond et al. 2012; SBS 2008a); no detections in 2015 and 2016 (BLM 2017). Project would bisect late successional forest through the nest patch (generally High NRF) and western portion of the core area (generally NRF) of this site. This NSO nest patch is also located within MAMU Stand C3090 (see table 3.3.3-13).
Klamath Mountains Physiographic Province										
PCGP 064.2 (Best Location)	Kent Creek	62.70-65.66	Private	None	6.67	1,011	0	0	<40% Home Range, <50% Core Area	Project located in regenerating forest approximately 220 meters (720 feet) from best location site located within strip of mid-seral forest adjacent to regenerating forest; one road travels through the nest patch; within the home range, the right-of-way would create additional fragmentation and create edge within older regenerating interior forest as well as create new edge in forest already affected by existing edge.
PCGP 090.2 (Best Location)	Bland Mountain	88.86-91.61	Roseburg BLM	Matrix	25.20	2,035	2.66	10.6	<40% Home Range, <50% Core Area	Project located through middle of best location nest patch; best location site identifed adjacent to an existing access road that also bisects the nest patch; consultations within agencies (see table S-1 in appendix S) presume the nest site is not at this best location site; northern portion of the right-of-way traverses through old-growth, including interior forest and bisects the stand.
PCGP 095.3 (Best Location)	Milo South	93.82-97.04	Roseburg BLM	LSR	39.74	1,795	1.44	3.6	<40% Home Range, > 50% Core	Project bisects nest patch and traverses through late successional forest within the nest patch, some of which has been burned and left standing from the 2015 Stouts Creek fire; the remainder of project is in early regenerating forest or in recent clearcut affected by the 2015 Stouts Creek Fire.

TABLE 3.3.4-15

Summary of NSO Nest Patches Crossed by the Proposed Action

MSNO or Site ID	**Site Name**	**Nest Patch Location (MP)**	**Landowner**	**Land Allocation**	**Available High NRF/NRF a/ (acres)**	**Length Crossed b/ (feet)**	**High NRF/NRF Affected c/**		**Pre-Action Habitat Condition d/**	**Additional Description**
							Area (acres)	**Percent of Available NRF**		
4008B	Hatchet Creek South	99.23-101.98	Roseburg BLM	LSR CHU KLE1	40.49 (25.73)	432	0.58 (0.58)	1.4	> 40% Home Range, >50% Core Area	Project follows existing road on edge of nest patch (approximately 275 meters or 911 feet from activity center); removes regenerating forest on edge of road. Stouts Creek Fire burned most of this nest patch, core area, and home range; activity center provided by BLM occurs in post-fire NRF (previously NRF, standing dead trees) adjacent to fire-related clearcut.
West Cascades Physiographic Province										
1620 (PCGP 160.7)	Big Elk	160.13-162.77	Rogue River N.F.	LSR CHU KLE4	50.62	1,873	2.14	4.2	>40% Home Range, >50% Core Area	Project occurs approximately 133 meters (437 feet) from Forest-Service provided activity center generally along regenerating strip; one road traverses eastern portion of nest patch; the project would create new edge extending from regenerating strip to access road in old-growth forest.
0994	Cox Creek	161.81-164.49	Rogue River N.F.	LSR CHU KLE4	61.36	1,126	0.43	0.7	>40% Home Range, >50% Core Area	Project located approximately 200 meters (650 feet) from activity center; project traverses through regenerating forest patch adjacent to late successional forest; would bisect regenerating interior forest in the nest patch.
East Cascades Physiographic Province										
0023	Buck Lake	172.35-174.72	Winema N.F.	CHU ECS 1	19.71	129	0.18	0.9	<40% Home Range, <50% Core Area	Project located approximately 285 meters (930 feet) from activity center; project parallels or is adjacent to Clover Creek Road in old-growth forest adjacent to regenerating forest.

a/ Available high NRF and NRF in the nest patch; see table Q-7 in appendix Q.
b/ Length is provided for Pipeline across the nest patch.
c/ Acres of NRF (high NRF and NRF) affected within the nest patch, if NRF affected; see table Q-7 in appendix Q. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., "post-fire NRF").
d/ FWS et al. (2008) considers NSO home ranges and core areas to provide suitable NRF if the available NRF is greater than 50 percent (Core Area) or is greater than 40 percent (Home Range).

Effects of fragmentation on NSO demographic parameters are complex. Fragmentation includes increasing levels of edge between older forests and younger forest types and NSO fecundity has been positively related to forest edge (Franklin et al. 2000, Olson et al. 2004; Hayward et al. 2011). FWS (2011c) has suggested that spotted owls evolved with natural disturbance processes (e.g., fire) that caused mosaics of forest age classes, edges included. While the size of old-growth patches was strongly related to nest site selection by NSO, extent of clearcut forest and indices of forest fragmentation were not (Meyer et al. 1998). Prey abundance and higher nutritional status have been related to forest edges (Franklin et al. 2000; Franklin and Gutiérrez 2002; Hayward et al. 2011), particularly the abundance of woodrats (Ward et al. 1998), and possibly flying squirrels (Rosenberg and Anthony 1992). On one hand, reproductive output was found to be greater at sites with more edge between older forest (mature and old growth) and other adjacent vegetation, while reproductive output declined in areas with greater amounts of interior forest (Franklin et al. 2000). Alternatively, NSO survival increased with more interior forest and increased edge (Franklin et al. 2000). As reviewed by Franklin and Gutiérrez (2002), locations in which NSO have high reproduction and high survivorship (collectively, high fitness) represent a balance between the amounts of interior forest and edges with older forest.

Increased fragmentation can also lead to decreased survivorship of NSOs by facilitating predation by great horned owls, northern goshawks, and other avian predators (Franklin et al. 2000; FWS 2011c). Competition with barred owls may also be facilitated by forest fragmentation, although the levels of competition are not straight forward (Dugger et al. 2011). With increased fragmentation, NSO have been found to expand their home range size (Schilling et al. 2013) which could lead to increased predation (larger areas equating to more time spent away from nests) and possibly increased competition (Dugger et al. 2011).

The provincial analysis area has already been subjected to extensive fragmentation by past land uses including transportation corridors, timber harvest and associated activities (i.e., road construction), and urban development. The Project would cross approximately 192.1 miles of four physiographic provinces (MP 0.00 to MP 190.58), of which 109.5 miles occur within NSO home ranges (table Q9 in appendix Q). Within the four physiographic provinces crossed by the proposed action, the Pipeline would be located within or adjacent to existing utility or road corridors for approximately 77.8 miles (40.5 percent of proposed pipeline miles in the NSO range; see table Q-4 in appendix Q), thus minimizing fragmentation within approximately 78 home ranges and NSO habitat. Table Q-4 in appendix Q identifies the location of NSO home ranges (including nest patches and core areas) in relation to existing rights-of-ways and corridors. However, additional fragmentation would occur within high NRF and NRF habitat, as well as dispersal and capable habitat due to the proposed project. Depending on local conditions, fragmentation may not be an adverse impact to NSO home ranges if prey abundance ultimately increases, but on the other hand, fragmentation could contribute to increased predation of NSO nests which would be detrimental.

Habitat Edge. Other indirect effects from construction of the Pipeline are also expected within habitat adjacent to the construction right-of-way, including within interior forest within NSO high NRF, NRF, dispersal, and capable habitat. The conversion of large tracts of old-growth forest to small, isolated forest patches with large edge areas can create changes in microclimate, vegetation species, and predator-prey dynamics. In general, microclimates along edges differ from those in forest interiors. Two main physical factors affecting and creating an edge microclimate are sun and wind (Forman 1995; Chen et al. 1995; Harper et al. 2005). Compared to the forest interior, areas near edges receive more direct solar radiation during the day, lose more long-wave radiation at night, have lower humidity, and receive less short-wave radiation. Such a change in humidity could affect migration and dispersal of flying insects, including tree parasites such as the Douglas-fir beetle (Chen et al. 1995) and promote expansions of infestations which can affect interior forest stand structure and formations of gaps in formerly closed stands (Furniss 1979). Humidity, coupled with soil moisture and temperature, also affects decomposition of litter and coarse woody debris; rates of litter decomposition were higher near edges with a shallower organic layer (Chen et al. 1995). Decreased humidity may also affect distribution of fungi that are dependent on old-growth forest environments. Since the diets of northern flying squirrels mostly consist of fungi (Verts and Carraway 1998), changes in interior forest microclimates could affect local abundance of prey utilized by NSOs.

Another physical factor affecting edge is edge orientation (Chen et al. 1995). For example, the general orientation of the Pipeline is from northwest to southeast. Therefore, edge effects would be most pronounced on the southwest-facing edges and weakest along the northeast-facing edges (see discussion in Chen et al. 1995).

Harper et al. (2005) reported that the mean distance of edge influence could occur to approximately 328 feet (100 meters) and influence 1) tree mortality, damage, recruitment, growth rate, canopy foliage, understory foliage, and seedling mortality, 2) amounts of canopy trees, canopy cover, snags and logs, understory tree density, herbaceous cover, and shrub cover, and 3) stand composition metrics such as species, exotics, individual species, and species diversity. In other younger coniferous forests or mixed forests with deciduous species, edge effects compared to interior forests have been much less pronounced (Heithecker and Halpern 2007; Harper and MacDonald 2002).

Old-growth and late seral forests are important to NSOs as NRF habitat, but edges associated with those NRF habitats have been shown to increase NSO fitness in terms of fecundity and survivorship (see Franklin et al. 2000, Olson et al. 2004; Hayward et al. 2011). Annual survival of NSO was positively associated both with amounts of interior old-growth forest and with length of edge between those forests and other vegetation types. Conversely, reproduction was negatively associated with interior forest, but positively associated with edge between mature and old-growth conifer forest and other vegetation types (Franklin et al. 2000). Similarly, Olson et al. (2004) found that a mixture of mid- and late succesional with young forest and nonforested habitats appear best for NSO reproduction and survival. Roads create edges that affect interior forest biotic and microclimatological conditions, even narrow forest roads 40 feet wide (Baker and Dillon 2000). Edges created by roads with low levels of traffic disturbance have been shown to have a positive effect on NSO nutrition and fecundity (Hayward et al. 2011), perhaps due to abundance of prey (wood rats) along edges, including those associated with roads. Edges may affect interior old growth forests, but not necessarily adversely affect NSO fitness.

Interior Forest Habitat. Other indirect effects from construction of the Pipeline are also expected within habitat adjacent to the construction right-of-way, including within interior forest that the NSO relies on for nesting habitat. To determine other indirect effects to NSO habitat (high NRF, NRF, dispersal only, capable) from construction of the Pipeline outside of habitat removal within the right-of-way, PCGP assessed effects to NSO habitat within 100 meters (328 feet) of proposed habitat removal, including effects to interior forest. To determine which tracts of forested land (late regenerating, mid-seral, late successional, and old-growth) should be considered interior forest, existing edges, such as wide-surface roads, large rivers, early seral forest, and nonforested habitat were buffered by 100 meters (328 feet), and forested habitat included in the buffered area was identified as forested habitat currently affected by existing edge (FWS 2014c). Smaller roads with existing canopy cover were buffered by 50 feet per direction of FWS (2014c). Forested habitat (late regenerating to old-growth forest) that was not included in buffered "currently affected" area was classified as "interior forest" and incorporated into the interior forest model. This APDBA considers the indirect effects of the newly constructed right-of-way on NSO habitat within 100 meters (328 feet) of habitat removal, including interior forest.

Table 3.3.4-16 identifies the length of proposed Pipeline crossing through NSO habitat within and outside of interior forest habitat, and summarizes the acreage of NSO habitat directly removed and indirectly affected within 100 meters (328 feet) of the Pipeline project (habitat removal) by physiographic province, landowner, and NSO Groups (summarized from table Q-9 in appendix Q).

Approximately 13,294 acres of NSO habitat (1,307 acres of high NRF/NRF habitat, 4,147 acres of dispersal only habitat, and 5,690 acres of capable habitat) occur within 100 meters (328 feet) of habitat removal, of which 4,326 acres (or 32.5 percent of NSO habitat within 100 meters of habitat removal) of interior NSO habitat would be indirectly affected (1,586 acres of high NRF/NRF habitat, 1,388 acres of dispersal only habitat, and 1,352 acres of capable habitat; tabulated in table 3.3.4-16). The majority of NSO habitat indirectly affected occurs within NSO groups crossed by the Pipeline project: 8,393 acres (63.1 percent) of all NSO habitat within 100 meters (328 feet) of habitat removal, which includes 2,996 acres of interior NSO habitat and 5,397 acres of NSO habitat currently affected by existing edge. Table Q-9 in appendix Q identifies the acres of NSO habitat affected within 100 meters (328 feet) from habitat removal by physiographic province and general landowner, including effects within critical habitat and LSR. Effects to NSO habitat adjacent to the construction right-of-way would decrease as the forested area (a maximum of approximately 1,568 acres; see table 3.3.4-12) outside of the 30-foot maintenance corridor is replanted with trees and returned to early regenerating stands; however, this replanting would occur on certain federal lands and non-federal lands on a case-by-case basis and replanted trees may also be harvested from non-federal lands or federal lands slated for timber harvest (i.e., Matrix lands).

Based on analyses summarized in table 3.3.4-16, at least 38.5 miles of interior forest would experience fragmentation as a result of the proposed project, creating at least 77.0 miles (38.5 miles x 2) of additional edge in NSO habitat; this considers interior forest crossed by the proposed project within older regenerating forest to old-growth forest. Additional fragmentation of approximately 23.5 miles within forest currently affected by existing disturbance ("other" forest in table 3.3.4-16) could be affected since approximately 40.5 percent (77.8 miles) of the project within the range of NSO occurs within or is adjacent/parallels existing disturbance (see co-locate table Q-4 in appendix Q; 101.3 miles minus 77.8 miles = 23.5 miles), creating approximately 47.0 miles of additional edge in forest already affected by existing disturbance. In addition to NSO habitat crossed and affected within the NSO range, approximately 52.3 miles of non-capable habitat would be crossed with approximately 1,347 acres removed (see table Q-9 in appendix Q). Figure 3.3.4-6 provides an example of the area considered for acreage of other indirect effects to NSO habitat (100 meters from habitat removal), both within and outside of interior forest as presented in table 3.3.4-16.

a/ Landowner is summarized by Federal (BLM Districts and National Forests) and Non-Federal (Private, State, Corps of Engineers, and Bureau of Indian Affairs Land).
b/ General Location identifies areas within Northern Spotted Owl Groups (areas within NSO home ranges; see table Q-10 in appendix Q) and areas outside of NSO groups (outside of NSO home ranges).
c/ Interior Forest: forested habitat farther than 100 meters (328 feet) from existing disturbance (i.e., wide-surface roads, existing corridors) or adjacent land use/vegetation type (i.e., agriculture, non-forest, early regenerating forest), and/or farther than 50 feet from smaller roads with existing canopy cover (FWS 2014c). Other Forest Type includes forested habitat that is currently affected by existing disturbance or adjacent land use/vegetation types within 100 meters (328 feet) of disturbance
d/ High NRF (FWS 2014c): forested habitat that is characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species.
e/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., "post-fire NRF").
f/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.
g/ Capable Habitat (FWS 2014c): habitat that is forested or could become forested (i.e., recently harvested timberlands) that do not provide dispersal or NRF characteristics.
h/ Total habitat only considers forested NSO habitat within the range of the NSO; non-capable habitat affected in range of NSO is included in table Q-9 in appendix Q.
i/ Project components considered in calculation of habitat "Removed": construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), pipe storage yards, rock source/disposal sites, and hydrostatic test locations.
j/ Other Indirect Effects considers habitat within 100 meters (328 feet) of habitat removal as measured from the edge of habitat removal/edge of right-of-way/TEWA.
k/ Acres identified as UCSAs have been incorporated into the 100-meter other indirect effects. UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.

Summarized from table Q-9 in appendix Q.

Predation

Few empirical studies exist to confirm that habitat fragmentation contributes to increased levels of predation on NSOs (Courtney et al. 2004). Great horned owls are known and potential predators of NSO (Johnson 1992; Gutiérrez et al. 1995), particularly in the context of effects of forest fragmentation on predation response, since great horned owls appear closely associated with forest openings and clearcuts (Johnson 1992; Laidig and Dobkin 1995). However, after a review of available evidence including predation by great horned owls, Courtney et al. (2004, pages 8–30) conclude: "there appears to be no reasonable basis for regarding an effect of fragmentation on predation levels as a primary or significant effect on NSO populations. Absent new information, the indirect effects of fragmentation through predation remains an untested hypothesis." Also, the FWS (2004b) 5-Year Review stated that indirect evidence from demography studies suggests that predation, particularly by great horned owls, is not a major influence on NSO populations as was originally considered in the 1990 ESA listing.

Table 3.3.4-13 and table 3.3.4-14 indicate that 97 home ranges would be affected from habitat removal by the proposed action and may experience additional fragmentation with construction of the Pipeline, including 40 core areas and eight nest patches (see also table Q-7 in appendix Q). It is possible that the 58 NSO sites that are below recommended threshold of available NRF habitat in the core area and/or home range (table 3.3.4-14), and/or would have interior forest habitat removed (86 NSO sites; see table 3.3.4-17) could experience a greater increase of predation, as great horned owls have been identified throughout the provincial analysis area during surveys in 2007, 2008, and 2015. Table 3.3.4-17 summarizes the number of home ranges that would have interior forest habitat (late regenerating forest to old growth) removed (86 home ranges) by the proposed action and could experience additional fragmentation.

Competition

Since the listing of the NSO, FWS (2011 and 2017) has identified competition from intrusive, non-native barred owls as a foremost threat, second only to habitat loss, contributing to the demise of NSO in the Pacific Northwest. Early investigations of interactions between spotted owls and barred owls indicated the barred owls should be considered a threat to spotted owls (Kelley et al. 2003). Gutierrez et al. (2007) documented multiple competitive advantages of barred owls (a niche generalist) over spotted owls (a niche specialist). Specifically, barred owls have a wider range in cluch size than NSO and have smaller home ranges than NSO, indicative of their use of wider variety of habitats and more varied diet than NSO (Gutierrez et al. 2007). Barred owls may reduce the density of prey species utilized by NSO (resource competition) and have been documented being aggressive to NSO with consequences to NSO social interactions (eg., reduced NSO vocalizations in vicinity of barred owls), potentially interference competition (Gutierrez et al. 2007). Similar observations have been reported by Hamer et al. (2007) , Sovern et al. (2014), and Dugger et al. (2016) which similarly conclude that NSO are being displaced, perhaps forced to extinction, by barred owls (Yackulic et al. 2012; Kroll et al. 2016; Dugger et al. 2016).

a/ Interior Forest: forested habitat farther than 100 meters (328 feet) from existing disturbance (i.e., wide-surface roads, existing corridors) or adjacent land use/vegetation type (i.e., agriculture, non-forest, early regenerating forest), and/or farther than 50 feet from smaller roads with existing canopy cover (FWS 2014c). Other Forest Type includes forested habitat that is currently affected by existing disturbance or adjacent land use/vegetation types within 100 meters (328 feet) of disturbance. Interior forest includes habitat from late regenerating to old-growth.

b/ FWS et al. (2008) consider core areas with 50 percent or greater suitable NRF habitat and home ranges with at least 40 percent suitable NRF habitat to be necessary to maintain NSO life history function. For detailed NRF/High NRF habitat available for each individual NSO and its habitat type (nest patch, core area, home range), refer to "pre-action" suitable habitat acres in table Q-7 in appendix Q.

c/ Owl Status: 1) Known sites represent NSO activity sites provided by BLM and Forest Service biologists within the provincial analysis area; 2) Best Location sites represent pairs or resident singles documented by PCGP during surveys in 2007 and 2008 with no nest site/activity center located, and; 3) PCGP assumed sites considered for analysis in this APDBA in areas that may provide nesting habitat for NSO.

Barred owls are known to use a wide variety of forest types, including early successional habitats, and some authors have suggested that timber harvest activities may favor the species. For instance, fragmentation of forest habitat may have created favorable conditions for survival and reproduction of barred owls. By contrast, NSOs appear to be more generally associated with old growth forest or forests that are structurally complex (Courtney et al. 2004). Therefore, timber harvest may have increased overlap of the two species' preferred and potential habitats which has led to increased competition.

Gutierrez et al. (2007) and Buchanan et al. (2007) considered management and research options that lead to understanding how to deal with the invasion of barred owls and competition with northern spotted owls. Both authors concluded that removal experiments (whether through translocations or lethal elimination) would provide the strongest approach for understanding barred owl effects on NSO populations. Results of removal experiments would lead to control of barred owls through some portion of NSO's range (Gutierrez et al. 2007; Buchanan et al. 2007). To this end, a pilot study was initiated in California in 2009 with an appropriate before-after/control-treatment study design with the treatment as lethal removal of barred owls (Dugger et al. 2016). Demographic paramenters including annual rate of population change (λ), fecundity, and survival of NSO in the the California study were compared to other locations across the species' range. The study found that the only instances of an increasing population rate of change for NSO in all locations occurred after lethal control of barred owls began in 2009 in the pilot study; barred owl removal combined with habitat conservation may slow or reverse declines of NSO populations on a local scale (Dugger et al. 2016). Other experimental study areas were initiated in Washington and Oregon in 2015 and scheduled to continue for five years (Wiens et al. 2017). Preliminary results indicate abiguous responses of spotted owls to removing barred owls during the first study year (Wiens et al. 2017).

Barred owls are present within the Pipeline project NSO provincial analysis area. Although survey design was not intended to locate or census barred owls or barred owl pairs, during surveys for NSOs conducted along the Pipeline route, barred owls were documented 79 times in 14 survey areas in 2007 (4 pairs), 115 times in 14 survey areas in 2008 (8 pairs), and 19 times in eight survey areas (3 pairs) in 2015 along the Blue Ridge portion of the Proposed Route – none within NSO home ranges. Of the barred owls documented, 46 were dispersed along the right-of-way within the Coast Range, 56 were documented within Klamath Mountains mostly along the eastern portion of the province, 21 were located in West Cascades, and 25 documented sites were located within the western portion of East Cascades province (see table 3.3.4-18). Davis (2007), provided an analysis using partial data (only 36 barred owl sites) provided in December 2007, that demonstrated barred owls located along the Pipeline occurred more often in marginal NSO suitable nesting, roosting, and foraging habitat than the NSOs documented during 2007 surveys, which were generally located within the more contiguous and suitable NRF habitat within the Pipeline project area. Reduction of suitable NSO habitat may have an effect on the NSO by providing a competitive advantage for barred owls, since some research and preliminary modeling by Davis (2007) has demonstrated that barred owls have a wider breadth of habitat use than the NSO and are more often located in marginal habitat than the NSO (Courtney et al. 2004).

TABLE 3.3.4-18

Summary of Barred Owls Detected During 2007, 2008, and 2015 Northern Spotted Owl Surveys

Total Documented within NSO Home Ranges	8	27	22	56	11	21	5	25	46	129

Table Q-7 in appendix Q provides a subscript "B" where barred owls were documented in the home range, core area, and/or nest patch.

Barred owls were documented in 46 of the 105 NSO home ranges during 2007/2008 PCGP survey efforts (see superscript "B" next to Site Name in table Q-7 in appendix Q), including five nest patches (two known NSO – UMP 0408 and UMP 0401), and three best location sites (PCGP 084.6, PCGP 097.6, and PCGP 165.8). A summary of barred owl locations for each physiographic province in respect to NSO home ranges and available suitable NRF habitat (high NRF and NRF) greater or less than 40 percent is provided in table 3.3.4-18. Habitat below the 40 percent available NRF habitat in the home range could be considered "marginal" habitat. Approximately 37 percent of the barred owls documented within NSO home ranges were documented in "marginal" habitat, and 63 percent of barred owls documented were located in NSO home ranges with more suitable NRF available (see >40 percent suitable NRF Habitat; table 3.3.4-18).

It is conceivable that construction of the Pipeline may serve as a corridor for barred owl expansion, but this is speculative. Review of available literature did not indicate that linear transportation corridors increase barred owl presence/expansion. If inclusion of these additional barred owl locations indicates that barred owls do occur more often in marginal NSO habitat than NSOs do, then focus should be on currently suitable NSO habitat (see Habitat Condition 1 in table Q-7 in appendix Q) being brought below FWS recommended thresholds by the proposed Project, and areas currently below thresholds that the proposed Project could further impact (see Habitat Conditions 2 through 4 in table Q-8 in appendix Q). With the exception of the Coast Range physiographic province, the majority of barred owls documented were located within NSO home ranges with adequate amounts of suitable habitat (greater than 40 percent suitable habitat available in home range and greater than 50 percent suitable habitat available in the core area).

Wildfire

Research demonstrates that NSO populations have declined following wildfires in previously occupied habitats. Clark (2007) documented declining occupancy in burned habitats with lower survival rates of spotted owls that had recently emigrated out of the burned habitat. Also, home ranges of spotted owls that persisted in the burned habitat were characterized by larger amounts of hard edges compared to home ranges outsited of burned areas (Clark 2007). However, Roberts et al. (2011) found that densities of California spotted owls inhabiting low to moderate serverity burned habitat were similar to densities in unburned habitat. California spotted owls foraged in high-severity burned forest more than in all other burn categories; high-severity burned forests had greater amounts of snags and higher shrub and herbaceous cover, which would likely be associated with increased abundance or accessibility of prey (Bond et al., 2009). High severity fires likely eliminate protective cover or perch sites for spotted owls compared to unburned or low to moderate severity fire that support intact forest canopy with protective cover or high prey availability (Eyes 2014). Additional observations from these studies indicate that activities associated with post-fire timber salvage also pose a significant risk to displacing spotted owls from otherwise occupied habitats.

In 2015, a large stand-replacing fire (Stouts Creek fire) occurred within the range of the northern spotted owl, burning approximately 26,452 acres on Roseburg BLM District, Umpqua National Forest, and some private landowners in the Days Creek-South Umpqua River and Elk Creek watersheds (Northwest Interagency Coordination Center 2015). On private lands, burned trees were harvested following the fire, whereas on federal lands, burned trees were left to stand. Approximately 10.7 miles (227 acres) of the Pipeline crosses the area burned by the Stouts Creek fire, generally from MP 95.5 through MP 108.8, including approximately 1.6 miles (57.36 acres) of burned forest that was harvested on private lands, and approximately 2.3 miles (73.95 acres) of burned forest that is still standing on federal lands: 1.57 miles (57.15 acres) in old-growth forest/late successional forest, 0.42 mile (13.16 acres) in mid-seral forest, and 0.24 mile (3.64 acres) in clearcut/regenerating forest (refer to table 3.3-9 or section 3.3.2.1 in PCGP's Resource Report 3). Additionally, Umpqua National Forest created a fire break within the fire boundary on 0.7 mile 7.0 acres) that would be crossed by the Pipeline project from approximately MP 106.8 to MP 108.8. In one location crossed by the Pipeline, the Stouts Creek fire burned an area that was dominated by contiguous, late successional/old-growth forest that provided highly suitable NRF habitat for the northern spotted owl. As noted earlier, areas where NRF habitat had been burned but was still standing has been identified as "post-fire NRF" in this APDBA: approximately 4,404 acres of "post-fire NRF" are present in the NSO provincial analysis area (approximately eight percent of all NRF in the analysis area; see table 3.3.4-5), of which 25.72 acres of "post-fire NRF" would be removed (seven percent of all NRF removed) by the Pipeline (table 3.3.4-13). Based on available sources, the Pipeline effects to "post-fire NRF" would primarily be to foraging habitat with some capability of providing suitable roosting structures.

Twenty NSO home ranges included for analysis within this APDBA had habitat affected by the Stouts Creek fire to varying degrees, and at least three activity centers analyzed in this APDBA either occur within habitat completely burned to the ground, within harvested habitat, or within post-fire NRF (see table Q7 in appendix Q and appendix Z2). Based on the information presented above, it is likely that NSOs using habitat affected by the Stouts Creek fire are still present, but utilize habitat in a different capacity. For example, "post-fire NRF" is likely used for foraging and possibly roosting, but may no longer provide the characteristics necessary for nesting. However, without additional surveys and per direction by the FWS, PCGP conservatively assumes NSO activity centers and supporting home ranges affected by Stouts Creek fire still support active NSO nests.

Construction of the Pipeline could increase the risk of fires; however, the exact risk of fires (either natural, or caused by human and/or pipeline activities) will be dependent on local conditions. Certain activities associated with construction and operation of the Pipeline, such as mowing, welding, and parking on dry, tall grass could increase the risk of starting wildland fires, especially if these activities occur within the fire season. PCGP has prepared a Fire Prevention and Suppression Plan (see Appendix K to the POD) in consultation with the BLM and Forest Service to reduce the risk of wildland and structural fires. This Plan is consistent with National Forest policies, BLM policies, current practices and plans. Conversely, the Pipeline right-of-way could also reduce or minimize the spread of fires by creating a fire break in forested areas similar to fire breaks constructed by Umpqua National Forest to control the 2015 Stouts Creek Fire along the Proposed Route between MPs 106.8 and 108.8.

Effects to Prey

Cleared areas would remove suitable habitat for arboreal prey species (flying squirrels, red tree voles), but could improve habitat for non-arboreal species (western red backed voles, deer mice) adjacent to cleared areas. NSOs seldom venture far into non-forested areas to hunt, although it is likely they would cross the Pipeline corridor at night to forage on both sides of the right-of-way. Edges can be areas of high prey availability, but also increased vulnerability (Zabel et al. 1995). Prey animals could be more exposed in the disturbed area and may move away from edges in the short term. Some minor changes in prey availability could occur as cover is disturbed and animals redistribute within the understory. Conversion of habitat on the right-of-way to non-forested conditions might attract other predators such as other owls, hawks, and mammals. This could increase competition for NSOs in the cleared right-of-way, but the exposure of prey could also benefit NSOs.

Some disturbance of habitat could improve forage conditions in remaining stands on both sides of the Pipeline corridor by bringing more light and resources into the stands and by stimulating forbs, shrubs, and other prey food. Once the initial impact of disturbance recovers (6 months to two years), the understory habitat conditions for prey food would increase over the next few years, until shrubs and residual trees create canopy and become more contiguous with adjacent forest stands.

Critical Habitat

The FWS (1992c) determined that the physical and biological habitat features (PCEs) that are essential for the recovery of the spotted owl are forested lands used or potentially used for nesting, roosting, foraging, and dispersal; more specificity to PCEs was provided in the revised critical habitat in 2012. Based on more current information on the life history, biology, and ecology of the species, the revised PCEs are summarized as (FWS 2012d): PCE-1 – forested habitat in a variety of seral stages that support the NSO across its geographical range; PCE-2 – forested habitat that provides for nesting and roosting, and could provide for foraging; PCE-3 – habitat the provides for foraging; and PCE4 – habitat that supports dispersal of spotted owls, which could provide NRF habitat, but could also be composed of other forest types between larger blocks of NRF habitat. Within this analysis, PCEs would be similar to NSO habitat mapped for the Pipeline: PCE-1 would be all forested habitat affected within the range of the NSO; PCE-2 would include high NRF as well as NRF; PCE-3 would include NRF and high NRF; and PCE-4 would include dispersal only habitat, as well as high NRF and NRF that provide dispersal habitat for the NSO.

Activities that disturb or remove the PCEs within designated CHUs might adversely modify NSO critical habitat. These activities may include effects to early-, mid-, or late-seral forests that support the NSO across its geographical range; nesting and roosting habitat; foraging habitat; and habitat to support the transience and colonization phases of dispersal (FWS 2012d).

In contrast, activities that would have no effect on critical habitat's PCEs almost certainly would not adversely modify the critical habitat. However, even though an action may not adversely modify critical habitat, it may still affect NSOs (e.g., through disturbance) and therefore be subject to consultation under the jeopardy standard of Section 7 of the ESA (FWS 1992c).

Approximately 37.4 miles of the proposed route cross seven designated critical habitat sub-units ORC-6, KLE-1, KLE-2, KLE-3, KLE-4, KLE-5, and ECS-1 (see table 3.3.4-19 and table Q11 in appendix Q), within which 35.0 miles cross NSO habitat. Table Q-11 in appendix Q provides the amount of high NRF, NRF, dispersal only, capable, and non-capable habitat within each CHU by landowner that would be removed and modified, which is summarized below in table 3.3.4-19. With the exception of CHU ECS-1, all CHU subunits occur completely within NSO home ranges, and partially within LSRs and Forest Service unmapped LSRs (see table Q-9 in appendix Q for overlap of CHUs with LSRs and unmapped LSRs).

Overall, the Project would remove 488.72 acres of NSO habitat from CHUs (86.43 acres of high NRF, 160.70 acres of NRF (includes 24.56 acres of "post-fire NRF"), 72.65 acres of dispersal only habitat, and 168.94 acres of capable habitat), of which 128.28 acres (25.07 acres in high NRF, 43.34 acres in NRF (includes 6.27 acres of "post-fire NRF"), 17.85 acres in dispersal only habitat, and 42.03 acres in capable) would be kept within an early seral state within the 30-foot operational corridor for the life of the Project (see table 3.3.4-19). Over the long term, 360.44 acres of NSO habitat within CHUs would return to their original state (outside of the 30-foot operational corridor) and begin functioning as dispersal only habitat (see table 3.3.4-19). Table Q-11 in appendix Q provides further detail of CHUs affected, including landowner by physiographic province within or outside of interior forest and identifies the acres of non-capable habitat affected within designated CHUs.

In addition to direct loss of critical habitat and effects to PCEs due to losses that were summarized in table 3.3.4-19, the Project's other indirect effects within 100 meters of habitat removal to NSO that were discussed above (fragmentation, edge, and interior forest) indirectly affect designated critical habitats and PCEs. Edge effects and effects to interior forest may induce changes to forest characteristics later in time and would indirectly affect PCEs. In particular, creation of isolated forest patches with large edge areas can create changes in microclimate, vegetation species, and predator-prey dynamics. Two main physical factors affecting and creating an edge microclimate are sun and wind (Forman 1995; Chen et al. 1995; Harper et al. 2005), which could directly affect characteristics of nesting trees and decrease canopy cover and stand conditions for future NSO habitat components described in the PCEs.

Interior forest has been defined as 100 meters (328 feet) from any existing edge of a contiguous forested stand (50 feet from canopy covered roads), including edges created by adjacent regenerating stands approximately 10 to 20 years old (see Harper et al. 2005). However effects of strong wind may extend beyond that distance (see Chen et al. 1995). Such effects are dependent on local conditions such as orientation of an edge; the magnitudes of change in humidity with distance from an edge are most extreme with south-facing edges, compared to east- and west-facing edges (see Figure 6 in Chen et al. 1995). Such effects may induce changes within PCEs. Long-term effects on edges and interiors of NSO habitat are less well defined and over time, edge effects would diminish as edges evolve from "hard" to "soft" (see for example, Peery and Henry 2010).

There is considerable overlap of forest habitat, including interior forest that is within NSO CHUs and within LSRs. Long-term effects from removal of forest within critical habitat and LSRs by the proposed project would be expected. Most indirect effects to forested habitat within 100 meters (328 feet) of habitat removal occur in NSO habitat that has been previously affected by existing edge, such as roads, waterbodies, early seral forest, and nonforested habitat (see "other interior forest" in table 3.3.4-16). Table Q-9 in appendix Q provides a more detailed tabulation of indirect effects to interior forest habitat within NSO critical habitat units and NWFP LSRs/unmapped LSRs by landowner and physiographic province.

Late-Successional Reserves

Additional habitat protection for the NSO was established when LSRs were adopted in the NWFP, and continued to be included in BLM 2016 RMPs. Within the provincial analysis area, NSO CHUs overlap with LSRs to varying degrees (see table Q-9 in appendix Q). The Pipeline crosses 27.6 miles of LSRs, including two allocated LSRs on Forest Service land: RO 223 (Umpqua National Forest) and RO 227 (Rogue River National Forest); see table 3.3.4-20.

a/ General Location identifies areas within Northern Spotted Owl Groups (areas within NSO home ranges; see table Q-10 in appendix Q) and areas outside of NSO groups (outside of NSO home ranges).
b/ High NRF (FWS 2014c): forested habitat that is characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species.
c/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., "post-fire NRF").
d/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.
e/ Capable Habitat (FWS 2014c): habitat that is forested or could become forested (i.e., recently harvested timberlands) that do not provide dispersal or NRF characteristics.
f/ Total habitat only considers forested NSO habitat within NSO critical habitat units; non-capable habitat affected NSO critical habitats is included in table Q-11 in appendix Q.
g/ Project components considered in calculation of habitat "Removed": construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), pipe storage yards, and hydrostatic test locations.
h/ UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.
i/ Other Indirect Effects considers habitat within 100 meters (328 feet) of habitat removal as measured from the edge of habitat removal/edge of right-of-way/TEWA.
j/ 30-foot Maintenance Corridor would be kept in a shrub/sapling state for the life of the project; all other habitat outside of the 30-foot maintenance corridor would be revegetated, except for those habitats on non-federal or matrix/harvest-based lands where there is less certainty that replanting would occur or be maintained on the landscape.

Note: More detailed information on BLM Districts and National Forests impacted in critical habitat units is located in table Q-11 in appendix Q. Overlap with LSRs can be reviewed in table Q-9 in appendix Q.

a/ General Location identifies areas within Northern Spotted Owl Groups (areas within NSO home ranges; see Table Q10 in Appendix Q) and areas outside of NSO groups (outside of NSO home ranges).
b/ High NRF (FWS 2014c): forested habitat that is characterized by large trees (> 32 inches dbh), high canopy cover (>60 percent), and multistoried structure with sufficient down wood and snags to support prey species.
c/ NRF (FWS 2012d, 2014c; North et al. 1999): conifer-dominated forested habitat greater than 80 years that does not meet the definition of High NRF but has multi-storied structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood. Acreage in parenthesis identifies the area of NRF (or High NRF) prior to the 2015 Stouts Creek fire that are currently dead standing trees (i.e., "post-fire NRF").
d/ Dispersal ONLY (FWS 2012d, 2014c): an average tree diameter of 11 inches dbh or greater; conifer overstory trees; canopy closure greater than 40 percent in moist forests and greater than 30 percent in dry forests; open space beneath the canopy to allow for NSO to fly; High NRF and NRF provide dispersal habitat, as well.
e/ Capable Habitat (FWS 2014c): habitat that is forested or could become forested (i.e., recently harvested timberlands) that do not provide dispersal or NRF characteristics.
f/ Total habitat only considers forested NSO habitat within the range of the NSO; see table Q-12 in appendix Q for effects to non-capable habitat in NWFP LSRs and unmapped LSRs.
g/ Project components considered in calculation of habitat "Removed": construction right-of-way, temporary extra work areas, aboveground facilities, permanent and temporary access roads (PAR, TAR), pipe storage yards, and hydrostatic test locations.
h/ Other Indirect Effects considers habitat within 100 meters (328 feet) of habitat removal as measured from the edge of habitat removal/edge of right-of-way/TEWA.
i/ Acres identified as UCSAs have been incorporated into the 100-meter other indirect effects. UCSAs would not be cleared of trees during construction and would not affect nesting structures or characteristics. These areas would be used to store forest slash, stumps and dead and downed log materials that would be removed and scattered across the right-of-way after construction during restoration and are considered as temporary insignificant understory habitat effects.
j/ 30-foot Maintenance Corridor would be kept in a shrub/sapling state for the life of the project; all other habitat outside of the 30-foot maintenance corridor would be revegetated, except for those habitats on non-federal or matrix lands where there is less certainty that replanting would occur or be maintained on the landscape.

Note: More detailed information on BLM Districts and National Forests impacted in critical habitat units is located in table Q-12 in appendix Q. Overlap with CHUs can be reviewed in table Q-9 in appendix Q.

Table 3.3.4-20 summarizes the impact to NSO high NRF, NRF, dispersal, and capable habitat within each LSR and Forest Service unmapped LSRs impacted (i.e. habitat affected (within 100 meters of habitat removal including UCSAs) or habitat removed) by the proposed Project. Overall, the Pipeline would remove 442.44 acres from LSRs (table Q-12 in appendix Q), of which 379.09 acres is NSO habitat or capable of becoming NSO habitat (68.63 acres of high NRF, 92.72 acres of NRF (includes 8.89 acres of "post-fire" NRF), 71.39 acres of dispersal only habitat, and 146.36 acres of capable habitat). After construction, approximately 100.23 acres (20.46 acres of high NRF, 25.80 acres of NRF (includes 2.53 acres of "post-fire NRF"), 19.29 acres of dispersal only habitat, and 34.56 acres of capable habitat) would be kept within an early seral state within the 30-foot-wide operational right-of-way for the life of the Project (see table 3.3.4-20). Over the long term, 278.98 acres of forested habitat within LSRs would return to their original state (outside of the 30-foot operational right-of-way) and begin functioning as dispersal only habitat (see table 3.3.4-20). Table Q-12 in appendix Q provides NSO habitat affected within NWFP LSRs and unmapped LSRs, by landowner and physiographic province within and outside of interior forest.

LSRs and Forest Service unmapped LSRs cover approximately 61,278 acres within the provincial analysis area and provide approximately 36,826 acres of high NRF and NRF habitat (includes 2,317 acres of "post-fire NRF;" see table 3.3.4-7). The proportional amount of available NRF habitat that would be removed (161.35 acres, including 8.89 acres of "post-fire NRF") within LSRs in the provincial analysis area is 0.4 percent, while 0.2 percent of available NRF would be affected in the short term within UCSAs (65.92 acres, including 17.23 acres of "post-fire NRF").

Cumulative Effects

Habitat removal and construction disturbance from the Pipeline are expected to be complete one year before the in-service date due to the longer construction period for the LNG terminal, access channel, and slip (figure 2.1.1-1). Consequently, the foreseeable future required for cumulative effects analysis would actually occur before implementation of the proposed action, not after its implementation, which is more often the case.

Cumulative effects to NSO would be generated by timber harvesting and other sources of nesting, roosting, and/or foraging (NRF) habitat losses on non-federal lands in the foreseeable future. High NRF is considered habitat that is characterized by large trees (greater than 32 inches dbh), high canopy cover (greater than 60 percent), and multistoried structure with sufficient down wood and snags to support prey species, and NRF consists of conifer-dominated stands older than 80 years that is multi-storied in structure with large overstory trees (20-30 inches dbh), moderate to high canopy closure greater than 60 percent, and sufficient snags and down wood, and does not meet the definition of High NRF (see section 3.3.4.2). As defined, High NRF and NRF NSO habitats correspond with forested and mixed coniferous forests older than 80 years.

Areas of NSO nesting/roosting habitats have been monitored as a component of the NWFP. In Oregon, NSO nesting/roosting habitat was evaluated in 1993 and in 2012 (Davis et al., 2016) within each of the physiographic provinces crossed by the Pipeline. Differences in areas of NSO habitat were described in the four physiographic provinces on federal land and all lands (federal and nonfederal) from which changes in NSO habitat on nonfederal lands were computed. Most of the losses of NSO habitat on federal lands were attributed to large fire events including the 2002 Biscuit Fire in the Klamath Mountains, the 2003 B&B Fire in the Western Cascades, and the 2003 B&B Fire and Davis Fire in the Eastern Cascades (Davis et al. 2016). However, losses associated with wildfire were negligible on non-federal lands where most of the decline in NSO habitat was due to timber harvest, primarily concentrated in the Oregon Coast Range and Western Cascades provinces (compare Table 6 with Table 7 in Davis et al. 2016)

In 2017, there were 7,214 acres of High NRF habitat and 11,124 acres of NRF habitat on non-federal lands within the provincial analysis area (see table 3.3.4-4 in section 3.3.4.2) in all four physiographic provinces, combined. During the 19-year period from 1993 to 2012 there was an overall net loss of NSO nesting/roosting habitat on non-federal lands within the Coast Range province (-1.84 percent), Western Cascades province (-1.51 percent), and Eastern Cascades province (-0.51 percent), but a slight increase in NSO habitat on non-federal lands in the Klamath Mountains province (+0.07 percent) (Davis et al. 2016). Percent loss of NSO habitat on non-federal lands during the 19-year period was used as the basis for the annual loss of High NRF and NRF habitats included in table 3.3.4-21. The rates of change on non-federal lands were assumed to be constant over time within the provincial analysis area. Areas of High NRF and NRF habitats present in 2020, presumed to be the first year of Pipeline implementation, would be expected to change at the annual rates of loss specific to each physiographic province with an overall slight net loss in 2020 (from 18,338 acres in 2017 to 18,234 acres in 2020). Using the annual rates of NSO nesting/roosting habitat loss, there would be an estimated 7,195 acres of High NRF and 11,039 acres of NRF habitats within the analysis area on non-federal land in 2020 (see table 3.3.4-21).

The Project would remove 9.18 acres of High NRF habitat and 59.98 acres of NRF habitat on non-federal (state and private) lands (see table 3.3.4-12 in section 3.3.4.3) in all four Physiographic Provinces, combined. The amount of High NRF habitat removed would be 0.14 percent of the High NRF habitat remaining on non-federal lands (7,195 acres) within all four provinces of the analysis area by 2020. Likewise, the amount of NRF habitat removed by the Pipeline would be 0.54 percent of the NRF habitat remaining on non-federal lands (11,039 acres) within all four provinces of the physiographic analysis area by 2020. When compared to the estimated amount of NSO habitat on non-federal land within the analysis area, the Project would affect a total of 60.77 acres, which would be 0.33 percent of the total High NRF and NRF habitat available within the foreseeable future in 2020.

TABLE 3.3.4-21

3.3.4.4 Conservation Measures

PCGP has implemented or proposed conservation measures including avoidance, minimization, and rehabilitation/restoration as described below.

Avoidance, Minimization, and Rehabilitation / Restoration

Conservation measures have been proposed by PCGP to minimize construction and operational impacts to NSO habitat within the provincial analysis area. Those measures have been compiled in table 2C in appendix N. Specific conservation measures that minimize project impacts on NSOs include those that:

- avoid timber clearing during the breeding and nesting season;
- avoid construction activities within 0.25 mile of NSO activity sites during the critical breeding season (March 1 – July 15);
- route the Pipeline through previously disturbed lands near LSRs so that impacts to these areas are minimized;
- minimize removal of forest by incorporating UCSAs into the Pipeline project design;
- utilize two-year construction schedule to minimize the overall TEWAs;
- flag large diameter trees on edges of construction right-of-way or temporary work areas where feasible to save from clearing, as outlined in the Plan of Development's Leave Tree Protection Plan;
- ensure that all trash, food waste, and other items attractive to crows, jays, and other corvids would be contained and removed from the project area on a daily basis to minimize potential predation of spotted owl nestlings;
- utilize logging methods to minimize damage to adjacent trees when clearing the right of way to reduce potential infestation from forest pathogens and insects; and
- minimize potential for establishment of invasive vegetation and establish control of noxious weeds.

Plans included in the appendices to PCGP's POD identify methods that would minimize effects to NSO habitat and/or nesting NSOs. The *Leave Tree Protection Plan* describes the preconstruction surveys that would be completed to clearly mark the boundaries of the Pipeline project's certificated working limits, and procedures to identify individual trees within and along the edges of the certificated work limits that can be conserved or left standing, as well as BMPs that would be employed to minimize damage to trees within UCSAs and protect trees not removed from the construction right-of-way (see appendix P to the POD, available upon request). An *Integrated Pest Management Plan* (see appendix N to the POD, available upon request) describes BMPs to address the control of noxious weeds, invasive plants, forest pathogens, and soil pests, as well as measures to minimize the potential spread of invasive species and potential adverse effects of control treatments. The *Blasting Plan* and *Air Noise and Fugitive Dust Plan* (see Appendices C and B to the POD, respectively – available upon request) provide mitigation measures and monitoring plans to minimize noise effects to nesting spotted owls during construction of the Pipeline.

During the Pipeline project route selection and construction footprint design processes (e.g., placement and sizing of temporary extra work areas), PCGP determined a alignment that would ensure the long-term safety and integrity of the proposed Pipeline through geotechnical evaluations while attempting to minimize adverse impacts to NSO nest patches, core areas, critical habitat, LSRs, and otherwise potential suitable habitat. However, not all designated critical habitat, LSRs, suitable habitat, and known NSO nest patches and core areas could be avoided. Major and minor route alternatives have been considered and incorporated into the Proposed Route that minimize effects to NSO and habitat (see PCGP's Resource Report 10).

PCGP prepared an *Avoidance and Minimization Plan for MAMU and NSO* (see appendix V1) that identifies the additional measures that have been incorporated into the project design to reduce impacts to both MAMUs and NSOs. This avoidance plan was developed through consultations with the FWS and the cooperating agencies (Interagency Habitat Quality Subgroup-Micro Siting Working Group, June 4, 2008). Application of measures outlined in the plan would minimize the impacts to suitable NSO habitat by 1) converting TEWAs to UCSAs to reduce the amount of suitable habitat removed by the Pipeline project, 2) moving TEWAs to avoid impacts to suitable habitat within core areas, and 3) moving the alignment to avoid NSO nest patches. A "Standard Rules Set" was developed during the meeting to further minimize effects to NSO nest patches, and this Standard Rules Set would be implemented prior to or concurrent with tree felling. The Standard Rules Set measures include:

- identify potential nest trees to be allowed to remain standing within TEWAs or edge of right-of-way;
- identify TEWAs to be reduced in size or eliminated to reduce removal of suitable habitat;
- identify any additional minor route adjustments that would not alter constructability but would further reduce removal of suitable habitat;
- identify any previously unknown nest trees discovered and assure that they are properly protected by applying seasonal restrictions associated with similar locations along the project alignment; and
- provide support to EIs by qualified biologists to identify habitat or potential nest trees.

Prior to timber clearing, PCGP would have experienced biologists cruise NSO core areas and nest patches where high NRF and NRF habitat would be modified by construction of the Pipeline and mark trees that have potential NSO nesting structures (i.e., snags, large cavities). PCGP would avoid removal of those marked trees, if feasible. Additionally, to minimize disturbance within forested areas, PCGP has designated nearly 676.44 acres (see table 3.3.4-12) of UCSAs within the range of NSOs that would not be cleared of trees but would be used to store forest slash, stumps, and dead and downed log materials during construction that would be scattered across the right-of-way after construction and during restoration. The UCSAs would be useful for the construction of the Pipeline project while not requiring removal of trees or understory vegetation and allowing the maintenance of high NRF, NRF, dispersal, and capable habitat function. Where feasible, PCGP would leave large trees on the edges of the construction right-of-way and TEWAs throughout the project area to benefit the NSO and other late-successional-dependent wildlife species.

To minimize effects to NSOs potentially nesting within 0.25 mile of the Pipeline, PCGP would remove timber outside of the NSO breeding season (after September 30 and before February 28) within at least 0.25 mile of activity centers (known, best location, and PCGP assumed sites) to ensure that trees with nesting NSO and owlets are not felled. To minimize disturbance and/or disruption to potentially nesting NSO within 0.25 mile of Pipeline construction, PCGP would construct the Pipeline where activity centers (known, best location, PCGP assumed) occur within

0.25 mile of the Pipeline project after the critical breeding period (after July 15), and only after timber has been felled outside of the breeding season. If PCGP decides to construct within 0.25 mile of NSO activity centers during the NSO critical breeding period (March 1 through July 15), PCGP would conduct reproductive follow-up surveys at NSO activity centers that are within 0.25 mile of the construction right-of-way the year of construction to determine if documented nest sites and/or pairs within 0.25 mile of construction activities are active. The follow-up surveys would either consist of two visits before May 1 at least one week apart or one survey after May 1 as described by the revised NSO survey protocol (FWS 2012i). If spotted owls are determined to not be nesting during reproductive follow-up surveys, construction of the Pipeline project could occur during the breeding season with no expected impact to nesting NSO; however, reproductive follow-up surveys should be repeated each year if construction activities during the critical breeding season are proposed within 0.25 mile of NSO activity centers (FWS 2012i).

To ensure that minimization measures would be applied to all potentially nesting NSO within 0.25 mile of the Pipeline project, one year prior to construction activities, PCGP would conduct spot check surveys within 0.25 mile of the construction right-of-way in known, best location, and assumed NSO home ranges, where permitted, as well as previously surveyed NRF habitat outside of analyzed NSO home ranges, to supplement the full survey efforts conducted in 2007 and 2008, as recommended by FWS. These surveys would determine if sites are still occupied or have moved, attempt to locate nest trees per protocol, determine if best location or assumed owl sites are occupied, adjust the construction schedule to apply seasonal constraints, if necessary, and apply minor route adjustments to further minimize impact, if feasible. The spot check surveys would include at least three night visits spaced a minimum of 7 days apart to confirm occupancy status (FWS 2012i).

During construction, PCGP would ensure that construction contracts include stipulations ensuring that all trash, food waste, debris, and other items attractive to crows, jays, and other corvids would be picked up and removed from the project area on a daily basis during the breeding season to minimize potential predation of northern spotted owlets. PCGP's EIs would be responsible for confirming that the construction contractor is following these stipulations.

Measures have also been proposed to rectify, repair, and rehabilitate and otherwise reduce impacts to forested habitats once construction of the Pipeline is complete. Those measures have been compiled in table 3C in appendix N. Specific conservation measures that would benefit NSOs include those that:

- replant conifer species outside of the 30-foot-wide maintenance corridor after construction, where feasible, which would contribute to the reestablishment of native vegetation and soften the edge effect created from construction of the Pipeline;
- contribute to forest habitat structural diversity (e.g., snags and downed timber); and
- minimize potential for increased human use of the reclaimed construction right-of-way and intrusion into undisturbed habitats.

Following construction, a maximum of approximately 1,568 acres of affected forested lands (the construction right-of-way and temporary extra work areas outside of the 30-foot-wide operational right-of-way; NSO habitat in table 3.3.4-12) would be replanted and allowed to return to pre-construction condition where possible with tree species in the approximate proportion to those species removed. This replanting would occur on certain federal lands and non-federal lands on a case-by-case basis. Replanted trees may also be harvested from non-federal lands or federal lands slated for timber harvest (i.e., Matrix lands). Tree establishment would be allowed to occur up to within 15 feet on either side of the centerline. Over the long term (80 years or more), revegetated areas outside of the 30-foot maintenance corridor may achieve tree structural characteristics comparable to those removed, had they not been affected, which could serve as NSO suitable habitat. Although nesting function may not be reestablished over the long term, the habitat may provide structures suitable for foraging, roosting, and dispersal as it regrows.

3.3.4.5 Determination of Effects

Species

The Project **may affect** NSOs because:

- suitable habitat is available within the provincial analysis area, and
- NSO pairs and resident singles have been located within the provincial analysis area during survey efforts.

The Project is **likely to adversely affect** NSOs because:

- noise from blasting during construction within 0.25 mile of NSO sites during the late breeding season would occur and could increase the risk of predation to fledglings that are generally not as able to escape as adults during the latter part of the breeding season.
- construction of the Pipeline would remove approximately 516.77 acres of high NRF and NRF habitat (including 25.72 acres of "post fire NRF" within the 2015 Stouts Creek fire area) within within the provincial analysis area. This would result in effects to NSO nest patches, core areas, and home ranges of known, best location, and PCGP assumed owls, some of which are currently below thresholds needed to sustain NSOs. Once suitable NRF habitat is reduced or modified in NSO home ranges, there is an increased likelihood that NSOs remaining in the Pipeline project area would be subject to:
  - displacement from nesting areas;
  - concentration into smaller, fragmented areas of suitable nesting habitat that may already be occupied;
  - increased interspecific (with barred owls) and intraspecific competition for suitable nest sites;
  - decreased survival due to increased predation and/or limited resource (forage) availability; and
  - diminished reproductive success for nesting pairs.
- construction of the Pipeline would remove and modify high NRF, NRF, dispersal only, and capable habitat for NSOs throughout the project area, including removal of habitat within the home range of 97 NSOs, 58 of which are currently below sustainable threshold levels of suitable habitat for continued persistence in their home range and/or core area.
- construction of the Pipeline would bring one NSO core area (best location activity center affected by 2015 Stouts Creek fire) below the 50 percent NRF threshold, and two NSO home ranges (known activity centers, one of which was affected by the 2015 Stouts Creek fire) below the 40 percent NRF threshold.

Critical Habitat

A **may affect** determination is warranted for NSO critical habitat because:

- the Pipeline would be within designated NSO critical habitat; and
- construction of the Pipeline would result in habitat impacts within designated critical habitat areas.

A **likely to adversely affect** determination is warranted for NSO critical habitat because:

- the Pipeline would remove or potentially downgrade PCEs in critical habitat sub-units ORC-6, KLE-1, KLE-2, KLE-3, KLE-4, KLE-5, and ECS-1 as defined in the Final Rule designating critical habitat for the NSO (FWS 2012e).

3.0 SECTION 3

3.1

3.2

3.3

3.4 HERPETOFAUNA

3.4.1 Green Turtle

3.4.1.1 Species Account and Critical Habitat

Status

Green turtles were listed as threatened under the ESA on July 28, 1978 (FWS 1978), except for an endangered population nesting on the Pacific Coast of Mexico. On March 23, 2015 the FWS and NMFS identified 11 Distinct Population Segments (DPS) including the East Pacific DPS, which ends approximately 100 miles south of the Project area (FWS and NMFS 2015)

Threats

In addition to the general threats to marine turtles mentioned below, the primary cause of green turtle population decline has been the harvest of both eggs and adults on nesting beaches and juveniles and adults on feeding grounds (NMFS 2017c).

NMFS has identified eight general threats to marine turtles, including green turtles. These threats include:

- Entanglement in and/or injury by fishing gear
- Ingestion or entanglement in marine debris
- Environmental contamination
- Disease, especially fibropapillomatosis in green turtles, but also reported in loggerhead and olive ridley turtles
- Loss or degradation of nesting habitat
- Beach armoring
- Artificial lighting
- Non-native vegetation

In addition, global climate change could have a potentially extensive impact on all aspects of marine turtles' life cycles and may affect the abundance and distribution of prey items (NMFS 2017d).

Species Recovery

A Recovery Plan for the U.S. Pacific green turtles was issued on May 22, 1998 (NMFS and FWS 1998a). The recovery goal is to delist the species, and the plan listed the following necessary actions:

- Minimize boat collision mortalities, particularly within San Diego County, California.
- Minimize incidental mortalities of turtles by commercial fishing operations.
- Support the efforts of Mexico and the countries of Central America to census and protect nesting East Pacific green turtles, their eggs, and nesting beaches.
- Determine population size and status in U.S. waters through regular surveys.
- Identify stock home range(s) using DNA analysis.
- Identify and protect primary foraging areas in U.S. jurisdiction.

The stepdown outline in the recovery plan included the following recommendations:

- Protect and manage turtles on nesting beaches.
- Protect and manage nesting habitat.
- Protect and manage East Pacific green turtle populations in the marine habitat.
- Protect and manage marine habitat, including foraging habitats.
- Develop standards for the care and maintenance of sea turtles, including diet, water quality, tank size, and treatment of injury and disease.
- Establish a catalog of all captive sea turtles to enhance use for research and education.
- Designate rehabilitation facilities.
- Support existing international agreements and conventions to ensure that turtles in all life-stages are protected in foreign waters.
- Encourage ratification of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) for all non-member Pacific countries, compliance with CITES requirements, and removal of sea turtle trade reservations held by member nations.
- Develop new international agreements to ensure that turtles in all life-stages are protected in foreign waters.
- Develop or continue to support informational displays in U.S. airports and ports of entry that have direct flights to Mexico and Latin America.

Life History, Habitat Requirements, and Distribution

The green turtle is globally distributed in tropical and subtropical waters generally between 30° north and 30°south of the equator. Many facets of the green turtle's life history and ecology remain unknown, including details of its residence in and use of the U.S. Pacific Coast. The NMFS identified 11 DPSs including the East Pacific DPS which is found from the California/Oregon border southward along the Pacific coast of North, Central, and South America to Central Chile including Mexico’s Revillagigedos Archipelago, and Ecuador’s Galapagos Archipelago. East Pacific green turtles regularly strand along the Oregon shoreline (FWS and NMFS 2015). Green Turtle nesting is widely dispersed in the Eastern Pacific Ocean. The two largest nesting aggregations for the East Pacific DPS are on the coast of Michoacan, Mexico and in the Galapagos Islands, with significant nesting on a variety of other beaches along the tropical eastern Pacific Coast.

Except during breeding migrations, green turtles tend to be found in shallow waters such as those inside reefs, bays, and inlets. The turtles are attracted to lagoons and shoals with an abundance of marine grass and algae. Seagrasses are the principal dietary component of juvenile and adult green turtles throughout the Caribbean region and degradation of seagrass beds has slowed recovery of green turtles due to reduced carrying capacity of seagrass meadows (NMFS 1998b). Green turtles apparently have strong nesting site fidelity and migrate long distances between feeding grounds and nesting beaches.

Green sea turtles grow to an average size of about 3 feet and weigh between 300 and 350 pounds. Hatchling green turtles eat a variety of plants and animals, but adults are vegetarian, feeding on sea grass and algae. The nesting season varies with the locality and clutch size varies from 75 to 200 eggs (FWS 2007d). Incubation of the eggs varies between 45 and 75 days. Age at sexual maturity is between 20 and 50 years (FWS 2007d).

Population Status

The mean annual number of nesting green turtle females has declined by 48 to 67 percent over the last three generations, which was estimated from index nesting sites (Marine Turtle Specialist Group 2004). East Pacific green turtles are widely distributed in coast waters south of the United States, in Mexico and Central America where the main aggregations are along the west coast of Baja California, in the Sea of Cortez, along the coast of Oaxaca, and breeding grounds of Michoacan, Mexico (NMFS and FWS 1998a). There is no known nesting by green turtles on the U.S. Pacific Coast (NMFS and FWS 1998a).

Critical Habitat

Critical habitat was established for this species on Culebra Island, Puerto Rico on September 2, 1998 (NMFS 1998b). No critical habitat for green sea turtles occurs on the U.S. Pacific Coast.

3.4.1.2 Environmental Baseline

Analysis Area

The analysis area applicable to green turtles is the area directly off Coos Bay out to the continental shelf break, which is represented as a depth of 200 meters. For this stretch of the Oregon coast the shelf break is approximately 12 nmi offshore from the Coos Bay estuary, the same as described above for blue whales (see figure 2.1.1-2). Within the marine analysis area, potential effects to green turtles would be associated with LNG carriers inbound and outbound from the LNG Terminal.

To date, the origins of LNG carriers arriving at the LNG Terminal and the destinations of LNG cargo that would be shipped from the LNG Terminal have not been identified. However, for the reasons discussed with respect to blue whales (see section 3.2.1.3), LNG carriers are assumed to traverse the marine analysis area perpendicularly—east and west—as they approach and depart from Coos Bay. The assumption of perpendicular transits is based on existing shipping traffic between Asia and the continental U.S. Pacific Coast travelling the “Great Circle route” (Pacific States/British Columbia Oil Spill Task Force 2002), as well information provided by the Coast Guard (Berg and Lawrenson 2015).

Species Presence

Green sea turtles have been sighted from Baja California to southern Alaska, but most commonly occur from San Diego south (NMFS 2007b). Green sea turtles primarily use three types of habitat: oceanic beaches (for nesting), convergence zones in the open ocean, and benthic feeding grounds in coastal areas (NMFS 2007b). Reports of strandings suggest that the green turtle is a frequent visitor off the California coast. The northernmost stranding was reported in 1993 in Homer, Alaska, although it was speculated that this turtle may have died farther to the south and drifted north (NMFS 1998b). Based on this data, green turtles are likely infrequent, transient visitors to the Oregon coast, but may occasionally be found in the marine analysis area within the LNG ship transit zone.

Habitat

Sightings offshore of the Pacific Coast have occurred but there are no known sea turtle nesting sites on the U.S. Pacific Coast (NMFS and FWS 1998a). The East Pacific green turtle was the most commonly observed hard-shelled sea turtle on the U.S. Pacific Coast (NMFS and FWS 1998a) but most of the sightings (62 percent) were reported from northern Baja California and Southern California. The northernmost known resident population of East Pacific green turtles occurs in San Diego Bay, in the warm effluent of a power plant (NMFS and FWS 1998a).

3.4.1.3 Effects of the Proposed Action

Direct and Indirect Effects

Direct effects of the proposed action include injury and/or mortality due to ship strikes, underwater ship noise, and potential adverse effects from fuel spills at sea. Spills could indirectly affect green turtles by impacting forage species. These effects are addressed below.

Ship Strikes by LNG Carriers
